Q&A

Non communicable diseases (NCD) cause one in every six deaths worldwide, more than major communicable diseases (AIDS, tuberculosis, and malaria) combined. Cancer is the most dominant NCD. The global incidence of cancer is increasing rapidly in countries with low and medium human development indices (HDI). It is anticipated that by 2022, up to 70% (14 million) of the 20 million annual new cancers are expected to occur in these countries. Multimodality imaging for the diagnosis and radiotherapy for treatment will be required for these patients to cure localized disease and to effectively palliate symptoms. The imaging and radiotherapy equipment manufacturers anticipate that the growth of their new business is going to occur in low to middle income countries (LMICs) with a projection of over 200% growth in equipment sales in the next 5 years. Correspondingly, the global pool of radiation oncologists and radiologists needs to increase by 100%, medical physicists and dosimetrists by 300%, and technologists by over 300%. Unfortunately, this personnel shortage is exacerbated by the fact that many of the LMICs do not have the resources and infrastructure to train and educate the growing numbers of professionals needed in the safe and effective use of diagnostic and therapeutic technologies.

The professional organizations such as AAPM, ASTRO, RSNA, and ESTRO; international agencies such as IAEA and UICC; NGOs such as ICEC, Rayos Contra Cancer, Radiating Hope, and RADAID International; and vendors are doing their best to mitigate these challenges by offering their own solutions. NGOs have tried to fill the coordination gap, but there has been limited success without full institutional backing. Thus, there remains little or no coordination of these efforts at the present time while the financial commitment, especially by radiotherapy vendors and the IAEA is substantial.

AAPM has made a strategic decision to coordinate all international activities under the umbrella of International Council. The committee structure of IC will support efforts in education, clinical training, research, and a broader scope of collaboration with other global stakeholders that has largely been unexplored. It will provide opportunities to grow its base globally and improve domestically and it will clearly demonstrate AAPM's global leadership in the field of medical physics.

Learning Objectives:

1. Understand the need for global collaboration.
2. Understand the scope of activities of categorical committees of International Council.
3. Understand the need for coordination and harmonization of projects with other global stakeholders.

Questions/Discussions/Interactive Exercise

The 2021 Annual Student Meeting aims to discuss the role of medical physicists in the industrial workplace and the necessary skills required to succeed in such an environment. The majority of the medical physics graduate students and trainees are unaware of the industrial internship opportunities available to them and lack guidance in terms of what elective coursework to take to successfully obtain an industry job post-graduation. Furthermore, many mid-career medical physicists struggle to successfully transition from a clinical/academic job to an industry job in case they desire to switch careers.

As part of this meeting, the three speakers will share their experiences as industry physicists, including the journey to where they are now. As a recent graduate, Dr. Christie Lin will connect with current graduate students and recent grads, discussing her recent transition from graduate school to the industry and offer advice for those interested in a similar career path. For mid-career clinical physicists who are considering switching careers to the industry, Maria Bellon will be speaking about her transition to ViewRay after many years as a clinical physicist. Additionally, an established physicist who has worked their entire career in industry, Paul Naine, will speak about his experiences and the future of medical physics in the industry.

These presentations will be followed by an interactive discussion and Q&A session with the speakers, facilitated by student moderators. Join us in this session to learn about life as an industry physicist and learn about the many paths taken by those currently in the industry.

Learning Objectives:

1. Learn about a day in the life of an industry physicist
2. Understand the didactic and non-didactic requirements to be successful in an industry job
3. Get insights into the future of the medical physics industry

Q&A

This symposium features 4 invited presentations on the development and application of machine learning approaches, infrastructure, and standards in medical imaging, including experts in health informatics representing the Society for Imaging Informatics in Medicine (SIIM) and image acquisition and reconstruction from the AAPM.

(1) Dr. Bennett Landman will discuss “Challenges and Opportunities in Validation of AI for Medical Imaging.” Artificial Intelligence (AI) is promising to transform how we capture, interpret, and understand medical images from both basic science and clinical perspectives. However, it is becoming increasingly apparent that biases in study populations, site-factors, and imaging designs can have unintended, and sometimes catastrophic, impacts on AI performance. Hence, AI validation is rapidly becoming an essential field of research.

(2) Dr. Kristy Brock will present on “Harnessing AI to Enable Advanced Image Guidance in Interventional Procedures.” AI has the potential to be both an enabling and transformational tool in image guided interventions. The ability to obtain automated, accurate, and consistent segmentation of tumors and normal tissues can enable advanced image analysis, targeting, and treatment evaluation. In addition, AI can transform the way that clinicians can predict the outcomes of treatment, allowing real-time optimization to drive improved outcomes.

(3) Dr. Jeff Fessler will address the topic of “Joint Optimization of Learning-Based Image Reconstruction and K-Space Trajectories for MRI.” Machine learning approaches to medical image reconstruction are of considerable recent interest, especially supervised approaches that use a corpus of training data. Accelerated MRI scans, where fewer k-space points than image voxels are acquired, is a natural setting for such reconstruction methods. Recently, machine learning methods for optimizing the k-space sampling have also had growing interest. This talk will summarize recent work where we jointly optimize non-Cartesian

k-space sampling, heeding physical constraints like gradient slew rate, and a learning-based image reconstruction method.

(4) Dr. Kathy Andriole will discuss “Standards-Based Integration of AI Tools into Clinical Practice.” The goal of many machine learning (ML) models is to provide clinical decision support for imaging examination interpretation. But ML can be applied at various points in the medical imaging chain, including at examination ordering, imaging modality protocoling, image creation and quality assessment, study diagnosis, reporting, and billing. Such applications may improve workflow efficiency and reduce errors and cost. Integrating ML tools into the clinical arena is challenging. Topics covered in this presentation include the integration standards required for ML inference implementation at various points throughout the radiological workflow. Illustrative clinical examples will be shown and the role of the medical physicist will be discussed.

Together, these presentations highlight the potential for interaction between experts in health informatics and medical physics to bring machine learning methods to clinical benefit in medical imaging. The joint symposium will reciprocate at the 2021 SIIM Conference on Machine Intelligence in Medical Imaging (CMIMI).

Learning objectives include understanding advances in: (1) infrastructure to enable collaboration on machine learning methods; (2) machine learning methods to enable advanced image-guided interventional approaches; (3) learning-based optimization for MR image reconstruction; and (4) standards for integrating AI in clinical practice.

SU-A-TRACK 4-03

Q&A & Panel Discussion

With the disruptive technology leap of solid state SiPM PET detectors, improvements in PET instrumentation and technologies are happening at a staggering pace. At the same time, rapid development of computational technologies has made artificial intelligence (AI) more feasible and increasingly important.

This symposium aims to describe current clinical status and future expectations of utilizing SiPM PET in radiology and radiation oncology patient care, as well as innovative technologies and novel AI features of emerging SiPM PET instrumentation focusing on how digital PET is better than analog PET. Physicists, physicians and technologists wishing to better understand novel PET systems and technologies are expected to attend this symposium.

Learning Objectives:

1. Understand and learn current challenges of clinical care as well as expectations of future improvement using SiPM PET technologies in both radiology and radiation oncology.
2. Learn physics of SiPM PET technologies and specify emerging SiPM PET instrumentations and their novel AI features.
3. Identify and learn the advantages of digital PET than analog PET from imaging acquisition to clinical application.

Topics:

1. Clinical Considerations of SiPM PET in Radiology and Radiation Oncology: Motivating Applications and Needs.
2. Technologies and AI Features of SiPM PET Instrumentation: What is available and how is digital PET better than analog PET?

SU-AB-TRACK 5-017

Q&A

In the USA, cancer patients are at very high risk for bankruptcy. Outside the USA, 90% of patients in low-income countries lack access to radiotherapy. Resolving this situation requires an understanding of what patients experience, and significant, out-of-the-box efforts to reduce costs and improve the robustness and efficiency of our current clinical equipment, workflows, and software tools. What role can medical physicists take in this important drive?

In this session we will first describe how radiotherapy costs are affecting our patients, followed by descriptions of physics-led efforts in reducing costs and improving access to care for patients across the world. We will describe projects to develop new treatment devices that will provide robust and low-cost solutions worldwide, and also improvements in process and workflow that will improve efficiency, thus reducing overall costs.

Learning Objectives:

1. Understand some of the challenges that patients can have in finding and receiving radiation therapy
2. Understand physics-related efforts in treatment design to improve treatment availability of radiotherapy across the world
3. Understand physics-related efforts in process efficiency to reduce costs of radiotherapy across the world

Artificial Intelligence in Treatment Planning and Delivery

SU-A-TRACK 6-01

Curbing the Errors from Automated Tools Based on An FMEA of an AI-Based Treatment Planning System

K Nealon^{1,2*}, P Balter^{1,2}, R Douglas², D Fullen², S Hernandez^{1,2}, P Nitsch², A Olanrewaju², M Soliman², L Court^{1,2}, (1) UT MD Anderson UTHealth Graduate School of Biomedical Sciences, Houston, TX (2) The University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: To prospectively assess the patient risk associated with the clinical use of a web-based, automated contouring and treatment planning tool. **Methods:** A Failure Modes and Effects Analysis (FMEA) was performed to quantify risk prior to clinical deployment of the Radiation Planning Assistant (RPA), an automated contouring and treatment planning tool. Potential errors were identified by a multidisciplinary team, consisting of representatives from physics, radiation therapy, dosimetry, physician, RPA development and quality improvement teams. Each failure mode was individually discussed and scored by all participants, over the course of twenty 90-minute meetings. A 1-10 scale for severity, occurrence and detectability was used, following TG-100 recommendations. **Results:** Of the identified failure modes, 56.6% (164/290) were common in manual radiotherapy processes, leaving 126 unique to RPA assisted workflows. The mean RPN of these errors was 56.3, with a maximum of 486. The top ten failure modes were caused by automation bias, a tendency of users to rely too heavily on results from automated systems, operator and software errors. An action threshold of 125 was set, and corrective actions were taken to the 21 failure modes above that limit. As a result, changes were made to the RPA including modifications to the user interface to remove unnecessary input and better training to highlight the importance of review of the automated output. After these changes, the FMEA was rescored and the mean and maximum RPN decreased to 33.7 and 288, respectively. **Conclusion:** The majority of high-risk failure modes were caused by automation bias or operator error, emphasizing the need to limit unnecessary user input while maximizing user review of output. As a result of this analysis, changes were made to the RPA software and RPN scores subsequently decreased, showing that the FMEA approach is an effective way to reduce risk for automated planning tools.

Generalizability Study of a Fluence Map Prediction Network

L Ma*, M Chen, X Gu, W Lu, University of Texas Southwestern Medical Center, Dallas, TX

Purpose: A deep learning-based fluence map prediction network (FMPN) was developed for predicting fluence maps from desired dose distribution. The network was trained with clinical head and neck (HN) VMAT plans. This work is to investigate the performance of FMPN for various clinical scenarios apart from the training data. **Methods:** The FMPN which maps projections of dose to fluence maps was trained only with clinical HN full-arc VMAT plans. To study the generalizability of FMPN, we designed three tests, each of which has a feature different from the training scenario. First, we test the trained network on a different treatment site, prostate. Second, we test the network on new delivery modalities, with three partial-arc VMAT plans and one IMRT plans. Third, we test the network using plans with different degrees of modulation (DOM), to see how well it predicts fluence maps for doses in a wide spectrum of DOM. The generalizability was quantified by comparing the dose of FMPN-predicted fluence maps to the ground truth dose (the desired dose, input of FMPN) using 3D Gamma passing rate with 3mm/3% criteria. **Results:** In the first test, FMPN achieved a prediction accuracy in prostate site (99.06±1.75%) as high as in training site (HN, 98.06±2.64%). In the second test, performance was excellent on partial-arc VMAT (99%-89%) and degraded on IMRT (87% with 5mm/5% criteria), which was reasonable because IMRT is too far away from training data (full-arc VMAT) from data distribution point of view. In the third test, FMPN can predict fluence map for plans with various DOM/quality (95%-97%) and accuracy doesn't vary with DOM. **Conclusion:** The FMPN trained on HN full-arc VMAT plans could generalize well to other treatment site, delivery modality and various DOM, showing great potential for clinical use.

SU-A-TRACK 6-03

Inverse Treatment Planning Using a Virtual Treatment Planner (VTP) for Prostate Cancer Treated with Intensity Modulated Radiation Therapy
D Sprouts^{1*}, C Shen², Y Chi¹, (1) University of Texas at Arlington, Arlington, Tx (2) University of Texas Southwestern Medical Center, Dallas, TX

Purpose: Although commercial treatment planning systems (TPSs) can automatically solve the optimization problem for treatment planning, human planners need to define and adjust the planning objectives/constraints to obtain clinically acceptable plans. Such a process is labor-intensive and time-consuming. In this work, we show an end-to-end study to train a deep reinforcement learning (DRL) based virtual treatment planner (VTP) that can behave like a human to operate the commercial TPS for high-quality planning. **Methods:** We considered prostate cancer IMRT treatment planning as a testbed. The VTP takes DVH of a plan as input and predicts the optimal adjustment action to improve plan quality. The training of VTP followed the state-of-the-art Q-learning framework. Experience replay was implemented with epsilon-greedy search to explore the impacts of taking different actions on a large number of automatically generated plans, from which an optimal policy can be learned. Since the major computational efforts in training were spent to perform plan optimization repeatedly, we implemented a GPU-based Eclipse-equivalent TPS using PYCUDA to improve the optimization efficiency. Upon the completion of training, the established VTP was deployed to plan for a set of testing patient cases. Similar to a human planner, VTP keeps adjusting the planning objectives/constraints in the TPS to improve plan quality until the plan is acceptable or achieves maximum adjusting steps. The generated plans were evaluated using the ProKnow scoring system. **Results:** VTP was successfully trained, validated, and tested with 10, 2, and 50 cases, respectively. With PYCUDA, the training efficiency was improved by 3 folds. The mean plan score ($\pm$ std.) of the 50 test cases was improved from 6.18 ± 1.75 to 8.11 ± 1.27 by VTP, with 9 being the maximal score-value. **Conclusion:** The proposed DRL-based VTP was able to operate the Eclipse-equivalent TPS to generate high-quality plans for prostate cancer IMRT.

SU-A-TRACK 6-04

Predicting Daily Record of Machine Performance Check Using Multi-Long Short-Term Memory Neural Networks

M Ma*, J Dai, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, China, Beijing, CN

Purpose: The test of machine performance check (MPC) monitors the status of Varian truebeam machine. The cumulative record of MPC tests shows the trend of machine performance and provides warning message for preventive actions. To precisely predict the future records of MPC tests, a generalized model using multi-long short-term memory (multi-LSTM) was introduced. **Methods:** A total of 1044 sets of daily MPC test data were collected. The 80% of data were used to train multi-LSTM model, while the remaining 20% of data were used to test the accuracy of the model. To enrich the data, cubic interpolation is used in the model. Furthermore, a greedy coordinate descent method was employed to find the optimal hyper-parameters of the model. The accuracy of the model was quantified by the mean absolute error (MAE), root-mean-square error (RMSE), and coefficient of determination (R^2). **Results:** The hyper-parameters are determined as 15 for the length of time lags, Adam for the optimizers, 0.001 for the learning rates, 150 for the number of epochs, 50 for the number of hidden units, and 32 for the batch sizes. The majority of MPC test records was predicted with an RMSE less than or equal to 0.005. Exceptions are the jaw collimation, collimation rotation offset, beam output change, and beam uniformity. The similar result was observed in MAE metric. The result of all MPC tests records with R^2 was higher than 85.00%. **Conclusion:** The multi-LSTM model can accurately predict all MPC test record. Predicting the future performance records of MPC tests will foresee possible machine failure, which allows early action of machine maintenance and reduces unscheduled machine downtime.

SU-A-TRACK 6-05

Towards Automatic Metastasis-Directed Therapy Planning in a Three-Dimensional Beam Model Using Reinforcement Learning

W Hrinivich^{1*}, M Deek¹, R Phillips², H Li¹, P Tran¹, J Lee¹, (1) Johns Hopkins University, Baltimore, MD, (2) Mayo Clinic, Rochester MN

Purpose: Automating metastasis-directed therapy (MDT) planning may improve plan consistency between users and centers, but variability in characteristics of metastasis lesions hinders existing supervised learning approaches due to training data requirements. The purpose of this study is to investigate the feasibility of reinforcement learning (RL)-based machine parameter optimization for automatic MDT planning for oligometastatic prostate cancer (OMPC), which eliminates dependence on prior plans for training and directly optimizes linear accelerator parameters. **Methods:** We implemented a three-dimensional (3D) deep-Q RL volumetric modulated arc therapy optimization algorithm for MDT as follows. Dose was computed in a 3D grid using matRad. The dose grid, target and organ contours were re-sampled to extract axial slices aligned with individual pairs of leaves in the multi-leaf collimator (MLC) model. These slices were used as input in a 2D deep-Q network, which predicted slice-specific leaf position and dose rate updates. Slice-specific dose rate updates were recombined for each control point using a voting strategy. RL was conducted using four OMPC patients to maximize target coverage and minimize bowel dose, and applied to one independent test case. Resultant dose was compared to simple conformal arcs to quantify improvement over un-optimized plans. **Results:** Training was conducted for 4,800 iterations taking 3 days. RL MDT maintained mean $\pm$ SD target coverage of $95.1 \pm 7.9\%$ in the training cohort and 100.0% in the test patient. Compared to the conformal arcs, RL MDT reduced maximum and mean bowel dose by $20.0 \pm 16.3\%$ and $38.0 \pm 18.6\%$ in the training cohort, and 1.5% and 37.6% in the test patient, demonstrating a preliminary trend toward improved dosimetry. **Conclusion:** These preliminary results suggest that RL MDT optimization is feasible in a 3D beam model despite variable targets and limited training time. Ongoing work involves increasing training cohort size and training time to enable high-quality auto-planning for MDT.

This work was supported by an AAPM Seed Research Funding Grant.

SU-A-TRACK 6-06

Towards Interpretable Intelligent Automatic Treatment Planning in Radiotherapy: Understanding the Decision-Making Behaviors of a Hierarchical Deep Reinforcement Learning Based Virtual Treatment Planner Network

C Shen*, L Chen, X Jia, (1) University of Texas Southwestern Medical Center, Dallas, TX

Purpose: Intelligent automatic treatment planning (IATP) in radiotherapy builds a virtual treatment planner network (VTPN) that automatically operates a treatment planning system (TPS) to generate high-quality plans by adjusting dose constraints in TPS like a human. It is important to interpret VTPN's decision-making behaviors to gain confidence for clinical applications. This study proposed a VTPN of a hierarchical architecture (HieVTPN) motivated by the decision-making process of human planners, and performed numerical studies to analyze and understand its behaviors in planning process. **Methods:** HieVTPN consists of three networks, i.e. Structure-Net, Parameter-Net, and Action-Net. In each step controlling the TPS to improve a plan, HieVTPN sequentially determines the anatomical structure to adjust dose constraints, the specific constraint of the selected structure, and the detailed adjustment action, respectively. A hierarchical deep reinforcement learning approach was developed to train HieVTPN to operate an in-house developed TPS to generate plans for prostate cancer intensity modulated radiotherapy. We analyzed the decision-making behaviors of the established HieVTPN on anatomical structure, parameter, and adjustment action levels, respectively. Scenarios triggering distinct decisions were characterized to understand the rationale of the decision-making behaviors, which were then compared with human intuitions. **Results:** HieVTPN were successfully trained to operate the in-house developed TPS to generate high-quality plans for all 59 testing patient cases, achieving an average plan quality score of $8.62 (\pm 0.83)$, with 9 being the maximal score. We found that the decision-making

behaviors of HieVTPN were understandable. By observing a plan, HieVTPN tended to pick the anatomical structure that needs the most attention, and adjusted the appropriate parameter corresponding to the selected structure towards the direction to improve the plan. Such decision-making behaviors generally agreed with the human experience. **Conclusion:** Our study demonstrated the agreement between the decision-making behaviors of HieVTPN in planning process with that of human based on intuitions.

SU-A-TRACK 6-07

Treatment Parameters That Impact IROC SRS Phantom Performance Evaluated Using AI

H Mehrens*, T Nguyen, S Edward, S Hartzell, M Glenn, D Branco, N Hernandez, P Alvarez, A Molineu, P Taylor, S Kry, UT MD Anderson Cancer Center, Houston, TX

Purpose: To analyze institutional performance irradiating IROC Houston's SRS head phantom. **Methods:** Irradiation results of 1072 SRS head phantoms between 2012-2020 were abstracted. Univariate analysis and random forest models were used to associate irradiation conditions with phantom results. Phantom results included pass/fail classification, average TLD ratio, and percent of pixels passing gamma. The following categories were evaluated in terms of how they predicted these outcomes: irradiation year, TPS algorithm, machine model, energy, and field size. Specifically, algorithm was categorized per TG-329, collimators were divided into three categories: cones, high-definition (MLC Leaf Width < 0.5 cm), and low-definition (MLC Leaf Width > 0.5 cm), and field size was calculated from the average extent of the measured 50% isodose line. **Results:** Pearson chi-squared test showed that algorithm ($p < 0.001$) and collimator ($p = 0.24$) were statistically significant predictors of pass/fail. Per Tukey's post-hoc test, pencil beam algorithm (AAA: $p = 0.01$, GBBS: $p = 0.15$, Monte Carlo: $p = 0.001$, Measured: $p < 0.001$, and Superposition/Convolution: $p = 0.015$) and cone collimator (high-definition: $p = 0.035$, low-definition: $p = 0.055$) were both more likely to be associated with failing phantom results. Our random forest models were able to achieve an overall prediction accuracy of $90.9 \pm 0.3\%$. For overall pass/fail, TLD result, and percent of pixels passing, the field size was the most important predictor, with poorer results associated with smaller fields. The next three most important variables were irradiation year, machine, and algorithm; however, the specific order of importance varied. **Conclusion:** Field size is the most important factor in determining the outcome of the phantom. Specifically, smaller fields (≤ 3 cm), which encapsulates the majority of cone collimators (72.7%) used, tends to produce more failures. Pencil beam algorithms were inferior to accurately predicting dose as compared to all other algorithms.

This work received funding from the NIH/NCI grants #CA180803 and #CA214526.

A. Sethi, Loyola University Medical Center:

Proof Is in the Plan: Pros and Cons of MRgART

During the course of treatment, a patient treatment plan may be compromised by anatomical changes resulting from weight loss, soft-tissue deformation, organ filling/emptying, peristalsis etc. This often requires plan adjustment or full-re-planning (adaptive radiation therapy). MR Guided Adaptive RT (MRgART) is a novel treatment paradigm to address dose variations due to above changes. Therapeutic ratio for many treatment sites can be improved with MRgART, but at the added expense of time investment with the patient on the table. The adaptive workflow introduces several new steps to the treatment process, such as, deformable image registration, contouring, plan optimization, QA and tumor tracking. Clinical implementation of MRgART will be discussed with a focus on resource utilization. We will also propose guidelines for clinical workflow enhancements in imaging, treatment planning and delivery. Importance of comprehensive system QA (end-to-end test) will be discussed along with QA thresholds and consistency checks for each step in the process chain. Finally, interesting clinical cases will be presented to emphasize efficient planning techniques for daily plan adaptation and improved clinical workflow.

Learning Objectives:

1. Present fundamentals of MR imaging in the IGRT environment while highlighting features unique to hybrid MR linacs.
2. Share clinical experiences of performing MRgART on low & high Tesla MR linacs.
3. Present clinical examples that emphasize smart plan adaptation and associated benefits.

Patient specific quality assurance is conducted to validate the accurate deliverability of a treatment plan. This QA procedure was designed to improve the quality and safety of radiation treatments particularly those utilizing inverse planning techniques and/or hypofractionation. Numerous products have been developed for this task. This guided tour will begin with an introductory presentation from the moderators on patient specific QA including necessity and the broad array of available techniques. Vendors will then showcase their latest developments and products in patient specific QA followed by a question-and-answer session.

Learning Objectives:

1. Describe the rationale for conducting patient specific QA including formal guidance and recommendations.
2. Review the inherent limitations associated with patient specific QA testing.
3. Explore the pros and cons of the varying techniques currently available.

SU-B-TRACK 1-05**Q&A**

While science is frequently considered a rigid discipline, recent times have highlighted the need for flexibility and adaptability in all areas of medical physics. Though COVID-19 forced our profession to creatively respond to external factors, opportunities exist for us to implement this type of creativity in our normal work environments on a regular basis. In this symposium, the speakers will discuss experiences with and opportunities for implementing creative change.

Parminder Basran, PhD – "Virtual Fellowships: A Novel Approach to Undergraduate Research Training and Mentorship" (Education Council)

For the summer of 2020, COVID-19 required the AAPM Summer Undergraduate Fellowship and Outreach Program to dramatically pivot from a conventional in-person undergraduate training experience to a virtual experience. Virtualizing fellowships forces a conscientious definition and refining of roles and responsibilities for the mentor, trainee, hosting institution and sponsors. Apart from the research experience itself, fellowship experiences include exposure to the clinical/research workplace, communicating with supervisors, researchers, non-physicists, residents, graduate students and fellow undergraduates, access to labs, equipment, and software, and the institution itself, by way of 'on-boarding' and such. While there are clear disadvantages of eliminating an in-person research experience, the successful virtualization of fellowships demonstrates many facets of the fellowship experience can indeed be provided online. This suggests virtual fellowships could become a novel vehicle for outreach to students currently unable to participate in this fellowship experience.

Maryellen Giger, PhD – "Extending AAPM Leadership to Advance Data Science in the Age of COVID-19" (Science Council)

MIDRC represents an NIBIB-funded partnership spearheaded by the medical imaging community and aimed at building data repositories to fuel COVID-19 machine intelligence research, coupled with optimal standardization, curation, and compliance with ethical responsibilities to honor patients' privacy. This partnership will lead to development and implementation of new diagnostics, including machine learning algorithms, that will empower population-wide

preventive and management strategies for COVID-19. This leadership collaboration among the ACR, RSNA, and AAPM is based on each organization's unique and complementary expertise within the medical imaging community, with AAPM bringing its expertise in physical image quality/harmonization and tailored distribution/metrology standards/evaluation metrics.

Brent Parker, PhD – “Sailing the High C's” (Professional Council)

The concept of creativity tends to be associated with the research and educational areas of medical physics, with the professional realm being thought of as being unimaginative. However, the COVID-19 experience forced many of us to creatively adapt to a changed work environment without even realizing the creativity that adaptation required. As Professional Council discussed the theme of this symposium and how it applies to professional issues, we identified areas where medical physicists have creative opportunities. As the proverb says, “Necessity is the mother of invention”, or in this case, creativity. As we look to the future of our profession, professional creativity will be necessary to demonstrate our value to our employers, our colleagues, and our patients.

SU-B-TRACK 4-03

N. Vasdev, University of Toronto:

Developing Novel PET Tracers for Brain Imaging

Theranostics, or the combination of both therapeutics and diagnostics for image guided therapies, is an emerging area of interest toward personalized and highly targeted approach. This joint symposium between the World Molecular Imaging Society (WMIS) and AAPM will highlight the current status and latest technologies in the growing field of theranostics. Dr. Hope will provide an overview of theranostics in PET/MR. Dr. Lapi will describe novel areas of interest in theranostics. Finally, Dr. Vasdev will discuss some current efforts in developing novel PET tracers in the brain. When taken together, these three invited speakers will summarize the state of the art knowledge in theranostics, review the current challenges and potential solutions, and share their perspectives of future directions for research and clinical implementation.

Learning Objectives:

1. Understand the principles of theranostics, the different approaches, and their advantages and drawbacks
2. Learn about emerging areas of clinical and research theranostics implementation
3. Understand the potential of using theranostics for target therapy.

A Fully Automated Approach for Labeling, Contouring, and Treatment Planning of Vertebral Bodies, Including Automatic Verification to Prevent Errors

T Netherton*, C Nguyen, C Cardenas, C Chung, A Klopp, L Colbert, D Rhee, C Peterson, R Howell, P Balter, L Court, MD Anderson Cancer Center, Houston, TX

Purpose: To develop a fully-automated framework that labels vertebral levels, contours vertebral bodies, detects labeling and contouring errors, and generates treatment plans within 10 minutes. Additionally, to ensure that diagnostic and simulation CT-based auto-planning is safe, efficient, and flags potential mistreatments. **Methods:** For labeling vertebral levels(C1-L5), a methodology was developed using two CNNs trained with independent patient populations(n1=897, n2=290). For contouring, UNet++ was trained, validated, and tested using diagnostic and simulation CT scans(n=220). For detection of contouring and labeling errors, 9 overlap, distance, and intensity metric features were calculated using 752 auto-contours from 56 CBCT, PET-CT, diagnostic-CT, and simulation-CT scans. Using these features as inputs, hyper-parameter optimization refined 9 machine-learning algorithms to detect errors. For planning, treatment plans were automatically generated based on auto-contour projections. To validate the entire framework, 60 treatment plans were generated on a new cohort of diagnostic and simulation scans varying in scan length, imaging protocol, presence of surgical implants, and metastatic burden. Clinical acceptability of the plans was evaluated by three radiation oncologists using a 5-point scale. **Results:** Automatic labeling was accurate for 94% of scans and demonstrated mean localization error <2.2mm. Mean Dice-Similarity-Coefficient/95th-percentile Hausdorff distance was 85.0%/1.8mm(cervical), 90.3%/1.8mm(thoracic), and 93.7%/1.6mm(lumbar). A random forest model detected contouring and labeling errors across various CT scan types with precision-recall-AUC=0.82. Within the validation cohort, the random forest model flagged all contouring and labeling errors (11/11) within prescribed treatment regions, including errors from patient plans (6/6) with atypical anatomy (e.g. T13, L6). For patients with typical anatomy, radiation oncologists scored 98% of simulation CT- and 92% of diagnostic CT-based plans as clinically acceptable or needing minor edits. End-to-end treatment planning time was 7.0±2.0 minutes. **Conclusion:** We demonstrated that this novel, end-to-end, fully automated process to label, contour, and plan was efficient, effective, and safe across various CT scan types.

AI Agent Competing with Human in Planning Challenge: A Human-Expert Level Virtual Treatment Planner Network for Prostate Cancer Stereotactic Body Radiation Therapy (SBRT)

C Shen^{1*}, C Men², Y Gao¹, L Chen¹, X Jia¹, (1) University of Texas Southwestern Medical Center, Dallas, TX, (2) Elekta, Newbury Park, CA

Purpose: Virtual treatment planner network (VTPN) has been previously developed to operate treatment-planning systems (TPSs) and adjust planning parameters to generate a plan in lieu of human planners. Previous applications were limited to relatively simple planning tasks on unrealistic in-house TPSs. This study reports the development of VTPN that is able to operate a realistic TPS for a real clinical task of prostate cancer SBRT treatment planning. We evaluate it objectively against human performance in the case in the planning challenge of ProKnow 2016 AAMD/RSS Plan Study. **Methods:** Due to technical challenge of directly interacting with a commercial TPS, we built a realistic TPS equivalent to a commercial TPS in terms of inverse planning. It uses the actual dose engine in the real TPS, and solves the identical optimization problem defined by the user-adjustable dose-volume constraints. A hierarchical VTPN was constructed to perform multi-level decision-making in planning process to adjust constraints to improve plan quality. We trained VTPN via end-to-end deep reinforcement learning with human experience as guidance. The established VTPN was applied to the case in the planning challenge of ProKnow 2016 AAMD/RSS Plan Study to generate a 7-field intensity-modulated radiotherapy plan. The resulting plan quality was compared against top plans in the challenge generated by expert human planners. **Results:** VTPN was successfully trained to operate the TPS, achieving an average plan score of 139.8 on validation cases. When applying the trained VTPN to plan for the case used in the planning challenge, it achieved a plan score of 140.5, ranked as the third highest score among all the 31 plans submitted for competition. **Conclusion:** VTPN can spontaneously learn planning strategies and handle complex prostate cancer SBRT treatment planning. This is the first time that VTPN achieves performance similar to expert human planners.

SU-B-TRACK 6-03

Evaluating the Clinical Acceptability of Deep Learning Contours in Prostate Radiotherapy

J Duan*, M Bernard, B Willows, L Downes, W Mourad, W St Clair, X Feng, Q Chen, University of Kentucky, Lexington, KY

Purpose: To comprehensively evaluate whether contours generated from Deep learning (DL) model can be safely used clinically in prostate radiotherapy. **Methods:** A 3D U-Net based model was trained on 84 patients and an additional 23 patients with intact prostate were randomly selected for testing. Structures that were used in clinical treatment were further review and modified by an experienced radiation oncologist (RO) as ground-truth (GT). Contours generated by the DL model (AI) were compared with GT contours using dice similarity coefficient (DSC), 95% Hausdorff distance (HD95), and mean surface distance (MSD). To quantify interobserver variability, prostate was recontoured by additional two expert ROs in every case. GT and AI contours were evaluated by the 4th RO in a double-blind study. Finally, Varian RapidPlan was used to create plans using AI or GT contours. Then both plans were evaluated on GT contours to see if the use of AI contour would produce a comparable plan. **Results:** AI demonstrates good geometrical accuracy on prostate with mean DSC, HD95, and MSD of 0.83 ± 0.05 , 0.60 ± 0.18 cm, and 0.21 ± 0.07 cm respectively. It shows no significant differences between the contours generated from three ROs ($p > 0.05$). Organ at Risk (OARs) also showed good agreement with the GT. In the double-blind study, 95.7% of AI contours were scored as either "Great" (34.8%) or "Acceptable without changes" (60.9%). Totally 69.6% (16 of 23) AI contours were considered equal or better than their counterparts. No significant differences were found in OAR dose from the use of AI instead of GT contours except for bladder and Seminal Vesicle ($P < 0.05$). However, all plans generated with AI contours satisfy the RTOG-0815 dose constraints even when evaluated using GT contours. **Conclusion:** The investigated 3D U-Net model provided reasonable contours that can be used directly in clinics.

Managing Tumor Changes During Fractionated Radiotherapy: Evaluation on a Deep-Learning-Based Predictive Model and a Re-Planning Strategy

R Li^{1*}, A Roy², N Kirby¹, N Bice¹, S Sivabaskar¹, M Fakhreddine¹, N Papanikolaou¹ (1) UT Health San Antonio MD Anderson Cancer Center, San Antonio, TX, (2) The University of Texas at San Antonio, San Antonio, TX

Purpose: We propose a treatment planning framework that accounts for weekly lung tumor shrinkage using CBCT images with a deep learning-based model. **Methods:** Sixteen patients with non-small cell lung cancer were reviewed with one planning CT and six weekly CBCTs each. A convolutional long short-term memory-based model was applied to predict the weekly deformation of the primary tumor based on the spatial and temporal features extracted from previous weekly CBCTs and target contours. Starting from Week 3, the tumor contour at Week N was predicted by the model based on the input from all the prior weeks (1, 2, ..., N-1), and was evaluated against the manually contoured tumor using dice coefficient (DSC) and average surface distance (ASD). Information about the predicted tumor was then used to re-optimize the treatment plan every week. The objectives were set to maximize the dose coverage in the target region while minimizing the toxicity to the surrounding OARs. Dosimetric evaluation of the target and organs at risk was performed on four cases, whereby we compared the conventional plan (ignoring shrinkage) to the shrinkage-based plan. **Results:** Average DSC and ASD between the predicted tumor and the actual tumor for Week 3, 4, 5, 6 were (0.81, 0.80, 0.76, 0.78) and (1.72, 1.64, 2.04, 1.97) mm, respectively, which are significantly superior to the scores of (0.70, 0.68, 0.66, and 0.63) and (2.81, 3.22, 3.69, and 3.74) mm between the actual and original volume. While target coverage metrics were maintained for the re-optimized plans, lung mean dose dropped by 2.32, 2.38, 0.36 and 1.25 Gy for four sample cases when compared to the original plan. **Conclusion:** We developed a deep-learning-based model for tumor shrinkage prediction. The proposed framework produces reasonable tumor contours and adaption can maintain target coverage while reducing the mean lung dose.

SU-B-TRACK 6-05

Mapping Motion-Induced Dose Variations on Bladder Surfaces: A Novel Surface-Based Dose Modeling for Accurate Dose Assessment in Fractionated Prostate Cancer Radiotherapy

Y Lao^{1*}, M Cao¹, Y Yang¹, A Kishan¹, W Yang², Y Wang³, K Sheng¹, (1) UCLA School of Medicine, Los Angeles, CA, (2) University of Southern California, Los Angeles, CA, (3) ASU, Tempe, AZ

Purpose: To introduce a novel surface-based dose mapping method for improved quantitative bladder dosimetric assessment in prostate cancer (PC) radiotherapy. **Methods:** Based on the planning and daily pre- and post-fraction MRIs of 12 PC patients, bladder surface models (SM) were generated on manually delineated contours and regionally aligned via surface-based constrained harmonic registration. Subsequently, bladder surface dose models (SDM) were created using face-wise dose sampling. This was followed by localized surface mapping of bladder intrafractional and interfractional dose variation on fractional SDMs. Discrepancies between the received dose, accumulated from daily SDMs, and the planned dose were then assessed on the corresponding SDMs. Complementary to the surface dose mapping, dose-surface-histograms (DSHs) based comparisons were also performed. **Results:** The intra-fraction motion substantially altered dose to mid bladder body, but not the bladder surface areas distal to or contiguous with the target. The overall intra-fraction comparisons, after multiple comparison corrections, are significant (< 0.0001) for both the SDMs and DSHs. A similar pattern of dose variations was also detected by inter-fraction comparisons. With surface registration to the common SM, the cumulative bladder dose significantly differs from the planned dose. The discrepancy is evident in the mid-posterior range that corresponds to a mid-to-high dose region. The received DSH significantly differs from the planned

DSH after permutation correction ($p=0.0122$), and the overall surface-based comparison after multiple comparison correction revealed a trend of difference ($p=0.0800$). **Conclusion:** We developed a novel surface-based intra- and inter-dose mapping framework, which was applied to a unique MR dataset for planning and guidance. The framework identified the pattern of inter-fraction dose changes, localized significant intra-fraction dose variations, and quantified planned vs. received dose differences on the bladder surface. The result indicates the importance of adopting the motion-integrated bladder SDM for bladder dose management.

SU-B-TRACK 6-06

Towards Daily Online Adaptive SBRT for Pancreatic Cancer: Dosimetric Analysis of Daily Adaptive Re-Planning Using Re-Optimization and Dose Escalation Techniques

J Niedzielski*, S Beddar, R Martin, L Perles, N Rebuena, E Holliday, G Smith, B Minsky, E Ludmir, P Das, E Koay, C Taniguchi, A Koong, G Sawakuchi, UT MD Anderson Cancer Center, Houston, TX

Purpose: To evaluate the benefit of daily adaptive re-planning for pancreas SBRT by using either daily plan re-optimization or fractional dose-escalation to attain maximal tumor coverage. **Methods:** Eight pancreatic cancer patients, originally treated with SBRT (36–40 Gy, 5 fractions) using daily CT-on-rails image guidance and breath-hold motion management, were re-planned on the daily treatment CT-on-rails images using 2 different techniques: (i) all patients had each of their 5 fractional plans re-optimized to preserve clinical target coverage and meet OAR constraints; and (ii) all patients were re-planned on each fraction to receive dose-escalated SBRT, using an iterative strategy that consisted of a dose-escalated PTV (DE-PTV), as well as simultaneous integrated boosts to both the tumor-vessel-interface (TVI) and gross-tumor-volume (GTV), while meeting organ-at-risk (OAR) constraints. Both the original and dose-escalated treatment plans, using the original planning CT, were recalculated on each treatment's CT-on-rails image and accumulated dose was calculated. Additionally, dose was accumulated using the 5 daily re-plans, for both strategies, and then compared to the clinically delivered and the dose-escalated treatment plans. **Results:** When compared to the accumulated dose from the original clinical plan, daily re-optimization resulted in an average 7.1% /6.7% increase in D100% of the GTV/TVI ($p=0.17/0.12$). Compared to the accumulated dose from the dose-escalated treatment plan, the daily adaptive dose-escalation approach had an average 10.7%/21.2%/20.4% increase in D100% for the GTV/TVI/DE-PTV ($p=0.20/0.02*/0.03*$), respectively. The daily adaptive dose-escalated approach was able to deliver an average 22.4%/32.8% increase to the GTV/TVI ($p=0.007/0.0001*$), when compared to the delivered dose of the original clinical plan. Without daily adaptation, dose-escalated plans would violate the D1.0cc<35Gy OAR constraint in 5/1/1 patients for the duodenum/stomach/small bowel, according to accumulated dose. **Conclusion:** Daily re-optimization of pancreas SBRT treatments leads to superior plan quality. Daily adaptive re-planning can maximize dose escalation, without violating OAR constraints.

SU-B-TRACK 6-07

Online Adaptive Radiotherapy: Assessment of Planning Technique and On-Table Adaptive Plan Quality

K Mittauer^{1,2*}, J Bryant¹, A Gomez¹, T Romaguera^{1,2}, D Alvarez^{1,2}, J McCulloch^{1,2}, R Herrera¹, D Doty¹, M Mehta^{1,2}, A Gutierrez^{1,2}, M Chuong^{1,2}, (1) Miami Cancer Institute, Baptist Health South Florida, Miami, FL, (2) Florida International University, Herbert Wertheim College of Medicine, Miami, FL

Purpose: Stereotactic body radiation therapy (SBRT) planning based on a static dataset of the simulation day anatomy is historically created over at least a week. We hypothesize that the quality of daily on-table adaptive plans is similar to that of the baseline plan when delivering stereotactic magnetic resonance image guided adaptive radiation therapy (SMART) for pancreas cancer (PCa) on a 0.35T MR Linac. **Methods:** Fifty ($n=50$) PCa patients received 50 Gy/5-fraction SMART. Baseline planning included: 3 mm gastrointestinal (GI) PRV, 50 Gy/100% and 33 Gy/66% optimization targets based on GI PRV, high-dose and low-dose conformity rings, and a contracted GTV for ablative 120%-140% region. For each adaptive fraction, GI anatomy was re-contoured, followed by propagation of planning structures and optimization. If conformity, coverage, or organ at risk (OAR) goals were not achieved, optimization was repeated until satisfactory. Plan quality was evaluated for target coverage (TC=PTV V100%/PTV vol), PTV D90% and D80%, homogeneity index (HI=PTV D2%/D98%), high-dose conformity (PITV), low-dose conformity (D2cm), and gradient (R50%). **Results:** OAR constraints were met on all baseline ($n=50$) and adaptive ($n=250$) plans. Mean $\pm$ SD PTV coverages for baseline and adaptive plans were 41.7 $\pm$ 6.3 Gy and 40.5 $\pm$ 6.3 Gy (D90%), 45.6 $\pm$ 5.6 Gy and 44.4 $\pm$ 5.5 Gy (D80%), and 76 $\pm$ 20% and 70 $\pm$ 20% (TC), respectively, all not statistically significant (NSS). Mean homogeneity and conformity indices were 0.84, 0.76 (PITV), 3.37, 3.43 (R50%), 1.54, 1.57 (HI), and 58%, 60% (D2cm), respectively, all NSS. Median number of adaptive re-optimizations was 2. **Conclusion:** For a site with GI interfraction motion causing daily changes in the spatial position of the dosimetric gradient, similar target coverage quality was observed between baseline and adaptive plans due to robustness of GI PRV technique subdividing the target. Planning rings enabled robustness in conformity. This work supports the feasibility towards utilizing a patient-independent template baseline plan for daily adaptation.

Electroacoustic Tomography for Monitoring Electroporation in Real Time

S Wang^{1*}, A Zarafshani², L Xiang¹, (1) University of California, Irvine, Irvine, CA, (2) Eastern Washington University, Spokane, WA

Purpose: Electroporation is a new technique that uses nanosecond to microsecond duration high-voltage electric pulses to create temporary pores in cell membranes or irreversibly destroys target cells for cancer treatment. The versatility of electroporation makes the technique ideal for direct drug delivery and cancer treatment. Electroacoustic tomography (EAT) is a novel imaging modality for electroporation treatment monitoring, that utilizes the existing energy deposited by high-voltage electrical fields created in the electroporation process. **Methods:** In EAT, ultrasound waves are generated by the deposited electric potential energy and captured by different configurations of ultrasound transducers. After being captured, the ultrasound information is used to reconstruct the geometric information of the electric field distribution in the target medium. In this work, we demonstrate the feasibility of electroacoustic tomography (EAT) by creating a 2D reconstruction of an electric field in the water. A custom high-voltage electric pulse generating device was made for delivering nanosecond duration pulses in water through two electrodes. A 500Khz ultrasound transducer was placed near the electrodes and rotated to capture the acoustic information from 180 positions. The corresponding 2D reconstruction of the electric field in water was completed by using filtered back-projection algorithm. **Results:** A 2-dimensional reconstruction of the electric field in water was obtained using the EAT system. The electric field and the electrodes were clearly visualized. **Conclusion:** The successful visualization of electric fields in water demonstrated the feasibility of EAT model for electroporation therapy. As a real-time capable and 3D capable novel imaging modality, EAT has the potential to greatly enhance the precision of electroporation treatment in the clinic.

Liver Delineation Using the Weighted A-Star Pathfinding Algorithm and Deep Learning on Ultrasound B-Mode Images for Cirrhosis Assessment Using Liver Biopsy as the 'Gold Standard'

I Gatos¹, P Drazinos², S Tsantis¹, P Zoumpoulis², I Theotokas², D Mihailidis³, G Kagadis^{1*}, (1) University of Patras, Rion, GR, (2) Diagnostic Echotomography SA, Athens, GR, (3) University of Pennsylvania, Philadelphia, PA

Purpose: To evaluate the diagnostic performance of a deep learning scheme on liver cirrhosis detection. Input data were segmented left liver lobes from ultrasound (US) B-Mode images delineated by a segmentation algorithm based on modified Weighted A-Star algorithm, on patients with Chronic Liver Disease (CLD) using liver biopsy (LB) as 'Gold Standard'. **Methods:** 69 consecutive CLD diagnosed patients (14 F0-F3 and 55 F4) underwent a regular abdomen US B-Mode and LB examination using the Metavir scale (F0-F4). A B-Mode image containing the left liver lobe was acquired and saved by an expert Radiologist performing the US examination. Then, a sophisticated segmentation algorithm based on 2D continuous wavelet transform (2D-CWT) and Weighted A-Star pathfinding was employed to delineate the liver surface boundaries from each patient's US image. Subsequently, a binary image was produced representing the left liver's lobe mask. A radiologist's delineation on the same images was used as 'Gold Standard' for segmentation. The segmentation results were evaluated by the Jaccard's Coefficient Index. Consequently, all mask images were fed to the GoogLeNet pre-trained deep learning scheme using LB fibrosis staging (F0-F4) as labels for fine tuning. Data was separated in two classes according to their steatosis grade: F0-F3 (Non-cirrhotic – Class 1), and F4 (Cirrhotic Class – Class 2). Mask images were separated in training (70%) and testing (30%) sets, and testing accuracies were calculated. The random image separation and GoogLeNet fine tuning processes were repeated 30 times. **Results:** The segmentation algorithm achieved a mean Jaccard Coefficient performance of 0.92 using the radiologist's delineation as reference. The deep learning scheme's mean accuracy reached 97% for the training data and 90% for the test data respectively. **Conclusion:** The results indicate that this scheme can be used as a supplementary diagnostic tool for cirrhosis detection on regular US B-Mode abdomen examination.

Quantitative Image Guidance In Vivo: Dual-Energy CT for Thermochemical Ablation

E Thompson*, M Jacobsen, R Layman, E Cressman, UT MD Anderson Cancer Center, Houston, TX

Purpose: Thermochemical ablation (TCA) is a minimally invasive therapy under development for hepatocellular carcinoma. TCA utilizes acid/base chemistry delivered simultaneously directly into the tumor to induce local ablation when administered. When delivered via a mixing catheter, acid (AcOH) and base (NaOH) react to completion at the catheter tip before delivery into tumor, producing the acetate salt, water, and releasing heat ($\Delta > 50^{\circ}\text{C}$) in sufficient quantities to induce lethal osmotic and thermal stress in tumor cells. However, these two reagents are not distinguishable from tissues, which makes monitoring delivery of TCA difficult. We address this issue by developing CsOH as a novel theranostic component of TCA that is detectable with CT. **Methods:** VX2 tumor fragments (0.3mL) from carrier animals were inoculated into the flank of New Zealand white rabbits and allowed to grow for 10 days until tumor diameter reached 1-2cm. Catheters were placed under ultrasound guidance and TCA was delivered as 5M AcOH and 5M NaOH doped with 250mM CsOH. Concentration selection was informed by previous studies. A split-filter DECT system (Definition Edge, Siemens Healthineers) was used to acquire images pre- and post-TCA treatment with the following parameters: 120kVp, Au/Sn filter, and CTDIvol=1.39mGy. 20mm line profiles were drawn on 70keV monoenergetic images (Syngo.via) through the ablation center (ImageJ, NIH). Cesium concentration was quantified using the HU and CsOH concentration relationship ($R^2=0.999$) determined in previous studies. **Results:** The resulting line profile has a maximum CT number of 692HU (220mM) near the center of the injection site and decreases to approximately 40HU (12mM) at the periphery of the ablated region, demonstrating higher cesium concentration near the center, decreased concentration at the periphery, and none beyond the ablation zone. **Conclusion:** DECT is a viable technique for quantitative monitoring to monitor tumor ablation when CsOH is incorporated as a theranostic agent in image-guided TCA interventions.

Recurrence Prediction for Head and Neck Squamous Cell Cancer Patients Using Local Binary Pattern-Based Dosimetrics

H Kamezawa*, H Arimura², (1) Teikyo University, Omuta, JP, (2) Kyushu University, Fukuoka, JP

Purpose: Our aim was to predict the recurrence after radiation therapy by using local binary pattern (LBP)-based dosimetrics for head and neck squamous cell cancer (HNSCC) patients. **Methods:** A total of 131 HNSCC patients has recurrence/non-recurrence information after radiation therapy were collected from HNSCC collection in The Cancer Imaging Archive. The cases were split into a training (80%) and a test (20%) dataset. The numbers of recurrence and non-recurrence were 39 (training: 29, test: 10) and 92 (training: 73, test: 19), respectively. Recurrence versus non-recurrence cases were imbalanced. Therefore, the recurrence group in the training dataset was balanced via the synthetic minority over-sampling technique method. A total of 327 dosimetrics features enrolled cold spot volume, histogram features, and texture features (gray-level co-occurrence matrix, gray-level run length matrix, gray-level size zone matrix, neighborhood gray tone matrix) were extracted from the original dose distribution (ODD) and LBP on gross tumor volume, clinical target volume, and planning target volume. The Cox-net algorithm was employed for feature selection and dosimetrics signature building in training dataset. The ODD and LBP models using support vector machine for the recurrence prediction were constructed with dosimetrics features extracted from ODD and LBP. The prediction performances were evaluated in training and test datasets by the accuracy and the area under the receiver operating characteristic curve (AUC). **Results:** The accuracy and AUC in the training dataset were 92% and 0.95, respectively, for the LBP model and 77% and 0.81, respectively, for the ODD model. In the test dataset, the LBP model demonstrated the higher performance (accuracy: 79%, AUC: 0.72) than the ODD model (accuracy: 48%, AUC: 0.71). **Conclusion:** The LBP-based dosimetrics (LBP model) could be feasible for accurately prediction of recurrence after radiation therapy in HNSCC patients.

Functional MRI-Based Radiomics for the Diagnosis of Major Depressive Disorder

K Sun^{1*}, S Zhao², G Liu¹, W Lu¹, J Qiu¹, L Shi¹, (1)Shandong First Medical University & Shandong Academy of Medical Sciences, (2) Beijing Anding Hospital, Capital Medical University

Purpose: We developed a functional magnetic resonance imaging (fMRI)-based radiomics model for the diagnosis of major depressive disorder (MDD). **Methods:** A total of 146 participants (84 healthy controls, 62 MDD patients) were randomly divided into a training set ($n = 110$) and a validation set ($n = 36$) using stratified sampling. The resting-state fMRI images were preprocessed, including co-registration, correction, normalization and segmentation, using public toolbox DPABI in MATLAB, resulting in three amplitude of low-frequency fluctuation (ALFF) images, three fractional ALFF (fALFF) images, and four regional homogeneity (ReHo) images for each participant. We extracted 1118 radiomics features from each preprocessed images using an open-source python package Pyradiomics, including first-order statistical descriptors, high-order texture features, wavelet features, and Laplacian of Gaussian (LoG) features. The Shapiro-wilk test was used to calculate the normality of data. The differences between healthy controls and MDD patients in normally distributed features were calculated using two-sample t-test, otherwise, two-sided Wilcoxon rank sum test. All statistical analyses were performed by using SPSS software. The features with $P < 0.05$ were enrolled into least absolute shrinkage and selection operator (LASSO) regression model for further feature selection. The most valuable

features selected by LASSO were used for a support vector machine (SVM) model. **Results:** Among the ten models that were built based on different fMRI images processing methods, three models performed best in classifying healthy controls and MDD patients, including ALFF, mfALFF (i.e., each voxel's fALFF was divided by the global mean fALFF), and ReHo models. The ALFF model outperformed mfALFF and ReHo (accuracy: 86% and 83%, area under curve [AUC]: 0.88 and 0.88, sensitivity: 75% and 75%, specificity: 92% and 87.5%) models with an accuracy of 100% (AUC: 1). **Conclusion:** This study demonstrates that the fMRI-based radiomics model can provide favorable predictive efficacy for the diagnosis of MDD.

Uniqueness of Radiomic Features in NSCLC: Beyond Reproducibility/Repeatability

G Ge*, J Zhang, University of Kentucky, Lexington, KY

Purpose: The uniqueness of radiomic features, combined with their reproducibility, determines the success of radiomic studies. In general, radiomic features extracted from a defined region of interest (ROI) is hypothesized unique to the ROI. This study is to investigate if the hypothesis is valid. **Methods:** Two cohorts of NSCLC patients were retrospectively retrieved from GE and Siemens CT scanners. The lung nodule (defined region) was delineated manually and radiomic features were extracted using IBEX. The same ROI was then translated randomly to four other tissue regions of the same image set: adipose, heart, lung beyond nodule, and muscle. The same features were extracted from the four tissue regions for comparison. Coefficient of Variation (CV) was calculated to test variation of features within different ROIs. The Concordance Correlation Coefficient (CCC) between radiomic features of the defined region (lung nodule) and a given tissue region were calculated to determine feature uniqueness. Identifying features as non-unique follows this process: 1) A feature is flagged within a tissue region when the CCC > 0.85 for ≥ 50% of patients; then 2) a feature is identified as non-unique when ≥ 2 tissue regions are flagged for that feature. **Results:** We analyze 14 patients from GE and 18 patients from Siemens. Of 123 features, 18 radiomic features in GE and 16 features in Siemens are identified as non-unique, with 11 features overlapping. The overlap features are features included in the GradientOrientHistogram, and InverseDiffMomentNorm and InverseDiffNorm within the 3D GrayLevelCooccurrence (GLC). The remaining non-unique features for GE are SumAverage from the 3DGLC and features in the Intensity Histogram Gauss Fit. While for Siemens the features are Energy and Entropy for both 2D/3DGLC and MaxProbability for 3DGLC. **Conclusion:** Approximately 10% or more radiomic features are not unique to a defined region. Radiomic feature uniqueness needs to be considered in future radiomics studies.

Investigation of Bias-Voltage Dependent Operational Characteristics of An Energy-Resolving Pixelated Cadmium Telluride Detector System Within An Experimental Benchtop X-Ray Fluorescence Imaging System

H Moktan*, R K Panta, S H Cho, UT MD Anderson Cancer Center, Houston, TX

Purpose: To study the bias-voltage dependent operational characteristics of an energy-resolving pixelated cadmium telluride (CdTe) detector system coupled with a parallel-hole collimator within an experimental benchtop x-ray fluorescence (XRF) imaging system. **Methods:** An experimental XRF CT (XFCT) system was revamped with a commercially available energy-resolving x-ray detector system, known as High-Energy X-ray Imaging Technology (HEXITEC), consisting of 1-mm-thick CdTe sensor with 80 × 80 pixels on a 250-μm pitch. HEXITEC was coupled with a 2mm-diameter aperture parallel-hole collimator. A cone-beam was produced from an x-ray tube operated at 125kVp and 24mA. This cone-beam beam was filtered with 1.8mm Tin and used to irradiate a phantom containing 200-μL of 0.1wt.% gold nanoparticle (GNP) solution placed at 15-cm from the x-ray source. The detector-collimator system was placed at 10cm from the phantom, orthogonal to the excitation beam direction. The Compton/XRF photon spectra from the GNP solution were measured for 60s at different bias-voltages ranging from -100 to -600V. The x-ray spectra from all the detector pixels corresponding to the 2-mm collimator aperture were added to obtain the final spectra. The net XRF signal was extracted using the deconvolution method developed in-house. The gold Kα1 XRF peak at 68.8keV was fitted with Gaussian distribution to obtain the energy resolution (FWHM). The net XRF signals and energy resolution at 68.8keV were used to determine the optimal bias-voltage setting for the benchtop XFCT system. **Results:** As the bias-voltage increased from -100 to -500V, the net gold XRF signal, mean per-pixel energy resolution, and the homogeneity of energy resolution across the collimated 7 × 7 detector pixel area were improved by ~44, ~41, and ~66%, respectively. **Conclusion:** This work investigated the bias-voltage dependent operational characteristics of HEXITEC consisting of 1-mm-thick CdTe sensor, and determined the optimal bias-voltage under typical operating conditions of benchtop XRF imaging/XFCT systems.

Coronary Computed Tomography Angiography Combined with Coronary Heart Disease Risk Stratification Prediction for Asymptomatic Type 2 Diabetes Mellitus Patients Screening

Q Liu*, J Qiu, H Zhao, Shandong First Medical University & Shandong Academy Of Medical Sciences, Tai'an, CN

Purpose: The clinical significance of coronary computed tomography angiography (CCTA) in asymptomatic type 2 diabetes mellitus (T2DM) patients was not clear. We performed a retrospective study to evaluate a method of coronary heart disease (CHD) screening in asymptomatic T2DM patients by the combination of CCTA and CHD risk stratification prediction. **Methods:** Data of 141 T2DM patients (58±8 years, 57% males) without known symptoms suggestive of CHD and underwent CCTA were retrospectively analyzed. Patients were classified into three groups based on UK Prospective Diabetes Study (UKPDS) CHD risk stratification prediction. Other 76 healthy screening persons underwent CCTA successively were chosen as control group. Difference of CCTA scores among groups were compared using Post Hoc Multiple comparisons. **Results:** Segment involvement score in intermediate risk group (4.6±3.2) and high risk group (5.3±3.3) was significantly higher than control group (2.9±2.9). This indicates that stenosis was more widely distributed in intermediate and high risk groups. Segment stenosis score in intermediate risk group (7.2±7.0) and high risk group (9.2±8.0) was significantly higher than control group (3.5±4.4). Stenosis modulus in intermediate risk group (1.2±0.6) and high risk group (1.5±0.6) was also significantly higher than control group (0.8±0.5). This means stenosis was more severe in intermediate and high risk groups. Percentage of severe proximal plaque in intermediate risk group (14.5%) and high risk group (28.6%) was significantly higher than control group (3.9%), which had been known to be associated with a poor prognosis. **Conclusion:** In the intermediate-high CHD risk groups, the distribution of coronary artery stenosis was more extensive and more severe. Combined with risk stratification prediction, CCTA may be used for screening CHD in intermediate-high risk asymptomatic T2DM patients.

Prediction of EGFR Mutations, Subtypes, and Uncommon Mutations in Lung Adenocarcinoma Based On Machine Learning

Y Kawazoe*, T Shiinoki, K Fujimoto, Y Yuasa, T Hirano, K Matsunaga, H Tanaka, Yamaguchi University

Purpose: Molecularly targeted drugs (MTD) have been widely used for patients who have non-small cell lung cancer (NSCLC). The epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor is one of MTD and its therapy has a longer progression free survival (PFS) than conventional chemotherapy. The purpose of this study is to predict EGFR mutation status using machine learning and CT images of NSCLC. **Methods:** This study was consisted of 172 patients with NSCLC who had undergone biopsy or surgical specimen. All NSCLCs were pathologically confirmed adenocarcinoma and EGFR mutation status (whether EGFR mutations or wild-type). Then, EGFR mutations were confirmed common or uncommon mutations. Furthermore, common mutations were confirmed subtypes whether 19del or L858R or others. Patients data were divided into training and test data. Total 1048 radiomic features were extracted, then radiomic features and 4 clinical features were used to construct the three prediction models (EGFR mutations vs. wild-type, common vs. uncommon mutations and 19del vs. L858R). Lasso was used to select features and two machine learning algorithms (support vector machine (SVM) and logistic regression (LR)) with five-fold cross-validation were applied. The prediction performance of each model was evaluated in terms of the AUCs in training and test data. **Results:** For the training data of EGFR mutations vs. wild-type, AUC of SVM and LR were 0.85 and 0.84. For the test data, AUCs were 0.78 and 0.77. For the training data of common vs. uncommon mutations, AUC of SVM and LR were 0.84 and 0.84. For the test data, AUCs were 0.82 and 0.79. For the training data of 19del vs. L858R, AUC of SVM and LR were 0.82 and 0.84. For the test data, AUCs were 0.71 and 0.67. **Conclusion:** The constructed models were relatively high performance. These may be useful in selecting appropriate MTD.

A Deep Learning-Based Radiomics Approach to Identify Patient with Early Tumor Regression Utilizing Planning CT Images for Adaptive Radiotherapy

S Tanaka^{1*}, N Kadoya¹, Y Sugai¹, M Umeda¹, Y Katsuta¹, K Ito¹, T Yamamoto¹, N Takahashi¹, K Takeda¹, S Dobashi², K Takeda², K Jingu¹, (1) Department of Radiation Oncology, Tohoku University Graduate School of Medicine, Sendai, Japan, (2) Department of Radiation Therapy, Tohoku University Graduate School of Medicine, Sendai, Japan

Purpose: We developed a deep learning-based radiomics (DLR) approach to identify early tumor regression in head and neck (H&N) cancer patients based only on planning computed tomography (CT) images for adaptive radiotherapy. **Methods:** Our study used CT images of 62 patients with H&N cancer who received radiation therapy. We calculated the regression rate of gross tumor volume primaries (GTVp) and nodal GTV (GTVn) per treatment day by subtracting the volume of boost CT from the volume of initial CT, and then dividing the value obtained by the number of treatment days. Subsequently, we used the median regression rate as a threshold and assigned two labels (change and non-change) for GTVp and GTVn to all patients. We extracted one axial image for each maximum GTVp and GTVn volume from the initial CT image, which was then loaded into the pre-trained deep learning (DL) model via transfer learning. Eventually, we succeeded in extracting several deep features from the last fully connected layer. The robust, non-redundant, and predictive deep features were then selected using four-feature selection metrics. The selected deep features were used to predict change and non-change of GTVp and GTVn in five machine learning (ML). A predictive performance was then evaluated by 0.632+ area under the curve (AUC) bootstrap. **Results:** Darknet DL and the Random forest (RF) ML model for predicting GTVp regression had the highest AUC values (0.89 [0.885–0.894, 95% confidence interval (CI)]), whereas values achieved from radiomics and clinical factors were 0.723 and 0.66, respectively. In addition, Densenet DL and RF ML model for predicting GTVn regression achieved the highest AUC values (0.86 [0.856–0.866, 95% CI]), whereas values achieved by radiomics and clinical factors were 0.723 and 0.66, respectively. **Conclusion:** Our DLR approach to identify patients with early tumor regression could outperform existing radiomics features and clinical factors.

Classification of Head and Neck Contours Using Extremely Randomized Trees

V Leandro Alves^{1*}, M H Soomro¹, J Siebers¹, (1) University of Virginia Health System, Charlottesville, VA

Purpose: To train a classification model that provides a class-probability estimate for labeling delineated Head and Neck (HN) organs at risk (OARs). **Methods:** A knowledge-based quality control system composed of an extremely-randomized-trees classifier (ERT) model trained using segmentations from 234 publicly available CT Head and Neck image-sets were used to solve an Organ-at-Risk (OAR) classification problem. The feature vector for each OAR comprises shape, image intensity, location, and orientation features. The dataset was augmented using SMOTE. 5-fold stratified cross-validation was used to obtain learning curves for ERT k-nearest neighbors vote (KNN) and Dummy Classifiers (DC) for a random classification baseline. Each model was evaluated using a stratified 5-fold iterator with different randomization in three repetitions. ERT output was further derived from the probability of an OAR being an HN organ. A probability threshold was selected that maximizes the detection recall, consequently minimizing the fraction of false negatives. The dataset contains 28 OAR delineations. The model was optimized to classify 12 common HN structures, and the remaining ones were kept as hold-out OARs. **Results:** The cross-validated recall was DC 0.09±0.02, KNN 0.98±0.01, and ERT 0.994±0.005. The training curves for ERT showed convergence after a sample size of around 500 OARs, showing excellent recall scores in both train and validation samples as a low probability of overfitting. The mean classification probability for in-sample and hold-out OARs were respectively 0.97±0.07 and 0.41±0.08. A minimum classification probability of 0.77 was obtained using grid-search, resulting in a global 0.96 recall score **Conclusion:** ERT classifies HN OARs with high recall and provides superior results compared to KNN and DC. ERT reduces the likelihood of ROI delineation mislabeling and might detect aberrant delineations. It enables mass ROI name standardization with low miss-classification errors for data-mining of heterogeneous historical priors.

Evaluation of Computer-Aided Nodule Assessment and Risk Yield (CANARY) in Korean Patients for Prediction of Invasiveness of Early Lung Adenocarcinoma

Juyoung Lee^{1,2*}, Seong Yong Park, M.D., Ph.D.³, Jin Sung Kim, Ph.D.¹, (1) Department of Radiation Oncology, Yonsei University College of Medicine, Seodaemun-gu, Seoul, KR, (2) Department of Integrative Medicine, Yonsei University College of Medicine, Seoul, KR, (3) Department of Thoracic and Cardiovascular Surgery, Yonsei University College of Medicine, Seoul, KR

Purpose: Discriminating the invasiveness of early lung adenocarcinomas clinically important, and several institutions have developed their own approaches

by using computed tomography images of patients. The purpose of this study is to evaluate Computer-Aided Analysis of Risk Yield (CANARY), a validated virtual biopsy and risk-stratification machine-learning tool for lung adenocarcinomas, in a Korean patient population. **Methods:** A total of 380 lesions were reviewed from 360 patients who underwent lung resection between January 2018 and July 2020. The lesions were classified as "indolent" (atypical adenomatous hyperplasia, adenocarcinomas in situ, or minimally invasive adenocarcinoma) or "invasive" (invasive adenocarcinoma) by following the Score Indicative of Lung Cancer Aggression (SILA) from the CANARY analysis results, and compared with the pathology report. **Results:** The mean age of the patients was 63 ± 9.8 years, and 219 (60.9%) were female. Each of the area under the curve (AUC) from the entire cohort and a dataset upsampled for an even distribution of two cases were 0.814 and 0.809, while the CANARY developer group announced the AUC of 0.912 with the cut-off SILA of 0.338. At the optimal threshold from our data, which was SILA of 0.229, CANARY found 47 out of 65 (72.3%) indolent cases and 242 out of 315 (76.8%) invasive cases. **Conclusion:** The AUCs of CANARY in Korean patients were considered excellent even though there was a meaningful difference in the optimal thresholds from the developer group. We found that adjusting the cut-off threshold is needed to use CANARY in other countries or races.

SU-lePD-TRACK 2-06

Development of Machine Learning Based Algorithm for Prediction of Invasiveness of Early-Lung Adenocarcinoma by Using Chest Computed Tomography

Juyoung Lee^{1,2*}, Seong Yong Park, M.D., Ph.D.³, Jin Sung Kim, Ph.D.¹, (1) Department of Radiation Oncology, Yonsei University College of Medicine, Seodaemun-gu, Seoul, KR, (2) Department of Integrative Medicine, Yonsei University College of Medicine, Seoul, KR, (3) Department of Thoracic and Cardiovascular Surgery, Yonsei University College of Medicine, Seoul, KR

Purpose: To locate and classify lung adenocarcinoma lesions, which are also called ground-glass nodules (GGN) from computed tomography (CT) images, are clinically helpful in determining the treatment plans and the extent of resection before surgery to lung cancer patients with high mortality rates. Herein we report a machine learning-based auto-detection and classification model of early lung adenocarcinoma by using chest CT images. **Methods:** An image dataset of 190 chest CT scan datasets from the same number of patients who received the pulmonary resection surgery was used to train and validation of the model. To detect and the GGNs and distinguish them into two large groups: "non-invasive" (including atypical adenomatous hyperplasia, adenocarcinoma in situ, and minimally invasive adenocarcinoma) or "invasive" (invasive adenocarcinoma), the two-step combination model was used in this study. First, Fully Convolutional DenseNet was applied to train the GGN segmentation model from the CT images. Then the true positive cases were categorized into one of two groups by using radiomics, a method of comprehensively classifying the features of tumors by quantifying large amounts of image features. **Results:** The mean age of the patients was 62 ± 9.6 years, and 122 (64.2%) were female. The segmentation model showed a dice score of 0.65, a true positive rate of 0.88 (36 out of 41), and averaged 1.5 false positives per case. Among 36 GGNs that the segmentation model detected, the area under the curve of the classification model scored 0.90. **Conclusion:** Our preliminary machine learning-based two-step GGN segmentation and classification model required management of false-positive cases but showed excellent performance on the classification for true positive cases. Therefore, our model could be expected to be of great help in clinical use if the false positives are reduced.

Multi-Scale Regional Fusion Based Interactive 3D Tumor Segmentation in Lung Cancer

R Wang^{1*}, J Yang², Z Mu³, Z Wang⁴, R Xu⁵, Z Zhou⁶, (1) Xidian University, CN, (2) Xidian University, Xi'an, CN, (3) (4) Peking University Cancer Hospital & Institute, CN, (5) Putian University, (6) University of Central Missouri, Warrensburg, MI

Purpose: Accurate lung tumor segmentation in computed tomography (CT) images is of great importance in diagnosis and target identification in lung cancer treatment. Most current segmentation methods require a large scale labeled data to train, while it is always difficult and time consuming to acquire labeled data. We aim to develop a new multi-scale regional fusion based interactive method for three-dimension (3D) tumor segmentation (MFIS). **Methods:** Since no data is needed to train the model, seven patients collected from Peking University Cancer Hospital (Beijing, China) are used for testing. The manually contoured tumor by an experienced radiologist is used as ground truth. MFIS consists of three steps: (1) normalization. To reduce the potential influence of image acquisition protocols on tumor segmentation, CT images are normalized through min-max normalization. (2) 3D tumor block extraction through interactive information. The interactive markers such as a simple line are drawing on 2D images to indicate the tumor region. (3) Multi-scale regional fusion. Three phases are included in this step, they are multi-scale super-voxel pre-segmentation to divide the 3D image into a number of super-voxel regions in first phase. Then Super-voxel region merging is performed to merge the region with maximal similarity as the tumor. Finally, multi-scale average fusion is performed to improve segmentation accuracy through capturing both local and global contextual information. Dice coefficient (Dice), true positive rate (TPR) and false positive rate (FPR) are used for evaluation. The ideal segmentation is higher Dice and TPR, while lower FPR. **Results:** The quantitative evaluation results for MFIS on Dice, TPR and FPR are 0.8821, 0.0052, and 0.8943, respectively. **Conclusion:** A new multi-scale regional fusion based interactive method for three-dimension (3D) tumor segmentation (MFIS) in lung cancer was developed. The experimental results demonstrated that MFIS can obtain better segmentation performance in a more efficient way.

Quantitative and Qualitative Evaluation of Translating an Adult Auto-Contouring Algorithm to Pediatric Patients

S Hernandez^{1,2}, L Court^{1,2}, D Rhee^{1,2}, M Soliman², C Cardenas^{1,2}, (1) UT MD Anderson Cancer Center UTHealth Graduate School of Biomedical Sciences, Houston, TX, (2) The University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: To perform a quantitative and qualitative assessment of using an adult auto-contouring algorithm to generate pediatric normal tissue contours. **Methods:** A clinically deployed, adult head-and-neck (HN) auto-contouring model was originally trained to delineate 16 normal tissue structures on 3,495 retrospective, adult HN patients. This work tested the model's ability to segment the same 16 structures on 143 retrospective pediatric CSI CT scans. Dice similarity coefficient (DSC) and Hausdorff distance (HD) were computed for each of the 16 HN structures. The DSC and HD were compared to the metrics achieved on the adult data set, using an unpaired t-test for each structure ($p < 0.05$ as statistically significant). To assess the clinical acceptability of the contours, we conducted a physician review using 20 patients and a scoring system of 1=no edits, 2=minor edits, and 3=major edits. The clinical acceptability of the pediatric contours was compared to what was achieved on the adult contours. **Results:** The average $DSC \pm 1\sigma / HD \pm 1\sigma$ (cm) achieved on the brain, brainstem, eyes(avg), lenses(avg), optic nerves(avg), parotids(avg), cochleae(avg), spinal cord, esophagus and optic chiasm, were $0.98 \pm 0.01 / 0.97 \pm 1.51$, $0.80 \pm 0.08 / 0.97 \pm 0.76$, $0.87 \pm 0.53 / 0.46 \pm 4.4$, $0.65 \pm 0.12 / 0.51 \pm 4.10$, $0.61 \pm 0.17 / 0.37 \pm 4.97$, $0.60 \pm 0.23 / 1.17 \pm 8.10$, $0.53 \pm 0.17 / 0.48 \pm 0.24$, $0.67 \pm 0.15 / 7.40 \pm 7.10$, $0.57 \pm 0.13 / 3.31 \pm 1.40$, and $0.34 \pm 0.16 / 0.89 \pm 5.40$, respectively. The difference between the adult and pediatric DSC values was not statistically significant. The difference between the HD of the esophagus was statistically significant ($p = 0.0001$). Physician review scored 8/16 pediatric and 14/16 adult contours as clinical acceptable (no or minor edits), respectively. Clinically unacceptable pediatric structures included the lenses (5%), optic nerves (5%), optic chiasm (42%), parotids (55%), mandible (5%), and esophagus (11%). The number of structures requiring major edits for patients <2 and >2 years old was 6 and 1, respectively.

Conclusion: Our results suggest that apart from very young patients (<2 years old), adult auto-contouring algorithms can automatically generate clinically acceptable contours on pediatric patients for a majority of HN structures.

Multi-Organ Segmentation on An Inference-Combined Dataset

T Marshall^{1*}, X Li², K Yang³, B Liu⁴, (1) Massachusetts General Hospital, Cambridge, MA, (2) Massachusetts General Hospital, Belmont, MA, (3) Harvard Medical School, Massachusetts General Hospital, Boston, MA, (4) Massachusetts General Hospital, Boston, MA

Purpose: To evaluate the performance of a single multi-organ segmentation by a convolutional neural network trained on a combination of two publicly available datasets of CT images. **Methods:** 88 CT images with segmentations of the liver, left kidney, spleen, gallbladder, esophagus, stomach, pancreas, and duodenum and 83 segmentations of the liver, bladder, and left and right kidneys are prepared from two different publicly available datasets. Five segmentations from the first set and eight from the second are excluded from training and used for validation. A DenseVNet is trained on each dataset, and inference performed on the other to generate segmentations of the missing organs. A combined dataset of 121 segmentations (including validation) is used to train a network to segment all 10 abdominopelvic organs. Dice similarity coefficients are used to evaluate accuracy, with a T-test used to identify significantly different accuracies. **Results:** For the liver and left kidney, differences in the average dice coefficients between segmentations are largely explained by differences in ground-truth segmentations provided by different observers. For organs inferred for part of the combined dataset, average dice scores on the validation set tend to decrease when trained on the combined dataset. However, for the spleen, esophagus, and stomach the difference is negligible, indicated by a very large p-value (>0.5) from a T-test on the dice coefficients. For other organs these p-values range from 0.005 to 0.16. **Conclusion:** By combining two datasets, the robustness of a multi-organ segmentation network can be improved by providing a more varied set of images and segmentations produced by more human observers. For more easily segmented organs, the accuracy of a multi-organ network may be preserved even when these organs are inferred for part of the dataset. For smaller, more difficult organs, using several dedicated networks may be necessary to achieve best results.

Segmentation of a Highly Deformable Organ Using a Machine-Assisted Interpolation Algorithm

D Luximon*, Y Abdulkadir, E Morris, P Chow, J Lamb, University of California, Los Angeles, Los Angeles, CA

Purpose: Accurate and robust auto-segmentation of highly deformable organs, e.g. stomach, remains an outstanding problem due to these organs' frequent and large anatomical variances. We propose a machine-assisted interpolation (MAI) that uses prior information, in the form of sparse manual delineations, to auto-segment the stomach in low field magnetic resonance images (MRI). **Methods:** Images from 96 patients undergoing 0.35T MRI-guided abdominal radiotherapy were collected. For each patient volume, the manual delineation of the stomach was extracted from every 8th slice. These manually drawn contours were first interpolated to obtain a rough segmentation mask of the stomach. A 64x64 pixel patch-based convolutional neural network (CNN) was first used to localize the position of the organ's boundary on each slice within a 5-pixel wide road. This boundary prediction was then used as an anatomical constraint for a second CNN, which output the final stomach segmentation. Both networks used a Dense-UNet architecture and were trained, validated, and tested on 79, 7, and 10 patients respectively. Algorithm performance was compared against linear interpolation and de novo auto-segmentation using a Dense-UNet trained on the same dataset. **Results:** MAI resulted in a mean 50th Hausdorff Distance (50HD) of 1.6 ± 1.1 mm and mean Dice Similarity Coefficient (DSC) of 0.91 ± 0.07 with 6% of slices with DSC<0.8. De novo auto-segmentation resulted in 50HD of 4.7 ± 11.8 mm and DSC of 0.80 ± 0.24 with 22% of slices having DSC<0.8. Linear interpolation resulted in 50HD of 2.7 ± 2.3 mm and DSC of 0.86 ± 0.12 with 26% of slices having DSC<0.8. Differences in 50HD, DSC, and fraction of slices with DSC<0.8 were all statistically significant between MAI and comparison methods ($p<0.001$). **Conclusion:** The proposed machine-assisted interpolation algorithm significantly outperformed de novo segmentation and linear interpolation in terms of accuracy and robustness for stomach segmentation.

A Deep Learning Approach for Contour Interpolation

C Zhao^{1*}, Y Duan¹, H Li², H Kim², L Henke², D Yang², (1) University of Missouri, (2) Washington University School of Medicine, St. Louis, MO

Purpose: Contour interpolation is an important tool to expedite manual segmentation of anatomical structures by allowing users to contour on discontinuous slices and fill-in the gaps. The conventional interpolation tool in clinical TPS is based on distance map interpolation and has difficulties in generating satisfactory results when the existing manual contours differ dramatically. This is especially apparent near the superior and inferior borders of organs, and for the gastrointestinal structures such as bowel. In this study, we developed a deep learning model to provide improved contour interpolation robustness and accuracy for these historically difficult cases. **Methods:** The deep contour interpolator was developed and trained using selected 5882 datasets containing images of multiple organs (lung, liver, esophagus, heart). Preprocessing steps include cropping, image resizing and intensity normalizing. A 3D UNet model was utilized and its softmax layer and segmentation layer were replaced by a regression layer. The input size is $128 \times 128 \times 8$ in 2 channels. The first channel is the top and bottom slices of a 5-slice patch and three middle slices duplicated. The second channel is the related masks, empty mask for middle slices. The outputs are the predicted organ masks for the 3 middle slices. **Results:** The dice coefficients and DTA (distance-to-agreement) values were computed to evaluate the performance. For 1117 independent testing cases, the dice score was 0.90 ± 0.13 for the difficult cases, comparing to 0.85 ± 0.17 by the conventional method. The max and 95th percentile DTA values, were 7.6 ± 13.2 and 4.5 ± 11 mm, comparing to 8.7 ± 14.8 and 5.2 ± 5.2 mm by the conventional method. A t-test was conducted that confirmed that our model statistically significantly out-performed the conventional method ($p<0.05$). **Conclusion:** These results suggest that the deep interpolator may produce more robust and accurate interpolation results than the conventional contour interpolation method for historically difficult cases.

Automated CTV Contouring for Prostate and Nodes Utilizing Deep Learning Contouring

V Malesevic*, L Potters, A C Riegel, Y Cao, J Baker, Northwell Health and Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Lake Success, NY

Purpose: Applications of automation are increasingly expanding into different aspects of cancer management in radiation therapy. At the forefront is the contouring of organs at risk utilizing artificial intelligence. Few studies, however, have utilized artificial intelligence for target segmentation in the pelvic region. We implement a first of its kind deep learning contouring (DLC) for the prostate and nodes clinical target volume (CTV). This study investigates the similarity of manual delineated CTV and planning target volumes (PTV), done by radiation oncologists, with ones completed using autosegmentation with a DLC model. **Methods:** DLC model training used one hundred patient's contours of the prostate and nodes. The model was validated by generated CTV contours on 30 patients and expanding by 0.5cm to get PTV. Fifteen of those patients had physician CTV contours and subsequent expansion for PTVEX, and fifteen had direct PTV (PTVDIR) volumes by the physician. Evaluation of the geometric similarity using the Dice Similarity Coefficient (DSC) and average distance (AD), a modification of the Hausdorff Distance, allows for contour comparison. **Results:** Average values and standard deviation for the DSC generated

on the CTV, PTVEX, and PTVDir are 0.68 ± 0.08 , 0.77 ± 0.05 , and 0.75 ± 0.05 . AD yielded 5.5 ± 1.1 mm, 6.0 ± 1.2 mm, and 6.5 ± 1.2 mm. Typically, deviations occurred at the superior aspect of the nodal volume and on the prostate's inferior and posterior, attributed to known inconsistencies in the training volume. A subjective observation by physicians yields that, in general, the contours are beneficial and should yield time savings. **Conclusion:** We demonstrate the automating DLC for the prostate and nodes is possible. Although not statistically significant, we find an increased correlation between PTV volumes when physician contours the CTV over PTV. Further curating of training data should yield increased effectiveness in CTV contouring.

Patient-Specific Anatomic Context and Shape Prior (PACS)-Aware Recurrent Network for Cone-Beam CT Lung Cancer Segmentation

J Jiang*, S Alam, I Chen, P Zhang, A Rimner, J Deasy, H Veeraraghavan, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: To train a AI auto-segmentation of lung tumors on weekly cone-beam (CBCT) using planning CT (pCT) and its clinical contour. **Methods:** We developed a novel Patient-specific Anatomic Context and Shape prior information or PACS-aware 3D recurrent registration-segmentation deep network for segmenting lung tumors from CBCT. Using an end-to-end trained network, the anatomic context from higher contrast planning CT and shape (delineated contours) priors are incorporated as additional input channels into a 3D recurrent CBCT segmentation network through progressively deformed sequence of images and contours, produced by the recurrent registration network. Our approach learns to progressively deform images and handles large deformations between pCT and a weekly CBCT without requiring deformation vector field (DVF) for training. The segmentation network losses are optimized using CBCT expert segmentations. We trained our model using 98,000 pCT and CBCT image patches of size $192 \times 192 \times 48$ extracted from 315 CBCT scans from 55 patients in a cross-validation setting. Independent testing was performed on 54 CBCT scans obtained from 10 patients. Performance comparisons was done against multiple state-of-the-art methods using Dice similarity coefficient (DSC), surface DSC and Hausdorff distance at 95th percentile (HD95) metrics. **Results:** Our method produced significantly ($p < 0.001$) more accurate tumor segmentations (DSC of 0.84 ± 0.08 , surface DSC of 0.98 ± 0.04 , and Hausdorff distance at 95th percentile of 3.33 ± 2.02 mm) than both deformable image registration and deep learning voxelmorph methods on independent test set. **Conclusion:** We introduced a patient-specific anatomic context and shape prior aware multi-modal recurrent registration-segmentation network for segmenting tumors on treatment CBCTs. Our approach significantly outperformed multiple methods and achieved promising accuracies on noisy and artifact-abundant cone-beam images.

Deep Learning-Based Intracranial Vessel Wall Segmentation: Good DSC with Biased NWI?

H Zhou^{1*}, J Xiao², Z Fan^{2,3}, D Ruan^{1,4}, (1) Department of Bioengineering, UCLA, Los Angeles, CA, (2) Cedars-Sinai Medical Center, Los Angeles, (3) Keck School of Medicine of USC, Los Angeles, CA, (4) School of Medicine, UCLA, Los Angeles, CA

Purpose: Vessel wall (VW) contouring is important in cardiovascular disease diagnosis. Deep learning methods have been applied to MR VW images to delineate the lumen and the VW, with good common segmentation objectives, in Dice similarity coefficients (DSC). On the other hand, to support quantitative clinical judgement, further measures need to be assessed and characterized. This study provides an in-depth investigation on the behavior of a popular clinical metric – the normalized wall index (NWI), which is defined by the VW area divided by the whole vessel area, on the cross-sectional slices. **Methods:** We investigated the combination of (a) different network structures, including 2D UNet, 2.5D UNet, and 2.5D UNet++, all with good DSC performance 0.9163 ± 0.0522 , 0.7452 ± 0.1046 ; 0.9080 ± 0.0641 , 0.7521 ± 0.1006 ; and 0.9116 ± 0.0723 , 0.7758 ± 0.0957 for the lumen and the VW, respectively; (b) two objective functions: DSC, and DSC plus Hausdorff distance loss; and (c) different training sample reweighting schemes, including random, uniform, importance sampling, and matched distribution between training and testing to establish performance upper-bound. We examined closely the impact on NWI prediction and its variation along the vessel, to generate hypothesis for the cause of such bias and guide further quantitative radiomic study. **Results:** The results showed persistent systematic bias and large variation on the testing NWI, regardless of network structure, objective function, or training set sampling scheme. The NWI bias ranged from 0.0592 ± 0.0237 to 0.0975 ± 0.0425 . **Conclusion:** NWI may not be sufficient as the sole quantitative basis for plaque burden judgement. Its ratio form could be more sensitive to mislabeling. We hypothesized (1) it may be beneficial to optimize the clinical endpoints directly as the segmentation objective; (2) the seemingly small variation in contour labeling in training labels could have a large impact on derived quantitative omics features and their associated confidence. A better scheme to homogenize manual labels is required.

Knowledge-Based HDR Catheter Position for Prostate Brachytherapy

T Wang*, Y Lei, Y Fu, J Roper, A Jani, J Bradley, T Liu, P Patel, X Yang, Emory University, Atlanta, GA

Purpose: Current high-dose-rate (HDR) prostate brachytherapy catheter placement is based on physicians' experience. It may lead to large plan quality variations among physicians, and increased placement randomness for individual physician. In this study, we proposed a learning-based method to predict HDR needle position for prostate cancer patients. **Methods:** The proposed learning-based framework consists of deformable registration network (Reg-Net), multi-atlas ranking and catheter regression. Binary masks of the organs-at-risks are first transformed into distance maps which describe the distance of each local voxel to the organ surfaces. For a new patient, Reg-Net deformably registers the distance maps from multi-atlas set to match this patient's distance map and then bring catheter maps from multi-atlas to this patient. Based on several similarity criterions, we select the top-ranked atlas' deformed catheter positions as predicted catheter position for this patient. Finally, catheter regression is used to refine the final catheter positions. A retrospective study on 90 patients with a five-fold cross-validation was used to evaluate the proposed method's feasibility. Plans were optimized based on both the clinical and predicted catheter pattern. **Results:** For all patients, on average, both clinical plan dose and new plan dose meet the common dose constraints when prostate dose coverage is kept at $V100=95\%$. The plans from predicted catheter pattern have slightly higher hotspot in terms of $V150$ by 5.0% and $V200$ by 2.9% on average. For bladder $V75$, rectum $V75$ and urethra $V125$, the average difference is close to zero, and the range of most patients is within ± 1 cc. **Conclusion:** We developed a novel learning-based method in predicting catheter locations for HDR prostate brachytherapy. It has great clinical potential since it can provide catheter location estimation prior to catheter placement, which could reduce the dependence on physicians' experience in catheter implantation and improve the quality of

prostate HDR treatment plans.

Accurate Automatic Rectum Segmentation for High-Dose Rate Brachytherapy of Cervical Cancer Treatment Planning

Y Gonzalez^{1,2*}, C Shen^{1,2}, K Albuquerque², X Jia^{1,2}, (1) UT Southwestern Medical Center, Dallas, TX (2) iTORCH Lab, UT Southwestern Medical Center, Dallas, TX

Purpose: Despite advances in deep-learning (DL) based automatic organ segmentation, automatic rectum segmentation is still challenging in high-dose-rate brachytherapy (HDRBT) of cervical cancer treatment planning, because of a lack of well-defined rectosigmoid boundary. DL models often cannot accurately determine this boundary, causing large errors when evaluating D2cc, as the superior part of rectum falls in the high dose region and 2cc volume is sensitive to segmentation results. This study develops a method to address this problem. **Methods:** We first performed an initial segmentation of rectum using a 3D U-Net that mapped a CT image to a rectum volume. We then used the superior-most slice of the initial rectum volume as initial condition to segment the rectum/sigmoid structure in a slice-by-slice fashion for 5cm along the superior direction to ensure rectosigmoid junction was included in the segmented volume. As such, a 2.5D U-Net was established to predict the sigmoid on a given slice based on the connectivity between previous adjacent CT slice and segmentation. We finally calculated the centroid of segmented volume in each slice and determined the centerline of the structure. The final rectum structure was determined by keeping the part inferior to the rectosigmoid junction defined as the place where the structure centerline turned for an angle over a threshold value. **Results:** We evaluated our method and a simple 3D U-Net-based rectum segmentation method against ground truth drawn by physicians. The error in superior rectum boundary position was 5.0 ± 5.0 mm in our method, while the error of 3D U-net was 15.7 ± 12.1 mm. When using the segmented structure for D2cc calculation, the error of our method and 3D U-net was $4.8\% \pm 3.9\%$ and $9.8\% \pm 10.2\%$. **Conclusion:** The proposed method overcame the challenge of conventional DL-based rectum segmentation, which allowed accurate computations of D2cc in HDRBT of cervical cancer treatment planning.

Influence of Loss Functions on Accuracy of Deep Learning Based Dose Distribution Prediction for Intensity Modulated Proton Radiation Therapy

S Momin*, J Harms, Y Lei, S Charyyev, J Zhou, J Roper, J Bradley, T Liu, X Yang, Department of Radiation Oncology and Winship Cancer Institute, Emory University, Atlanta, GA

Purpose: This study investigated the influence of different loss functions on dose prediction accuracy for intensity modulated proton radiation therapy (IMPT). **Methods:** We proposed a dual-pyramid-network (DPN) with late-fusion-network (LFN) to generate high-quality pseudo-Monte Carlo (MC) proton plans using low-quality pencil-beam (PB)-based dose plans and corresponding CT as inputs. The proposed deep-learning network architecture includes three subnetworks: CT-only, PB dose-distribution only and late fusion subnetwork. The CT only and PB dose-distribution only subnetworks are based on U-Net architecture and extract features from the CT and PB dose distribution of each patient. Individual features are then combined in the LFN. The subnetworks were trained through three loss functions (L1-norm, L0.5-norm, and combined L1+L0.5), respectively, with constant hyperparameters in three separate models. Five-fold cross-validation experiments were performed on 40 prostate cancer patients. Predicted pseudo-MC dose distributions were compared with the target MC dose via gamma analysis under 1%/1mm, 2%/2mm and 3%/3mm acceptance criteria. Obtained dose-volume-histograms (DVHs) from each trained model were evaluated against the high-quality MC DVHs. **Results:** Dose map comparison results show that L1-norm loss function performs well in low dose region, whereas L0.5-norm function performs well in high dose regions. The combined loss function achieved the best dose distribution prediction accuracy. L1norm, L0.5norm, and combined (L1+L0.5) loss functions achieved $30.8 \pm 20.3\%$, $71.9 \pm 17.3\%$, and $90.1 \pm 5.8\%$ under 1%/1mm acceptance criteria and $56.2 \pm 26.2\%$, $92.5 \pm 5.6\%$ and $95.1 \pm 0.8\%$ under 2%/2mm acceptance criteria averaged over 40 patients from cross validation. The DVHs obtained from combined loss model had the closer agreement with the ground-truth MC DVHs compared to model with individual losses. **Conclusion:** We quantitatively investigated dose prediction accuracy based on three different loss functions to generate high-quality pseudo-MC proton plans via the proposed LFN-DPN. Overall results identify the combined (L1+L0.5) loss function to be the best candidate for deep-learning-based dose prediction of IMPT and highlights the importance of choosing an appropriate loss function.

Application of An Artificial Neural Network to Predict Equivalent Uniform Dose and Tumor Control Probability in Radiation Therapy of Lung Cancer Using Treatment Plan Data

M Pudasaini^{1*}, S Pella², T Leventouri¹, W Muhammad¹, (1) Florida Atlantic University, Boca Raton, FL, (2) FAU & 21st Century Oncology (Genesis Care), Boca Raton, FL

Purpose: To apply an artificial neural network (ANN) in order to predict equivalent uniform dose and tumor control probability in external beam radiation therapy of lung cancer treatment plans. **Methods:** Retroactive lung cancer treatment plans of 100 patients were chosen for this study. The tumor control probability (TCP) of tumor target and equivalent uniform dose (EUD) were calculated for all plans using Niemierko's EUD based linear-quadratic model. The expected outputs for ANN were calculated EUD and TCP. The inputs for ANN were treatment modality, location of tumor, prescribed dose, fractions, planning target volume (PTV), the maximum dose to the tumor, and mean doses to the OARs. All numeric data were normalized in the range 0 to 1, while non-numeric inputs were categorized into binary numbers (0 or 1). Our ANN is based on a Scaled Conjugate gradient algorithm with two hidden layers having 15-10 nodes with 11 inputs and 2 outputs. The data were employed 70% for training and 30% for validation and testing. **Results:** We found EUD and TCP for the target volume with an overall regression value of 0.97. The Mean absolute difference for predicted and expected values for EUD and TCP are found 0.0510 ± 0.0704 and 0.0439 ± 0.0708 respectively. In some cases, we encountered a large error (~ 0.14), where TCP were 50% or lower in palliative treatment case. **Conclusion:** These results indicate that ANN can be employed to predict TCP and EUD. The outcome of this research can be further improved by studying a large cohort of patient's treatment plans.

Improved Dosimetric Performance of VMAT Total Marrow Irradiation Using Knowledge-Based Planning Approach

K Ahn^{1,2*}, M Koshy^{1,2}, J Partouche², D Rondelli¹, P Patel¹, Y Hasan², H Liu², B Aydogan², (1) University of Illinois at Chicago, Chicago, IL, (2) University of Chicago, Chicago, IL

Purpose: We present updates on knowledge-based planning (KBP) driven linac-based total marrow irradiation (TMI). A KBP model was developed to handle multiple-isocenter volumetric modulated arc therapy (VMAT) covering a large target volume from head to mid femur. **Methods:** Fifty-one patients previously treated in our clinic were selected for the model training, while 12 patients from another clinic were used for validation. All plans used a 3-isocenter, 13-arc VMAT technique to cover sub-target volumes of head and neck (HN), chest, and pelvis. Both the HN and pelvis plans used the chest plan as the base dose to reduce hot spots around the field junctions. This leads to a wide range in dose-volume histogram (DVH) plots of target volumes. To address this, re-optimized plans without the base-dose plan were added to the library to train the KBP model. The performance of KBP-TMI model was then tested using a cohort of 11 clinical plans that did not use KBP. Conformity index and homogeneity index were evaluated using V95%/planning target volume (PTV) and D0.03cc/Rx dose, respectively. **Results:** KBP achieved our clinical goals (Rx dose = D95%) within 2-3 iterative optimizations, which used to take 4-6 days of effort without

KBP. Both KBP and clinical plans had mean dose values in the range of 108%-112% of the prescribed dose for PTVs, 22%-30% for lenses and oral cavity, and 41%-64% for brain, heart, lungs, bowels, liver, kidneys, eyes. Statistically significant reductions with KBP were observed in the mean dose values to brain, lungs, eyes and lenses. KBP substantially improved conformity index (1.5 ± 0.1 vs 1.8 ± 0.1) and homogeneity index (1.25 ± 0.02 vs 1.33 ± 0.03). **Conclusion:** Our study demonstrates that VMAT-TMI powered by KBP improves dosimetric performance with uniform quality. Moreover, it improves planning time considerably to allow its wide-spread clinical implementation.

SU-lePD-TRACK 5-06

Implementation of a Conditional Generative Adversarial Network for Automatic Prediction of 3D Dose Distributions in Prostate Cancer

J Cunningham*, S Zhu, B Luo, Z Dai, N Wen, Henry Ford Health System, Detroit, MI

Purpose: The treatment planning process is time-consuming due to the complexity of iterative optimizations, this bottleneck can be resolved through deep learning dose prediction. However, this process excludes the mechanical parameters necessary for a deliverable plan. We aim to generate a streamlined VMAT planning process for prostate cancer using the Eclipse photon optimizer (PO) to generate a deliverable plan from an automatically predicted 3-dimensional (3D) radiation dose distribution. **Methods:** A conditional generative adversarial network, trained with 127 patients, was used to predict normalized 3D radiation dose distributions for 5 prostate cancer patients treated to 79.2Gy in 44 fractions, which were then imported into the treatment planning system. The PO was used to define the optimization parameters based off the predicted dose volume histogram. One optimization was performed using three consistent optimization objectives at predefined points for each OAR (rectum, bladder, penile bulb and right/left femoral heads) and PTV. Key dosimetric parameters were compared between the original planned, predicted and deliverable doses. 3D gamma analysis using plan delivery logs was performed using 3%3mm criteria. **Results:** Dosimetric comparison demonstrated that the deliverable doses had improved PTV coverage and comparable dose to OARs to the predicted and planned dose. The PTV coverage (D95%) on average increased from 96.0% to 100.6% between predicted and deliverable dose. The D50%(Gy) and V20Gy(%) for the bladder and rectum on average increased from 27.6Gy and 57.0% to 28.6Gy and 57.4% and 37.3Gy and 78.7% and 39.4Gy and 79.5% respectively. The right and left femoral D5%(Gy) decreased from 29.9Gy to 29.6Gy and 34.0Gy and 33.9Gy, respectively. Mean dose to the penile bulb increased from 26.2Gy to 29.1Gy. The average passing rate for 3D gamma analysis was 99.6%. **Conclusion:** With deep learning predicted doses, we can generate a deliverable plan with radiation dose distributions comparable to the predicted dose.

Improving Target Detection for Real-Time Markless Lung Tumor Tracking Using Deep Learning

GP Chen*, Y Liang, Y Zhang, XA Li, Medical College of Wisconsin, Milwaukee, WI

Purpose: To investigate the feasibility of using deep learning to improve markless lung tumor detection on x-ray radiograph images during real-time motion tracking and correction (RMTC). **Methods:** A convolutional neural network (CNN), designed with Matlab (Mathworks, R2020a), was trained, validated and tested with 194 radiograph images acquired at different gantry angles and couch positions from 12 lung cancer patients treated with RMTC during helical tomotherapy. The dataset was divided into training (70%), validation (15%) and test (15%) subsets. The ground truth lung tumor contours on the radiographs were obtained by transferring the contours from DRR with manual editing. All radiographs were normalized based on the intensities of voxels enclosed in a region of interest (ROI) corresponding to the tumor motion ranges on the DRR. Performance of the trained and validated CNN was measured by comparing the predicted target contours of the test data subset with the ground truth using Dice similarity coefficient (DSC) and the distance between the centers from the predicted and the ground truth contours, (dCNN-GT), which was also compared to the distance between the detected center in the RMTC system and the ground truth center (dRMTC-GT). **Results:** The training and validation achieved sufficient accuracy (99.68%). The average DSC was 0.76 ± 0.24 . The average dCNN-GT was 1.48 ± 1.05 mm, slightly smaller than the average of dRMTC-GT (1.69 ± 1.00 mm). On average, the time needed for a prediction was 119 ± 29 ms with an Intel Core™ i7-6700 CPU@3.40 GHz PC. **Conclusion:** The CNN model can quickly predict target center on x-ray radiograph with accuracy equal or slightly better than the current system detection. With further development using large datasets, the deep learning may be used to improve target prediction for real-time markless lung tumor tracking.

Therapy: Brachytherapy Dosimetry

SU-lePD-TRACK 6-01

Monte Carlo Characterization of High Atomic Number Inorganic Scintillators for in Vivo Dosimetry in Ir-192 Brachytherapy

V Kaveckyte^{1,2*}, E B Joergensen^{3,4}, J G Johansen⁴, A Carlsson Tedgren^{1,2} (1) Department of Health, Medicine and Caring Sciences, Linköping University, SE-58185 Linköping, Sweden (2) Department of Medical Radiation Physics and Nuclear Medicine, Karolinska University Hospital, SE-17176 Stockholm, Sweden (3) Aarhus University, Health Graduate School, DK-8000 Aarhus, Denmark (4) Department of Oncology, Aarhus University Hospital, DK-8200 Aarhus, Denmark

Purpose: To use Monte Carlo (MC) simulations for the characterization of several existing high atomic number (Z) inorganic scintillator dosimeters designed for in vivo dosimetry of ¹⁹²Ir brachytherapy treatments. **Methods:** An MC code system PENELOPE-2014 was used to determine the absorbed-dose energy dependence of ZnSe:O (Z(eff)= 32) and CsI:Tl (Z(eff)= 54) relative to water (D(det)/D(wat)) and the influence of scatter conditions which change between detector calibration, experimental characterization, and in vivo measurements. Additionally, the change in photon spectrum due to the pelvic bones and its impact on detector response was evaluated to mimic treatments in the pelvic area. Detector design influence was also investigated. **Results:** ZnSe:O and CsI:Tl have a large absorbed-dose energy dependence relative to water (up to four and ten times, respectively). Its change over the radial distance range relevant for in vivo dosimetry was comparable for the two materials despite a large difference in their Z(eff). The D(det)/D(wat) dependence on phantom size was negligible up to 2 cm distance but increased to 14 % at 5 cm distance from the source. Neither detector design nor pelvic bones had influence on the detector response. Volume averaging was few percent. **Conclusion:** Most of the experimental studies investigating high-Z detectors use water phantoms that provide full scatter which differ from the in vivo measurement conditions. Our work shows that the change in ZnSe:O and CsI:Tl detector response is not negligible and shall be evaluated to avoid erroneous absorbed dose to water determination. Similar conclusions would apply for other high-Z detector systems. Additionally, although the D(det)/D(wat) dependence is large for high-Z inorganic scintillators, it can be well-characterized and agrees with the experimental data for ZnSe:O. Without an MC study, such conclusions could not be drawn since the experimentally determined detector response could be affected by its scintillation properties.

Evaluating Dosimetric Accuracy of EBT3 Radiochromic Film Calibration Using 6 MV Photon Beam in HDR Ir-192 Dose Measurement

L Huang*, J Chang, H Gaballa, Northwell Health, Lake Success, NY

Purpose: To evaluate the accuracy of Ir-192 film dosimetry using the calibration curve from 6 MV photon beams, and design a novel method for direct film calibration using the Ir-192 source. **Methods:** EBT3 films were calibrated with the 6 MV photon beams on one Truebeam and the Ir-192 source on the GammaMed unit of our institution. We irradiated 18 film pieces (0 to 10 Gy) for each radiation source. All films were scanned 1-day post-irradiation on an EPSON EXPRESSION 10000XL scanner with "Portrait" placement using 48 bits, 150 dpi, and no color correction. Pixel values and calibration curves were acquired from RIT V6.8 using all 3 channels. The irradiated films using the Ir-192 source were reloaded in RIT and a different ROI was chosen to test the accuracy of both calibrations. Moreover, we irradiated an independent test case with the Varian surface applicator (1.5 cm cone) and performed composite analysis between dose maps generated by these two calibrations. **Results:** It was found the red channel has the best performance in point dose measurement (on average, 6 MV: 3.3% from the expected value, Ir-192: 0.3%), comparing to green (6 MV: 3.91%, Ir-192: 0.65%) and blue (6 MV: 4.43%, Ir-192: 2.15%) channels. The discrepancy was less significant (~1.82%) in the high dose region (300 cGy~1000 cGy) for red channels as well. With red channel, the composite analysis showed 83.15% passing rate for 1mm&1%, 89.23% for 1mm&2%, and 98.71% for 1mm&3%. The number of points failed only the percent dose difference (%Diff) criteria is found to be 0 when %Diff > 4%. **Conclusion:** This preliminary study showed a higher error for Ir-192 film dosimetry if films are calibrated using 6 MV photon beams. We suggest the films should be calibrated directly using the cylinder applicator and Ir-192 source for more accurate film dosimetry.

SU-lePD-TRACK 6-03

Evaluating the Fidelity of Post-Plan Vs. Pre-Plan Dosimetry for 3D-Printed Brachytherapy Surface Molds

J Steers*, M Kamrava, T Phillips, Cedars-Sinai Medical Center, Los Angeles, CA

Purpose: To investigate dosimetry of pre-plan vs. post-plan dosimetry for patients treated with 3D-printed brachytherapy surface applicators. **Methods:** Patients treated in our clinic with surface brachytherapy undergo iterative pre-planning prior to the creation of a 3D-printed mold. The pre-plans are used to determine mold designs that result in the desired coverage and limited hot spots for each patient's anatomy and treatment site. Pre-plans for treated patients were compared to post-plans obtained with the printed mold on the patient anatomy to determine the extent to which pre-plans predict the final plans as evaluated with the actual treatment CT-scan. **Results:** To-date, five patients have been treated with 3D-printed molds for surface brachytherapy including three noses, one three-site forehead, and one cheek. For all patients, pre- vs. post-plan D90% and D95% were within 2.5% (average differences: 0.6% and 0.7% for D90% and D95%, respectively), where post-plans had higher coverage compared to pre-plans for all but one case. The post-plan V150% were all within 2% (average 0.6%) of the pre-plan, with most post-plans being slightly hotter than the pre-plan likely due to improved coverage in the post-plan. The average change in CTV minimum, mean, D90%, D95%, D100%, V100%, V110%, V120%, V130%, V140%, and V150% parameters were all less than $\pm 1.5\%$, while average maximum point CTV difference was within 4% over all cases. **Conclusion:** 3D-printed brachytherapy surface molds created for clinical use exhibit very good agreement between planned and final dosimetry on the patient. The pre-planning process for 3D-printed applicators allows for modifications to depth of catheters, intra-catheter spacing, and catheter orientation to achieve the desired dosimetry for surface brachytherapy. This process allows for dosimetric goals to drive the mold design, as opposed to mold design governing the achievable dosimetry which is often the case when using handmade or commercially available flap molds.

SU-lePD-TRACK 6-04

A Comprehensive Study to Design A Novel Direction Modulated Brachytherapy (DMBT) Vaginal Cylinder (VC) Using GEANT4 Monte Carlo Simulation Code

M Meftahi*, W Song, Virginia Commonwealth University, Henrico, VA

Purpose: To design a new DMBT VC applicator to address the lack of dose coverage at the VC apex due to anisotropy effect and to provide directional modulation for coverage of lesions that cannot be covered using the common VC applicators at the very critical region of the vaginal cuff. **Methods:** The new DMBT-VC was modeled in GEANT4 MC code, as single lumen and made of PPSU plastic. The central part of that including the lumen was considered to be a detachable 8 mm diameter tandem rod made of PEEK plastic. First, we extracted a standard dose distribution from BrachyVision TPS of the VC applicator with PEEK tandem. Second, to provide directional intensity modulation, the PEEK tandem was replaced with MR-compatible tungsten alloy or alternatively iridium tandems, with similar dimensions to optimize the coverage at the apex utilizing directional radiation beam generated. Two widely used 192Ir sources, Varian's GammaMedPlus and VS2000 were simulated. Further, we studied the applicator functionality for improving coverage for lesions that are located beyond the typical 5mm isodose prescription line from the surface using both DMBT tandems. **Results:** The analysis showed that the new applicator can improve the lack of coverage at the apex due to anisotropy which were about 2mm and 4mm for GammaMedPlus and VS2000, respectively, using all DMBT tandems. In addition, the DMBT applicator was able to successfully modulate the prescription isodose line by up to 13 mm and 18mm using tungsten and iridium tandems, respectively, beyond the VC surface at vaginal apex without overdosing the peripheral sides through inverse optimization. **Conclusion:** Results showed that the novel DMBT VC can remedy the anisotropy effect and provide coverage for deep-seated lesions at vaginal cuff. This is of major clinical value as the vaginal apex is a frequent site of recurrence in patients.

Predictive Modeling for Rapid Online Evaluation of Plan Quality During Intraoperative Gynecological Brachytherapy

P Dreyer^{1,2*}, M Paudel^{1,2}, E Leung^{1,2}, A Taggar^{1,2}, M Wronski^{1,2}, (1) Sunnybrook Health Sciences Centre - Odette Cancer Center, Toronto, ON, CA, (2) University of Toronto, Toronto, ON, CA

Purpose: The current standard of care for locally advanced gynecological cancers is external beam radiotherapy (EBRT) with brachytherapy boost to the high risk clinical target volume (HRCTV). During intraoperative brachytherapy treatment planning, the patient is under anesthesia, therefore an acceptable plan must be achieved within a limited timeframe. The purpose of this work is to develop a model that can predict the plan quality, allowing the planner to evaluate if an acceptable plan has been achieved. **Methods:** Using an internal database of patients treated with gynecological brachytherapy, two models were developed using MATLAB (Mathworks, R2018b); (1) a distance-based model and (2) an iterative computational model. The distance model evaluates the achieved HRCTV D90/OAR D2cc as a function of quality metric OAR distance to HRCTV. The iterative model evaluates the achieved HRCTV D90/OAR D2cc as a function of the quality metric predicted HRCTV D90/OAR D2cc. The iterative model further accounts for implant quality, represented by activated dwell positions. Regression analysis was performed on both models. **Results:** The distance based model is less precise in its ability to predict achieved HRCTV D90/OAR D2cc ($R^2=0.83$) in comparison to the iterative model ($R^2=0.97$) indicating the importance in accounting for implant quality in the iterative model. Assuming an EBRT dose of 45Gy in 25 fractions, the iterative model can consistently predict the combined dose from brachytherapy and EBRT within $\pm 7\%$, with 95% confidence. **Conclusion:** The iterative model can be used during brachytherapy treatment planning to rapidly determine whether a new intraoperative treatment plan is consistent with the plan quality that has been achieved previously within the center. Future work will include demonstrating the utility of this model in a clinical setting by evaluating its robustness over a range of patient anatomy and implant quality.

Monte Carlo Simulation of the Permanent Implant - GammaTile

B Rogers*, C Ferreira, University of Minnesota - Twin Cities, Minneapolis, MN

Purpose: GammaTile (GT Medical Technologies, Tempe AZ) is a permanent brain implant used to treat certain brain tumors. A GammaTile treatment program has been established at our institution. Post-op treatment planning is performed clinically with a TG-43 based treatment planning system (TPS). The TPS calculates dose to water and doesn't account for heterogeneities. The purpose of this work was to investigate differences in dose deposited due to heterogeneities, in particular to examine dose to the skull and skin following GammaTile implantation utilizing Monte Carlo simulation. **Methods:** Each GammaTile contains four CS-1, Rev2 131Cs seeds (IsoRay Medical Inc., Richland, WA) embedded in DuraGen (Integra Lifesciences, Plainsboro, NJ) collagen tile measuring $2.0 \times 2.0 \times 0.4 \text{ cm}^3$. Each seed has an air kerma strength of 3.5U at the date of implant. MCNP Monte Carlo simulation (MCNP5) was used to simulate the dose distribution around a single GammaTile implanted permanently. MC simulated doses were obtained both in water and in a heterogeneous medium, including brain, skull bone (thickness=0.7 cm), skin (thickness=0.5 cm), and air. For comparison, the total dose deposited was also calculated using BrachyVision (Varian Medical Systems, Palo Alto, CA). **Results:** Initial simulated dose distributions in water were within 7% agreement with comparable dose distributions generated by BrachyVision. When bone was located 1 cm from a single GammaTile, the total dose simulated to the bone and skin were 28.3 Gy and 2.74 Gy, respectively. Doses for bone and skin at the same distance calculated with the treatment planning system were 10.4 Gy and 4.96 Gy, respectively. MC simulated values are 2-3 times the values calculated using TG-43. **Conclusion:** Considerable dose to the skull bone is possible and even likely from GammaTile therapy. Initial simulations included a single GammaTile. Future simulations will include more representative of a clinical arrangement containing multiple GammaTile units.

Correction Factors for a Planar Windowless Extrapolation Chamber Measuring Surface Absorbed Dose to Water from An Unsealed Thin-Film Alpha-Emitting Radionuclide

A Khan*, W Culberson, L DeWerd, Department of Medical Physics, School of Medicine and Public Health, University of Wisconsin-Madison, Madison, WI

Purpose: To establish a primary standard of absorbed-dose-to-water for targeted alpha therapy radionuclides by measuring surface absorbed-dose-to-water from a point-like Po-210 radionuclide using a planar, windowless extrapolation chamber. The measured ionization current at each airgap must be corrected to account for side-losses of charged particles at finite air-gaps ($k(\text{div})$), the finite radius of the Po-210 source ($k(\text{point})$), the difference in backscatter between the medium surrounding the air-cavity and water ($k(\text{backscatter})$), and δ -ray disequilibrium due to the absence of build-up material ($k(\delta)$). In this study, we determine the magnitude of these correction factors using Monte Carlo (MC) simulation. **Methods:** GEANT4 was used to model the extrapolation chamber and circular, 3 mm diameter Po-210 source on a silver substrate along with a cylindrical air-cavity with the radius determined by COMSOL Multiphysics™ electrostatic simulations. The Po-210 source was simulated as a surface source and the absorbed dose to air was calculated for 100-250 μm airgaps. $k(\text{div})$ was determined by extrapolating the calculated absorbed dose at zero airgap, $k(\text{point})$ was determined by simulating a point source, and $k(\text{backscatter})$ was determined by setting the material surrounding the cavity as water. The $k(\delta)$ correction factor was calculated by considering local absorption of δ -rays generated in the cavity. **Results:** The radius of the air-cavity was calculated to be 2.02 mm according to the electrostatic simulations. The $k(\text{backscatter})$ and $k(\delta)$ correction factors were found to be in the 0.882-0.911 and 1.020-1.041 ranges, respectively, and their deviation from unity was observed to decrease with increasing airgap. In contrast, $k(\text{point})$ and $k(\text{div})$ were observed to linearly increase with increasing airgap with magnitudes in the 1.051-1.062 and 1.243-1.591 ranges, respectively. $k(\text{div})$ was determined to be the largest correction factor. **Conclusion:** MC-based correction factors were calculated for an extrapolation chamber measuring surface absorbed-dose-to-water from an alpha-emitting radionuclide.

Q&A

On March 11, 2020 the World Health Organization officially declared the novel coronavirus (COVID-19) a pandemic. In light of the subsequent restrictions and recommendations in educational and clinical settings, many educators were required to make radical changes to their courses mid-semester in an attempt to transition from face-to-face to online instruction. In the clinic, residency program directors and faculty grappled with ways to provide “equivalent” hands-on experiences remotely. Academic instructors had to quickly learn how to use several new platforms with varying levels of assistance from institutions to provide video-conferencing, assignment submissions, and virtual exam proctoring. What quickly became apparent was that didactic and clinical training techniques used for face-to-face interactions could not be directly virtualized. During the symposium, four educators will discuss their experience, the challenges they encountered, and the positive lessons they learned in order to improve instructional strategies moving forward.

Learning Objectives:

After attending this Symposium, the participant will:

1. Understand how to overcome challenges of online learning by applying active learning strategies that spark curiosity.
2. Learn how to apply opportunities to humanize courses to foster a learning community that encourages learners to participate.
3. Identify what digital education resources are currently available online.

4. Learn about the usefulness and drawbacks of commercial tools and applications in teaching and mentoring when coupled with the use of a tablet.
5. Understand how eLearning course modules may be used to supplement/replace some elements of residency training.
6. Identify issues that can inhibit student and resident learning in the virtual environment and techniques to manage these issues.
7. Consider how student and resident evaluation can be performed effectively in a virtual environment.
8. Recognize opportunities to improve our pedagogical strategies resulting from the forced transition to the virtual environment.

Audience Q & A

Ryan Fisher - MPPG #12: Fluoroscopy Dose Management

Medical physics practice guideline # 12, "Fluoroscopy Dose Management" aims to outline the role of the diagnostic qualified medical physicist in practical patient dose management for fluoroscopically-guided interventional (FGI) procedures. This role includes helping facilities set up policies related to dose management, including pre-procedure patient consent, intra-procedure dose index level notification, and post-procedure follow up for potential tissue reactions. Additionally, the document includes suggestions for methods of complying with various state regulatory requirements and Joint Commission standards related to fluoroscopy, including tracking radiation doses, setting dose index thresholds, and analyzing dose index data, and includes discussion of the challenges posed by these requirements. This presentation will cover the content of the new practice guideline, as well as potential changes to the Joint Commission fluoroscopy radiation overdose sentinel event.

Learning Objectives:

1. Understand recommendations for physicists' responsibilities related to fluoroscopically-guided interventions outlined in the forthcoming medical physics practice guideline.
2. Understand changes related to the Joint Commission's prolonged fluoroscopy sentinel event standard.

Mahadevappa Mahesh - First CPT Code for Diagnostic Medical Physics: What to Know and How to Use This Code

The very first CPT code (76145 – Medical physics dose evaluation for radiation exposure that exceeds institutional review threshold for diagnostic medical physics) was approved and became active from January 1st, 2021. The presentation includes explanation of the code and its origin along with discussion on when it could be used. The presentation will include sample cases with step-by-step guide on how to evaluate and complete the report. There will be discussion on how to go about setting the code in the clinic.

Learning Objectives:

1. To learn what is CPT code 76145
2. To examine when the code could be used and what should be in the report.
3. To become familiar with the threshold values that warrants the use of this code

A. Kyle Jones- ACR Dose Index Registry for Fluoroscopy (DIR-Fluoro)

The American College of Radiology (ACR) Fluoroscopy Dose Index Registry (DIR) is the latest addition to the National Radiology Data Registry (NRDR). During the pilot phase of the registry, fluoroscopy dose index data was collected from nine pilot sites over a period of 22 months from March 1, 2018 through December 31, 2019. Ultimately, dose index data from almost 40,000 unique clinical procedures was collected, reviewed, and analyzed. These procedures were mapped to one of 127 ACR Common IDs which allowed for comparison of dose indices for similar procedures among pilot sites. Broader roll-up categories were also developed, which allowed for comparison of procedures across multiple ACR Common IDs and provided sites with less granular clinical facility procedure names a pathway to analyze their submitted data and produce reasonable comparisons to the pilot group as a whole.

Learning Objectives:

1. Outline the process for sites to participate in the ACR Fluoroscopy DIR.
2. Review the dose index data collected during the pilot phase of the ACR Fluoroscopy DIR.
3. Discuss strategies for using DIR data and comparisons for quality improvement.

Q&A & Panel Discussion

The COVID-19 pandemic presents a critical public health crisis. Essential biomedical research and development is needed to urgently address surveillance and early detection of COVID-19 resurgence; differential diagnosis of COVID-19 patients; prognosis; and prediction and monitoring of response for use in patient management. Since the start of the pandemic, medical imaging has played key roles in these patient monitoring and assessment tasks. In response to this need, leaders from the RSNA, ACR, and AAPM along with NIBIB have jointly developed the Medical Imaging and Data Resource Center (MIDRC) for rapid, flexible, and large collection of well-curated imaging studies to facilitate development of and externally validate machine intelligence (AI) algorithms for the various tasks described above. MIDRC is a multi-group, two-year NIBIB-funded project hosted at the University of Chicago and coordinated among 23 institutions including two intake portals operated by RSNA-RICORD and ACR-CIRR that integrate quality control and data harmonization. A public access, exploration, and analysis portal and commons is being developed on the Gen3 data ecosystem. Twelve collaborative research projects exist to expedite translation of machine learning and AI from scientific findings and technical resources to public dissemination and clinical benefit. In this symposium, we will review the status of MIDRC, the role of AAPM's Data Science Committee, and the important role that medical physicists have in MIDRC for quality assessment and data harmonization, machine intelligence assessment through metrology and task-based evaluations, and the conduct of grand challenges.

Learning Objectives:

1. Learn about MIDRC and the AAPM's leadership and development roles in it.
2. Understand the need for large, well-curated medical imaging datasets to facilitate development of AI and to externally validate such algorithms in order to enable translation to clinical use.
3. Understand the essential medical physics research needed to address the role of medical imaging for monitoring, diagnosis, and assessment of the COVID-19 patient.

Funding for MIDRC is from NIBIB COVID-19 Contract 75N92020D00021

Thoughts on The Clinical Implementation of AI Tools in Treatment Planning Process

Recent advances in segmentation, planning, and QA are largely enabled by innovative applications of artificial intelligence (AI) techniques. AI refers to methods that improve and automate challenging human tasks by systematically capturing and applying relevant knowledge in these tasks.

Over the past decades, a number of AI approaches have been developed to address different needs of system intelligence in treatment planning, ranging from search strategies to knowledge representation to machine learning. In particular, deep learning techniques have found tremendous success in the segmentation of normal anatomical structures as well as treatment target volumes; and also have shown great promise in accurately predicting dose distributions and fluence maps resulting in completely automated algorithms for generating treatment plans with clinically viable qualities. Robust systems that integrate multiple AI and machine learning algorithms have also been developed to automate entire clinical workflows in radiation therapy. Moreover, quality assurance has also benefited significantly from recent advances. Data-driven intelligent algorithms are making the QA process more efficient and effective.

This session presents recent developments of AI algorithms and other novel approaches to improving segmentation, planning, and QA in the treatment planning process; and discusses the potential changes of clinical workflow these technologies may bring.

Learning Objectives:

1. Understand current AI techniques and algorithms that have been developed for segmentation, planning and quality assurance
2. Understand the issues related to developing AI tools in these targeted applications
3. Understand potential challenges in implementing and integrating these techniques in clinical workflow and preparations for adoption

A Robust Method to Quantitate Tracer Activity in Organs and Lesions with Clinical SPECT/CT Systems

J James*, J Bian, J Halama, Loyola University Medical Center, Maywood, IL

Purpose: It is essential that a robust method be used to quantitate activity from SPECT/CT for organ based radiation dosimetry. Aim of this study is to validate the accuracy of a universal method to perform quantitative measurements across vendors and differing reconstruction methods. **Methods:** An IEC Image Quality phantom cover was 3D printed to hold 1-2-3-4-5-6 cm diameter hollow spheres with a minimum separation of 2.5 cm between surfaces. The spheres and the phantom chamber had ^{99m}Tc sphere/background activity concentrations of no background, 8:1, 4:1 and 2:1. SPECT/CT acquisitions were performed on the Philips-BrightView and GE-Discovery-670 using clinical acquisition protocols. Quantitative SPECT reconstructions for: 1) BrightView was performed using SUV-SPECT on Hermes and 2) GE using (a) Q.Metrix on GE-Xeleris, and (b) SUV-SPECT on Hermes. Image reconstructions were iterative with CT attenuation-correction, scatter-correction and resolution-recovery. The total activity in the spheres was measured by placing volumes-of-interest (VOI) of diameter: 1) matching the sphere diameter (VOI₁), 2) expanded by 2 cm (VOI₂), and 3) expanded by 3 cm (VOI₃). VOI₂ includes spill-out of sphere tracer that is observed outside the sphere boundary. VOI₃ is to estimate background tracer activity concentration just outside VOI₂ and is needed to apply a background correction for VOI₂. The measured/true activity fractions (TF(spheres)) for the 6 spheres and the background concentration (TF(BKG)) were computed. **Results:** Overall the TF's were within 10% (GE) and 15% (BrightView) of the truth, except for scans with 2:1 sphere/background that has significant artifacts and non-visualization of all spheres that lead to measurement inaccuracies. Across all measurements, BrightView with Hermes reconstruction was 0.89 ± 0.05 , GE-Discovery-670 with Q.Metrix was 0.97 ± 0.03 and with Hermes was 0.95 ± 0.04 . **Conclusion:** Utilizing an expanded VOI to capture all sphere activity in the measurement together with a background correction is a robust method for performing quantitative analysis of SPECT/CT images.

SU-C-TRACK 6-02

Harmonization of Four PET Scanners Through the Use of a Uniformity Phantom and a Sphere Simulation Tool

D Gomez Cardona¹*, J Browne², L Stecker³, R Pooley³, (1) Gundersen Health System, La Crosse, WI, (2) Mayo Clinic, Rochester, MN, (3) Mayo Clinic, Jacksonville, FL

Purpose: Quantitative positron emission tomography (PET) with 18F-fluorodeoxyglucose (18F-FDG) can provide important information for staging cancer and monitoring therapy response. However, to reduce quantitative bias and variability, hospitals should standardize their imaging procedures and harmonize

the SUV response of their fleet of PET scanners. The aim of this study was to harmonize the response of four PET scanners in our practice through the use of a uniformity phantom and a sphere simulation tool which predicts optimal reconstruction filter settings[1]. The predicted reconstruction settings were validated experimentally using the NEMA NU2-2007 phantom. **Methods:** Four PET systems, GE Discovery MI, GE Signa PETMR, Siemens Biograph 40, and Siemens Biograph Vision were assessed. The total activity of 18F-FDG in the uniformity and NEMA phantoms was 70MBq; the NEMA phantom spheres-background ratio was 20:2kBq/ml. The uniformity and NEMA phantoms were scanned for 20 min/bed position (1-3 bed positions) and 2 min/bed position (1 -2 bed positions), respectively. Two clinical reconstruction settings were evaluated for each scanner to identify baseline settings. The optimal post-filter settings were predicted using the uniformity phantom and the sphere simulation tool. These settings were applied to the NEMA phantom data to validate the sphere simulation tool. For each sphere in the NEMA phantom, the maximum voxel value and an adaptive 50% isocontour mean value were calculated[2]. **Results:** The recovery coefficient (RC) curves obtained for the NEMA and uniformity phantom show close agreement (Figure 1a and 1b). Figure 1b also displays a harmonized RC curve after specific filter settings were applied. Figure 2a and 2b display pre- and post-harmonization results of the NEMA phantom following the application of the predicted filter settings. **Conclusion:** Scanner harmonization can be achieved using vendor specific uniformity phantoms and the sphere simulation tool rather than the more expensive and complex NEMA phantom.

SU-C-TRACK 6-03

BEST IN PHYSICS (IMAGING): Image Quality and Lesion Detectability in New DDG-PET/CT Utilizing 50% of PET Data

MA Thomas*, T Pan, UT MD Anderson Cancer Center, Houston, TX

Purpose: Prospective data-driven gated (DDG) PET requires advance selection of patients who may benefit from gating, and leaves DDG-PET/CT registration to chance. Retrospective DDG of both PET and CT can reduce CT radiation dose, shorten scan time, improve PET/CT registration, and correct tumor motion on all patients. The first DDG-PET/CT (DDG-PET and DDG-CT) has been prototyped for patient care in a network of seven PET/CT scanners. Here, the impacts of misregistration and motion correction on image quality and lesion detectability were assessed with the new DDG-PET/CT technique. **Methods:** A low-dose cine CT was acquired in misregistered regions to enable both average CT (ACT) and DDG-CT for attenuation-correction of static and DDG-PET, respectively, yielding baseline PET/CT, PET/ACT and DDG-PET/CT. For DDG-PET, end-expiration data was derived from 50% of PET data at 30% from end-inspiration. For DDG-CT, end-expiration CT data was extracted from cine CT by lung CT number and body contour. SUVmax, SUVmean, SNR, and CNR were compared for 121 lesions from 21 consecutive patients. **Results:** Improved registration with ACT did not change SNR. DDG-PET/CT showed decreased background and lesion SNR with median $\pm\sigma$ changes of $-24\pm10\%$ ($p<0.0001$), equivalent to using $\sim 57\%$ of total PET counts. Changes from baseline in SUVmax and CNR were $21\pm41\%$ ($p<0.0001$) and $6\pm76\%$ ($p=0.27$) for PET/ACT, and $68\pm65\%$ ($p<0.0001$) and $37\pm141\%$ ($p<0.0001$) for DDG-PET/CT. Lesions with ambiguous detectability at baseline (CNR <10) showed the most significant CNR increases in DDG-PET/CT, with nearly all lesions reaching CNR >5 . **Conclusion:** Using 50% of PET data in DDG-PET leads to the expected increase in image noise. However, the increase in SUV due to improved registration and motion correction in DDG-PET/CT is more substantial than the increased image noise. Therefore, lesion detectability is still largely improved with DDG, especially for lesions with uncertain detectability (CNR <10) at baseline.

This research was supported in part by NIH grants 1R21CA222749-01A and R03EB030280, and a ROSI grant from UT MD Anderson Cancer Center. It was conducted at the MD Anderson Center for Advanced Biomedical Imaging in-part with equipment support from GE Healthcare. T.P. was a consultant for Bracco Medical Systems, LLC.

Longitudinal PET/CT Imaging of ^{64}Cu for Radiopharmaceutical Therapy Dosimetry

M Merrick*, L Dunnwald, A Tiwari, J Sunderland, S Graves, University of Iowa, Iowa City, IA

Purpose: Radiopharmaceuticals for diagnostic and therapeutic purposes have rapidly emerged in recent years. With recent FDA approval of ^{64}Cu -DOTATATE ($t(1/2):12.7\text{h}$; $\beta^+ :17.6\%$), there has been excitement over the possibility of using this imaging agent to predict the dosimetry of ^{177}Lu -DOTATATE ($t(1/2):6.6\text{d}$) or ^{67}Cu -analogs ($t(1/2):2.6\text{d}$). Pre-treatment PET/CT imaging is considered standard practice, so the possibilities of pre-treatment planning and quantitative assessment of potential benefit from therapy are highly attractive. The purpose of this work is to establish the qualitative and quantitative limitations of late-timepoint ^{64}Cu PET imaging. **Methods:** An anthropomorphic chest phantom (SNMMI-CTN) containing spherical 'tumors' was filled with ^{64}Cu -DTPA. Initial tumor-to-background ratio was 1.07:9.61 $\mu\text{Ci/mL}$, for a total fill activity of 11.02mCi. PET/CT images were acquired (GE Discovery MI PET/CT;10min/bed position;2-bed-positions/scan) and reconstructed (VPFX-4i16s) every 12hours for 7days and then every 24hours for 3days. Reconstructed images were assessed qualitatively to determine tumor detectability as a function of tumor size and time. Quantitative activity recovery-coefficients (RC-SUVmean) were calculated as a function of sphere-size and decay-time. Additionally, a radioactive half-life was calculated from activity measurements over-time to assess system linearity over a range of activity levels. **Results:** All lesions (7–37mm) were visualized 4days (~ 8 half-lives) after injection. Spheres with diameter range 7-17mm were gradually lost to background noise during days 5–7, with only the 22, 28, and 37mm spheres being visualized on day 8. Quantitative analysis of measured radioactivity vs. time indicated excellent PET response linearity even under low-count-density conditions. A ^{64}Cu half-life of $12.79\pm0.03\text{hours}$ was measured, which is $\sim 0.7\%$ higher than accepted value. RC-curves demonstrated an increase in variability at late time-points, however, generally the measured RC-curve shape was maintained out to 6days post-injection. **Conclusion:** Copper-64 appears to be an excellent diagnostic pair for theranostic applications. This study has confirmed that late-timepoint imaging following administration is possible, thus demonstrating promise for pre-treatment radiopharmaceutical dosimetry.

SU-C-TRACK 6-05

NCINM2.0: Organ Dose Calculator for Patients Undergoing Nuclear Medicine Procedures - Implementation of the ICRP Reference Phantoms and Biokinetic Models

D Villoing, C Lee*, National Cancer Institute, Rockville, MD

Purpose: To implement two major updates into the previously-published organ dose calculation program, NCI dosimetry system for Nuclear Medicine (NCINM): (1) a library of S values calculated using the International Commission on Radiological Protection (ICRP) reference pediatric and adult voxel phantoms and (2) the ICRP biokinetic models for selected radiopharmaceuticals. **Methods:** We calculated a library of photon and electron SAFs for a total of 68 source organs and 55 target organs by using the ICRP reference newborn, 1-, 5-, 10-, 15-year-old, and adult male and female voxel phantoms. We then derived S values from the SAFs for a total of 299 radionuclides frequently used in nuclear medicine procedures using the energy spectra from ICRP Publication 107. We also extracted the biokinetic models for twelve radiopharmaceuticals from ICRP Publication 80 and 106. The S values and biokinetic models were implemented into the NCINM program. We compared our organ doses for 18F-FDG with those from ICRP Publication 106. **Results:** We found that the organ doses from ICRP Publication 106 are overall smaller than those from NCINM. The breast dose from the ICRP 106 is about 20% of that of NCINM for the 1-year-old child phantoms. As an exception, the urinary bladder wall dose of ICRP is up to 2.5-fold greater than that of NCINM. **Conclusion:** We implemented a new library of S values based on the ICRP reference pediatric and adult phantoms and the biokinetic models of twelve radiopharmaceuticals into NCINM. The upgraded NCINM should be useful for nuclear medicine physicists to readily estimate organ doses in major nuclear medicine procedures based on the international reference anatomical and biokinetic models.

Organ Doses Following Intra-Hepatic-Arterial Administration of 99mTc-MAA in Planning Dosimetry for 90Y-SIRT

SC Kappadath*, BP Lopez, A Mahvash, UT MD Anderson Cancer Center, Houston, TX

Purpose: Expected organ doses from the intra-hepatic-arterial (IHA) administration of 99mTc-macro-aggregated-albumin (MAA) for lung-shunt-fraction (LSF) estimation prior to 90Y-SIRT or radioembolization are now requested by the FDA for new 90Y-radioembolization trials. Unfortunately to date, no such values have been published. Traditionally, organ doses from any radionuclide administrations are estimated through MIRD-based dosimetry following a laborious prospective study to establish radiotracer biodistribution through serial imaging. Here, we instead relate the possible IHA 99mTc-MAA biodistributions, considering the worst-case LSF and 99mTc-MAA disassociation values, to the published biodistributions and organ doses following intravenous 99mTc-MAA and intravenous 99mTc-pertechnetate administrations to estimate organ doses following IHA 99mTc-MAA. **Methods:** Three potential IHA 99mTc-MAA biodistributions were considered. Case1) all 99mTc-MAA is sequestered in the liver (0% LSF, 0% disassociation), and organ doses are estimated with OLINDA1.1 with a liver source organ of 99mTc-MAA (8.67MBq-h/MBq residence time). Case2) all 99mTc-MAA exits the liver into venous circulation (100% LSF, 0% disassociation), and organ doses follow intravenous 99mTc-MAA ICRP-80 values. Case3) all 99mTc-MAA disassociates and exits the liver into venous circulation (100% LSF, 100% disassociation), and organ doses follow intravenous 99mTc-pertechnetate ICRP-80 values. We report worst-possible individual organ doses (highest values across Cases) and the expected organ doses for typical LSF and disassociation (weighted linear combinations of Cases). **Results:** The liver (98.6 mGy/GBq), lung (66.0 mGy/GBq), and colon (42.0 mGy/GBq) received the largest doses in Case1, Case2, and Case3, respectively. Following 0.185 GBq (5 mCi) IHA 99mTc-MAA, the liver and lung doses were 18.2 and 12.2 mGy (worst-case), 15.8 and 2.3 mGy (typical 10% LSF, nominal 5% disassociation), and 11.7 and 3.3 mGy (high 20% LSF, high 20% disassociation). **Conclusion:** Our novel approach uses published intravenous 99mTc-MAA and 99mTc-pertechnetate dosimetry in conjunction with OLINDA1.1 liver dosimetry to provide previously unknown and unpublished worst-case and typical-case organ doses following IHA 99mTc-MAA.

Uncertainty Propagation Methods for Personalized, Image-Based 131Iodine SPECT/CT Radiopharmaceutical Therapy Dosimetry

D Adam*, I Marsh, J Grudzinski, T Bradshaw, P Hill, B Bednarz, University of Wisconsin, Madison, WI

Purpose: The assessment of uncertainty in personalized, image-based, radiopharmaceutical therapy (RPT) dosimetry is complicated and is commonly ignored in clinical routines because it is not as developed as it is for external beam radiotherapy. As such, this work investigates the uncertainties associated with ¹³¹I SPECT/CT based Jaszczak phantom studies and provides the groundwork for the estimation of dosimetric uncertainties for patient-specific RPT treatments. **Methods:** ¹³¹I SPECT/CT cylindrical Jaszczak phantom studies were conducted. The first phantom study (5.64L with 105 kBq/ml ¹³¹I) established a calibration factor for the SPECT camera and the second phantom study included hot-sphere inserts (257 kBq/ml ¹³¹I with 10:1 insert to background ratio) with volumes of 0.5-16ml to establish recovery coefficient (RC) partial volume corrections. GE Xeleris 4.0 was used to reconstruct images with CT-based attenuation, scatter, and resolution corrections enabled. Segmentations were manually performed on the CT image. The uncertainties in the volume, RC, mean counts, total sensitivity, and cumulative uncertainty were then calculated. **Results:** In general, the uncertainty decreased as the size of the structure increased. The largest uncertainties were the mean counts and RC which are dependent on the volume determination and the RC fitting function. The range of uncertainties for volume (17.3% to 54.7%), RC (22.32% to 95.71%), mean counts (13.2% to 106.4%), total sensitivity (7.47%), and cumulative activity (25.6% to 113%) were calculated. **Conclusion:** The uncertainties for ¹³¹I SPECT/CT RPT can be larger than 100% for small structures and thus require the utmost consideration in the administration of RPT treatments. Patient-specific RPT dosimetry becomes much more valuable for clinical translation if the associated uncertainties are also measured and reported for the physician's reference.

S. Leng, Mayo Clinic:

Dual Energy Computed Tomography, Metal Artifact Reduction and Photon Counting Detectors – Latest Development and Potential for Monte Carlo Dose Calculation

Monte Carlo (MC) dose calculation has recently been implemented in primary commercial treatment planning systems (TPS) as well as various in-house platforms for proton therapy. MC promises smaller dose uncertainties, particularly in patients with high heterogeneities within the treatment field (e.g. bone/lung) or large surgical implants. Newly developed dual-energy computed tomography (DECT) and metal artifact reduction (MAR) techniques complement MC capabilities. However, there are no reports yet on how proton therapy centers implement these new technologies. Therefore, an NCI-sponsored NRG survey was distributed to operating USA proton centers in 2019 to determine the feasibility for including MC and companion techniques in cooperative group clinical trials. The use of MC for primary dose calculation and optimization is found to be prevalent and, therefore, likely feasible for clinical trials, where MC is encouraged for patients without implant materials. For patients with metal implants, there is consensus to use MAR and override tissues surrounding metals. However, there is no consensus about DECT regarding virtual mono-energetic images or the extraction of material information for implants and human tissues. The development and standardization of these advanced technologies are strongly encouraged for vendors and clinical physicists alike. In this joint imaging therapy symposium, we will review the latest developments of MC and imaging methods to facilitate their implementations in clinical trials with updated consensus practice recommendations and to mitigate the identified bottleneck issues. (max 250 words)

Learning Objectives:

1. Report of NRG survey results of MC implementation and companion imaging techniques, including current status and bottleneck issues (Liyong Lin)
2. Report on the latest development of MC in commercial TPS and in-house platforms (Jan Schuemann)
3. Report on the latest development of DECT and MAR techniques (Shuai Leng)

SU-D-TRACK 1-05**Q&A**

The session will present a case study on the processes involved in conducting a clinical trial and the skill sets needed for various steps in the process. Perspectives will be provided for research, industry, and educational points of view. While Medical Physicists can take on the role of 'clinical studies manager', specific training and certification already exists for that role and is not the focus of this discussion. The case study will be used as an example of the need for medical physicists to develop new skill to meet the future needs of the profession (e.g., data anonymization and deidentification, financial understanding, bringing innovation closer to marketable commercial product, educational needs to prepare future physicists in these areas).

Rebecca Fahrig, PhD

A View of Clinical Trials from Industry

Medical Physicists have the opportunity to play several different roles in Industry, including supporting research, pre-development, development, and product definition and productization. One key role is to support the creation of clinical evidence that proves the benefit of medical physics technology (imaging and therapeutic) to the Healthcare Community. Clinical studies literacy helps to ensure that the evaluation and clinical implementation of innovative and complex technology is supported by Medical Physicists, and that Medical Physicists continue to be seen as crucial to successful transition of a technology from concept to clinic.

Understanding the pre-development process

-What makes a prototype 'close to' product?

oWhen is a prototype ready for clinical evaluation?

-Different regulatory environments for Medical Product testing and release : EU, USA, China, etc.

Bringing the technical details to the table in the planning phase

-Evaluating Risks and Benefits – our sweet spot

-AI and Software as a Product : clinical data access and management

Wayne Newhauser, PhD

A View of Clinical Trials from Education

There are opportunities for many medical physics faculty, students and residents to learn about and participate in clinical trials. Example areas of interest include study design, quality assurance, dosimetry intercomparisons, treatment planning protocols, IRB protocols, data analysis, dose reconstructions, compliance, accreditation, scientific communications, to name a few. Based on the example case presented, we will compare the list of competencies needed against the typical graduate curricula (e.g., as specified by the AAPM Report 197), e.g., scientific methods, radiation physics, dosimetry, medical research ethics, protected health information, etc. Graduated levels of skills in related scientific disciplines will be considered, including statistics, epidemiology, radiation biology, where requirements may vary from familiarity with basics concepts to proficiency to perform certain tasks. Lastly, we will identify selected additional resources available to build skills of relevance to participating in clinical trials.

Robert Nishikawa, PhD

A View of Clinical Trials from Academia

Medical Physicists play a pivotal role in establishing the safety and efficacy of a new technology. Safety and efficacy are the sine qua non for approval of a

medical device to be used clinically, as defined by the Food and Drug Administration (FDA). The FDA often requires a clinical trial to establish safety and efficacy, and these trials are almost always conducted by academia. Medical Physicists can either lead the study or support the study in collaboration with other scientists. In either role, it is necessary or at least beneficial to understand the different components in conducting the trial. In this presentation, I will discuss the different components of a clinical trial, with emphasis on data anonymization and deidentification; and the IRB process.

A Subject-Specific 5D Cardiac and Respiratory Motion Model Reconstructed from Free-Breathing 2D Cine MRIs

X Wu*, y Zhang, H An, H Gach, S Goddu, H Li, D Yang, Washington University in St. Louis, St. Louis, MO

Purpose: To treat tachycardia disease using the noninvasive cardiac radiation ablation, an accurate patient-specific heart motion model is required for treatment planning and motion management. In this study, we developed a procedure to generate a subject-specific 5D (3D+cardiac+respiration) heart motion model from free-breathing continuous 2D CINE MRI movies without additional ECG and respiratory signals. **Methods:** Seventeen 2D CINE MRI movies of a healthy volunteer was acquired continuously in the sagittal view at 17 positions at 5mm intervals, covering the entire heart. Each CINE movie was acquired for 60 seconds (8f/s, 100x100x480, 1.5x1.5x5mm3). In each movie frame. The cardiac signal was extracted from the heart area, and the respiratory signal was extracted from the average image intensity of the selected box in the diaphragm. Each signal was fitted to a combination of short cine curves. The final cardiac and respiratory phase values were assigned based on the fitting results. 3D volumes of selected cardiac and respiratory phase pairs were constructed from the 2D frames at all sagittal positions based on the assigned values and the temporal and spatial continuity. The deformation fields among the constructed 3D volumes of the selected cardiac and respiratory phases were computed using a group-wise deformable registration method. A PCA analysis was applied on the computed deformation fields to create the final 5D motion models. **Results:** The proposed procedure was applied for 2D cine MRIs of a healthy volunteer. The 5D motion model was composed successfully and 3D heart volumes at any cardiac and respiratory phases can be constructed using this model. **Conclusion:** We developed a procedure to generate a 5D subject-specific heart motion model from continuous 2D CINE MRI movies. It will be useful in managing cardiac and respiratory motions in radiation therapy for cardiac diseases.

Automated Predictive Models for Lung ART

J Kavanaugh¹*, G Hugo¹, Z Ji¹, J Fontenot⁴, (1) Washington University School of Medicine, St. Louis, MO, (2) Mary Bird Perkins Cancer Center, Baton Rouge, LA

Purpose: Mid-treatment anatomic changes for patients undergoing radiation therapy for lung cancer can alter the accuracy of delivered vs. planned dose. Changes visible on the daily conebeam CT (CBCT) can be classified into five types: tumor regression, tumor alignment, nodal target alignment via two surrogates (carina and thoracic vertebrae) and lung density. To maintain the intended treatment quality, adaptive radiotherapy (ART) modifies the treatment plan to account for each type of change. However, the evaluation on when to adapt is completed manually, resulting in a subjective and inconsistent application. To address these limitations, five predictive ART models were created to identify when to implement ART. **Methods:** Models were trained utilizing 1158 CBCT datasets from 43 patients treated 2010–2018. The “ground-truth” need for ART was evaluated on each CBCT by two trained clinical staff, with ART indicated when anatomic deviations exceeded predefined tolerances across three consecutive days. The rate and magnitude of anatomic changes were quantified using a subset of 368 features derived from image registration similarity criteria applied between the simulation CT and on-treatment CBCT. These quantifying criteria, along with the “ground-truth” ART evaluation, were input data for predictive logistic regression models, with one model for each type of anatomic changes. The models were evaluated with a 10-fold cross-validation, focusing on the specificity, sensitivity, and first identified fraction compared to “ground-truth”. **Results:** The models identified ART with a range of sensitivity (78.9%–100%) and specificity (93.5%–100%) across five types of anatomic changes. Model accuracy to predict the specific fraction for ART ranged from -3.58 ± 5.35 to 0.14 ± 7.54 fractions, with negative numbers indicating ART prediction occurring before the “ground-truth”. **Conclusion:** A method for automated ART predictive modeling in lung cancer patients was developed and provided a high degree of accuracy to predict the need for ART for each individual fraction.

Biomechanical Simulation of Lung Motion for Tumor Position Estimation During Radiation Therapy

M Ranjbar¹*, P Sabouri², S Mossahebi³, A Sawant³, P Mohindra³, G Lasio³, L Topoleski¹, (1) University of Maryland, Baltimore County, Baltimore, MD, (2) Miami Cancer Institute, Miami, FL, (3) University of Maryland School of Medicine, Baltimore, MD

Purpose: To address challenges inherent in single-cycle respiratory-correlated CT (4DCT), several surrogate-based motion models (SMMs) have been proposed. These models utilize the a-priori correspondence between the surrogate and internal anatomy observed during the 4D-simulation. Commonly occurring changes in this correlation and extrapolation beyond their training dataset can result in model breakdown. To address such issues, we present a hybrid finite-element (FE) model with transient boundary conditions (BCs) to estimate tumor position during radiotherapy delivery. **Methods:** 4DCT data, VisionRT surfaces (VRT), and ~30–50s lateral and anterior-posterior fluoroscopic projections (FLs) were collected from five lung cancer patients. A previously validated volumetric SMM that integrated a few FLs to construct and update the correlation between VRT and internal motion was used to generate transient deformations for the lung-surface (as BCs). The exhale lung and tumor topology were imported into ABAQUS multi-physics software and a FE lung-tumor model was constructed. GTV position estimation was evaluated by comparing estimated centroid and Hausdorff distance with respect to the corresponding 4DCT phase. Transient BCs were used, and lung-tumor motion was simulated during the treatment session. **Results:** 95th percentile absolute difference between FE-estimated and 4DCT-delineated GTV centroid in the SI/AP/LR directions were 2.7/2.4/1 mm respectively. Submillimetre median errors were observed for all patients. For two patients, large errors (8mm and 5 mm) were present in peak-inspiration due to GTV-delineation inaccuracies from 4DCT binning artifacts. GTV excursions outside of the ITV were observed in transient simulations, but GTV motion was mainly within the PTV. For one FL-acquisition, baseline-shifts were present, with GTV outside of the PTV more than 50% of its time. **Conclusion:** Our findings indicate that the tumour can move outside the irradiated volume. Clinical implementation and application of our model can lead to improvements in more precise RT delivery and target margin accuracy.

Motion Management During Breath-Hold SBRT Liver Treatments: External Optical Monitoring Is Not Adequate – First Results of the TROG 17.03 Liver Ablative Radiotherapy with KIM (LARK)

D Nguyen^{1,3,4*}, T Moodie², C Sengupta³, E Sullivan², T Blacketer², R O'Brien³, J Booth⁴, Y Lee⁵, T Wang², P Keall³, (1) University of Technology Sydney, Ultimo, NSW, AU, (2) Crown Princess Mary Cancer Centre, Sydney, NSW, AU, (3) ACRF Image X Institute, University of Sydney, Sydney, NSW, AU (4) Royal North Shore Hospital, Sydney, NSW, AU (5) Department of Radiation Oncology, Princess Alexandra Hospital, Brisbane, QLD, AU

Purpose: During liver SABR treatment, breath-hold at end exhale or deep inhale is often used to manage target motion. Typically, breath-holds are monitored with a surface monitoring technique such as the Varian RPM. In the LARK trial, we deployed a real-time IGRT system to monitor the internal target motion. Here, we investigate the differences between external and internal monitoring for breath-hold SABR. **Methods:** Seven patients with colorectal metastases in the liver were treated at end-exhale (5 patients) or deep-inhale (2 patients) breath-hold on a Varian TrueBeam (dual-arc VMAT, 6FFF). A margin of 5mm in all directions was applied to the GTV to create the PTV. Three gold fiducial markers (3mm×1mm diameter) were implanted around the patient's tumours for real-time IGRT tracking surrogate. During treatment, the patient internal motion was monitored with an in-house 3D real-time IGRT method utilizing intrafraction kilovoltage imaging at 10Hz. External surface position monitoring (Varian RPM) was also used to measure the patient's breath-hold. Couch shifts were performed following kV pair imaging if the internal motion exceeded 3mm for two consecutive breath-holds. An isocenter shift method was used to reconstruct the delivered motion-included dose with real-time IGRT and with external monitoring alone. **Results:** With real-time IGRT, the 95% confidence interval of the target motion was [-2.3, 2.5]mm, [-3.0 3.0]mm, [-2.7 3.0]mm in LR, SI and AP. With external monitoring, the 95% confidence interval of the target motion would be [-2.4, 2.9]mm, [-3.7, 5.4]mm, [-3.6 3.3]mm in LR, SI and AP. Dosimetrically, with real-time IGRT, the PTV D95 was within 2.7% of the planned value for all patients. With external monitoring alone, the PTV D95 would be underdosed by 4.5±3.8%. **Conclusion:** Real-time IGRT is more accurate for target motion monitoring during breath-hold liver SABR treatments. External monitoring alone resulted in target underdose due to undetected internal motion.

Reconstruction of DRR-Like KV-DR Using CycleGAN-Based Image Synthesis for Intra- and Extracranial SRT/SRS

D Lee^{*1,2}, S LEE³, H Cho¹, (1) Yonsei University, Wonju, KR, (2) Samsung Medical Center, Seoul, KR (3) Boston Medical Center, Boston, MA

Purpose: A kV digital radiograph (kV-DR) using ExacTrac® X-ray source (BrainLAB AG, Munich, Germany) undergoes degradation of image quality due to radiotherapy accessories equipped for patient immobilization. We proposed a deep learning model based on cycleGAN image synthesis to improve the image quality of ExacTrac kV-DR. **Methods:** A total of 2574 paired kV-DRs and digitally reconstructed radiograph (DRR) were obtained from stereotactic radiotherapy (SRT/SRS) treatments for patients with brain or spine cancer. The DRR-like synthetic kV-DRs were generated from kV-DRs directly obtaining from ExacTrac using a deep learning-based image synthesis network. 2166 and 234 of kV-DR and DRR pairs were used for training for testing, and 92 and 82 pairs were used for testing from brain and spine cases, respectively. The images were normalized into [0, 1], and then the order of the paired data cases was shuffled to prevent the overfitting in network training. The mean absolute error (MAE), the root-mean-square error (RMSE), and the peak signal-to-noise ratio (PSNR) were used to quantify the image quality of the synthetic kV-DR. **Results:** The synthetic kV-DR (MAE=0.26±0.08, RMSE=0.33±0.09, and PSNR=9.83±0.33 dB) showed a better image quality compared to ExacTrac kV-DRs (MAE=0.34±0.14, RMSE=0.39±0.14, and PSNR=8.62±3.07 dB). The average MAE, RMSE, and PSNR values were 0.21±0.06, 0.29±0.07, and 11.06±8.45 dB for the brain cases and 0.31±0.07, 0.39±0.08, and 9.83±2.42 dB for spine cases, respectively. **Conclusion:** We successfully suppressed the artifacts in the kV-DRs originated from radiotherapy accessories and generated a DRR-like synthetic kV-DRs from ExacTrac based on deep learning network. The proposed model can improve the tumor localization accuracy for SRS/SRT radiotherapy.

Respiratory Adaptive Computed Tomography (REACT) to Reduce Artifacts in Helical 4DCT Scans

E Mathias*, N Morton, R O'Brien, University of Sydney, Eveleigh, NSW, AU

Purpose: 4DCT imaging plays an important role in current 4D radiotherapy treatment planning. Conventional helical 4DCT scans are prone to image artifacts caused by breathing irregularity and the difficulty in satisfying the data sufficiency condition. To reduce image artifacts in helical 4DCT scans, we have developed a prospective couch velocity adaptation and gating protocol, known as REACT that allows an acquisition in a phase-specific displacement gating window and adapts the pitch based on the patient's breathing. **Methods:** Conventional helical 4DCT scans and prospective respiratory gated 4DCT acquisition (REACT helical) were simulated for 10 patients from the Virginia Commonwealth University tumour motion database using the REACT software. The REACT acquisition in helical mode was simulated both with a constant pitch and a variable pitch value which was updated in response to real-time changes in the patient's breathing rate. An initial training period was used to learn the patient's breathing characteristics and then to determine potential beam gating. The performance of the scans was measured using trace RMSE during imaging (a surrogate for breathing irregularity and image quality) and beam on time (a surrogate for imaging dose). **Results:** As compared to a conventional helical 4DCT, the average breathing irregularity (RMSE) during imaging was reduced by 36.84% and 12.06% for the constant pitch REACT acquisition and the variable pitch REACT acquisition respectively. The average beam on time increased by 49.23% for the variable pitch REACT acquisition as compared to a constant pitch REACT acquisition. **Conclusion:** The results demonstrate the potential of using the REACT method with an adaptive pitch to reduce image artifacts in helical 4DCT scans. While the gating protocol allows for reduction in breathing irregularity related artifacts, varying pitch allows to close the data sufficiency gap.

SU-D-TRACK 4-07

Towards Closed-Loop Control Head Motion Correction with Soft Actuators in MRI-LINAC Systems

O Ogunmolu*, R Wiersma, University of Pennsylvania, Philadelphia, PA

Purpose: To realize real-time automatic patient head motion correction during radiation therapy with non-magnetic and non-radiation attenuating actuators. Contrary to current methods, this (i) removes need for frames or thermoplastic masks; (ii) corrects the complex intra/inter-fractional geometric uncertainties; (iii) and is compatible with standalone MRIs or combined MRI-Linac systems. **Methods:** Following our recent investigation, we now present the real-time deformation framework of a soft actuator within the erstwhile-fabricated mechanism and describe the sensing and closed-loop pneumatic control system. We clamp fabricated actuators using 3D-printed PLA holders and fit the planar actuator with a pipe fitting connector. Compressed air at low pressure (~3-10 psi)

is supplied through a firm polyurethane air tubing into a pressure transducer connection, whose outlet conveys the airflow into a proportional solenoid valve, which in turn leads to the pipe fitting connection of the soft. We construct a standard current source electronic regulator that varies the air flow into the solenoid valve. Finally, a flex sensor, meshed laterally along the center of the actuator during curing measures deformation. **Results:** Effective closed-loop deformation of the actuator chamber is now realized as a result of the designed mechanism. By measuring the deformation of the actuator with an integrated flex sensor, we can proportionally adjust the airflow into the solenoid valves thereby allowing accurate regulation of the head motion. **Conclusion:** This work shows the potential of real-time head motion correction with non-magnetic and a radiation-transparent soft actuator, arranged in systematic fashion around a patient's head. This mechanism is useful in emerging hybrid MRI-Linear accelerators. Its inherent actuation medium (air) eliminates the risk of electronic/metallic parts that are unsuitable for the MRI's magnetic fields and assures safe human-robot interaction.

A Systematic Approach to Balancing Radiotherapy Risk Management and Infection Control During a Pandemic

N Islam*, S Wadi-Ramahi, R Lalonde, M Huq, UPMC Hillman Cancer Center and University of Pittsburgh School of Medicine, Pittsburgh, PA

Purpose: To develop a systematic risk management method that uses failure modes and effects analysis (FMEA) to design mitigation efforts to control pandemic infection spread, while ensuring safe delivery of quality radiotherapy. **Methods:** We define Infection containment failure mode (ICFM) to be any scenario where transmission of the infection occurs within the clinic. A two-stage approach has been developed for application of FMEA to radiotherapy workflow during a pandemic. In stage 1, the FMEA is focused on ICFMs, where risk priorities are evaluated based on available data and modeling of the pandemic infection. An infection risk priority number (IRPN) has been defined as a function of time, distance and protective gear. Subsequently, infection containment mitigation plans are integrated into the radiotherapy workflow. In stage 2, a traditional FMEA will be conducted on the adjusted workflow with a focus on radiotherapy failure mode (RFM) prevention. Furthermore, additional RFM mitigation plans will be introduced in the workflow, thereby iteratively returning to stage 1 for reevaluation of additional ICFMs. **Results:** The COVID-19 pandemic has been used to illustrate the two-stage systematic approach to risk management developed in this work. Selected parts of the radiotherapy process have been used to demonstrate examples of ICFM identification and failure mode mitigation. For a pre-pandemic CT-simulation workflow, 14 ICFMs were identified. For each ICFM, the IRPN was calculated based on average time, distance, and degree of protective gear with values ranging from 3 - 100. Various infection control measures were subsequently added to the CT-simulation workflow thereby reducing the IRPN scores. The modified workflow was then evaluated for RFMs and subsequently additional mitigation plans were introduced. **Conclusion:** The framework developed in this work offers a tool for radiotherapy clinics to systematically assess risks, adjust workflows, and allocate resources in response to the challenges during a pandemic.

SU-D-TRACK 6-02

Application of Machinery FMEA (MFMEA) for the Risk Assessment of Machine Issues Using An In-House Electronic Reporting System

T Teo¹*, S Kucuker Dogan², B Zawislak¹, M Gopalakrishnan², I Das², (1) Northwestern Memorial Hospital, Chicago, IL, (2) Northwestern Memorial Hospital, Northwestern University Feinberg School of Medicine, Chicago, IL

Purpose: Despite the capability to perform remote monitoring and preventive maintenance for radiotherapy machines, treatments are often interrupted by unforeseen machine issues. In contrast to the process-based FMEA for clinical workflow analysis (i.e. AAPM TG100), a machinery FMEA (MFMEA) was devised for the machine issues and treatment interruptions recorded in an in-house electronic reporting system. The impact of these events on treatment schedule, patient safety, and operators' competency in resolving these issues is assessed. **Methods:** Reported machine issues were classified under five sub-systems: beam-generating system, beam-limiting, kV-imaging, control software, and patient couch. MFMEA was implemented with four modules to analyze the impact of a component failure in each of the sub-systems. MFMEA modules include (1) functional analysis – identifies components of each sub-system (e.g. MLC for beam-limiting); (2) failure analysis – describes functional failures (e.g. stuck MLC), impacts (e.g. treatment terminations) and causes (e.g. faulty MLC-motor); (3) risk analysis – describes the ease of detecting the failure; and (4) risk management – risk prioritization and preventive measures. Scoring for occurrence, severity, and detectability for each component failure were guided by data such as the frequency of error reported, duration of downtime, and detection rate through routine QA and from a remote monitoring software. **Results:** Based on a total record of 215 issues reported over one year on one machine, 40% (kV-imaging), 29% (beam-limiting), 16% (beam-generating), 8% (control software), and 7% (patient couch) failures correspond to 20 component failures generated. The top three component failures (with their risk-priority-number) are – CBCT (424), couch positioner (214), and MLC (176). **Conclusion:** The risks encountered with machine issues and interruptions have been analyzed for the first time using an MFMEA model with data from an electronic reporting system. Trainings and preventive measures for improving treatment efficiency are identified based on the risk model

Automatic Detection of Vertebral Body Misalignment Errors in Cone-Beam CT Guided Radiotherapy Using a Convolutional Neural Network

D Luximon*, J Neylon, J Lamb, University of California, Los Angeles, Los Angeles, CA

Purpose: Vertebral misalignments during cone-beam computed tomography (CBCT)-guided radiotherapy can lead to wrong-site treatment. We propose an automatic error detection algorithm that uses a three-branch convolutional neural network (CNN) to detect vertebral body misalignments using planning computed tomography (CT) images and setup CBCT images. **Methods:** Planning CTs and setup CBCTs were collected from 160 patients undergoing radiotherapy treatment in the thoracic or abdominal region using Varian TrueBeam and NovalisTx treatment machines. To simulate vertebral body misalignment errors, the setup and planning images were misaligned by one vertebral body and for each patient, one superior and one inferior misalignment were generated. The clinically applied registration was used to derive true-negative (no error) data. For each of the aligned and misaligned 3D image pairs, 2D slice pairs were extracted in each anatomical plane about an isocenter within the vertebral column. The 3 slice pairs obtained were then used as inputs to a three-branch CNN which returned a probability of vertebral misalignment. Each of the 3 branches was used to extract features from one of the orthogonal image planes, which were then joined in a single densely-connected layer. The CNN was trained on 140 patients and tested on 20 patients. The algorithm performance was quantified using a receiver operating characteristic (ROC) analysis. Due to the rarity of vertebral body misalignments in the clinic, a minimum threshold value yielding a specificity of at least 95% was selected. **Results:** The ROC analysis resulted in an area under curve of 0.985 with a 95% confidence interval of [0.978 0.992]. The sensitivity was found to be 90% for a fixed specificity value of 95%. **Conclusion:** Our CNN-based algorithm can accurately identify off-by-one vertebral body misalignments in planning CT and setup CBCT registrations, leading towards the possibility of an on-line error prevention system.

Multi-Institutional Validation of a Convolutional Neural Network-Based Approach to the Detection of Vertebral Body Misalignments in Planar X-Ray Setup Images

J Charters¹, J Kunz², J Lamb¹, D Low¹, O Morin³, R Petragallo^{1*}, D Saenz⁴, B Salter², G Valdes³, B Ziemer³, (1) University of California Los Angeles, Los Angeles, CA, (2) University of Utah, Huntsman Cancer Hospital, Salt Lake City, UT, (3) University of California San Francisco, San Francisco, CA, (4) University of Texas HSC SA, San Antonio, TX

Purpose: Alignment to the incorrect vertebral body remains a rare but serious patient safety risk in image-guided radiotherapy (IGRT). Our group has previously presented a prototype convolutional neural network (CNN)-based approach for automatic detection of these errors in a planar stereoscopic x-ray IGRT system. Here we expand on our previous work to examine the robustness of our model when applied to multi-institutional data. **Methods:** A single-institutional model was trained using x-ray and digitally reconstructed radiograph (DRR) image pairs from 87 thoracic spine radiotherapy patients treated at a single institution using a stereoscopic x-ray IGRT system. Training data used simulated off-by-one vertebral body errors created by shifting DRRs by one vertebral body in both directions along the spinal column using a semi-automated method. 70 patient datasets were used to train the CNN model and 17 used for testing the detection accuracy. This trained model was then applied to 167 patient datasets collected from 3 external institutions to evaluate model robustness. Subsequently, the CNN was re-trained using data from all four institutions. Of this combined dataset, 204 patients were used for re-training and 49 reserved for testing. For all datasets, all treatment fractions were used in each of the patients. **Results:** When the single-institution CNN was used to classify unseen image pairs from collaborating institutions, the resulting receiver operating characteristic area under the curve (AUC) was 0.94. However, with the specificity fixed at 99% the corresponding sensitivity was 32.9%. For the model re-trained and tested on multi-institutional data, an AUC of 0.99 was obtained, and a sensitivity of 91.9% when specificity was fixed at 99%. **Conclusion:** We have demonstrated a CNN-based vertebral body misalignment model that is robust to multi-institutional image data. The incorporation of cross-institutional data into the training dataset significantly improves final classification accuracy.

Radiotherapy Application of Causal Analysis Based On Systems Theory (CAST)

L Wong^{1*}, N Leveson¹, T Pawlicki², (1) Massachusetts Institute Of Technology, Cambridge, MA (2) UC San Diego, La Jolla, CA

Purpose: Radiation therapy (RT) accidents are commonly investigated with Root Cause Analysis (RCA) based on chain-of-events models. This work aims to analyze an RT incident using a technique based on a systems- and control-theory model and to describe early impressions of this approach. **Methods:** Causal Analysis based on Systems Theory (CAST) was applied to an RT incident recreated as a publicly-available video (i.treatsafely.org, #118350879) involving a pediatric patient that received a suboptimal treatment. We performed the five parts of the CAST methodology: 1) gather basic information about the accident, 2) create a safety control structure, 3) analyze the relevant components, 4) identify systemic factors, and 5) create a safety improvement program. These steps were performed by an experienced clinical physicist who has extensive experience with RCA and an expert in systems safety engineering and CAST. A qualitative comparison between CAST and RCA was completed. **Results:** A diverse set of contextual factors contributed to the incident. Including the mental model flaws of the frontline staff, these contextual factors revealed additional contributions by technology providers, management, as well as regulatory and advisory bodies. Four systemic factors (e.g., communication and coordination, economics, etc.) were also involved in the incident. Multiple intervention ideas were generated covering technology, practice change, and management to prevent incident recurrence. Overall, CAST enabled a robust analysis of the accident. For the non-safety expert, the CAST analysis forced incident analysis from multiple levels which is different than the conventional RCA approach that primarily targets frontline personnel. However, the CAST methodology is more complicated to use than RCA for the non-safety expert. **Conclusion:** While CAST appears to be a more robust methodology than RCA, achieving its potential requires prior knowledge about the procedure. Also, some terminology modifications can be beneficial to make it more easily comprehensible when introducing it to clinicians.

The Utility of Medical Physics Proton Peer Review for Clinical Trials

P Taylor*, J Lowenstein, D Followill, S Kry, UT MD Anderson Cancer Center, Houston, TX

Purpose: To highlight the value of IROC's on-site proton audits and key findings. **Methods:** IROC has performed 38 on-site measurement-based peer reviews of proton centers participating in NCI-funded clinical trials. The reviews covered beam calibration, lateral and depth measurements, mechanical checks, treatment planning, and quality assurance (QA) practices. The CT Number to Relative Linear Stopping Power (RLSP) conversion was tested with a phantom with known RLSP values, and by comparing the institution's curve to other proton centers. **Results:** Institutions received an average of 3 [1, 8] recommendations for practice improvements. The number of deficiencies did not decrease over time, highlighting the continued need for this type of peer review. The most common deficiencies were for QA (97% of centers), CT Number to RLSP conversion (50%), and treatment planning (45%). 32% of institutions failed at least one lateral beam profile measurement (<90% of pixels passing 3%/3mm, 10% threshold), despite passing internal QA measurements. These failures occurred for several different plan configurations (large, small, shallow, and deep targets), and at different depths in the beam path (proximal to target, central, and distal). CT Number to RLSP conversion curves showed deviations at low, mid, and high CT Numbers. This test highlights areas of inconsistency between proton centers, with many centers falling outside 2σ of the mean curve of their peers. All deficiencies from the peer review were discussed with the institutions, and many implemented dosimetric, treatment planning, and practice changes to improve the accuracy of their system and consistency with other institutions. **Conclusion:** This peer review program has been integral in confirming comparability and consistency across proton centers for clinical trials, minimizing deviations for outcomes data.

Development of a Text-Mining Based Methodology for the Identification of Trending Topics in a Radiation Oncology Incident Learning Database

RG Price*, YJ Huang, BJ Salter, University Utah, Salt Lake City, UT

Purpose: Incident-learning is a powerful tool necessary for continuous improvement of quality and safety within radiation oncology. However, as the percentage of captured incidents increases, so does the difficulty of identifying important trends/topics meriting the highest attention of the internal safety committee. This study utilized automated text-mining procedures to identify important topics for review. **Methods:** Data was exported to CSV for 133 incident reports from our institutional RO-ILS database. Narratives were extracted, and data was imported to Orange, an open-source data-mining tool, for processing and analysis. Text was converted to lower case before using regexp for tokenization (breaking into single-word pieces). Punctuation and unimportant words were filtered using a list of stopwords (words such as "the"). Finally, tokens were used to create a range of N-gram phrases (phrases with N number of words) which were counted and regularized to relative weighted "importance" before visualization using word clouds. Phrases with largest weightings were further investigated to determine if this was indicative of a topic that needed additional action. **Results:** The N-gram phrase "v-sim" was observed to receive a high

weighting. This represented a previously unidentified issue and, upon further investigation, was recognized as being indicative of both the number of events identified at the patient's v-sim appointment, as well as events that occurred due to shortened sim-to-treatment timelines. "Setup instructions" also received a high weighting, and was identified as being indicative of a previously known trend caused by incorrect or unclear setup instructions. This was encouraging, as it validated the potential of the tool. Other notable findings included "iso-center", which was tagged in many events with various topics. This was ascertained to be indicative of the large number of error pathways that can result in isocenter related problems. **Conclusion:** Preliminary use of text-mining tools shows promise for identifying relevant safety-related topics for review.

Parallels and Intersections in Thoracic Proton Therapy

SU-D-TRACK 7-04

Q&A

Thoracic proton therapy is challenging because of high tissue heterogeneity and volatility. The effects of uncertainties on proton range are accentuated in the thorax due to the respiratory motion and time structure of the proton pencil beam, making implementation of new developments more intricate than for other sites. This session will focus on how technological advancements in a. Plan optimization and evaluation and b. Adaptive planning and delivered dose accumulation, are implemented for thoracic targets. The latest in treatment planning systems such as Monte Carlo-based 4-dimensional robust optimization and estimation of biological weighted dose will be presented along with their benefits, disadvantages, and inadequacies in and around the lungs. Robustness evaluation methods based on dose calculation of error and anatomy scenarios recently replaced PTV evaluations in proton therapy and will also be introduced. In addition, estimations of delivered dose will be explored in the session. Methods of reporting dose distributions that include delivery log files, daily IGRT and patient monitoring data, and repeated scan images will be presented. Remaining issues in reporting fractional and cumulative doses that include the effects of uncertainties, errors, physiological motions, and anatomical deformations as well as plan adaptations will be reviewed. Practice differences between photons, older and new technology protons and their repercussions will be discussed. The Dutch Model Based perspective from thoracic patient selection to planning techniques and treatment evaluation methods will be presented.

Learning Objectives:

1. Be updated on the latest treatment planning techniques applied in proton thoracic therapy
2. Learn about dose evaluation both planned and delivered
3. Explore differences between European and North American practices in thoracic proton therapy

CBCT Manual Vs. Semi-Automatic Single and Multi-Slice Low Contrast Resolution Analysis

N Becerra Espinosa^{1*}, L Claps², P Alaei³, (1) University of Minnesota, Minneapolis, MN, (2) Memorial Sloan Kettering, New York, NY

Purpose: To compare methods for quantifying low contrast resolution for monthly CBCT QA using manual and semi-automatic software analysis. **Methods:** The Phantom Laboratory's Catphan 504 CBCT images containing sub-slice and supra-slice low contrast disks were evaluated for twelve months. The number of supra-slice disks visible out of a maximum of twenty-seven was recorded after visual inspection of the images. Using Radiological Imaging Technology's (RIT) Radia Complete Imaging QA software analysis, a central slice in the CT515 module was selected and analyzed for each month. Selecting the same central slice as the middle, an average of seven slices was taken and evaluated using the same software. The number of disks detected using each **Method:** manual, single slice, and multi-slice, was then compared using Bland Altman analysis, and paired two-sample t-test. **Results:** In all three **Methods:** manual vs. RIT single slice, manual vs. RIT seven slice averaging, and RIT single slice vs. RIT seven slice averaging, the differences were statistically significant within a significance interval of $\alpha=0.05$. The degree of statistically significant difference was lowest between the manual vs. RIT single slice ($t=-3.70$, $p=0.0018$), increasing in the RIT single slice vs. RIT seven slice averaging ($t=-3.94$, $p=0.0012$), and reaching a maximum in the manual vs. RIT seven slice averaging ($t=-12.50$, $p=3.83E-8$). This maximum difference coincides with higher low contrast disk detectability with the RIT seven slice averaging method, and lower disk detectability with manual user observation. Bland Altman analysis shows an increasing bias going from manual to seven-slice averaging, and generally wide

limits of agreement. **Conclusion:** Semi-automatic multi-slice averaging greatly improves supra-slice low contrast disk detectability in the CT515 module. The method can provide users with a reliable mean to accurately assess monthly CBCT low contrast module performance.

Evaluation of Megavoltage Cone-Beam Computed Tomography Doses in Thoracic Radiation Therapy

S Yan, J Zhu, S Yan*, Department of Radiation Oncology Physics and Technology, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Ji'nan, Shandong provinceCN

Purpose: Daily megavoltage cone-beam computed tomography (MVCBCT) imaging verification ensures the accuracy of treatment delivery but raises a cumulative dose to normal tissue. This study aimed to investigate imaging doses and cancer risk attributable to megavoltage cone-beam computed tomography undergoing thoracic radiation therapy. **Methods:** A total of 206 patient datasets (age range: 2-60 years; chest circumference range: 40–109 cm) were retrospectively assessed with chest circumference. An Eclipse clinical treatment planning system was used to calculate imaging dose distributions of MVCBCT scans using 10×10 cm² field size, 200° arc length, and low dose (5MU) protocol. Optically stimulated luminescence dosimeters (OSLDs) inserted in three anthropomorphic phantoms (equivalent to a 5-year, 10-year old child, and adult male) were then scanned using this scanning protocol by a Halcyon MV-CBCT. We used regression analysis of more than 200 MVCBCT doses to develop an empirical model of chest circumference, and cancer risk was calculated using the BEIR VII. **Results:** The maximum difference between the TPS calculated dose and the phantom validated dose was less than 4.9%. The organs at risk (OAR) mean doses decreased monotonically with increasing chest circumference. The median doses to the heart, spinal cord, lungs were 4.3, 3.1, and 2.9 cGy/scan. **Conclusion:** Results showed a good agreement between experimental measurements (with OSLDs) and TPS simulations for three anthropomorphic phantoms. Imaging doses and cancer risk are highly correlated with chest circumference in image-guided thoracic radiation therapy. Under the same CBCT imaging protocols, pediatric patients received even more than twice of imaging dose compared to adults due to their smaller body sizes.

Efficient Visualisation of Changes in CBCT During Radiotherapy to Detect Lung Infections

M van Herk^{1*}, G Price², A Clough², J Sanders², C Faivre-finn^{1,2}, C Eccles², M Aznar¹, (1) The University of Manchester, Manchester, GB, (2) The Christie Hospital NHS Foundation Trust, Manchester, GB

Purpose: Cancer patients are vulnerable to COVID-19 and other infections. Daily CBCT is common for image-guided radiotherapy. To protect patients and staff lung infections must be detected timely, which is possible on daily thoracic CBCT. However, it is time consuming to inspect all slices of a thoracic CBCT, especially for longitudinal changes. Here we develop and optimise a tool for rapid detection lung of infections by visual comparison of daily images projected in 2D. **Methods:** All daily thoracic CBCTs are processed overnight by a pipeline containing registration, cropping to lungs, filtration, and maximum intensity projection. Parameters were optimised visually using 150 cases. A visual timeline of the treatment is presented in a report and animation. Images are reviewed each morning by a radiographer who flags issues to a clinical oncologist to determine if further action is required. The tool was retrospectively evaluated in 285 patients treated between January and June 2020 and prospectively implemented in a clinical workflow and departmental quality system in July 2020. **Results:** Rigid registration outperformed deformable registration, the latter being affected by lung lesions. Optimal cropping was the planning CT lungs - 3mm, balancing sensitivity for peripheral lesions and rejection of pleural effusion changes. Blurring ($\sigma=1\text{cm}$) in AP direction suppressed healthy lung structures while maintaining infection contrast. Report generation took ~60s per case, and inspection ~12s. To date, over 400 patients were prospectively evaluated and 4 asymptomatic patients were diagnosed with COVID-19 based on CBCT imaging changes. A further patient was identified as having a non COVID-19 lung infection on CBCT. **Conclusion:** We developed and validated a near real-time tool to identify lung density changes on CBCT indicative of COVID-19 or other lung infections. CBCT imaging provides a unique opportunity to study temporal progression of lung infections and protect patients and staff.

SU-lePD-TRACK 1-04

Cone-Beam Computed Tomography (CBCT) to Computed Tomography (CT) Image Translation with Perceptual Loss to Eliminate Cone-Beam Artifacts

S Yoo*, B Choi, I Park, J Kim, H Kim, Department of Radiation Oncology, Yonsei University College of Medicine, Seoul, Korea

Purpose: Cone-beam computed tomography (CBCT) is widely used for image-guided radiation therapy (IGRT). The application of CBCT can be extended to adaptive radiation therapy (ART) for dose accumulation and re-planning, which are currently limited in accuracy due to degraded image quality from cone-beam artifacts. Thus, this work presents an advanced deep learning (DL) algorithm for generating synthetic CT from CBCT by incorporating perceptual loss. **Methods:** Patient cohort for the DL model consisted of 43 scans with paired CBCT and CT images. The dataset was split into 35 patients for train-set, 3 for valid-set, and 5 for test-set. We utilized a two-dimensional FC-DenseNet as the DL architecture to eliminate the cone-beam artifacts of CBCT. CT slices were deformable registered and resampled to CBCT using MIM software and MATLAB. With L1-loss only, we found that details in bone structure disappeared in synthetic CT generation. To enhance the translating performance, the perceptual loss besides L1-loss was newly applied. Data augmentations (flip, rotation, blur) were conducted to increase the data size for training. The similarity metric to assess the trained networks employed structural similarity index (SSIM) and mean absolute error (MAE). **Results:** 5 patients with paired CBCT/CT images were randomly selected to validate the trained networks. Two networks with L1-loss and (perceptual loss+L1-loss) resulted in similar MAEs (0.050 and 0.044). The L1-loss based network may well produce slightly lower MAE as the L1-loss emphasizes compressing MAE. Contrarily, in SSIM, our proposed network with additional perceptual loss outperformed that with L1-loss only (0.756 to 0.824). It implies that the perceptual loss substantially contributed to improving the similarity of synthetic CT produced from CBCT to real CT images. **Conclusion:** Our DL model with perceptual loss was demonstrated to promote the performance of CBCT to CT image translation, which can strengthen the usefulness of CBCT in radiotherapy.

Identification of Modes of Tumour Regression During Radiotherapy

L Amugongo^{1*}, A Green², D Cobben³, M van Herk⁴, E Vasquez Osorio⁵, A McWilliam⁶, (1) University of Manchester, Manchester, LAN, GB, (2) University of Manchester, (3) The Clatterbridge Cancer Centre Nhs, (4) The University of Manchester, Manchester, GB, (5) University of Manchester, (6) University of Manchester

Purpose: Safety of adapting lung cancer radiotherapy (RT) to tumour shrinkage depends on whether microscopic disease is left behind - the question of elastic versus non-elastic regression. The purpose of this project is to quantitatively distinguish these modes of tumour regression in non-small cell lung cancer (NSCLC) patients. **Methods:** First, simulations of pure elastic and non-elastic regression were created. To quantify tumour regression, in both real and simulated cone-beam CTs (CBCTs), registration of all CBCT to day one CBCT was performed using NiftyReg algorithm. Data from 150 locally advanced NSCLC patients receiving the same prescription was used. From simulations, a methodology based on the determinant of the Jacobian (local volume change) was developed. The gross tumour volume (GTV) was triangulated and, at each facet, ten Jacobian values were sampled along lines perpendicular to the surface. Jacobian values were combined to classify tumour changes spatially and in time. Finally, modes of tumour change were compared between tumours of different histology and TNM stage. **Results:** In simulated data, our approach can distinguish elastic and non-elastic tumour regression combining Jacobian values 1.2cm

inside and outside the GTV boundary. Values near the boundary were unreliable. Patients showed a mix of elastic and non-elastic behaviour, but no real patient showed pure elastic regression. 88%(N=125) of patients showed stable disease in the first two weeks of RT. At treatment completion, 32%(N=46) of the patients showed tumour regression, predominately non-elastic. Slight differences in the mode of tumour change were found with histology and TNM stage. **Conclusion:** This work found regional differences in mode of lung tumours change on CBCTs. Patients with pure elastic regression, however, were not observed in our data. Our results suggest that safe adaptive RT for lung cancer patients requires careful consideration to avoid underdosing of microscopic tumour residuals after non-elastic regression.

ROI Based Deep Learning Enhancement for CBCT Based Radiomics Analysis

M Huang^{1*}, Z Zhang², Y Lai³, Y Chang⁴, Z Jiang⁵, J Lee⁶, F Yin⁷, L Ren⁸, (1) Duke University, Department of Radiation Oncology, Durham, NC, (2) Duke University, Durham, NC, (3) the University of Texas at Southwest, TX, (4) Duke University, Durham, NC, (5) Duke University, Durham, NC, (6) Duke University, Department of Radiation Oncology, Durham, NC, (7) Duke University, Department of Radiation Oncology, Durham, NC, (8) Duke University, Department of Radiation Oncology, Durham, NC

Purpose: To investigate the impact of CBCT image quality and ROI-based deep learning image enhancement on radiomics analysis. **Methods:** CBCT image quality is affected by scattering, beam hardening and noise, which directly impact its accuracy for radiomics analysis. This study focuses on investigating the accuracy of CBCT-based radiomics analysis and the efficacy of using deep learning to improve the accuracy. Around 900 CBCT projections were simulated from each patient's CT images using Monte Carlo method to contain primary signal, scatter signal and noise. The projections were then fed into the Varian Itool package to mimic clinical CBCT reconstruction. A Pix2Pix Generative-Adversarial-Network was used to improve the CBCT image quality based on CT images as ground truth. The deep learning model was trained for both enhancing the whole body and the ROI around the tumor using 11 lung patients and tested using 3 patients. Radiomics analysis was performed for both CBCT and enhanced CBCT and compared to ground-truth CT to evaluate their accuracy. **Results:** The CBCT image quality was significantly improved after the AI-based enhancement. 18 First order, 22 GLCM, 16 GLRLM, 16 GLSZM, 14 GLDM, and 688 wavelet features were computed for the CT, original CBCT, whole body-based enhanced CBCT, and ROI-enhanced CBCT. Under best scenario, the first 86 features improvement was 83.4%, 18.9%, 13.3%, -11.9% and 17.6% for each radiomics feature zone based on ROI image augmentation, and improved 88.9%, 21.7%, 15.9%, -12.2%, 18.2% based on whole-body image augmentation. The sensitivity of features against image quality was consistent for all 3 patients. **Conclusion:** Image quality is vital for establishing accurate CBCT based radiomics analysis, and deep learning can effectively improve the radiomic feature accuracy, especially for low-order features. The superior performance for low-order features is likely due to their consistency with the L1-loss function used in deep learning training.

Patient-Specific Deep Learning Model for Enhancing 4D-CBCT Image for Radiomic Analysis

Z Zhang*, M Huang, Z Jiang, Y Chang, K Lu, F Yin, L Ren, Duke University Medical Center, Durham, NC

Purpose: 4D-CBCT provides phase-resolved images valuable for radiomics analysis for outcome prediction throughout the treatment course. However, 4D-CBCT suffers from streak artifacts caused by under-sampling, which severely degrades its accuracy for deriving radiomic features. Previously we developed group-patient-trained deep learning methods to enhance the 4D-CBCT quality for radiomics analysis, which was not optimized for individual patients. In this study, we developed a patient-specific model to further improve the robustness and accuracy of 4D-CBCT based radiomics analysis for individual patients. **Methods:** The patient-specific model was trained using intra-patient data. Specifically, patient planning 4D-CT was augmented through image translation, rotation and deformation to generate 305 CT volumes from 10 volumes to simulate possible patient positions during the image acquisition. 120 projections were simulated from 4D-CT per phase and were used to reconstruct 4D-CBCT using FDK back-projection algorithm. Breathing motion traces were simulated using a regular breathing curve containing 120 breathing cycles. The patient-specific model was trained using these 305 sets of patient-specific 4D-CT and 4D-CBCT data to enhance the 4D-CBCT to match with 4D-CT. For model testing, 4D-CBCT were simulated from a separate 4D-CT scan acquired from the same patient, and were then enhanced by the patient-specific model. Radiomics features were then extracted from the testing 4D-CT, 4D-CBCT, and enhanced 4D-CBCT for comparison. **Results:** Compared with a group-based model, patient-specific training improved the accuracy of radiomic features, especially for the first order features. First order improved 75.97% and the total radiomics improved by 31.62% from the group-based model to patient specific model. For example, first-order median feature improved 82.39% and texture non-uniformity-GLDM improved 88.09%. **Conclusion:** This study demonstrated that the patient-specific model is more effective than group-based model in improving the accuracy of the 4D-CBCT radiomic features, which can consequently improve the precision for outcome prediction in radiotherapy.

SU-lePD-TRACK 2-01

Theoretical Investigation of the Signal and Spatial Resolution Performance of HgI₂ Converters Incorporating Pillar-Supported Frisch Grid Structures for Digital Breast Tomosynthesis

L Shen*, Y El-Mohri, Q Zhao, L Antonuk, University of Michigan, Ann Arbor, MI

Purpose: The theoretical signal and spatial resolution performance of particle-in-binder mercuric iodide (PIB HgI₂) x-ray converters incorporating pillar-supported Frisch grid structures are reported. The grid serves to reduce hole signal contribution, and thus image lag, under digital breast tomosynthesis (DBT) irradiation conditions. **Methods:** Each converter employs a top, continuous electrode and 100 μ m pitch, bottom pixelated electrodes. Finite element analysis was used to calculate electric field and weighting potential maps in the converter. A trajectory tracking algorithm used these maps to follow the transit of electrons and holes through the converter and determine induced signal. The signal performance of the converter along with the modulation transfer function (MTF) were investigated as a function of various grid parameters in order to identify grid designs that optimize performance. **Results:** Examination of MTF and signal performance as a function of grid pitch (the center-to-center distance between two neighboring grid wires), RGRID (the ratio of grid wire width to grid pitch) and projection image number in a DBT scan, indicates the following. (1) Higher RGRID and smaller grid pitch provide better suppression of hole signal, but diminish total signal due to narrower gaps between grid wires. (2) Grid pitches considerably smaller than the pixel pitch are more effective for

maintaining MTF close to the ideal of a sinc function corresponding to the pixel aperture – irrespective of RGRID. (3) For a total DBT scan exposure of 15 mR, charge accumulation on the insulator pillars has insignificant effect upon performance – other than a slight improvement of total signal across consecutive images for high RGRID. **Conclusion:** PIB HgI₂ converters incorporating a pillar-supported Frisch grid at a grid pitch of 20 μ m and RGRID of 35% suppress up to ~76.5% of hole signal, while preserving total signal and MTF compared to a detector without a grid.

Spectral Simulation for a Dual-Layer Detector for Dual-Energy Contrast-Enhanced Breast Imaging

H Huang*, X Duan, A Howansky, J Stavro, A Goldan, A Lubinsky, W Zhao, SUNY Stony Brook, Stony Brook, NY

Purpose: Dual-energy (DE) contrast-enhanced (CE) breast imaging requires registered low energy (LE) and high energy (HE) images for DE subtraction and is susceptible to patient motion. The motion artifacts could be more severe for CE digital breast tomosynthesis. Dual-layer (DL) detectors allow acquisition of LE and HE images in one x-ray exposure which minimizes patient motion. We aim to investigate a DL detector design for DE CE breast imaging and evaluate the impact of the thickness of x-ray filter and detector layer on the iodine detectability. **Methods:** The DL detector consists of a top layer (TL) of amorphous selenium to generate the LE images and a bottom layer (BL) of columnar cesium iodine for the HE images with a glass substrate in between. The x-ray spectrum was simulated using tungsten target and rhodium (Rh) filter at 49 kVp with intensity that leads to a total radiation dose of 1.5 mGy to a 4-cm breast with 50% density. We calculated the x-ray spectrum for photons interacted in the TL and the BL for different Rh filter and TL thicknesses. The image signal was determined based on the x-ray energy deposition in the TL and BL and included quantum noise. We calculated the signal-difference-to-noise-ratio (SDNR) for 1 mg/cm² iodine in the DE-subtracted image and evaluated the tube-current time product (mAs) for different Rh filter thicknesses. **Results:** Increasing the Rh filter thickness improves the spectral separation in the TL and BL and increases the iodine SDNR. Decreasing the TL thickness reduces the HE photon interactions in the TL and further increases the iodine SDNR. Rh filter with 200 μ m thickness achieves the highest iodine SDNR with practical mAs. **Conclusion:** The proposed dual-layer detector is feasible for DE CE breast imaging to minimize patient motion.

Breast Thickness Map Estimation and Its Associated Correction in DBT Imaging

S Lee^{1,*}, H Kim², H Lee³, S Cho⁴, (1) KAIST, Daejeon, 44, KR, (2) KAIST, Daejeon, KR, (3) Massachusetts General Hospital, Boston, MA, (4) KAIST, Daejeon, KR

Purpose: Breast compression is still required during the digital breast tomosynthesis (DBT) image acquisition. Because of the rounded shape of a breast, it cannot be constricted into a single uniform thickness particularly near the periphery. Current segmentation-based thickness correction methods are error-prone and do not necessarily represent the x-ray physics. **Methods:** We propose a convolutional neural network (CNN) based breast thickness correction method. Not only a normalized log projection image but also a Euclidean distance map were prepared as network inputs. A distance map is generated by calculating the Euclidean distance of each internal pixel of the projection image to the closest point of the skin-line. We utilized patch-based learning to reduce computational costs whilst maintaining the image resolution of DBT projections. By providing distance map along with a log projection image, one can preserve the positional information of the patched image. We introduce a concept of the thickness map, which is a projection of a hypothetical binary volume mask that distinguishes inside and outside of a breast. We define a thickness corrected image by dividing the projection image with the corresponding thickness map in a pixel-wise manner. Thickness corrected images are the targets of the network training. Dataset for training and testing was constructed with help of the VICTRE phantom and MC-GPU simulation. **Results:** In the simulation study, the proposed network successfully corrected the breast thickness nonuniformity. A low root-mean-square deviation (NRMSE) down to 1.976% and high structural similarity (SSIM) up to 99.997% were obtained quantitatively. **Conclusion:** We have developed a CNN-based breast thickness correction method. By offering a distance map along with the projection, the proposed network successfully performed the breast thickness correction. Our method may benefit several applications including DBT image quality enhancement, scatter correction, density estimation, and multimodal imaging such as DBT plus diffuse optical tomography.

Monte-Carlo Simulation of the Detective Quantum Efficiency of Cadmium Telluride X-Ray Detectors for Photon-Counting Mammography

J Day*, J Tanguay, Ryerson University, Toronto, ON, CA

Purpose: Photon counting offers the possibility of single-shot spectroscopic imaging and electronic noise rejection, but charge sharing will degrade image quality. We used Monte Carlo (MC) methods to simulate the detective quantum efficiency (DQE) of cadmium-telluride (CdTe) photon-counting x-ray detectors for breast imaging and compared results against published DQEs for energy-integrating systems that use amorphous selenium (a-Se) detectors. **Methods:** We calibrated and validated a MC model of x-ray interaction and detection in CdTe photon-counting x-ray detectors against an XCounter Thor detector. Our model accounted for charge sharing, electronic noise and anticoincidence logic. We then optimized the detector thickness for a 28kVp Mo/Mo spectrum hardened by 3.9cm of lucite as a function of electronic noise level and pixel size with and without inter-pixel anticoincidence logic. The figure of merit used for optimization was the integral of the DQE. The optimized DQE was compared to published values of the DQE of energy-integrating a-Se systems for 85 μ m pixels. **Results:** Without anti-coincidence logic, the optimal DQE(0) was 0.72 at the optimal detector thickness of 300 μ m, which is comparable to the DQE of a-Se systems in clinical use. Anti-coincidence logic reduced the photon-counting DQE(0) by 14% due to an associated increase in electronic noise. Reducing the electronic noise level to ~1.5 keV in combination with anti-coincidence logic resulted in a DQE(0) of 0.84. **Conclusion:** Increasing the DQE of photon-counting CdTe detectors relative to that of energy-integrating a-Se detectors will require the use of anti-coincidence logic to suppress charge sharing, and electronic noise levels to less than ~1.5keV, which is approximately half of that of the system used in this work. Future work will focus on contrast-enhanced spectral mammography.

Assessment of Case-Based Repeatability of AI Using Mammographic Radiomics of Breast Lesions

H Whitney^{1,2*}, P Amstutz^{1,2}, K Drukker², H Li², H Abe², M Giger², (1) Wheaton College, Wheaton, IL, (2) University of Chicago, Chicago, IL

Purpose: Assessment of case-based repeatability of artificial intelligence algorithms can provide insight into potential clinical use over a range of cases. Previous studies have demonstrated that variation in training cases impacts repeatability. This study investigated impact of classifier on case-based classification repeatability using human-engineered radiomic features extracted from full-field digital mammography (FFDM) images of breast lesions, for three different classifiers: linear discriminant analysis, support vector machine, and random forest. **Methods:** A retrospective, HIPAA/IRB compliant collection of 268 unique lesions (138 malignant, 130 benign) was used. There were 516 FFDM images; most lesions (144) were imaged in two or three views. Lesions were automatically

segmented; 29 radiomic features were extracted for each image. Classifier training/testing was conducted using a 0.632 bootstrap/1000 iterations, with cancer prevalence maintained in each bootstrap sample. The same bootstrap samples were used for the classifiers. Classifier outputs were averaged from different views of the same lesion to obtain case-based output (CBO). Performance in the task of distinguishing malignant from benign lesions was evaluated by the 0.632+ bootstrap-corrected area under the receiver operating characteristic curve (AUC). The bootstrap samples were used to calculate confidence intervals for AUC and the difference in AUC in pair-wise comparisons between classifiers. Difference in AUC was significant if the 98.33% confidence interval (CI, adjusted from 95% for multiple comparisons) failed to include zero. Case-based repeatability by classifier was characterized by repeatability profiles, i.e., histograms of median 95% CI of CBO as function of median CBO across all cases from the bootstrap samples. **Results:** Classifier performance failed to demonstrate statistically significant differences, but classifier output was more repeatable when the random forest classifier was used. **Conclusion:** This suggests that even if classifiers appear to perform similarly in terms of AUC, classifier choice can impact repeatability and should be considered when developing computer-aided diagnosis systems.

Deep Learning Method for Volumetric Segmentation of Dense Tissue in Tomosynthesis Using Computer Simulations

J Gomes¹, Y Barbosa², T Do Rego³, T Silva⁴, T Vent⁵, A Maidment⁶, B Barufaldi^{7*}, (1) Universidade Federal Da Paraiba, Joao Pessoa, Brazil, (2) Universidade Federal Da Paraiba, Joao Pessoa, Brazil, (3) Universidade Federal Da Paraiba, Joao Pessoa, Brazil, (4) Universidade Federal Da Paraiba, Joao Pessoa, Brazil, (5) University of Pennsylvania, Philadelphia, PA, (6) University of Pennsylvania, Villanova, PA, (7) University of Pennsylvania, Philadelphia, PA

Purpose: The use of deep-learning systems in clinical care requires extensive evaluations to develop effective, safe, and acceptable artificial intelligence applications. This study aims to evaluate and optimize nnU-Net models to estimate volumetric breast density (VBD) in digital breast tomosynthesis (DBT) images. **Methods:** A virtual clinical trial (VCT) framework was employed to simulate 2,010 anatomical breast models, with distribution of dense compartments varying from 0.1% to 50%. DBT projections were simulated using the acquisition geometry of a clinical tomosynthesis system. The projections were reconstructed using 0.1mm, 0.2mm, and 0.5mm slice spacing. Further, we developed and trained three nnU-Net models using the 51 center-most slices of the DBT reconstructions along with the respective ground-truth tissue labels. For each model, 75% and 25% of ground-truth labels and DBT images were used for training and test, respectively. The effect of the reconstructed slice spacing in the nnU-net models was evaluated using sensitivity (TPR), Jaccard, and Dice metrics. **Results:** The accuracy of the nnU-Net varies significantly with smaller reconstructed slice spacing. Images reconstructed with 0.1mm slice spacing resulted in a performance improvement that represents a mean Jaccard increase of up to 41%, 32%, 31%, and 37% (P<0.001), for phantoms simulated using 10%, 20%, 30%, and 50% of dense compartments, respectively. Changes in performance are also noted in the mean Dice and mean TPR metrics. **Conclusion:** Computer simulations can optimize DBT acquisition parameters to improve VBD segmentation. Results from simulations with ground truth provide evidence for a better understanding of deep learning outcomes. The nnU-Net performance has been shown to improve the VBD segmentation in DBT using reconstructions with smaller slice spacing. Ultimately, we believe that a plethora of VCT-based strategies will be developed to optimize VBD segmentation.

A Reader Model to Compute Detectability of Lesions with Varying Size in X-Ray Images of the Breast

M. L. Lago*, A. Badano, Food & Drug Administration, Silver Spring, MD

Purpose: Model observers have traditionally been applied to simple tasks where the lesion location is known exactly (LKE) or the lesion morphology is known exactly (SKE). However, these conditions are far from a clinical scenario. Here, we propose an observer model to detect masses of different size. This model can be used in virtual clinical trials comparing Digital Mammography (DM) and Digital Breast Tomosynthesis (DBT) images. **Methods:** We generated irregular spiculated masses of seven different sizes. Using the VICTRE pipeline, we generated 2270 DM and DBT samples for each size. Average glandular dose was consistent with the clinical dose levels and with the dose reported in the VICTRE project. We trained a Channelized Hotelling Observer (CHO) template per size by isolating the mass from the rest of the tissues. With target-only images, we trained multiple CHO models for different channel sizes and computed the performance using full sample sizes containing all the breast tissues in target-present and target-absent images. Finally, we analyzed the AUC for both modalities at different lesion sizes for 30 reader models. **Results:** The best channel set combination for DBT and DM show a consistent increase in detectability with DBT always higher than DM. Both modalities seem to track in terms of the benefits of having larger signals in the AUC values. As lesion size increases, the size of the channels should increase accordingly. We compared the AUC for a wide range of channel sizes and found that DBT images are more sensitive to channel sizes than DM. **Conclusion:** As the size of breast lesions increases, we found a monotonic increase in AUC for both modalities. The DBT modality shows the best AUC performance for all sizes for the best corresponding channel combination.

Cone Beam CT (CBCT) Based Synthetic CT Generation Using Deep Learning Methods for Dose Calculation of Nasopharyngeal Carcinoma Radiotherapy

X Xue^{1*}, Y Ding¹, J Shi², X Hao³, X Li¹, D Li¹, Y Wu¹, H An², W Wei¹, M Jiang³, X Wang⁴, (1) Hubei Cancer Hospital, Wuhan, CN, (2) University of Science and Technology of China, Hefei, CN, (3) Huazhong University of Science and Technology, Wuhan, CN, (4) Rutgers-Cancer Institute of New Jersey, NJ

Purpose: Cone beam CT (CBCT) for the purpose of setup alignment inhibits its further use in adaptive radiotherapy due to artifacts and inaccurate Hounsfield

units (HU). We compared three deep learning methods to generate high quality synthetic CT (sCT) images from CBCT and planning CT (pCT) for dose calculation of nasopharyngeal carcinoma (NPC) radiotherapy. **Methods:** 169 NPC patients with a total of 20926 slices of CBCT and pCT images were included. The CycleGAN, Pix2pix and U-Net models were used to generate the sCT images. The mean absolute error (MAE), root mean squared error (RMSE), peak signal to noise ratio (PSNR), and structural similarity index (SSIM) were used to quantify the accuracy of the proposed models in a testing cohort of 34 patients. Radiation dose were calculated on pCT and sCT by three deep learning models following the same protocol. Dose distributions were evaluated for 4 patients by comparing the dose-volume-histogram (DVH) and 2D gamma index analysis. **Results:** The average MAE and RMSE values between sCT by three models and pCT reduced by 15.4 HU and 26.8 HU at least, while the mean PSNR and SSIM metrics between sCT by different models and pCT added by 10.6 and 0.05 at most, respectively. There were only slight differences for DVH of selected contours between different plans. The passing rates of gamma index analysis for 4 patients under 3mm/3% 3mm/2%, 2mm/3% and 2mm/2% criteria were all higher than 95%. All the sCT had achieved better evaluation metrics than those of original CBCT, while the performance of CycleGAN model was proved to be best among three methods. **Conclusion:** The dosimetric agreement confirmed the HU accuracy and consistent anatomical structures of sCT by deep learning methods. The results demonstrated that the sCT could be readily incorporated for further adaptive radiotherapy dose calculation in clinical practice.

SU-lePD-TRACK 3-02

Deep Learning Based Synthetic CT Generation with Multi-Sequence MRI for MRI-Only Radiotherapy

S Wu^{1*}, Y Peng², d qian³, R Wang³, X Deng², (1) Department of Radiotherapy, Affiliated Cancer Hospital and Institute of Guangzhou Medical University, Guangzhou, Guangdong, CN, (2) Department of Radiotherapy, Sun Yat-sen University Cancer Center, Guangzhou, Guangdong, CN(3) Perception Vision Medical Technology, Guangzhou, Guangdong, CN

Purpose: Synthetic CT(sCT) generation with MR image plays an essential role in MR-only radiotherapy, which can be used for density estimation and dose calculation in treatment planning. Currently, the reliability of sCT generation methods depends on two aspects: the MR-CT registration errors, which can be eliminated by CycleGAN with unpaired training data, and contract divergence in different sequences which could affect the nonlinear mapping of MR-CT. This study is to investigate the effect of different sequence MRI by evaluating the image quality of sCTs. **Methods:** T1, T2, T1C-MR images and planning CT(pCT) images of 151 patients were acquired on the same day. 126 cases were randomly selected for training. Three CycleGAN-based models were respectively trained with each sequence MRI. 25 cases with non-rigid registration were selected as the testing set. The mean error(ME) and mean absolute error(MAE) between plan CT and sCT of each model were used to measure the CT value accuracy, which was calculated within soft tissue, bone, and whole body, respectively. **Results:** The MEs calculated between pCT and T1, T2, T1C-based sCT images, were (154.92±87.93) vs. (173.27±97.62) vs. (262.78±91.74) within soft tissue, (1363.99±294.94) vs. (337.21±50.4) vs. (661.63±168.43) within bone, (22.12±29.47) vs. (17.05±10.51) vs. (35.28±20.75) within the whole body. The MAEs were (186.41±61.75) vs. (197.33±58.62) vs. (293.56±72.72) within soft tissue, (186.41±61.75) vs. (197.33±58.62) vs. (293.56±72.72) within bone, (31.28±28.1) vs. (27.64±10.41) vs. (42.6±23.82) within the whole body. The quantitative analysis indicated that T1C based generated model achieves higher accuracy than the other models in H&N radiotherapy. **Conclusion:** The T1C MRI can provide sufficient anatomy information and tissue contract in synthetic CT prediction of head and neck region, which offers a substantial potential for density estimation and dose calculation in radiotherapy. The generation method and evaluation will investigate synthetic CT prediction with more complex tissue in various body parts.

Image Synthesis for Planning and Target Tracking of MR-Based Stereotactic Radiation Therapy

G Szalkowski*, D Nie, T Zhu, P Yap, J Lian, University of North Carolina at Chapel Hill

Purpose: To identify the model training parameters that result in the synthetic CTs with the best fiducial visualization and normal tissue accuracy for MR-only stereotactic radiation therapy to the pelvis. **Methods:** We previously developed a machine learning model to create synthetic CTs from the paired MRs. The model is applied for 11 CT/MR (conventional T2) image sets used for previous Cyberknife (Accuray, Inc) radiosurgery treatments. The MR images were pre-processed to mimic the appearance of fiducial-enhancing images. Model performance was evaluated on three factors, fiducial contrast ("realistic" vs manually enhanced), patch sizes and numbers of image pairs in the training. Four observers identified the fiducial centers in the synthetic and real CTs and associated DRRs to evaluate the fiducial reconstruction accuracy. The CT and DRR images were also qualitatively compared using mean squared error (MSE) and peak-signal-to-noise-ratio (PSNR). The same treatment plan was calculated on the real and synthetic CT. **Results:** We found that the manually enhanced images, largest patch size (128x128 pixels), and 9 image pairs in the training set gave the best clinically applicable synthetic CTs and the highest contrast for the reconstructed fiducials. The fiducial appearance in the synthetic CTs, as well as the DRRs generated from them had similar contrast and visualization to the real CT. There was no significant difference found for the fiducial localization for the CTs and DRRs ($p>0.05$). The mean MSE between the true and synthetic CTs was 2.77%±1.31% and the mean PSNR was 32.45±4.61. The MSE and PSNR for DRRs were 1.2±1.5% and 22.8±5.7, respectively. 3D gamma analysis on the dose distributions calculated on the real and synthetic CTs both pass 100% (2%/2mm)**Conclusion:** Our machine learning based method generates synthetic CTs for accurate treatment planning and DRRs with sufficient image contrast for target tracking in prostate stereotactic radiotherapy.

SU-lePD-TRACK 3-04

Implementation and Validation of Non-Uniform Body Region Specific 3D Age Scaling Factors (ASF) to Scale Whole-Body Computed Tomography (CT) Anatomy to Any Arbitrary Age

A Gupta^{1,2*}, C Owens^{1,2}, T Netherton^{1,2}, C Lee³, S Shrestha^{1,2}, S Smith¹, R Weathers¹, S Kry^{1,2}, P Balter^{1,2}, D Followill^{1,2}, J Long^{1,2}, R Howell^{1,2}, (1) The University of Texas MD Anderson Cancer Center, Houston, TX USA (2) The University of Texas MD Anderson Cancer Center UTHealth Graduate School of Biomedical Sciences at Houston, Houston, TX USA (3) National Cancer Institute, Rockville, MD

Purpose: To scale whole-body computed tomography (CT) based anatomy non-uniformly in 3D to provide age-specific phantoms for retrospective dosimetry in late-effects studies. This is necessary because the University of Florida/National Cancer Institute (UF/NCI) computational phantom series (the gold-standard pediatric phantoms) are limited to discrete ages which could result in uncertainty in dose reconstruction when discrete-aged phantoms are used instead of age-specific phantoms. **Methods:** Fourteen UF/NCI phantoms (52 organs in each) were downsampled from their nearest older discrete age (1, 5, 10, 15, and 30 years old) using our in-house body-region-specific age scaling factors which accounts for non-uniform growth of head, neck, trunk, and legs in 3D. To validate the scaling, percent change in height, Dice Similarity Coefficients (DSC), mean distance to agreement (MDA), and Euclidean distance (ED) were calculated between the original and scaled anatomy for whole-body, brain, heart, liver, pancreas, and kidneys. Typical 6MV Wilms' tumor plans were constructed on a downsampled 3.9-year-old (median age of Wilms' tumor cohort from the Childhood Cancer Survivor Study) and 5-year-old male phantoms to quantify differences in V10, mean dose, D1, D50, and D95 for in-/near-beam organs. **Results:** For whole-body, brain, and heart, the DSC, MDA, and ED were ≥ 0.61 , ≤ 1.23 cm, and ≤ 2.90 cm, respectively. For liver, pancreas, and kidneys, the DSCs fell below 0.50 with MDA and ED up to 2.29cm and 4.09cm, respectively. Lower agreements were attributed to higher variation in organs' shape across the age range. The heights of phantoms were within 5% of reference heights. In the dose study, a maximum V10 difference of 0.5% was obtained for the pancreas (near-beam organ). Absolute dose differences in organ-to-organ dose comparisons were within 20cGy for each metric. **Conclusion:** CT based anatomy can be scaled to any arbitrary age with accurate anatomical shape, size, and

position and accurate dose reconstruction for late-effect studies.

Self-Attention Generative Adversarial Network for Synthetic CT Generation from CBCT in Head and Neck Radiotherapy

S Wu^{1*}, S Liu², D Qian², R Wang², H Chen², Y Lu³, Y Sun⁴, (1) Department of Radiotherapy, Affiliated Cancer Hospital and Institute of Guangzhou Medical University, Guangzhou, Guangdong, CN, (2) Perception Vision Medical Technology Co. Ltd., Guangzhou, CN, (3) School of Computer Science and Engineering, Sun Yat-Sen University, Guangzhou, Guangdong, CN, (4) Sun Yat-sen University Cancer Center, Sun Yat-Sen University, CN

Purpose: Cone Beam CT(CBCT) is commonly used for accurate patient positioning and anatomic changes tracking during the IGRT, which performs poorly on organ segmentation and dose calculation in adaptive radiotherapy(ART) because of the strong artifacts and Hounsfield unit(HU) inaccuracy. To overcome the CBCT limitation, we proposed a self-attention Generative Adversarial Network(GAN) to generate Synthetic CT(sCT) from CBCT, improving the CT number accuracy while keeping the same anatomy. **Methods:** 38 cases H&N patients(30 for training, 8 for testing) with planning-CT(pCT) and CBCT in the first treatment fraction were included. We proposed a self-attention condition GAN generate CBCT-based sCT, with non-local block for image artifacts denoising and feature representation enhancement. To demonstrate the model performance, a Res-Unet generation model was trained for the comparison. The mean absolute error(MAE) and peak signal-noise ratio(pSNR) between the pCTs and sCTs were calculated for evaluating synthesis performance. **Results:** The MAEs were (79.52±13.54) HU vs. (77.48±6.6) HU (P=0.0015) within the whole body, (97.29±12.52) HU vs. (56.06±6.28) HU (P=0.0005) within soft tissue for the U-net vs. the proposed method. The pSNRs were(33.24±0.83) vs. (34.06±0.69) (P=0.0494)within the whole body, (35.96±1.18) vs. (37.44±0.77) (P=0.0098) within soft tissue for the U-net vs. the proposed method. Significant differences in MAE and pSNR were observed in the whole body and soft tissue. **Conclusion:** Qualitative and quantitative evaluation indicates that the proposed method can synthesize sCT with accurate CT numbers and best texture information, especially in soft tissue and the body. This potentially enables advanced CBCT applications for ART.

SU-lePD-TRACK 3-06

Synthetic Contrast MR Image Generation Using Deep Learning

Y Liu*, T Wang, Y Lei, J Roper, J Bradley, T Liu, X Yang, Emory University, Atlanta, GA

Purpose: Gadolinium-based dye is often used as the contrast agent during MR imaging examinations. In addition to extra cost, labor and time, contrast-enhanced MR imaging can cause patient discomfort and side effects. We propose a deep learning-based method to synthesize contrast-enhanced MR from non-contrast MR images. **Methods:** A cohort of 274 brain cancer patients from a public dataset, the Brain Tumor Segmentation Challenge (BRATS2015) was used. They have both non-contrast and contrast-enhanced MR images. A self-attention cycle generative adversarial network (cycleGAN) was used to learn the mapping from non-contrast images to contrast MR images. Attention U-Net was used as a generator of CycleGAN to force the trained model to extract information that can represent the specific difference between non-contrast MRI and contrast MRI, namely, the tissue contrast difference. The proposed method was trained on 224 patients and evaluated on the rest 50 patients. **Results:** The discrepancy between the ground truth contrast MR and synthetic contrast MR images were compared. The mean absolute error (NMAE) was 0.035±0.004. The peak signal-to-noise ratio (PSNR) was 32.4±2.6. And structural similarity index (SSIM) was 0.97±0.06. **Conclusion:** It is shown that the proposed method has great potential in accurately generating contrast MR, and therefore bypassing the contrast administration step during MR scan, which can save labor, time, cost and mitigate patient discomfort.

SU-lePD-TRACK 3-07

Artificial Intelligence (AI) Based Missing Tissue Generated Synthetic CT Preparation for Planning in Limited Field of View (LFOV) MR-Only Simulation

S Kim^{1*}, S Kim², (1) Catholic University of Korea, Seoul, KR, (2) Virginia Commonwealth University, Glen Allen, VA

Purpose: MR-only simulations often suffer from limited field of view (LFOV), resulting in incomplete body outlines. A novel approach of generating such missing tissue using machine learning and optical imaging has been conceived. **Methods:** The method consists of 3 steps. 1) Patient body outline in interest is obtained using an optical imaging method. 2) An MR image set in limited FOV (MR-in-LFOV) is converted to a synthetic CT image set in limited FOV (syn-CT-in-LFOV). This task can be accomplished using any one or combination of existing methods such as an intensity based approach, an atlas based approach and a machine learning based approach. 3) The syn-CT-in-LFOV is expanded to a synthetic CT image set in full FOV (syn-CT-in-FFOV) using a machine learning based missing body generation algorithm. The main goal of step 3 (i.e., generation of missing part of image) has not been proven and we focused on its realization using regular CT images in this study. For proof of the concept, we built a model using 10,005 training images taken from the cancer imaging archive (TCIA) and performed tests with other data sets not used in training. All training and evaluation were performed on a 64-bit Windows 10 Enterprise workstation. Computing hardware included an Intel Xeon W3520 quad-core CPU, 32 GB RAM, and two Nvidia GeForce GTX 1080 Ti graphic cards with a total 7168 cores and 22GB GPU RAM. **Results:** The completion network was trained for 250 iterations and the entire training procedure took roughly 5 days. The model provided missing tissues in tested cases. **Conclusion:** It is demonstrated that the approach introduced can realistically complete CT images despite large occluded areas. This approach is also expected to reduce geometrical distortion that is dominant at periphery in typical MR images

A 3D-Printed Prostate Phantom for Quality Assurance in HDR Brachytherapy

D Murrell*, J Pautler, D Hoover, London Regional Cancer Program, London, ON CA

Purpose: To design and build an anthropomorphic prostate phantom for dosimetric quality assurance testing in HDR brachytherapy. **Methods:** The prostate model was developed from 3D ultrasound images of a fully implanted prostate previously treated with HDR brachytherapy at our institution. Images and clinical contours were imported into Slicer3D to create the design elements of the phantom. Space was included in the model to allow for insertion of clinical brachytherapy needles and a variety of dosimeters. The model was printed on a Lulzbot 3D printer at 100% infill using 2.85 mm PLA filament. A CT of the printed phantom was acquired, and a test brachytherapy plan created in BrachyVision and then delivered using a GammaMedIX afterloader. Dosimetry measurements were taken in triplicate using an A1SL ion chamber and corrected for temperature and pressure. **Results:** The phantom consists of a 7.2 cm (L/R) x 6 cm (A/P) x 7.5 cm (S/I) block which encompasses four removable prostate quadrants and 12 needle tracks. It is bisected to include a central coronal plane film; the prostate is further split at midline for a sagittal plane film. There are 4 locations to insert optically stimulated luminescence dosimeters (OSLDs). There are 2 locations to insert an A1SL ion chamber, roughly corresponding to the positions of the urethra and rectum. The nominal total treatment time for the test plan was 315.5 seconds for a 10 Ci source. At the urethral and rectal positions, the average total charge over triplicate measurements was 28.0 ± 0.2 nC and 18.3 ± 0.1 nC, respectively; the percent difference with repeat measurements was <2% and <2.5%, respectively. **Conclusion:** 3D printing an anthropomorphic prostate phantom for HDR brachytherapy quality assurance was feasible using an inexpensive desktop printer. Initial ion chamber constancy measurements have reasonable agreement. Future work will include self-calibration as well as OSLD and film dosimetry.

Development of Reference Plan-Based Verification System for Intracavitary Brachytherapy for Uterine Cervical Cancer

Y Akino^{1*}, F Isohashi¹, T Arimura², Y Seo¹, T Hirata¹, K Tamari¹, K Hayashi¹, K Ogawa¹, (1) Osaka University Graduate School of Medicine, Suita, Osaka, JP, (2) Osaka University Hospital, Suita, Osaka, JP

Purpose: For high-dose-rate intracavitary brachytherapy for uterine cervical cancer, all procedures including CT imaging, treatment planning, verification, and irradiation are performed within a few hours. Although verification is important for safe treatment, patient-specific quality assurance by secondary check software or measurement are not common. In this study, we developed a system which automatically check treatment plans. **Methods:** Reference treatment plans were generated for all patterns of Tandem & Ovoid applicators constructed in air. A software was developed to compare the clinical plans with the reference plan and automatically check the dwell positions, applicator length and offset, weights of dwell time, applicator geometry, and the coordinates of the reference points (Point A). The total dwell time of the reference plan was corrected for source intensity and prescribed dose to predict the total dwell time of the patient plans. Three-dimensional dose distribution was also calculated using the AAPM Task group 43 update 1 equation, and V100%, D90% of target, and D2cc of critical organs were evaluated. 517 plans of 155 cases were retrospectively analyzed. **Results:** Calculation time for each plan was 10.4 ± 3.3 s (range 3.3 - 21.1 s). Differences between the predicted and clinical total dwell time were $3.8\% \pm 5.4\%$ (range -13.1% - 19.1%) and $-0.4\% \pm 11.7\%$ (range -28.9% - 36.5%) for point A prescription and optimized plans, respectively. The ratio of total dwell time to the predicted value showed quadratic correlation with the ratio of V100 of the patient plans to that of reference plans, with an error of $0.0\% \pm 0.5\%$ (range -1.5% - 3.0%). The software successfully detected errors of the plans with deliberate mistakes. **Conclusion:** The software developed in this study enabled quick evaluation of the accuracy and validity of the treatment plans even for the optimized plans.

SU-lePD-TRACK 5-03

Development of a Dynamic-Shield Applicator Enabling Intensity-Modulated Brachytherapy for the Treatment of Rectal Cancer

A Thibodeau-Antonacci^{1*}, T Vuong², H Bekerat^{1,2}, L Liang^{1,2}, S Abbasiengad Enger^{1,3}, (1) McGill University, Montreal, QC, CA, (2) Jewish General Hospital, Montreal, QC, CA, (3) Lady Davis Institute, Montreal, QC, CA

Purpose: Rotationally-symmetric dose distributions provided by brachytherapy sources deliver a high dose to the tumor, but often with poor target conformity resulting in dose spillage to the organs at risk (OAR). By incorporating dynamically-rotating metallic shields, intensity-modulated brachytherapy (IMBT) opens the possibility to deliver more conformal dose distributions. The goal of this study was to develop a novel MRI-compatible dynamic-shield IMBT applicator for the treatment of rectal cancer and compare the results with conventional high-dose-rate brachytherapy (HDR-BT) with and without static shielding. **Methods:** For dynamic-shield IMBT, a single-grooved, MRI-compatible, 15 mm diameter tungsten shield with a 180° emission window was designed. A cylindrical intracavitary applicator (length 28 cm, diameter 2 cm) (Elekta Brachytherapy, Veenendaal, The Netherlands) with a central lumen that fits an 8 mm diameter tungsten rod for static shielding was also modeled. For both applicator models, four rectal cancer patients were retrospectively planned using an in-house Monte Carlo based treatment planning system called RapidBrachyMCTPS and a generic Ir-192 source. The plans were optimized using a fast mixed-integer optimization method. The prescribed dose was 3 fractions of 10 Gy. The resolution of the scoring grid was $3 \times 3 \times 3$ mm³ and 10⁶ decay events were simulated. **Results:** For the same target coverage, the contralateral healthy rectal wall D2cc, rectum D50 and pelvis D50 decreased on average by 38.93%, 18.82% and 18.75% when using dynamic-shield IMBT compared with HDR-BT with the static shield and by 53.04%, 68.35% and 36.62% compared with HDR-BT without the static shield. However, the inferior and superior dose spill regions D2cc were 11.14% and 9.57% greater compared with static-shielding HDR-BT. The treatment times were below 30 minutes for all cases. **Conclusion:** The designed dynamically-rotating IMBT applicator for the treatment of rectal cancer shields the OAR more effectively with the possibility to increase the delivered dose to the tumor.

Commissioning and QA of 3D-Printed Molds for Surface Brachytherapy

T Phillips*, J Steers, Cedars-Sinai Medical Center, Los Angeles, CA

Purpose: To describe key commissioning and quality assurance methods for 3D-printed brachytherapy surface applicators. **Methods:** Prior to clinical implementation of 3D-printed surface brachytherapy molds, a comprehensive commissioning plan was developed, including tests to determine channel tunnel radius, deliverable radius of curvature, and HU thresholds for accurate body contour creation. QA procedures for patient-specific molds were also established. **Results:** Tunnel radius and curvature must be determined to ensure deliverability. Based on catheters and afterloader used, the proper tunnel radius and curvature radius were determined by iterative testing. For 4.7Fr catheters (~1.55mm radius) a tunnel radius of 1.8 mm was too narrow, while a 2mm tunnel radius was compatible. The radius of curvature recommended by the vendor (14 mm), plus larger and smaller radii, were tested for deliverability with the afterloader (Varisource iX, Varian). Plans with radii of curvature <14mm were undeliverable. Body contour directly affects mold fit and must be optimized. HU settings were iteratively adjusted and used to create the body contour for test prints on an anthropomorphic phantom. A window/level of -380HU to +300HU (with hand editing of the surface at this W/L setting) produced molds that fit the phantom with minimal air gaps. This method was utilized on several clinical cases, producing molds with excellent fit (<3mm gap). QA of 3D-printed molds is essential to ensure accurate plan creation and delivery. QA included visual inspection, deliverability of test plans with catheters fixed in place, post-processing of rough patches, and patient CTs with the mold to evaluate both fit and mold integrity. **Conclusion:** This report describes commissioning and QA necessary for clinical implementation of 3D-printed surface brachytherapy applicators. These techniques have allowed clinical implementation of deliverable, highly customizable, and well-fitting molds for treatment of complex surface geometries with brachytherapy where commercial surface flaps or handmade molds are often problematic.

Integrating Rotatable Tandem Applicator to Conventional Ovoid Applicator for Complete Framework of Intensity Modulated Brachytherapy (IMBT) for Cervical Cancer

H Kim^{1*}, Y Goh², D Kim¹, J Kim¹, Y Lim³, (1) Department of Radiation Oncology, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, KR, (2) Department of Radiation Oncology, Asan Medical Center, Seoul, Korea, KR (5) National Cancer Center, Goyang-si, KR

Purpose: A new rotatable tandem applicator for intensity modulated brachytherapy (IMBT) in intracavitary brachytherapy(ICR) was recently proposed. This work presents an integrated framework with rotatable tandem applicator and ovoid applicator by modifying dose deposition matrix and plan optimization algorithm. **Methods:** The rotatable, single-channel tandem applicator enables for generating asymmetric dose distribution by rotating Ir-192 source in selected transverse direction. The previous work focused on plan optimization with tandem applicator only that constrains the number of source dwell points and activated rotational angles for enhancing delivery efficiency, while excluding ovoid applicator. To comprehend ovoid applicator in inverse planning, this work computed Monte-Carlo (MC) simulated dose distributions for 10 available dwell points belonging to ovoid applicator. Combining the dose information from tandem and ovoid applicators constructs dose deposition matrix for inverse planning. The optimization algorithm constrained the dwell points in tandem with group-wise in L2, 1/2-norm and element-wise sparsity in approximated L0-norm to minimize number of activated angles and entire elements, while constraining the dwell points by element-wise sparsity only in ovoid applicator. The complete framework is validated by three clinical cases, compared against conventional ICR, and IMBT with tandem applicator. **Results:** Integrated IMBT framework increased the number of dwell point by comprehending ovoid applicator, while it did not affect the number of dwell points and activated angles assigned to tandem applicator. Although IMBT with tandem enabling fluence-modulation spared critical organs relative to conventional ICR, insufficient geometric target coverage led to greater target volume exposed to high dose of radiation. IMBT with both tandem and ovoid applicators enhanced target volume homogeneity by optimizing dwell points in ovoid applicator, while maintaining enhanced dose sparing to critical organs. **Conclusion:** IMBT with integrated framework was achieved by new dose deposition matrix and modified plan optimization algorithm, which yield superior dose sparing and target volume homogeneity simultaneously.

Dual-Source Optimization for HDR Prostate Brachytherapy

H Frank*, S Park, K Sheng, UCLA School of Medicine, Los Angeles, CA

Purpose: High dose rate (HDR) brachytherapy is used to treat prostate cancer in mono-, combination-, or salvage settings. Iridium-192 is the most common source, but Ytterbium-169 has also been considered for its lower energy and potential to spare nearby sensitive organs, e.g., the urethra. However, a planning method to optimize the utilization of both energy sources for efficient plan delivery has not been presented. In this study, we develop a framework that jointly optimizes Ir-192 and Yb-169 dwell times for urethra sparing with a total treatment time penalty. **Methods:** The planning problem was formulated as a group sparsity optimization problem to minimize the number of channels used by both sources. The optimization problem was solved using the fast-iterative shrinkage-thresholding algorithm. The HDR source dose distributions were modeled following the AAPM TG-43 formalism for 10 Ci Varian Varisource (VS2000 ¹⁹²Ir) and 10 Ci Model M42 ¹⁶⁹Yb HDR sources. Three treatment plans were generated to deliver a 15 Gy/fx prescription dose for a retrospective patient with 19 channels using Ir-192 only, Yb-169 only, and dual-source. **Results:** The three plans resulted in similar dose distribution to the PTV, rectum, and bladder. The minimum dose in the most irradiated 0.1 cm³ of the urethra were 15.13, 16.50, and 15.00 Gy for the Ir-192, Yb-169, and dual-source plans, respectively. The group sparsity term effectively reduced the total number of channels used for the dual-energy approach. The total dwell times were 15.41, 49.43, and 26.70 minutes for the Ir-192, Yb-169, and dual-source plans, respectively. **Conclusion:** Dual-energy brachytherapy combines the penetration of high energy and rapid drop-off of low energy Gamma rays for greater flexibility in plan dosimetry. We developed a novel framework to optimize the delivery efficiency for dual-source treatment. Further improvement in plan dosimetry and OAR sparing may require optimization of catheter locations.

SU-lePD-TRACK 5-07

Proton Arc Therapy as An Alternative to Syed Interstitial High Dose Rate (HDR) Brachytherapy for Treating a Gynecological Cancer Patient with Lateral Disease Extension

B Yi*, S Mossahebi, E Nichols, M Guerrero, N Lamichhane, P Mohindra University of Maryland School of Medicine, Baltimore, MD

Purpose: To investigate if single energy proton arc therapy (SEPAT) plans generate improved dose to organs at risk (OARs) compared to the Syed interstitial high dose rate brachytherapy (Syed HDR) for a patient with gynecological cancer with lateral disease extension. **Methods:** SEPAT delivers proton arc beams by modulating energy at the beam nozzle while maintaining the same incident energy at the gantry during rotation. An index case, high-risk CTV (HRCTV) measuring 76 cc with the lateral dimension of 5.1 cm treated with 14 interstitial needles and 6-cm long tandem in the uterus was selected. Full arc SEPAT plan was designed using 125-157 MeV modulated 157 MeV incident proton beams. **Results:** Target coverage of the SEPAT plan was comparable to the Syed HDR plan: 100% of the HRCTV received 90 % of the prescribed dose (V90) for SEPAT, compared to V90 of 90% for Syed HDR. SEPAT robust plan (± 3mm, ±2.5%) generated lower target coverage, 93% dose for V90, which remains to be higher than Syed HDR. D2cc of bladder and rectum were considerably lower for SEPAT plan with 90% (SEPAT) vs 121% (Syed HDR) and 55% (SEPAT) vs 69% (Syed HDR) of prescribed dose, respectively. Other OAR doses such as small bowel and large bowel were also lower with the SEPAT plan than Syed HDR. The SEPAT robust plan demonstrated 98% and 70% of D2cc of bladder and rectum, respectively. **Conclusion:** In a case with locally advanced gynecological cancer with lateral disease extension, SEPAT generated a dosimetrically superior plan in comparison to the Syed HDR brachytherapy with interstitial needles. SEPAT may provide a non-invasive alternate to HDR brachytherapy with superior dosimetric profile. Further study is needed with more cases to confirm the result with statistical confidence.

Monte Carlo (MC) Simulation of Total Skin Electron Therapy (TSET) with TOPAS and EGSnrc

W Zhong^{1*}, G Ding², Y Ong¹, T Zhu¹, (1) University of Pennsylvania, Philadelphia, PA, (2) Vanderbilt University, Nashville, TN

Purpose: Cherenkov imaging is applied to TSET as a non-invasive and real-time remote monitoring technique. Monte Carlo (MC) simulations of TSET with TOPAS are capable of generating and propagating Cherenkov photons as well as transporting radiation. This study compares doses that are simulated using both TOPAS and EGSnrc, and are benchmarked with data in order to validate the accuracy of simulations of realistic incidents in a real clinical treatment geometry. **Methods:** The complete physical processes of all particles from a clinical electron beam interacting with different materials of phantoms are simulated by using TOPAS. A treatment head model, patient phantom model, and TSET clinical treatment setting including geometry, chemical compositions, and optical properties of materials, especially of human tissues, are all studied and simulated with TOPAS. The 6 MeV electron beam phase space files scored before incidence on the JAWS are provided by Varian. Realistic clinical incident beams used in TSET including the setup geometry are simulated with both TOPAS and EGSnrc. The results are compared and benchmarked with experiments. **Results:** MC simulations of TSET are validated by comparing with measurements, such as PDD in water at 100 cm SSD, PDD in solid water at 500 cm SSD with a 3 mm beam spoiler, and vertical profiles at 500 cm SSD in a PVC board with the spoiler in single and dual fields. The calculated dose distributions from TOPAS agree with those from EGSnrc. Simulations with TOPAS also show the relationship between dose distributions and distributions of Cherenkov photons emitted from phantom surfaces. **Conclusion:** The agreement between TOPAS, EGSnrc, and data establishes the accuracy of the simulated incident beams and dose distributions. By using the relationship between dose distribution and Cherenkov photon distribution we are able to monitor the patient skin dose during the radiation delivery of TSET.

Initial Assessment of the Suitability of 3D PRESAGE Phantom for Relative Dose Measurements in a FLASH Electron Beam

C Elliston^{1*}, Y Wang¹, G Garty², J Adamovics³, C Wu¹, (1) New York Presbyterian/Columbia University Irving Medical Center, New York, NY, (2) Radiological Research Accelerator Facility, Irvington, NY, (3) Heuris Inc & Rider University, Princeton, NJ

Purpose: To assess the suitability of the 3D PRESAGE phantom for relative dose measurements in a high dose per pulse FLASH electron beam. **Methods:** Irradiations were performed at the Radiological Research Accelerator Facility (RARAF) using a Varian iX linear accelerator, modified to deliver a high dose per pulse 9 MeV electron beam. By varying the pulse frequency and SSD, PRESAGE phantoms were irradiated at four dose rates: 6 Gy/min, 40 Gy/s, 86 Gy/s, and ~900 Gy/s. At each position, except for the exit window (~900 Gy/s), the dose rate was determined using an advanced Markus chamber. A dose of 5-7.1 Gy was delivered to each phantom. The dose to the phantom was then evaluated using an in-house optical CT scanner. Due to the expected uncertainty in measuring absolute dosimetry at such a high pulse rate, we compared the percentage depth dose curves for this study. The resultant PDD curves were compared with each other and to the PDD curve measured using EBT3 Gafchromic film which has been shown to have no dose rate dependence. **Results:** PDD curves measured for the four PRESAGE phantoms were very similar over dose rates ranging from 6 Gy/min used in conventional radiation therapy to an ultra-high FLASH dose rate of about 900 Gy/s. No dose rate dependency was seen. Comparisons to EBT3 Gafchromic film were similar but some differences were observed. Discrepancies among between PDD are possibly due to difficulties in setup and alignment. **Conclusion:** PDD curves measured in PRESAGE 3D phantoms for a wide range of dose rates were comparable to those obtained using Gafchromic film, indicating the PRESAGE may be useful for relative dose measurements in FLASH electron beams. Further studies should be performed to investigate differences observed between film and 3D phantom and to investigate PRESAGE for absolute dosimetry in FLASH.

The LIAC 12 MeV Intraoperative Electron Radiotherapy Unit: Bi-Directional Assessment of Field Symmetry and Independent Evaluation of the SWL-LIAC Simulation Software

M Mosleh-Shirazi^{1, 2*}, R Rashidfar^{1, 3}, S Karbasi², M Pashnehsaz⁴, M Mahdavi^{1, 3}, (1) Ionizing and Non-Ionizing Radiation Protection Research Center (2) Department of Radio-oncology (3) Department of Radiology, School of Paramedical Sciences (4) Breast Diseases Research Center, Shiraz University of Medical Sciences, Shiraz, Iran

Purpose: The LIAC intraoperative electron radiotherapy (IOERT) accelerator is commissioned for clinical use mostly based on the manufacturer's SWL-LIAC simulation software, which substantially reduces the number of difficult-to-set-up measurements needed. Moreover, in clinical IOERT practice, the appropriate beam energy is chosen based on the target tissue thickness using the beam data modeled by this software. We aimed to independently validate the accuracy of SWL-LIAC's calculated outputs, namely, percentage depth-doses (PDDs), off-axis dose profiles and relative output factors (ROFs), against experimental data. **Methods:** For all the available energies (6, 8, 10, 12 MeV), PDD measurements were made for all sizes of the flat-ended applicators (3 to 10 cm) and several beveled applicators. Profiles and ROFs were measured for the more frequently used applicators in clinical practice and the reference 10 cm diameter applicator. Meticulous measurements were made using a p-type electron diode in a water phantom, aided by inhouse custom-made positioning tools and confirmed using radiochromic film dosimetry. The measured and calculated scans were compared using multi-criteria one-dimensional gamma analysis. **Results:** Eighty-five percent of the calculated ROFs showed a $\leq 2\%$ agreement with the measurements. The average gamma passing rate for PDDs was 100% using a 2mm/1% (global dose difference) criterion. Repeated measurements showed that the measured in-plane profiles were somewhat tilted, which was confirmed by the manufacturer. The average gamma passing rate of all profiles was 95.5% (2mm/3%); Without considering the in-plane profiles, this value was 97.6%. Most of the profile points that failed the gamma criteria were in the peripheral region of the inner field and the shoulder regions of profiles. **Conclusion:** The accuracy of SWL-LIAC calculations can be deemed acceptable for most clinical applications. However, assuming isotropic off-axis profiles is unwarranted and measuring profiles in both directions for all energies at installation and acceptance testing is indicated.

This work is part of a postgraduate thesis by R. Rashidfar, financially supported by the Vice-Chancellery of Research, Shiraz University of Medical Sciences (project number 98-01-10-19770).

Radiation-oncology Department of Shiraz University of Medical Sciences is a Reference Hospital for PTW-Freiburg.

Customize Electron Energy Beams on TrueBeam Linear Accelerators

S Gao^{*}, M Muruganandham, W Du, J Ohrt, R Kudchadker, P Balter, UT MD Anderson Cancer Center, Houston, TX

Purpose: To facilitate optimal planning, we implemented two new electron energy beams (7- and 11-MeV) on two Varian TrueBeam linacs. **Methods:** To better meet clinical needs we worked with the vendor to create two additional customized electron energies without hardware modifications. For each of these

beams we set the bending magnet current and then optimized other beam specific parameters to achieve depths of 50% ionization (I50) of 2.9-cm for 7-MeV and 4.2-cm for the 11-MeV beams with the 15×15cm² cone. This was done using an Ionization Chamber Profiler (ICP, Sun Nuclear) with double-wedge-phantom (DW). Beams were steered and balanced to optimize symmetry using the ICP. After all parameters were set with the vendor, a full commissioning was done including measuring beam profiles, PDDs, output factors (OF) at standard and extended SSDs. The measured data was compared between two linacs and also against the calculated values from our TPS model (RayStation) following MPPG 5.a. **Results:** The values of I50 initially determined with ICP/DW agree to those from PDD scanned in-water phantom within 0.2-mm for 7- and 11-MeV on both linacs. Comparison of the beam characteristics from two linacs indicated that, flatness and symmetry were in agreement within 0.4%, point-by-point differences of PDD are within 0.01±0.3% for 7- and 0.01±0.3% for 11-MeV beams. The OF ratios between the two linacs were 1.000±0.007 for 7- and 1.004±0.007 for 11-MeV beams. The TPS calculations and measurements indicated that the point-to-point ratios (low-gradient regions) were 0.2±0.8% and Distance-To-Agreements (high-gradient regions) were 0.8±0.6mm, all meet the MPPG5.a criteria. **Conclusion:** We were able to add in two new beam energies with no hardware modifications. The tuning of the new beams was facilitated by the ICP/DW system allowing us to have the procedures done in a few hours and achieve highly consistent results across two linacs.

A TPS Independent Automated Software to Detect Electron Applicator-Body Collisions

D McClatchy^{1*}, J Pursley¹, C Holdsworth², (1) Massachusetts General Hospital, Boston, MA, (2) Brigham and Women's Hospital, Boston, MA

Purpose: Electron applicator collisions with the patient are difficult to discern in most treatment planning systems (TPS) which do not display a model of the applicator. Collisions discovered during a pre-treatment plan check or worse, during the first treatment must be re-planned, causing additional work and costly patient treatment delays. We developed a TPS independent program that accurately predicts collisions and determines the proximity of the body and bolus to the applicator using DICOM files exported from any TPS. **Methods:** External dimensions and position of all electron applicators relative to isocenter for a Varian linac were physically measured. A MATLAB script was developed that creates and renders 3D representations of the applicator, body contour, and bolus contour extracted from the plan and structure DICOM files. The script calculates either the overlap or minimum distance between the applicator and body+bolus contours. The script was retrospectively tested on 9 electron plans (n=3 shoulder, n=1 scalp, n=5 breast) from 8 patients planned in either Eclipse (n=4) or RayStation (n=4), and prospectively utilized during an initial plan check. **Results:** Retrospectively, the software correctly identified 2 plans for one patient where the applicator intersected with the body, which was discovered during the first day of treatment. For the remaining 7 plans, the shortest distance between the applicator and body/bolus contour were calculated and rendered, and accurately predicted no collisions (n=6, dist.>3cm; n=1 dist.<3cm). Prospectively, the software was utilized during an initial breast-boost plan check and predicted an overlap at the armpit preventing a patient delay. This predicted collision was confirmed by the therapists by simulating the original boost-setup before treating with a corrected plan. **Conclusion:** The developed software provides quantitative measurements and accurate visualizations of the proximity of the electron applicator to the external body and bolus contours for any TPS.

SU-lePD-TRACK 6-06

Verification of a Cost-Effective and Cerrobend-Free Workflow for Customized 3D-Printing Based Skin Collimation

M Polizzi^{*}, J Sohn, S Kim, Virginia Commonwealth University, Richmond, VA

Purpose: Secondary skin collimation is the optimal methodology for reducing electron scatter and preventing irradiation of non-involved tissue. However, the process of molds is cumbersome and commercial solutions are cost-prohibitive. We investigate the feasible clinical use of a 3D printed shaper filled with tungsten balls for skin collimation. **Methods:** Using a 3D model a 3D printing based skin collimator (3D-SC) was produced. The thickness of the 3D-SC was set at 8 mm and filled with 2 mm tungsten balls (17.5 g/cm³). Measurements were performed with 6 MeV in solid water at 0.5 cm depth with GafchromicTM EBT3 films. The film was irradiated with 300 MU. The irradiated film was scanned and analyzed with an OmniPro I^mRT (IBA Dosimetry). A clinical case is used to demonstrate the ease of implementation. **Results:** The penumbra (90% to 20%) value measured was 0.175 mm for the 3D-SC. Compared to this, the conventional Cerrobend cut-out created 0.72 mm penumbra. The total print time of the 3D-SC was less than 5 hours. Once the CT scan was acquired, our clinical case was modeled in our 3D planning software within 30 minutes. **Conclusion:** Skin collimation's efficacy is confirmed with the 3D-SC. This process is efficient (e.g., less labor-intensive than molding), cost-effective, and the shielding (tungsten balls) is reusable. Future work will verify this methodology with additional patient cases involving large curvature and irregularity.

SU-lePD-TRACK 6-07

Feasibility Study of Using Custom 3D-Printed Bismuth Shields in Electron Beam Treatment

A Sheikh^{1*}, B Overshiner², Y Yue^{1, 2, 3}, C Desrosiers^{1, 2, 3}, K Huang^{1, 2, 3}, (1) Indiana University, (2) IU Health University Hospital, (3) Indiana University-School of Medicine, Indianapolis, IN

Purpose: Low-energy electrons (6-9 MeV) are often used to irradiate tumors on patient's skin. External shields are used to minimize the radiation exposure to non-treatment areas. Comparing to lead shield, 3D printed shield can be made more conformal to the patient's skin surrounding the lesion, which reduces the radiation to the outside region and increases patient's comfort. This study evaluates the capability of bismuth-based 3D-shield as an alternative to lead in attenuating the electrons. **Methods:** Four rectangular (12x12cm) shields of varying thicknesses (one 1mm, two 2mm, and one 5mm) were 3D-printed using bismuth-based filament, which can be combined to create thickness from 1mm to 10mm. Each shield was printed solid with a 100% infill on a MatterHackers Pulse XE 3D printer with an enclosure using GMASS bismuth ABS filament. Transmission for the shield of different thickness from electrons with energies of 6, 9, 12, 16, and 20 MeV was measured using an ion chamber and a 10x10 cm² cone. The depth of measurement was 1.4cm for 6E and 2.5cm for other energies. SSD was 100cm. **Results:** The transmission of the 3D-shield were within 5% for 6E and 9E beam with ≤ 10mm thickness. The transmission was 3.57%, 1.81%, 1.28%, and 1.12% for 6E beam with shield of 7 to 10mm, respectively. For the 9E beam, the acceptable thickness was 10mm with the transmission of 4.77%. **Discussion and Conclusion:** To use 3D-printed bismuth radiation shields as an alternative to lead sheets is promising. For 6E beam, from 7mm above, the dose can be reduced to less than 5%. The transmission for 10mm shield is within a reasonable range for 9E beam. For the other energies, the transmission was over 5% with 10mm bismuth shield. However, tungsten can be used to reduce the thickness and will be studied in the future.

Establishing Efficient and Effective Systems for Policy and Procedures

SU-E-TRACK 1-00

Establishing Efficient and Effective Systems for Policy and Procedures

Moderator: Mohammad Bakhtiari, William E. Kahlert Regional Cancer Center, Westminster, MD

SU-E-TRACK 1-01**P. Halvorsen, Beth Israel - Lahey Health:****Policies and Procedures: Why Bother, and Why Should the Physicist Play a Key Role?****SU-E-TRACK 1-02****M. Bakhtiari, William E. Kahlert Regional Cancer Center:****Policies and Procedures: Developing Policies and Procedures That Work for Your Clinic****SU-E-TRACK 1-03****K. Moore, UC San Diego:****Policies and Procedures: Practical Strategies for Effective Implementation and Maintenance****SU-E-TRACK 1-04****Audience Q&A**

The phrase “Policies and Procedures” is viewed by many as a dry, administrative function without significant value to clinical practice. For many years, the primary focus of the AAPM’s task group activities was centered on equipment, with numerous recommendations for commissioning and ongoing quality control and quality assurance related to equipment safety and performance. Recent years have seen an increased recognition of the importance of process toward ensuring safety and consistent quality. The multi-society Safety is no Accident publication, the broad adoption of structured incident learning, and the publication of the Task Group 100 report have emphasized the risks of poorly defined workflows. This presentation will summarize what we have learned from recent initiatives and how policies and procedures fit into a comprehensive quality management system, with emphasis on the importance of accessible policies and procedures to guide clinical workflows.

While we have learned that policies and procedures provide value to clinical operations, where do they really fit in and how do they influence our actions? Developing effective policies and procedures is much more than just simply meeting an administrative checkbox. The culture of both the larger organization and in the immediate environment will influence design. Design of policies and procedures will clearly affect the effectiveness, so a suggested hierarchical structure of policy-procedure-work instruction-records will be presented. This presentation will look at where organizational management and task and technology factors may be organized to set team members to succeed rather than fail in the clinical process (notice, interpret, decide how to address a problem, develop an effective plan, or act on a developing problem).

The purpose of Policy and Procedure documents is to be used, practical considerations of how to craft them to be effectively integrated into normal clinical workflows must be considered. We will discuss examples of effective and ineffective Policy and Procedure documents, focusing on clarity (or lack thereof) in writing and presentation. Nearly as important as writing documents effectively are the processes for accessibility, version control, traceable approvals, and maintenance. We will discuss strategies for efficiently satisfying these criteria, with a focus on accessibility in a highly digitized, modern quality management system.

Learning Objectives:

1. Importance of policies and procedures in a practice. Importance of following P&Ps in preventing incidents (data from RO-ILS will be presented). Get familiar with the differences between policies, procedures, and processes. Examples of “good” and “not so good” P&Ps.
2. Incorporating P&Ps into a quality improvement program (TG-100, FMEA and incident learning). The quality metrics for evaluating the P&Ps.
3. Standardization for Writing and editing P&Ps (formatting templates, outlines, terminologies, etc)
4. Document management systems; technical aspects of incorporating P&Ps into daily practice. Easy and quick access to P&Ps from different applications, platforms, and devices. Task management tools for easily assigning tasks and monitoring the performance of the P&Ps.

O'Connor, Mayo Clinic:****New and Innovative CZT-Based Gamma Cameras****SU-EF-TRACK 2-04****Audience Q & A**

A number of non-Anger planar and SPECT gamma cameras (pixelated, solid state, multiple small field-of-view), including those dedicated to myocardial perfusion and molecular breast imaging, are now commercially available, and their clinical use is becoming common. As a consequence, the likelihood that a nuclear and diagnostic medical physicist will encounter these non-traditional cameras in clinical practice is increasing. The underlying physics, performance characteristics, calibration and quality control, and annual evaluation of these cameras differ substantially from those of the conventional Anger camera. Secondly, due to their unique construction and purpose, the collection of conventional phantom data for accreditation present several problems that are not trivial to overcome. The purpose of this session is to provide attendees with information related to the underlying physics, calibrations, quality control and performance characteristics of various classes of non-Anger gamma cameras; as well as, appropriate accreditation tests.

Dedicated myocardial perfusion imagers (Piotr Slomka, PhD)

This lecture will describe solid state detector performance, collimator design and characteristics, dedicated quality control, and new types of artifacts and evaluation in the clinical practice, associated with dedicated cardiac non-Anger SPECT cameras.

Large field-of-view pixelated gamma cameras (Leonard W. Zimmermann, MS)

This lecture will focus on non-Anger large field-of-view gamma camera detector and collimator characteristics, system calibration and commissioning, and annual performance evaluation.

New and innovative CZT-based gamma cameras (Michael K. O'Connor, PhD)

This lecture will describe molecular breast imaging (MBI) and next-generation Ring gantry CZT-based systems, as well as acceptance testing and ACR accreditation associated with both of those classes of non-Anger gamma cameras.

Learning Objectives:

1. Understand the underlying physical principles of the various types of non-Anger gamma cameras
2. Become familiar with non-Anger gamma camera calibrations and quality control
3. Learn about non-Anger gamma camera performance characteristics and how to evaluate them to satisfy accreditation groups

Emerging AI Breast Imaging Applications

SU-E-TRACK 3-03

Q&A & Panel Discussion

Although the primary goal of breast imaging modalities is to detect and diagnose breast cancers, mammography and advanced imaging techniques such as breast MRI may also provide useful information about breast cancer risk. A wealth of evidence has identified imaging markers that, when used in conjunction with other patient information, can aid in predicting whether breast cancer is currently present or more likely to develop in the future. In this session, we will hear about the latest research tools and commercial products to assess breast density on 2D mammography and tomosynthesis. We will learn about research of radiomic features that can be extracted from mammography to inform clinical risk prediction. We will discuss new risk markers identified on MRI and other contrast-based imaging that can provide additional risk information beyond density. Finally, we will discuss the role of AI tools for identification and application of imaging markers associated with breast cancer risk. Together, the work discussed here has high potential to impact clinical practice by identifying women who may benefit from tailored breast screening or risk-reduction strategies.

Learning Objectives:

1. Discuss the latest research tools and commercial software for breast density assessment and extraction of radiomic features with mammographic techniques.
2. Recognize new risk markers from breast imaging and their potential contribution to risk prediction.
3. Consider the role of AI tools in breast imaging for risk assessment.

Standards to Reduce Variability in Quantitative MRI

SU-EF-TRACK 4-07

Panel Discussion

Magnetic resonance imaging (MRI) is playing an increasingly large role in the treatment of cancer with radiation therapy. With applications ranging from biologically informed treatment planning to in-room motion management, MRI is a versatile tool with far-reaching advantages. This session covers several cutting-edge MRI methods and their application to radiation therapy planning and delivery. The first talk will cover the use of real-time MR guidance for tumor tracking for multiple targets in the presence of patient motion. Quantitative MRI metrics are rapidly being adopted as imaging biomarker surrogates for tumors and organs at risk. One approach, magnetic resonance fingerprinting, will be described as a state-of-the-art method for rapid quantitative MRI. Next, a presentation will be given on overcoming the challenges of quantitative imaging on low field MRI-guided radiation therapy systems. To ensure rigor and reproducibility in quantitative MRI, a presentation on standards to reduce variability will be given. Finally, a talk on the novel use of MRI for patient specific radiation therapy treatment planning for high-grade brain tumors in a clinical trial will be presented by a physician.

Learning Objectives:

1. Describe real-time multi-target tracking on an MRI-guided radiation therapy system.
2. Understand the concept of magnetic resonance fingerprinting for rapid quantitative MRI.
3. Describe the challenges of quantitative imaging on low field strength MRI scanners.
4. Describe standards to reduce variability in quantitative imaging.
5. Introduce methods for patient-specific treatment of glioblastoma tumors in a clinical trial.

A Consensus Report from the Global Harmonisation Group On Clinical Trials: Report Dose-To-Medium

S Kry^{1*}, J Lye², C Clark³, N Andratschke⁴, A Dimitriadis⁵, D Followill⁶, R Howell⁷, M Hussein⁸, M Ishikawa⁹, S Kito¹⁰, T Kron¹¹, J Lee¹², J Michalski¹³, A Monti¹⁴, N Reynaert¹⁵, P Taylor¹⁶, K Venables¹⁷, Y Xiao¹⁸, J Lehmann¹⁹, (1) MD Anderson Cancer Ctr., Houston, TX, (2) Australian Radiation Protection and Nuclear Safety Agency, Yallambie, VIC, AU, (3) UCLH, London, SRY, GB, (4) University Hospital Zurich And University of Zurich, (5) (6) UT MD Anderson Cancer Center, Houston, TX, (7) UT MD Anderson Cancer Center, Houston, TX, (8) National Physics Laboratory, (9) Hokkaido University, Sapporo, JP, (10) Jcog, (11) Peter MacCallum Cancer Instit., Melbourne, AU, (12) Nih Radiotherapy Trials Quality Assurance Group, (13) Washington University, Saint Louis, MO, (14) European Organisation For Research And Treatment of Cancer, (15) University of Gent, Gent, BE, (16) UT MD Anderson Cancer Center, Houston, TX, (17) Nih Radiotherapy Trials Quality Assurance Group, (18) University of Pennsylvania, Philadelphia, PA, (19) Newcastle Mater Hospital, Hunter Region Mail C, AU

Purpose: To promote consistency in global clinical trials by recommending a uniform framework as it relates to radiation transport and dose calculation in water versus in medium. **Methods:** The Global Quality Assurance of Radiation Therapy Clinical Trials Harmonisation Group (GHG; www.rtgaharmonization.org) is comprised of 5 primary member organizations: IROC, EORTC, RTTQA, JCOG, and TROG and several observer organizations: IAEA, RDS, ADCS and NPL. The GHG compared the differences between dose to water in water (Dw,w), dose to water in medium (Dw,m), and dose to medium in medium (Dm,m). This was done based on a review of historical frameworks, existing literature and standards, clinical issues in the context of clinical trials, and the trajectory of radiation dose calculations. Based on these factors, recommendations were developed. **Results:** No framework was found to be ideal or perfect given the history, complexity, and current status of radiation therapy. Nevertheless, based on the evidence available, the GHG established a recommendation preferring dose to medium in medium (Dm,m). If an institution's planning system can only calculate dose to water in water (Dw,w), this is acceptable. **Conclusion:** Dose to medium in medium (Dm,m) is the preferred dose calculation and reporting framework. Use of this common framework will provide global standardization for clinical trial data reporting and interpretation of trial results.

SU-E-TRACK 5-02

A GPU-Accelerated Monte Carlo Engine for Calculation of MLC-Collimated Electron Fields

E Brost*, H Wan Chan Tseung, J Antolak, Department of Radiation Oncology, Mayo Clinic, Rochester, MN

Purpose: To develop a GPU-accelerated Monte Carlo (MC) engine incorporating the Varian TrueBeam linac head geometry for rapid calculation of electron fields collimated using the photon multi-leaf collimator (MLC). **Methods:** A CUDA framework was created for the following: (1) transport of electrons and photons through the linac head geometry, taking into account multiple scattering, Bremsstrahlung, Moller, Compton, and pair production interactions; (2) electron and photon propagation through the CT geometry, taking into account all aforementioned interactions plus the photoelectric effect; and (3) secondary particle cascades through the linac head and within the CT geometry. The linac head collimating geometry was modelled according the specifications provided by the vendor, who also provided phase space files above the collimator jaws. The MC was benchmarked against EGSnrc by simulating individual interactions with simple geometries and pencil beam dose calculations in water phantoms. Lastly, MC-calculated dose distributions for MLC-collimated electron fields were compared to measurements in a water phantom. **Results:** Pencil beam dose distributions within a water phantom are in good agreement with DOSXYZnrc. Angular and spatial distributions for multiple scattering and secondary particle production are in good agreement with EGSnrc. Dose profiles for MLC-collimated 6-20 MeV electron beams had differences of <5% for 5x5 cm² and 10x10 cm² field sizes as compared to measurement. The computation time on a single NVIDIA GTX TITAN X card is 15 minutes for 10⁸ electron histories, which is approximately 100 times faster than published results in a similar geometry using a single-CPU core. **Conclusion:** The GPU-based MC can quickly calculate dose for electron fields collimated using the conventional photon MLC. Dose profiles in homogeneous medium agree well with DOSXYZnrc and measured data. The fast calculation times will allow for rapid calculation of electron fields for mixed photon and electron particle therapy.

Dr. Eric Brost was funded for his work by the Mayo Clinic School of Graduate Medical Education. Dr. John Antolak is funded, in-part, by Varian Medical Systems, CA, USA.

SU-E-TRACK 5-03

Correlation of Treatment Time to Target Volume for GammaPod Treatments: A Simple Second Calculation"

L Chen*, S Becker, S. McAvoy, E. Nichols and M Guerrero, University of Maryland School of Medicine, Baltimore, MD

Purpose: The GammaPod is a novel device for stereotactic breast treatments that employs 25 rotating Co-60 sources while the patient is continuously translated in three axes to deliver a highly conformal dose to the target. There is no commercial software available for independent second calculations. The purpose of this study is to determine an efficient way to estimate GammaPod treatment times based on target volume and use it as a second calculation for patient-specific QA. **Methods:** Data was extracted from the plan reports of 65 breast cancer patient treatments. Similar to the Curie-seconds concept in brachytherapy, we considered dose-rate*time/(prescribed dose) as a function of target volumes. Using a MATLAB script, we generated linear (with 95% confidence interval) and quadratic fits and tested the resulting equations in an additional set of 18 patients. **Results:** We found a strong correlation between the dose-rate*time/(prescribed dose) and a patient's target volume for both the linear and quadratic models. The linear fit was selected for use and using the polyval function in MATLAB, a 95% confidence interval (CI) graph was created to depict the accuracy of the prediction for treatment times. Testing the model in 18 additional patients with target volumes ranging from 29cc to 193cc yielded treatment times from 10 to 25 minutes that in all cases were within the predicted CI. The average absolute difference between the predicted and actual treatment times was 1.2 minutes (range 0-4 minutes). The average percent difference was 7.3% (range 0-20%). **Conclusion:** This work has resulted in a viable independent calculation for GammaPod treatment times. After multiple tests, the spreadsheets are ready for clinical use to predict and verify the accuracy of breast cancer treatment times.

SU-E-TRACK 5-04

Introducing Kernel Truncation and Sparsity into Dose Calculations for IMRT Optimization

H Stephens¹*, Q Wu², Q Wu², (1) Duke University, Durham, NC, (2) Duke University Medical Center, Durham, NC

Purpose: The adoption of AI and Machine Learning techniques is greatly improving planning efficiency. Modeling these algorithms can involve numerous iterations in which the dose calculations can become a bottleneck. The reliance on commercial treatment planning systems introduces unnecessary overhead due to the constant flow of data. Here we present and investigate the effect of kernel truncation and sparsity on the dose and fluence calculation for the purposes of designing a dose engine for AI/ML algorithms. **Methods:** The basis for this algorithm relies on beamlet and voxel discrimination in which numerous beamlets and voxels are pruned. This results in a constant time reduction in computation time and storage. The resulting deposition matrix is now highly sparse and can be treated and manipulated as such. We compared our dose calculation against calculations in both a water phantom and patient anatomy geometry to the AAA algorithm in Eclipse, the standard clinical dose engine. Our fluence optimization algorithm was tested on the TG-119 prostate phantom. Our system was developed using the Julia programming language. **Results:** The dose calculation algorithm had errors of less than 1% for field sizes up to 30x30 cm². Comparing dose-volume objectives the optimizer produced a distribution that differed from the constraints on average by 0.1% for the PTV, 2.9% for the rectum, and 2.85% for the bladder. For beamlet resolutions common in multi-beam treatments, the calculation had a performance around 17 times faster than a full dense calculation on the same hardware. **Conclusion:** The sparsity and truncation greatly improved computational efficiency while maintaining accuracies needed to be introduced in AI/ML applications. This improvement will greatly aid in the development cycle for AI/ML applications in radiation therapy.

SU-E-TRACK 5-05

Polar Coordinate Based Pencil Beam Dose Calculation Algorithm for VMAT

W Tseng¹*, B Lu, University of Florida, Gainesville, FL

Purpose: To propose a pencil beam (PB) dose calculation algorithm for volumetric modulated arc therapy (VMAT) that can reduce dose discrepancies due to angular under-sampling issue and improve the computational efficiency. **Methods:** 6 MV 1x1 mm² pencil beams were simulated and calculated on ArcCheck phantom under EGSnrc environment. Monte Carlo generated PB kernels were collected in Polar system for each bixel in a 40x40 cm² grid. These kernels were fine-tuned based on a squared field dose from a commercial treatment planning system (TPS, Pinnacle³) and then fitted using multiple Gaussians. Fluence for VMAT arc was calculated using detectors' eye view with leaf end, tongue and groove, and transmission factors corrected. Dose in Polar system for an arc can be calculated by a summation of convolutions of the corresponding PB fitting kernels and fluence for each bixel using fast Fourier transforms. Dose was converted to Cartesian system and compared with the dose from TPS using gamma analysis. Ten VMAT arcs were studied to evaluate the robustness of the algorithm. **Results:** The average gamma passing rate between the calculated and TPS dose was 96%(2%/2mm) and 98%(3%/3mm). With a 2x2x2 mm³ calculation grid, the proposed algorithm can provide a comparable computational efficiency (~150s) as TPS for common arcs and a shorter computational time for arcs with large fields using a PC equipped with a quad-core CPU. **Conclusion:** We proposed a Polar coordinate based pencil beam algorithm that can be implemented for VMAT dose calculation. It improves the computational efficiency of VMAT dose calculation since the convolution is applied to Polar system, whereas the convolution in the traditional discretized algorithm needs to be done for each discretized apertures with small angular separations. This algorithm can also reduce dose discrepancies due to angular under-sampling issue, which improves the accuracy of VMAT dose calculation.

BEST IN PHYSICS (THERAPY): Clinical Implementation of AI-Based 3D Dose Prediction Model as Physician Directive Support Tool to Streamline Head and Neck Planning Process

M Mashayekhi¹*, R McBeth, Z Trivedi, D Nguyen, S Jiang, M Lin, UT Southwestern Medical Center, Dallas, TX

Purpose: There exist some inherent shortcomings with the current treatment planning practice—e.g. deliverable dose to OARs is unknown a priori. In addition, the heterogeneity of clinical practices can lead to variation in the achievability of the planning goals and the resulted plan quality. The goal of this study is to incorporate an AI-based dose predictor into the treatment planning pipeline to develop a hybrid approach of physician intelligence and artificial intelligence that improves the planning efficiency, uniformity, and quality. **Methods:** We developed a 3D AI-based dose predictor based on a hierarchically densely connected U-net model. The model is trained separately on definitive and post-operative plans. We integrated the model with Eclipse treatment planning system via Application Programming Interface (API) to allow seamless 3D dose and the uncertainty estimation in TPS upon the completion of contour. In phase one implementation, we tested the API and the expert model on 60 retrospective cases treated by 3 different physicians to build the confidence level of prediction quality for different practice styles. In phase two implementation, all four head and neck physicians use the dose predictor as a decision support tool to construct their planning directives for 60 patients prospectively. The physician directives and the achieved plans for phase one and two were compared to quantify the efficacy of AI-guided physician directive workflow. **Results:** Our analysis shows increased practice uniformity among the physicians and improved achievability and plan quality of the plans upon application of AI. A dose difference of 3Gy was considered clinically significant. The frequency that resulted plan achieved within 3Gy from the physician directives has increased from only 47.5% to 86.7% upon implementing AI. **Conclusion:** AI guided physician decision support improved the uniformity of practice, directive achievability, and the final plan metrics in a significant percentage of patients.

SU-E-TRACK 5-07

Prediction of Organ-At-Risk Doses Using An Artificial Intelligence Algorithm: Clinical Validation and Estimated Benefit to Treatment Planning for Lung SBRT

P Brodin¹*, L Schulte², D Pappas², W Martin³, X Shen³, A Basavatia³, N Ohri¹, M Garg¹, S Kalnicki³, C Carpenter², W Tome¹, (1) Albert Einstein College of Medicine and Montefiore Medical Center, Bronx, NY, (2) Siris Medical, Newburyport, MA, (3) Montefiore Medical Center, New York, NY

Purpose: To validate the clinical performance of an artificial intelligence (AI) algorithm to predict pre-treatment organ-at-risk (OAR) doses for lung SBRT

using only the planning CT, target and OAR contours. We also assessed the treatment planning benefit of having access to these dose predictions. **Methods:** AI models were trained for dose prediction using 213 patients treated with lung SBRT, using a gradient-boosted regression tree algorithm with regularized feature selection. Twenty patients not included in the training set were used to test OAR dose prediction performance, ten with 5x10Gy and ten with 3x18Gy. We also performed blinded re-planning with access to the OAR dose predictions but without access to clinically delivered plans, with target coverage set to equal that of the delivered plans. Differences between predicted and delivered doses were assessed by root-mean square deviation (RMSD) and OAR doses across all three comparisons were evaluated using one-way ANOVA tests. **Results:** Prediction performance was good with ANOVA tests showing no significant difference between prediction, delivered and re-planned OAR doses (All $p > 0.30$). The RMSD was 2.9Gy, 5.3Gy, 4.3Gy and 1.7Gy for max dose to spinal cord, esophagus, heart and trachea for 5x10Gy and respectively 1.7Gy, 1.9Gy, 2.9Gy and 2.6Gy for 3x18Gy. Three patients with doses close to the acceptable 52.5Gy max for great vessels had excellent dose prediction with average 3.4Gy difference. In blinded re-planning, lower OAR doses than clinically delivered were achieved for 6/10, 3/10 and 6/10 patients for spinal cord, heart and esophagus at 3x18Gy, and respectively 5/10, 5/10 and 7/10 patients for 5x10Gy. **Conclusion:** Pre-treatment prediction of OAR doses showed good agreement with delivered lung SBRT plans and access to these predictions led to lower OAR doses for several patients when re-planned. This prediction will allow upfront discussions of achievable dose fractionation and important OAR and target dose trade-offs.

A Multi-Modality Radiomics-Based Model for Recurrence Risk Stratification in Non-Small Cell Lung Cancer

J Christie^{1*}, O Daher¹, M Abdelrazek¹, P Lang¹, V Nair², S Mattonen¹, (1) Western University, London, ON, CA, (2) University of Washington School of Medicine, Seattle, WA

Purpose: To develop a multi-modal model integrating quantitative imaging features from the tumor and non-tumor regions of interest, descriptive features, and clinical data to improve risk-stratification of patients with non-small cell lung cancer (NSCLC) over cancer staging. **Methods:** A dataset of 135 patients with early-stage NSCLC who had surgery as their primary form of treatment was analyzed. The tumor and peri-tumoral volumes on both CT and PET were segmented, while the bone marrow (L3-L5 vertebral bodies) was segmented on PET. The Quantitative Image Feature Engine was used to compute shape, size, first-order, and texture radiomic features from these volumes. Combined with the clinical and descriptive features, feature selection was performed on the 1030 features to select the top features to predict time to recurrence in the training cohort ($n=94$). A Cox model was built in the training cohort and evaluated on the testing cohort ($n=41$). Model performance was assessed using the concordance index and compared to a baseline clinical model with cancer staging. **Results:** A total of 14 features were selected as the top performing features. Twelve of the top features were texture features with the remaining two features being cancer stage and patient age. The model achieved a concordance of 0.84 and 0.81 in the training and testing cohorts, respectively. The locked model outperformed that of a gold standard clinical model consisting of stage-only, with concordances of 0.69 and 0.68 in the training and testing cohorts, respectively. **Conclusion:** Our model outperformed the stage-only model for NSCLC recurrence prediction and risk stratification. These results demonstrate that radiomics has the potential to augment staging information in a clinical setting. These non-invasive software tools can be implemented into the clinic and will allow physicians to more accurately identify patients who are at higher risk of treatment failure.

SU-E-TRACK 6-02

Computer-Assisted Diagnosis of Hepatic Portal Hypertension: A Novel, Attention-Guided Deep Learning Framework Based On CT Imaging and Laboratory Data Integration

Y Wang*, X Li, M Konanur, B Konkel, E Seyferth, N Brajer, M Bashir, K Lafata, Duke University, Durham, NC

Purpose: To develop a deep learning framework that integrates CT imaging with laboratory data to predict the hepatic venous pressure gradient (HVPG) of patients at risk of portal hypertension (PHTN). **Methods:** We retrospectively identified 198 patients with CT imaging, laboratory results, and HVPG measurements. PHTN was defined as HVPG ≥ 5 mmHg. Laboratory results included albumin, platelet count, and APRI, all of which are associated with the pathogenesis of PHTN. We designed a novel attention-guided deep learning approach that targets the left hepatic lobe surface nodularity, which has been linked to HVPG. The liver was segmented using a self-adapting nnU-Net model, from which the liver tip and center-of-mass were detected as anatomic landmarks. The surface of the left hepatic lobe was then detected using a rotationally-invariant bounding box technique to partition the liver relative to its tip and center-of-mass. Surface nodularity variation in the superior-inferior direction was captured by incorporating adjacent CT slices. The resulting 3-channel image of the left hepatic lobe's surface served as input to a ResNet-152 deep learning architecture trained to predict PHTN. To incorporate laboratory data, positional encoding was used to transcribe raw lab results into a high-dimensional feature-space, which was concatenated to the fully connected layer of the ResNet-152 model prior to PHTN prediction. Performance of the joint-model (imaging+laboratory) was compared to both the imaging-only and laboratory-only models. **Results:** The joint-model consisting of both imaging data and laboratory data achieved an AUC of 0.74 and an accuracy of 0.71, resulting in an increase in model performance relative to both the imaging-only model (AUC=0.60; accuracy=0.62) and the laboratory-only model (AUC=0.58; accuracy=0.60). **Conclusion:** A novel deep learning paradigm was developed to predict PHTN based on the integration of CT imaging and laboratory results. Our results suggest that CT imaging and laboratory data provide complementary diagnostic information.

SU-E-TRACK 6-03

JACK KROHMER EARLY-CAREER INVESTIGATOR COMPETITION WINNER: Multi-Group Multi-Block Data Integration for Harmonizing 18F-FDG-PET/CT Radiomics Associated with Circulating Tumor Cells and Predicting Recurrence-Free Survival Across Independent Lung Cancer Radiotherapy Studies

S Lee*, G Kao, S Feigenberg, Y Fan, Y Xiao, University of Pennsylvania, Philadelphia, PA

Purpose: To combine independent studies with a multi-group multi-block (MGMB) integrative method for harmonizing ¹⁸F-FDG-PET/CT radiomics associated with circulating tumor cells (CTCs), and evaluate the impact on predicting recurrence-free survival (RFS) after radiotherapy in non-small cell lung cancer (NSCLC). **Methods:** The present study investigated two independent studies, consisting of 56/50 patients with early-stage/locally-advanced NSCLC (ES/LA-NSCLC) treated with stereotactic body radiotherapy (SBRT)/definitive concurrent chemoradiotherapy (CCRT), with pretreatment ¹⁸F-FDG-PET/CT imaging and CTC assessment via a telomerase-based assay. Each study included 1,548/1,562 PET/CT radiomic features extracted from gross tumor volume plus 5 baseline clinical parameters (CPs). MGMB data integration was performed to integrate four (CT/PET/CP/CTC)-block feature sets and combine both studies (ES-NSCLC SBRT and LA-NSCLC CCRT) by using sparse MGMB generalized partial least squares (PLS) regression with unsupervised feature

selection (UFS). Algorithm for RFS data stacking was implemented for RFS analysis as a classification problem. Block PLS-discriminant analysis (PLS-DA) was performed to integrate the four-block feature sets and predict locoregional/distant RFS after radiotherapy, where one study group served as a training set while the other as a testing set. The same analysis was conducted via single-group multi-block (SGMB) data integration that naively concatenated both studies while integrating the four-block feature sets by using sparse MB generalized PLS regression with UFS. Predictive performance of the block PLS-DA on the testing set for locoregional/distant RFS was compared using Harrell's c-index between MGMB and SGMB integrative approaches. **Results:** For predicting locoregional/distant RFS, the MGMB vs. SGMB integration obtained c-indices of 0.653/0.609 vs. 0.547/0.530 for the pre-SBRT ES-NSCLC study and c-indices of 0.736/0.758 vs. 0.730/0.882 for the pre-CCRT LA-NSCLC study, respectively. **Conclusion:** The MGMB integration of ^{18}F -FDG-PET/CT radiomics and CTC improved predictive performance through exploring potential correlation between studies, indicating that the MGMB integration may reduce prediction bias for RFS when combining independent NSCLC radiotherapy studies.

This project was supported by NCI grants, U24CA180803(IROC) and U10CA180868(NRG). Dr. Kao is a co-founder and has equity in Liquid Biotech USA, Inc., a University of Pennsylvania PCI-developed company through the UPStart program.

SU-E-TRACK 6-04

Multi-Institutional Data Analysis of Radiomic Signature Set to Predict Overall Survival in Glioblastoma Patients

E Carver*, Z Dai, J Snyder, B Griffith, L Poisson, L Rogers, N Wen, Henry Ford Health System, Detroit, MI

Purpose: This study aims to expand upon published literature in radiomics and deep learning to: 1) Apply deep learning to segment GBM on MRI, generating consistent ROI for radiomics. 2) Effectively employ harmonization to find a radiomic signature set (RSS) that competitively predicts GBM patient overall survival on independent datasets. 3) Integrate RSS with clinical/genetic patient information to perform a complete prognostic assessment. **Methods:** 180 MR datasets including T1, T2, T1CE, and Flair were obtained through BraTS, IVYGAP, and our institution (140/18/22) for training/ independent validation. Preprocessing included resampling, registration, skull-stripping, N4 bias-correction, and normalization. Whole Tumor, Tumor Core and Enhanced Tumor were delineated on the multi-modality MRI by physicians in the training dataset. Contours used for validation datasets were generated by 2D U-Net employing synthetic MR (synMR) data augmentation by GAN. Features were extracted by CAPTK, a radiomic toolbox, and feature harmonization included ComBat with quantile normalization. Feature selection was done by LASSO and a 12-feature signature set was constructed. Predictive power of RSS was assessed by calculating the area under the curve of a receiver operating characteristic curve (AUC-ROC) created by Support Vector Machine (SVM). RSS robustness was assessed using independent validation datasets. Complete prognostic assessment was performed by comparing RSS against known clinical/genetic prognostic features (Age, Karnofsky Performance Scale, IDH1, MGMT, EGFR3) using a sub-dataset containing 59 of 180 patients, based on availability. **Results:** U-Net performance and RSS prognostic ability was assessed using independent auto-contoured datasets; AUC for IVYGAP and Institutional datasets are 0.93 and 0.96, respectively. Using the sub-dataset, RSS outperformed known clinical/genetic features; AUC of 0.57. Including RSS with clinical/genetic features improved AUC to 0.83. **Conclusion:** U-Net performance shows ability to fully automate RSS workflow. RSS shows encouraging preliminary results as it shows strong predictive power on independent datasets and outperforms/aids commonly used clinical/genetic features.

SU-E-TRACK 6-05

Multi-Class Classification Based On Multi-Loss Strategy and Auxiliary Deep Learning Network with Applications in Medical Imaging

Z Fan*, S He², E Chen^{1,6}, S Ruan³, X Wang⁴, H Li^{1,5} (1)University of Illinois at Urbana-Champaign, Urbana, IL (2)Washington University in St. Louis, St. Louis, MO (3)University of Rouen, Rouen, France (4)University of Illinois at Chicago, Chicago, IL (5)Carle Foundation Hospital, Urbana, IL (6) Carle Illinois College of Medicine, Urbana, IL

Purpose: Multi-class classification has wide applications in medical imaging fields. However, the performance decreases due to the issues of inter-class data similarity and data imbalance. Previously proposed deep-learning methods commonly trained the network through the minimization of single loss function to learn discriminative features for classification, which might increase the risks of overfitting. Therefore, a multi-class classification strategy is proposed to address the issues and improve the classification performance. **Methods:** The proposed framework backbone includes a feature-extraction network (Feat-Net) and a multi-class classifier. Two auxiliary networks--reconstruction network (Recon-Net) and discriminator-network (Disc-Net)-- are proposed to support the training of Feat-Net and extract class-differentiable features to improve classification performance. Inspired by the design of GAN, Recon-Net aims to recover the images to be similar to the input images using Feat-Net-extracted features, while Disc-Net aims to distinguish the reconstructed and original images. Three networks are trained iteratively by updating Disc-Net only and updating Feat-Net and Recon-Net jointly through the minimization of pre-defined multiple loss functions. In this way, the Feat-Net can extract more informative features stably from the input images compared to traditional methods. Two case studies, the 3-class COVID-19 classification with X-ray images and the two-class stratification of risks of head-and-neck cancer treatment failures with PET images, were employed to evaluate the framework performance. **Results:** The framework achieved superior performances compared to the baseline method with 4.6% and 2.5% improvement on F1-score on two case studies, respectively. Also, it was observed that the effectiveness of the proposed framework depends on the depth of Feat-Net and the size of input images. **Conclusion:** This study indicates that the auxiliary networks and multi-loss strategy can improve the performance of multi-class classification. The modularized design allows flexibly tailored architectures fitting for varied applications. Extending the framework to other complex tasks would be investigated in the future.

SU-E-TRACK 6-06

A Radiomics-Boosted Deep Learning Model for COVID-19 and Non-COVID-19 Pneumonia Detection Using Chest X-Ray Image

Z Hu^{1*}, Z Yang², F Yin², K Lafata², C Wang², (1) Duke Kunshan University, Kunshan, Jiangsu, China, (2) Duke University Medical Center, Durham, NC

Purpose: To develop a deep-learning model that integrates radiomics analysis for enhanced performance of COVID-19 and Non-COVID-19 pneumonia detection using chest X-ray image **Methods:** Based on a pre-trained VGG-16 architecture, the deep-learning design consists of a 5-Dense layer neural network with varying sizes, while the last three convolutional layers were set as free parameters for training. In radiomics analysis, a 2D sliding kernel was implemented to map the impulse response of radiomic features throughout the entire X-ray image; thus, each feature is rendered as a 2D map in the same dimension as X-ray image. Two deep-learning models were trained: in the 1st model, X-ray image was the sole input; in the 2nd model, X-ray image and 2 radiomic feature maps(RFM) selected by the saliency map analysis of the 1st model were stacked as the input. Both models were developed using 812 chest X-ray images with 262/288/262 COVID-19/Non-COVID-19 pneumonia/healthy cases, and 649/163 cases were assigned as training-validation/independent test sets. For each model design, 25 versions were trained with random assignments of training/validation cases following 7:1 ratio in training-validation set. Sensitivity, specificity, accuracy, and ROC curve results from both model designs were analyzed. **Results:** In 1st model using X-ray as the sole input, the 1)sensitivity, 2)specificity, 3)accuracy, and 4)ROC Area-Under-the-Curve (AUC) of COVID-19/Non-COVID-19 pneumonia detection were 1)0.91±0.08/0.78±0.07, 2) 0.93±0.04/0.94±0.05, 3)0.92±0.03/0.89±0.02, and 4)0.96±0.03/0.92±0.03. In the 2nd model design, two RFMs, Entropy and Short-Run-Emphasize, were selected with their highest cross-correlations with the saliency maps of the 1st model. The corresponding results demonstrated significant improvements($p<0.05$) of disease detection: 1)0.95±0.03/0.85±0.04, 2)0.97±0.02/0.96±0.02, 3)0.97±0.02/0.93±0.02, and 4)0.99±0.01/0.97±0.02. The reduced variations suggested a superior robustness of 2nd model design. **Conclusion:** The inclusion of radiomic analysis in deep-learning design improved the performance and robustness of COVID-19/Non-COVID-19 pneumonia detection, which holds great potential for clinical applications in the COVID-19 pandemic.

SU-E-TRACK 6-07

Spatial Reconstruction of Statistically Significant Radiomics Signatures Using 3D Wavelet Decomposition in Tumors of Oropharyngeal Cancer
H Bagher-Ebadian*, F Siddiqui, A Ghanem, S Zhu, M Lu, B Movsas, I Chetty, Henry Ford Health System, Detroit, MI

Purpose: We applied 3D-wavelet-decomposition to spatially reconstruct statistically significant radiomics-features within images of the tumor for patients with oropharyngeal-squamous-cell-carcinomas(OPSCC's), for characterization of HPV. **Methods:** One-hundred-twenty-eight OPSCC-patients with known HPV-status (60-HPV+ and 68-HPV-, confirmed by immunohistochemistry-P16-protein-testing) were retrospectively studied. Three-dimensional-wavelet-decomposition analysis was performed on the contrast-enhanced CT-images of patient gross-tumor-volumes to decompose the tumor's intensity and spatial-frequency information into 3D-decomposition levels with series of orthonormal high-pass and low-pass wavelet-coefficients (WCs). Log-Energy-Entropy of the WCs for all the decomposition levels were calculated as radiomic-features. A Least-Absolute-Shrinkage-and-Selection-Operation (Lasso) technique combined with a Generalized-Linear-Model (Lasso-GLM) was applied on these features to identify and rank the optimal feature subsets with most representative information for prediction of HPV-status. Lasso-GLM classifier was constructed and validated using random-permutation-sampling of the features. Average Area-Under-Receiver-Operating-Characteristic (AUC), and Positive and Negative Predictive-values (PPV/NPV) were computed to estimate the generalization-error and prediction performance of the classifier. Ultimately, the optimal radiomic-features selected by the Lasso-analysis were used to select the significant wavelet-sub-bands and their respective WCs to perform inverse-wavelet-transform to reconstruct the tumor zones containing the highest information towards prediction of HPV-status. **Results:** Four entropy-based features from two decomposition-levels, including two low-frequency (LLL3/LHL3) and two high-frequency components (HHL1/HLL1) were found to be statistically significant discriminators between HPV-negative and HPV-positive cohorts respectively. The wavelet-based-Lasso-GLM classifier's prediction performance was: AUC/PPV/NPV=0.798/0.745/0.826. Results imply that tumor zones with smaller-components (higher-details/spatial-frequencies: components-sizes<~2mm) contain important radiomic information for characterization of HPV+ patients while tumor zones with larger-components (low-spatial-frequencies: components-sizes>~8mm) contain information for classification of HPV-cases. This study also confirms that compared to the central-zones of tumors, peritumoral-regions contain more information for characterization of the HPV-status. **Conclusion:** Results suggest that radiomics can be used to discriminate spatial-regions of importance toward the contribution of HPV. By associating this information with tumor pathology, one can potentially link radiomics to underlying biological mechanisms.

Minimizing Secondary Adverse Effects of Radiation Therapy: QUANTEC and Newer Results

SU-EF-TRACK 7-06

Q&A

The course will start with an introduction to radiation biology. The mechanisms involved in biological effects from ionizing radiation at the cellular and tissue levels and the radiation dosimetry terms used in radiation biology and in radiation protection will be reviewed. Concepts such as Linear Energy Transfer (LET) and Relative Biological Effectiveness (RBE) will be defined. Epidemiological data on cancer induction and tissue injuries, including radiation effects on children and the developing embryo, will be described. Increases in the risk of second cancers following radiation therapy, as well as data on radiation induced tissue reactions, such as cardiovascular effects, for follow up times up to 20-40 years, published by ICRP, NCRP and BEIR Committees, will be examined. The latest risk estimates per unit dose for stochastic effects and the threshold doses for tissue injuries will be presented and their potential impact on radiotherapy treatments assessed.

Fractionation of radiotherapy treatments will be discussed. Topics presented will include: Why has radiotherapy been fractionated (repair of late-reacting normal tissue cells, the L-Q model and the narrow "Window of Opportunity"), and what is the effect of overall treatment time (repopulation of cancer cells and representation in the L-Q model)? Also presented will be the radiobiological basis of clinical trials of various fractionation schemes such as hyperfractionation, accelerated fractionation, accelerated hyperfractionation, and hypofractionation, and the reason for all the recent interest in hypofractionation (highly conformal radiotherapy widens the Window of Opportunity).

Proton and light ion beams are rapidly emerging external-beam radiotherapy modalities. These combine the advantages of ballistic selectivity with distinguished biological properties emerging from their elevated ionization density which, especially for heavier ions, can result in a selectively enhanced biological effectiveness in the tumor region. However, this introduces a new level of complexity to be properly accounted for in treatment planning. This presentation will review the basic radiobiological principles, quantities, and models for clinical application of protons and light ions, along with highlighting the still open questions, emerging new trends, and instrumentation requirements for addressing them.

The physics and biology of ultra-fast FLASH radiation will be discussed at two levels: the cell and body levels. At the cell level, a recombination theory during

radiolysis will be discussed. FLASH radiation increases the recombination of intermediate products that leads to reduction of free radicals and hence reduces DNA damage. A simulation and an experimental study will be presented to support this theory. At the body level, FLASH radiation can “freeze” motion and blood flow. A simulation study demonstrated that FLASH radiation dramatically reduces the radiation killing of immune cells in blood, and thus potentially reduces radiation-induced lymphopenia, which may lead to improve tumor control and normal tissue sparing.

Outcome-related mathematical models seek to capture the known trends in dose-volume-tolerance for normal tissues (normal tissue complication probability, or NTCP), or dose-volume-eradication for tumors (tumor control probability, or TCP). We will briefly review the underlying radiobiological and mathematical characteristics of a few predictive models for normal tissues and tumors and point to their uses to understand radiobiological mechanisms, design protocols, and, eventually, guide personalized plan optimization.

Outcome-related mathematical models seek to capture the known trends in dose-volume-tolerance for normal tissues (normal tissue complication probability, or NTCP), or dose-volume-eradication for tumors (tumor control probability, or TCP). We will briefly review the underlying radiobiological and mathematical characteristics of a few predictive models for normal tissues and tumors and point to their uses to understand radiobiological mechanisms, design protocols, and, eventually, guide personalized plan optimization.

The course will end with a general discussion.

Learning Objectives:

1. To distinguish between stochastic effects and tissue reactions and their impact on radiotherapy treatments
2. To realize how the linear-quadratic equations model the effects of radiobiological parameters in radiotherapy
3. To understand the radiobiological rationale of proton and heavier ion therapy, along with remaining challenges and opportunities
4. To learn outcome-related mathematical models for normal tissues and tumors that eventually will guide personalized plan optimization
5. To understand the FLASH mechanism and its potential reduction of normal tissue toxicity

SU-EF-TRACK 8-06

Q&A

Patient-specific quality assurance (PSQA) is an integral aspect of modern radiotherapy. As the complexity of radiotherapy treatment plans has grown over the years, so too has the need to verify that various treatment delivery systems are accurately delivering each patient-specific treatment. This guided tour will begin with an introductory presentation from the moderators covering the basics of PSQA including its rationale and various types of equipment that have been used historically to measure PSQA. Vendors will then showcase their most recent hardware and software solutions for measuring, analyzing, and recording PSQA data followed by a question-and-answer session.

Learning Objectives:

1. Describe the rationale of patient-specific QA
2. Review various classes of equipment that have been used to measure PSQA and understand their advantages and technical limitations
3. Understand the extent of what PSQA is checking for and how it fits into the larger radiotherapy QA process

Audience Q&A

This presentation will describe reimbursement changes implemented in 2021 and proposed changes for 2022, including the radiation oncology alternative payment model. A review of changes that impact radiation oncology and radiology will be provided. A discussion of the Hospital Outpatient Prospective Payment System (HOPPS), the Medicare Physician Fee Schedule (MPFS), and the ambulatory surgery settings will be discussed. Lastly, an overview of the resources available to membership and tips for interacting with the professional economics committee will be provided.

Learning Objectives:

1. Basic understanding of payment models impacting medical physics clinical services.
2. Basic understanding of the 2022 HOPPS and MPFS proposed rules, including the RO-APM.
3. Basic understanding of economics and policy resources that are available from the AAPM and how to interact with the professional economics committee.

Anisotropies in Super-Resolution in 3D Magnification Mammography Using a Next-Generation Tomosynthesis System

R Acciavatti*, T Vent, C Choi, P Noel, A Maidment, Hospital of University of Pennsylvania, Philadelphia, PA

Purpose: In breast imaging, microcalcifications detected in a screening exam can be characterized with better detail in magnification mammography. In this exam, the breast is elevated closer to the x-ray source, and a 2D image is acquired. Unlike clinical systems, the next-generation tomosynthesis (NGT) system built in our lab is capable of 3D magnification mammography. We are also designing the system to generate super-resolution (SR) reconstructions. In our earlier work modeling the tomosynthesis acquisition in screening mammography, we found that there are anisotropies in SR at various positions in the image. This study analyzes how the anisotropies in SR vary with the use of magnification. **Methods:** A high-frequency sinusoidal test object was analyzed with theoretical modeling. The input frequency was oriented in the direction of x-ray source motion. Image quality in the reconstruction was quantified using the Fourier transform. The amplitude of low-frequency information was measured relative to the input frequency; this ratio should be as small as possible to achieve SR. We used these calculations to identify anisotropies in SR at various magnifications. For experimental validation of the anisotropies, a bar pattern phantom was analyzed with the NGT system. **Results:** In screening mode, there are anisotropies in SR in the direction perpendicular to the breast support; i.e., in various slices of the reconstruction. With theoretical modeling, we demonstrated that the spacing between anisotropies is reduced with increasing magnification; however, the relative amplitude of low-frequency (aliasing) signal at the anisotropies is not as pronounced as in screening mode. The anisotropies were validated experimentally with the NGT system. **Conclusion:** SR can be achieved in tomosynthesis reconstructions. Using the conventional acquisition geometry, anisotropies in SR exist in both screening and magnification tomosynthesis. Our future work will use this model of SR to optimize the acquisition geometry for magnification tomosynthesis.

SU-F-TRACK 3-02

Histological Validation of Anatomical Imaging for Breast Modeling

A Sen*, C Kingsley, A Kulp, M McCulloch, B Willis, K Brewer Savannah, A Contreras, M Bordes, T Huynh, N Fowlkes, G Reece, K Brock, UT MD Anderson Cancer Center, Houston, TX

Purpose: Develop a framework to register in vivo and ex vivo images with histology using a novel cryo-microtome for validation of anatomical structures to improve tissue modeling and imaging signals. **Methods:** Breast tissue obtained from a mastectomy patient and a formalin-fixed entire breast including chest wall from a cadaver were imaged using magnetic resonance (MR) imaging (3D T1 and 3D T2 Dixon, fat/water-saturated, in/out-of-phase). Specimens were frozen and embedded in optical cutting temperature (OCT) compound. The OCT block was placed in a cryo-microtome mounted with an overhead camera (Xerra, Emit Imaging). Slices of 33µm and 50µm were successively shaved off the block for the tissue and cadaver specimens, respectively. After each shaving, the blockface was photographed. At select tissue sites (connective/adipose, muscle, skin, fibroglandular), 20µm sections were transferred onto cryotape for manual H&E staining and histological analysis. A 3D blockface image was automatically reconstructed from the photographs by aligning fiducial markers embedded into the OCT block. The 3D MR, blockface images, and histology images were rigidly registered. Target registration errors (TRE) were computed based on corresponding points marked at fibroglandular intersections (5 for tissue, 10 for cadaver). The overall MR-histology registration was used to compare the MR intensities at tissue extraction sites with a one-way ANOVA. **Results:** The MRI-blockface TREs were 0.34±0.11mm and 0.73±25mm for the tissue and cadaver datasets, respectively (both less than respective MR slice thicknesses of 0.35 and 1.00mm). The blockface-histology registration showed alignment of anatomical structures and tissue boundaries. The MR intensities at the four tissue sites showed statistically significant differences (P<0.01). Each pair of tissues except skin-connective/adipose were also significantly different (P<0.01). **Conclusion:** Fine sectioning in a highly controlled imaging/sectioning environment enabled accurate registration between the MR image and histology and differentiation of tissue types in the MR image.

Research reported was supported in part by resources of the Image Guided Cancer Therapy Research Program from The University of Texas MD Anderson Cancer Center and the Helen Black Image-Guided Fund.

Direct-Indirect Dual-Layer Detector for Contrast Enhanced Digital Breast Tomosynthesis: Feasibility Using Image Simulation

X Duan*, H Huang, A Howansky, J Stavro, A Lubinsky, A Goldan, W Zhao, Stony Brook Medicine, Stony Brook, NY

Purpose: Contrast enhanced digital mammography and tomosynthesis (CEDM and CEDBT) use weighted subtraction of images acquired at energies below and above the k-edge of iodine to enhance the conspicuity of malignant lesions. Traditionally, low energy (LE) and high energy (HE) exposures are taken separately (dual-shot), which allows better energy separation and breast tissue cancellation. However, it is more prone to patient motion artifact. Dual-layer detector allows CEDM with a single shot, eliminating motion between LE and HE images. In this work, we propose the combination of direct and indirect flat-panel imagers (FPI) and an x-ray filter to improve spectral separation of dual-layer detectors for CEDM and CEDBT. **Methods:** The system consists of a k-edge filter (200 micron Rh) and a dual-layer detector, with a direct conversion (200 micron a-Se) FPI in the front (LE) and an indirect CsI (400 micron) FPI in the back (HE). We used the VICTRE tool to conduct image simulation of a digital breast phantom (half uniform and half with breast tissue structure), which was inserted with spherical iodinated objects with different sizes and concentrations. The LE, HE and subtracted images were compared for three different conditions: dual-shot, dual-layer (both indirect detectors) and dual-layer (with direct-indirect-filter combination). **Results:** Dual-shot offers excellent tissue separation and high iodine SDNR if no patient motion is involved. Iodinated objects have reasonable SDNR values with the k-edge filter and a-Se/CsI detector combination, even with the imperfect energy separation. If the top a-Se FPI is replaced with an a-Se based photon counting detector (PCD) SWAD, the highest SDNR can be obtained. **Conclusion:** The combination of direct-indirect FPI dual-layer detector and k-edge filter can potentially produce good breast tissue cancellation and SDNR that approaches that of dual-shot technique. The results are substantially better than dual-layer detectors that uses the same x-ray conversion material.

SU-F-TRACK 3-04

Image Quality Evaluation of a Compressed-Sensing Algorithm for Image Reconstruction in Dedicated Cone-Beam Breast CT Using Offset-Detector
S Vedantham*, H Tseng, A Karellas, University of Arizona, Tucson, AZ

Purpose: We have developed a new version of a dedicated, prone, cone-beam breast computed tomography (CBBCT). This system uses a CMOS detector in offset-detector configuration for imaging large breasts, while maintaining an optimal air-gap between the breast and the detector for scatter rejection. For this geometry, image quality achieved with a compressed-sensing (CS) algorithm was compared to Feldkamp-Davis-Kress algorithm with Wang's weights (FDK-Wang). **Methods:** 30 clinical breast CT datasets with calcifications acquired on a CBBCT system (300 views in 360-degrees) with a large-area (40x30-cm), centered, a flat-panel detector with 1024x768 pixel matrix, were selected. The sinograms were truncated to 768x768 and 640x768 -pixels along the fan-angle to emulate offset-detectors. A modified and GPU-enabled version of a CS-based algorithm, referred to as FIRST, and the FDK algorithm with a weighting window (FDK-Wang), were used to reconstruct these truncated sinograms. FDK reconstructions from complete sinograms served as reference. Signal-to-noise ratio (SDNR), bias, variance, root-mean-squared-error (RMSE), and the full-width at half-maximum (FWHM) of calcified lesions in two orthogonal directions were quantified. **Results:** The FWHM of calcifications did not differ ($P>0.262$) among reconstruction algorithms and detector formats, implying comparable spatial resolution. For a chosen offset-detector, the FIRST algorithm outperformed the FDK-Wang in terms of RMSE, bias, variance, and SDNR. For FIRST reconstructions with 768x768 (640x768) pixels, the median RMSE (cm-2), bias (cm-1), variance (cm-2) and SDNR were 6.45E-6 (7.63E-6), 7.17E-4 (9.26E-4), 3.37E-5 (4.29E-5), and 8.5 (6.54), indicating better performance with the 768x768 pixel matrix. The variance and SDNR from FIRST reconstructions with 768x768 pixels outperformed the reference FDK reconstructions from complete sinograms. The reconstruction time varied with breast size (25-45 minutes). **Conclusion:** This study indicates the feasibility of using CS-based, FIRST algorithm to reconstruct sinograms from offset-detectors. Our results indicate that FIRST reconstructions from 768x768 pixel matrix achieved the best performance.

SU-F-TRACK 3-05

Two-Dimensional Breast Tomosynthesis with a Stationary Array of Thermionic Cathodes for Higher Resolution Images and Fast Acquisition

J Boone^{1*}, A Sisniega², J Siewersden³, P Schwoebel⁴, (1) UC Davis Medical Center, Sacramento, CA, (2) Johns Hopkins University, Baltimore, MD, (3) Johns Hopkins University, Department of Biomedical Engineering, Baltimore, MD, (4) SRI International, Albuquerque, NM

Purpose: To develop a two-dimensional (2D) stationary thermionic x-ray source array for breast tomosynthesis, in order to dramatically improve image quality and reduce acquisition time. **Methods:** A Multiple X-ray source Array (MXA) was developed with 11 focal spots distributed along a ~28 cm long rotating anode shaft which supports eleven ~10 cm diameter anode disks. Individual thermionic (hot) grid-pulsed cathode assemblies supply pulsed electron beams which strike the end of each disk. All x-ray sources are within the same vacuum enclosure and are individually addressable using TTL control electronics. Coupled with a flat panel detector, this 11-source array of x-ray sources was used to collect tomosynthesis data using an orange as a test object. By adding a second row of cathodes on the other side of the anode disks, two rows of 11 x-ray focal spots will produce a 2D array (2 x 11) of sources for breast tomosynthesis. A breast CT data set was used to simulate 22 projection images with the 2D source distribution, and a model-based iterative reconstruction algorithm with spatially invariant regularization was used to reconstruct tomosynthesis images. **Results:** The 11-source x-ray tube demonstrated rapid acquisition, robust performance at 35 kV, and small focal spots (~0.3 mm each). Computer simulation of the proposed 2D array tomosynthesis system with 22 source positions shows a marked improvement for in-plane sharpness and thinner slices. Acquisition time using a 20 FPS detector would be 1.1 sec. **Conclusion:** All clinical breast tomosynthesis systems use a one-dimensional arc with acquisition times ranging from 3.7 to 25 s. Due to constraints on acquisition time, moving sources are not practical for 2D geometry tomosynthesis. The proposed stationary hot-cathode source array provides rapid acquisition (1.1 s for 22 sources) for low motion artifact tomosynthesis images with much better slice separation and in-plane object delineation.

JMB and JHS have patent-pending with royalties from The Phantom Lab.

SU-F-TRACK 3-06

Validation of Automated MTF Measurement for Digital X-Ray Imaging Quality Control

A Bey^{1*}, C MacLellan², D Zhang³, M Palmer⁴, (1) Boston Children's Hospital, Boston, MA, (2) Beth Israel Deaconess Medical Center, Boston, MA, (3) Boston Children's Hospital, Boston, MA, (4) Beth Israel Deaconess Medical Center, Boston, MA

Purpose: To validate an automated MTF-measurement procedure for achieving accurate and objective assessment of digital x-ray system spatial resolution in routine quality control surveys. **Methods:** The automated procedure (autoMTF) was evaluated for a full-field digital mammography system, a Senographe Pristina (GE Healthcare, IL), wherein the manufacturer prescribes sub-system MTF sampling at defined object frequencies. The autoMTF procedure utilizes a detection algorithm to (i) locate the line-pair phantom (ii) place elliptical ROIs in prescribed locations, and (iii) output tabulated ROIs statistics from which MTF samples can be calculated. Phantom images were acquired for both targets (Mo, Rh), both focal spots (small SFS, large LFS), two bar patterns, and phantom directions (width, length). Manual and autoMTF measurements were performed by placing four ROIs in each image: at the "space", "bar", and two line-pair sections (2.09 and 3.93 lp/mm for LFS, 5 and 8 lp/mm for SFS). Images were copied to external storage media (CD or USB drive) for autoMTF processing. Performance in terms of procedure time and accuracy was evaluated by three participating medical physicists. **Results:** The autoMTF completed the resolution testing, including storage media manipulation, in an average of 4 min. compared to manual measurements in 15-30 min. Test outcome (pass/fail) was equivalent for both procedures. Physicist measurements exhibited larger percent deviations (2-24%) compared to autoMTF, as well as more inter-variability, for the most challenging ROIs, i.e., higher spatial frequencies. **Conclusion:** This work produced a tool to facilitate oftentimes tedious and lengthy spatial resolution evaluations that are prone to error and inter-observer variability. The autoMTF algorithm is versatile and can be ported to similar spatial

resolution testing in other modalities such as digital radiography and fluoroscopy. Future investigations will utilize the autoMTF tool to quantitatively assess physicist subjectivity in performing line-pair phantom tasks.

SU-F-TRACK 3-07

Automating Tumor Functional Diameter Measurement with Molecular Breast Imaging for Treatment Response Assessment

BP Lopez*, GM Rauch, SC Kappadath, UT MD Anderson Cancer Center, Houston, TX

Purpose: Recent small-cohort studies have investigated using Molecular Breast Imaging (MBI) with ^{99m}Tc -sestamibi to assess tumor response following neoadjuvant chemotherapy (NAC). We present a robust automated methodology to estimate true functional uptake diameters in MBI capable of accurate size-based response assessment. **Methods:** Over 1,000 unique simulated images, sampling clinically-relevant tumor diameters ($d=5\text{--}25\text{mm}$), tumor depths ($z=1\text{--}11\text{cm}$), tumor/background volumetric-concentration ratios ($\text{TBR}=10,20,40$), breast thicknesses ($b=1\text{--}12\text{cm}$), were generated using our validated Geant4-based simulation of GE Discovery NM750b MBI to design and test a diameter estimation methodology. The methodology's accuracy/precision was additionally tested on simulated images of 78 ellipsoid tumors and phantom images of 3 spheres ($d=9.89, 15.43, 24.82\text{mm}$, $\text{TBR}=10,20$, $z=2,3\text{cm}$) within a $b=9\text{cm}$ container. **Results:** Our methodology calculates uptake diameter as $1.17 \cdot \text{FWHM} + 1.64$, where FWHM is automatically interpolated from a background-corrected profile through the tumor centroid (orientation user-specified) in a 3×3 median filtered single-detector image. The resulting absolute error [$\text{mean}=\text{accuracy}, 1\sigma=\text{precision}$] for $d \geq 15\text{mm}$ spherical tumors was $[0.1\text{mm}, 0.9\text{mm}]$, with accuracy differing $<0.6\text{mm}$ across tumor depths, TBRs, and breast thicknesses. Thus, we are able to accurately measure tumor uptake diameters $\geq 15\text{mm}$ and identify differences $\geq 3\text{mm}$ (corresponding to $\geq 20\%$ change after intervention) with $>99\%$ confidence, independently of most common biologic (e.g., uptake distribution) and imaging (e.g., view and compression) conditions during acquisition. These values are clinically relevant, as ultrasound size analysis in 28 patients revealed that 1) pre-NAC all tumors had diameters $\geq 15\text{mm}$ and 2) mid-NAC 100% of partial responders (per RECIST1.1) and 89% of patients had changes $\geq 3\text{mm}$. Methodology performance remained constant at $[0.1\text{mm}, 0.7\text{mm}]$ with $d \geq 15\text{mm}$ ellipsoid tumors but decreased to $[1.9\text{mm}, 2.3\text{mm}]$ with all $d=10\text{mm}$ simulated tumors. Performance in the phantom images was $[0.0\text{mm}, 1.1\text{mm}]$, $[2.2\text{mm}, 1.7\text{mm}]$, and $[5.5\text{mm}, 5.0\text{mm}]$ for 24.82mm , 15.43mm , and 9.89mm spheres, respectively. **Conclusion:** Our automated methodology accurately estimates functional uptake diameters $\geq 15\text{mm}$. MBI-based response assessment in 70+ patients undergoing NAC is underway.

A Hierarchical Optimization Framework for Gamma Knife Treatment Planning

M Chen*, Z Yang, Z Wardak, X Gu, W Lu, UT Southwestern Medical Center, Dallas, TX

Purpose: Gamma Knife (GK) is a widely used stereotactic radiosurgery system for brain lesion treatment. Its treatment planning, however, may require solving a large-scale optimization to determine many variables, including an unknown number of isocenter positions, collimators, and intensities. We propose a hierarchical optimization framework to address this large-scale problem. **Methods:** The framework is built by three critical components: kernel-decomposition-based (KD) dose model; multi-resolution shot initialization and dose grid with shot migration capability; and hierarchical collimator optimization. The KD dose is a shift-invariant kernel scaled by the normalized mean TMR. Both shot initialization and dose grid take resolutions of 1, 2, and 4 mm on the 1-mm-margin, 2-mm-margin, and the remaining interiors of the region of interest (ROI), respectively. For shot initialization, the ROI is the target; while for dose grid, the ROIs are the 4-mm dilations of the planning structures, including the target and organs-at-risk. Hierarchical collimator optimization starts with cones for shot locations and migrations followed by sector durations. Though not limited to, the optimization is primarily based on linear programming for its simplicity and effectiveness in sparse solution. We tested this framework using 12 AVM clinical cases retrospectively. **Results:** The KD dose had Gamma Index (2%/2 mm) passing rates of 99% compared with Monte Carlo calculation for the studied cases and linear complexity that calculated shot dose in sub seconds. The sampling strategy further reduced the complexity compared to using the whole ROI without losing its representation. Hierarchical collimator optimization sped up the convergence and completed in few seconds. Compared to the clinical plans, the optimized plans by this framework on average had improved coverage (96% $>100\%$), selectivity (62% $>78\%$), homogeneity (1.99 >1.62), gradient index (5.42 >3.78), and radiation time (59min $>55\text{min}$). **Conclusion:** The proposed framework addresses multiple fundamental aspects in GK optimization for efficient and quality treatment planning.

Assessing the Practicality of Using a Single KBP Model for Multiple Linac Vendors

R Douglas*, A Olanrewaju, L Zhang, L Court, University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: To evaluate the effectiveness of a commercial knowledge-based planning (KBP) tool by applying a single KBP model to three treatment machines with different beam and MLC characteristics (Varian C-arm, Varian Halcyon and Elekta Versa HD). **Methods:** A RapidPlan model for head-neck VMAT treatments was developed and finetuned for a Varian 2100 linac. For fifty retrospective head-neck patients, we generated three sets of VMAT plans using an automated treatment planning system (Radiation Planning Assistant). Each plan used a different treatment machine: Varian 2100, Elekta Versa HD, and Varian Halcyon. The Varian 2100 plans were reviewed by radiation oncologists in a separate study. For each patient, we calculated the dosimetric differences (Versa or Halcyon minus Varian 2100) between each plan. We also calculated the percentage of plans that meet established clinical dosimetric recommendations for normal and planning structures. **Results:** The mean differences from our Varian 2100 plan for brainstem (D_{max}), contralateral parotid (D_{mean}), ipsilateral parotid (D_{mean}) and spinal cord (D_{max}) were $0.76 \pm 1.57\text{Gy}$, $0.46 \pm 0.59\text{Gy}$, $0.53 \pm 0.44\text{Gy}$, $0.80 \pm 1.1\text{Gy}$, respectively for the Versa plans; and $0.46 \pm 3.46\text{Gy}$, $-0.45 \pm 0.59\text{Gy}$, $-0.34 \pm 0.49\text{Gy}$, $-0.14 \pm 1.24\text{Gy}$, respectively for the Halcyon plans. The mean difference in high dose PTV coverage were less than 3% for prescription dose ($V100\%$) and hotspots ($V105\%$ and $V110\%$). 100% of plans for all machines met the clinical dosimetric recommendations for brainstem ($D_{\text{max}} < 54\text{Gy}$), spinal cord ($D_{\text{max}} < 45\text{Gy}$) and high dose PTV ($V95\% > 95\%$). For contralateral parotid, 41 Varian 2100 plans met recommendation ($D_{\text{mean}} < 26\text{Gy}$), compared to 41 Versa and 40 Halcyon plans. For ipsilateral parotid, 23 Varian 2100 plans met recommendation, compared to 20 Versa and 25 Halcyon plans. **Conclusion:** We successfully applied a single RapidPlan model to generate comparable plans across three different treatment machines with different beam and MLC characteristics. This supports the use of head-neck RapidPlan models in centralized planning workflows that support clinics with different linac models/vendors.

Landmark-Based Field Aperture Generation for Automatic Whole-Brain Radiation Planning

Y Xiao^{1*}, D Rhee¹, T Netherton¹, L Zhang¹, A Aggarwal², C Trauernicht³, H Simonds³, L Court¹, C Cardenas¹, (1) MD Anderson Cancer Center, Houston, TX, (2) King's College London, London, UK, (3) Stellenbosch University, Cape Town, South Africa

Purpose: To develop and compare two landmark-based approaches for automatic whole-brain treatment planning that can be configured to suit local clinical practices. **Methods:** Field apertures for both approaches used landmarks based on organ contours seen in beams-eye-view digitally reconstructed radiographs (DRRs), with the relationship between the landmarks and field borders configurable to suit local clinical practice. For Approach 1, a previously trained deep learning model was used to create contours on CT scans, and these contours were projected onto DRRs. For Approach 2, organ contours were directly segmented on DRRs using a deep learning model trained/validated/tested using 724/182/224 patients. Field apertures were then created using the DRR contours from both approaches and compared with manually outlined field apertures using Hausdorff Distance (HD) and Mean Surface Distance (MSD). Additionally, quality assurance for the contours on DRRs from Approach 1 and 2 were compared using Dice-Similarity-Coefficient (DSC). In total, eight landmark-based rules consisting of anterior, carinal, posterior, caudal, and anterior-caudal bounds were applied, and five setting options included selecting vertebral bodies, anterior-caudal bound shapes, and extent of brain expansion and skin flash were provided for creating field aperture variations. **Results:** The average DSC of organ contours segmented on DRRs regarding brain, eyes, lens, C1, and C2 were 0.97 ± 0.01 , 0.88 ± 0.05 , 0.55 ± 0.18 , 0.89 ± 0.04 , and 0.87 ± 0.07 , respectively. The performance of the generated field apertures from a single configuration in terms of the average HD and MSD for Approach 1 resulted in 16.43 ± 6.95 and 11.63 ± 7.26 mm, respectively, and 16.93 ± 6.87 and 12.18 ± 6.92 mm for Approach 2. **Conclusion:** We have developed and tested two landmark-based methods to define whole-brain field apertures. Both gave similar results compared to the manually outlined field apertures. The flexible configuration for creating field aperture variations also provided flexibility in adapting this traditional treatment approach to local clinical practices.

Toward Semi-Automatic Biologically Effective Dose Treatment Planning for Gamma Knife Radiosurgery

T Klinge^{1,2,3*}, H Talbot⁴, I Paddick⁵, S Ourselin³, J McClelland², M Modat³, (1) Wellcome/EPSRC Centre for Interventional and Surgical Sciences, University College London, London, GB (2) Centre for Medical Image Computing, University College London, London, GB (3) School of Biomedical Engineering & Imaging Sciences, King's College London, London, GB (4) CentraleSupélec, Université Paris-Saclay, Gif-sur-Yvette, FR (5) Queen Square Gamma Knife Centre, National Hospital for Neurology and Neurosurgery, London, GB

Purpose: Gamma Knife (GK) radiosurgery treatments exhibit considerable variations in treatment times, influencing the delivered radiation's biological effectiveness. We investigate the feasibility of generating semi-automated treatment plans based on the biologically effective dose (BED) to tackle this issue. We thus create high-quality iso-effective treatment plans through the optimisation of per iso-centre beam-on times and delivery sequence. **Methods:** Using a BED model considering bi-exponential repair during treatment delivery leads to a non-convex optimisation problem, and optimising the shot order poses a combinatorial problem. Therefore, we implemented two optimisation algorithms. One accurate but slow, based on mixed-integer linear programming (MILP) using a purposely developed convex under-estimator for the BED. The other utilising two established local methods (L-BFGS-B and an adapted 2-opt) alternatively, significantly faster but more prone to local minima issues. We evaluated the post-optimisation results to determine if the more rapid approaches could produce results close to those from the more demanding MILP approach. The different approaches were executed on 14 cases of Vestibular Schwannoma, using the iso-centre configurations from the original physical dose treatment plans and using a 60 min treatment as a BED reference. **Results:** In terms of the final objective function values, the faster optimisations came within 1.2% (0.02-2.08%) of the convex MILP approach while requiring significantly less computation time (minutes vs hours-days). The issue of reduced biological effectiveness with increasing treatment times, which was evident in the initial BED95 values, was resolved by the BED optimisations. Overall, the Paddick Conformity Index (PCI) for the BED distribution was improved, both in average and range, from initially 0.81 (0.58-0.9) to 0.88 (0.78-0.93) with negligible differences between the optimisation approaches. **Conclusion:** We demonstrate the feasibility of efficient BED-based treatment planning to ensure iso-effective treatments across varying treatment times and highlight the prospect of further improvements in treatment plan quality.

Knowledge-Based Cardiac Sparing Treatment Planning for Lung Radiotherapy

J Harms*, J Zhang, O Kayode, J Wolf, S Tian, N McCall, K Higgins, R Castillo, X Yang, Winship Cancer Institute of Emory University, Atlanta, GA

Purpose: High radiation doses to the heart are correlated with poor overall survival in radiotherapy patients with stage III non-small cell lung cancer (NSCLC). Cardiac sparing is an optimization goal of all lung treatment plans, but optimization based on the whole heart has limitations. Optimization of treatment plans using cardiac substructures can reduce cardiac dose, but is not feasible in most clinics due to the extra time needed for planning. This study builds a knowledge-based cardiac sparing planning (KBCSP) model for cardiac dose reduction using a set of treatment plans for patients with stage III NSCLC. **Methods:** Cardiac substructures were delineated for 33 patients and treatment plans were re-optimized to reduce dose to substructures and the heart. A KBCSP model was developed from these plans using target volumes and organs-at-risk (OARs) including the heart but excluding substructures. To test the model's efficacy for cardiac dose reduction, a second KBP model was trained from the same 33 patients, using the original clinical treatment plans. Both models were evaluated in a cohort of 30 separate stage III NSCLC patients. **Results:** Both models produced acceptable target coverage, dose uniformity, and dose to OARs. Compared to the KBP-based plans, KBCSP-based plans showed significant reductions in mean dose to the esophagus and lungs while performing similar or better in all evaluated heart dose metrics. Compared to the clinical KBP model, the KBCSP model showed reduced ($p < 0.05$) heart mean and maximum doses, as well as volumes receiving 60 Gy, 50 Gy, and 30 Gy. **Conclusion:** The KBCSP model successfully captured the cardiac-sparing expertise and improved plan quality for patients in a validation cohort. This KBCSP model offers an automated approach to reduced cardiac dose without explicit delineation of cardiac substructures, which may reduce heart toxicity and improve overall survival in radiotherapy patients with NSCLC.

Deep Learning-Based Dosimetric Plan Quality Assessment for Prostate Radiotherapy

Y Nomura*, C Huang, Y Yang, N Kovalchuk, M Surucu, M Buyyounouski, L Xing, Stanford University, Stanford, CA

Purpose: This study developed a novel dosimetric plan quality evaluation method for prostate radiotherapy using a multivariate deep neural network (DNN). **Methods:** First, 60 prostate CT images with segmented contours of planning target volume (PTV), clinical target volume (CTV) and organs at risk (OARs)

were collected. These were divided into 48 patients for training of a DNN model, 6 for validation, and 6 for testing, respectively. Second, intensity-modulated radiation therapy (IMRT) dose distributions were calculated for each patient from seven equally spaced photon beams. Dose-volume histograms (DVHs) of PTV, CTV and OARs and homogeneity index (HI), conformity number (CN), dose coverage index (DCI) and gradient index (GI) of PTV were calculated for each dose distribution. Third, reference quality of the dose distributions was manually assessed by a treatment planner who had access to volumetric CT images, dose distributions and DVHs. Moreover, an in-house plan quality metric (PQM) technique was applied to calculate analytical dosimetric plan quality values. Finally, a multivariate DNN model was generated to predict PQM or the manual plan quality by using HI, CN, DCI, GI and DVHs as inputs. For evaluation, the DNN-calculated qualities of test data were compared with actual plan quality values. **Results:** The DNN model estimates PQM and the manual quality values accurately. Averaged relative absolute error and its standard deviation over all test data were less than 4.00% for both PQM and the manual plan quality values. Computation time for calculating one quality value is 0.03 seconds with a single GPU. **Conclusion:** A novel dosimetric plan quality assessment method was established using a multivariate DNN. This technique can predict, as a “virtual” planner, plan qualities calculated from multiple assessment methods with high accuracy. This method will be useful for DNN-assisted treatment planning to improve treatment plans and reduce inter-planner quality variation.

Development of a Framework to Assess Robustness of Dynamic Trajectory Treatment Plans

H A Loebner^{1*}, W Volken¹, S Mueller¹, J Bertholet¹, P-H Mackeprang¹, G Guyer¹, D M Aebersold¹, M F M Stampanoni², P Manser¹, M K Fix¹, (1) Division of Medical Radiation Physics and Department of Radiation Oncology, Inselspital, Bern University Hospital, and University of Bern, Bern, Switzerland, (2) Institute for Biomedical Engineering, ETH Zurich and PSI, Villigen, Switzerland

Purpose: To develop a flexible Monte Carlo (MC) based robustness calculation and evaluation framework to assess treatment plan robustness of dynamic trajectory radiotherapy (DTRT, extending VMAT by dynamic table and collimator rotation) treatment plans, by exploring the impact of uncertainties in patient setup and mechanical accuracy of machine components on the dose distribution. Additionally, a novel robustness index (RI) is defined, with the aim to condense the dosimetric robustness against multiple error scenarios (ESs) into one number. **Methods:** An in-house MC based dose calculation framework is extended to assess robustness of treatment plans. This extension allows to automatically start dose calculations for user-defined ESs. Each ES can be a combination of patient setup uncertainties and of the following machine components: Angles of gantry, collimator, table-yaw, table-pitch and table-roll and positions of jaws, MLC banks and single MLC leaves. The framework allows the simultaneous evaluation of the ESs on a GUI according to user-specified dosimetric criteria such as D2%, mean dose, gamma analysis or dose difference to the nominal dose distribution (no error). The RI is defined by the fraction of ESs passing the previously defined DVH/Gamma criteria. The application of the framework is demonstrated on a DTRT plan for a nasopharynx case. **Results:** The DTRT plan is evaluated for combinations of systematic errors in gantry, collimator and table angle between -4° and +4°. Robustness criteria of >90% Gamma-passing-rate (2%/2mm evaluated on CTV) lead to a RI 64.1%; and <1 Gy deterioration of D2% and D98% (of CTV) to RI 99.7%. **Conclusion:** The extended framework was successfully implemented and demonstrated on a DTRT plan. Effects of uncertainties in patient setup and mechanical accuracy of machine components on the dose distribution can be evaluated in a user-friendly GUI to assess treatment plan robustness. Automatic Stent Recognition Using Deep Neural Network for Quantitative Intra-Fractional Motion Monitoring in Pancreatic Cancer Radiotherapy

X He^{*}, W Cai, F Li, P Zhang, L Cervino, T Li, X Li, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: Stent has been often used as an internal surrogate to monitor intra-fractional tumor motion during pancreatic cancer radiotherapy. Based on the stent contours generated from planning CT images, current intrafraction motion review (IMR) system on Varian TrueBeam only provide a tool to verify the stent motion but lack of quantitative information visually. The purpose of this study is to develop an automatic stent recognition method for quantitative intra-fractional tumor motion monitoring in pancreas cancer treatment. **Methods:** 466 IMR images from 11 pancreatic cancer patients were retrospectively selected in this study, with the manual contour of the stent on each image served as the ground truth. An objective attention modeling mechanism was integrated into the U-net framework to deal with the optimization difficulties when training a deep network with 2D kV IMR images and limited training data. For supervision, we used the binary cross-entropy loss combined with a Dice loss for training. The deep neural network was trained to capture more contextual information to predict binary stent masks. 68% of 466 images were randomly selected for training (85%, 269 images) and validation (15%, 47 images), while the rest (150 images) were used for testing. **Results:** Our stent segmentation results were compared with the manually segmented contours. The trained model achieved a detection rate of 93%. The mean stent Dice similarity coefficient (DSC), 95% Hausdorff distance (HD95), 2D mean surface distance (MSD), and residual mean square distance (RMSD) were 0.91 ± 0.08 , 1.12 ± 1.84 mm, 0.26 ± 0.43 mm, and 0.38 ± 0.59 mm, respectively. **Conclusion:** We developed a novel deep learning-based approach to segment the stent from kV IMR images automatically, demonstrated its clinical feasibility, and validated its accuracy compared to manual segmentation. The proposed technique could be a useful tool for quantitative intra-fractional motion monitoring in pancreatic cancer radiotherapy.

Dual-Energy Real-Time Stereoscopic X-Ray Image Guidance for Markerless Lung Tumor Tracking

C Peacock, M Sattarivand^{*}, Nova Scotia Health Authority

Purpose: The purpose of this work is to develop real-time markerless tracking of lung tumors during patient free-breathing, guided by stereoscopic dual energy (DE) x-ray imaging. **Methods:** Incremental and motorized motion stages were designed and used to simulate lung tumor respiratory motion within an anthropomorphic phantom. A set of tumor motion experiments were performed using spherical tumor models with diameters ranging from 6.4 to 25.4 mm. A series of stereoscopic high (140 kVp) and low (60 kVp) energy x-ray images of the phantom were acquired with the moving tumor insert using the ExacTrac stereoscopic imaging system (Brainlab AG, Germany). The high and low energy images were combined by weighted log subtraction to create stereoscopic DE images. Conventional stereoscopic single energy (SE) (120 kVp) images were also acquired for comparison. Digitally reconstructed radiographs (DRRs) were calculated from tumor-only volumes within CT images of the phantom, and tumor templates were cropped from these DRRs. Normalized template-image cross correlation and stereoscopic triangulation were used to calculate the 3D tumor positions from stereoscopic image pairs, which were compared to a ground truth from known tumor locations and the accuracy, precision and success rate of localization were calculated. **Results:** The success rate of tumor localization using DE imaging was consistently higher than that of the SE technique for both incremental and dynamic motion experiments with most dramatic improvement for the smaller tumors (<20mm). The accuracy of tumor localization using the DE technique was generally sub-millimeter (range 0.53 - 1.10 mm). **Conclusion:** DE stereoscopic imaging outperforms the SE technique to localize lung tumors in real-time particularly for smaller tumors. With some alterations to existing stereoscopic image guidance systems, markerless lung tumor tracking would be feasible.

This work was supported by the ACOA (Atlantic Canada Opportunities Agency) Atlantic Innovation Fund.

Implementation of High-Quality Motion-Compensated Simultaneous Algebraic Reconstruction Technique (mc-SART) Cone-Beam CT (CBCT) Imaging Using the 5D Model in a Prospective Patient Study

K Singharo^{1*}, D O'Connell¹, J Fu¹, M Lauria¹, B Stiehl¹, A Raldow¹, J Hegde¹, A Lee¹, A Santhanam¹, D Low¹, J Lewis², (1) Dept. of Radiation Oncology, University of California, Los Angeles, Los Angeles, CA, (2) Dept. of Radiation Oncology, Cedars-Sinai Medical Center, Los Angeles, CA

Purpose: Clinically used pre-treatment imaging methods for external-beam radiotherapy of lung cancer such as 3D/4D-based CBCT imaging can result in low quality images. Here, we implement a novel 5D-model-based motion-compensated simultaneous algebraic reconstruction technique (mc-SART) method to create a patient- and treatment-day-specific volumetric image and motion model from free-breathing cone-beam projections and respiratory surrogate measurements. **Methods:** Four lung cancer patients receiving external beam radiotherapy were prospectively enrolled in this study. Patient-specific breathing traces were recorded using an in-house respiratory monitoring system. Raw CBCT projections were saved after a single fraction for each patient. CBCT projections were sorted into 8 bins based on breathing amplitude and flow. The mc-SART framework involves creating an initial reference image and motion model, and then iteratively improving them using a modified version of SART. The initial reference image was defined using a reconstructed SART image from end exhale/zero flow projections. The motion model was created using deformable image registration between the reconstructed bins and least squares fitting to the 5D model parameters. The initial reference image was deformed to a particular amplitude and flow and a modified version of SART was applied to include motion compensation. The model output is a volumetric reference image and a motion model that can be used to generate volumetric images at any other time point from breathing traces. **Results:** Signal-to-noise-ratio (SNR) measurements were performed in soft tissue and lung regions for FDK-reconstructed, 4D-SART and mc-SART reference images. The soft tissue and lung SNR measurements for mc-SART images was 160% and 28% greater than FDK-reconstructed image and, 26% and 43% greater than 4D-SART reconstructed images. **Conclusion:** We have developed a method to create a high-quality motion-compensated reference image and motion model with real patient data. This framework opens up the possibility of creating model-based volumetric images during treatment delivery.

One-Second into the Future: A Deep Learning Method to Predict 3D Lung Cancer Target Motion to Account for Adaptation Latency

Q Hoang¹, J Booth², V Caillet^{2,3}, P Keall³, D Nguyen^{2,3,4*}, (1) School of Biomedical Engineering, University of Sydney, Camperdown, Australia, (2) Royal North Shore Hospital, Sydney, NSW, AU, (3) ACRF Image X Institute University of Sydney, Camperdown, NSW, Australia, (4) University of Technology Sydney, Ultimo, NSW, AU

Purpose: To develop an intrafraction 3D motion prediction algorithm to compensate for latency of up to one second between motion observation and adaptation in real-time IGRT systems. The AAPM TG264 recommended an end-to-end latency of less than 0.5 seconds for MLC tracking for real-time adaptation of intrafraction motion. This is hard to achieve when current real-time imaging systems has 200-500 ms between images (MRI linac, Varian and Elekta intrafraction fluoroscopy), hence the need for motion prediction. **Methods:** A motion prediction system based on a Long-Short-Term-Memory (LSTM) network topology for signal forecasting was developed. A separate network was trained for each motion axes of Left-Right (LR), Superior-Inferior (SI) and Anterior-Posterior (AP). Intrafraction motion acquired with Calypso from 7 lung cancer was used. Each patient received either 4 for 5 fractions, resulting in 29 fractions and 15 hours of recording in total. The network was trained with two different training configurations: with 2-minutes and 4-minutes of motion for each patient. The LSTM weights were updated when a new target position was observed. The prediction interval values addressed were 0.5s and 1s. The neural network's prediction was compared against the actual motion. **Results:** With 2-minutes training, the prediction error was 0.04 ± 1.13 mm, 0.02 ± 1.18 mm and -0.05 ± 1.28 mm for 0.5s prediction and -0.05 ± 1.12 , 0.04 ± 1.27 mm and -0.05 ± 1.30 mm for 1s prediction in LR, SI and AP, respectively. The error reduced when the training data increases to 4 minutes for both 0.5s and 1s prediction. The root-mean-square-error was <1 mm for all motion axes. The range of motion in the tested patient database was $[-8.3, 11.3]$ mm, $[-34.8, 7.7]$ mm and $[-16.1, 9.3]$ mm in LR, SI and AP. **Conclusion:** A deep learning prediction algorithm was developed and tested for 3D lung tumour motion. Up to 1 second forecasting was achieved with sub-mm accuracy, enabling compensation of latency in motion adaptation systems in real-time.

BEST IN PHYSICS (MULTI-DISCIPLINARY): Real-Time Dose-Optimized Multi-Target MLC Tracking for Locally Advanced Prostate Cancer

E Hewson^{1*}, D Nguyen^{1,2,3}, J Booth^{3,4}, P Keall¹, L Mejnertsen¹, (1) ACRF Image X Institute, University of Sydney School of Health Sciences, Sydney, NSW, AU, (2) School of Biomedical Engineering, University of Technology Sydney, NSW, AU, (3) Northern Sydney Cancer Centre, Royal North Shore Hospital, Sydney, NSW, AU, (4) School of Physics, University of Sydney, Sydney, NSW, AU

Purpose: The accuracy of radiotherapy for patients with locally advanced cancer is compromised by independent motion of multiple tumors. Multi-target MLC tracking has been developed to adapt to multiple targets in real time. However, geometrically adapting the MLC aperture to target motion by directly translating the planned aperture results in sub-optimal delivered dose. It was hypothesized that optimizing multi-target MLC tracking based on accumulated dose would reduce dosimetric errors compared to geometric-based multi-target tracking for locally advanced prostate cancer. **Methods:** A dose-optimized multi-target tracking algorithm that adapts the MLC aperture to correct for dosimetric error was developed for moving prostate and static lymph node targets. The dose-optimized algorithm accumulated the planned dose to the prostate and lymph node PTVs during treatment and shifted the prostate dose volume in the direction of motion. The adapted MLC apertures were calculated to minimize the difference between the planned and delivered doses accumulated up to that point. This algorithm was evaluated by simulating three locally advanced prostate cancer VMAT plans and three prostate motion traces with a relative interfraction displacement. The performance of dose-optimized multi-target tracking was compared to geometric-based multi-target tracking and no tracking using a 3D gamma comparison between delivered and planned doses with a 2%/2 mm pass criterion. **Results:** The mean gamma-failure rate was lowest for dose-optimized tracking, with $11.2 \pm 3.7\%$ for the prostate and $0.6 \pm 0.4\%$ for the nodes. The gamma-failure rate for geometric-based tracking was $24.4 \pm 7.0\%$ for the prostate and $0.8 \pm 0.8\%$ for the nodes. When no tracking was used, the gamma-failure rate was $34.0 \pm 15.6\%$ for the prostate and $21.7 \pm 1.8\%$ for the nodes. **Conclusion:** This study developed a dose-optimized multi-target tracking method that can correct for dosimetric deviations during treatment for locally advanced prostate cancer. Dose-optimized tracking reduced error compared to geometric-based tracking and no tracking for both the prostate and nodes.

Synthesizing Real-Time In-Treatment 4D Images Based on Optical Surface Signals and Pre-Treatment Images: A Proof-Of-Concept Study

Y Huang*, Y Zhang, Peking University Cancer Hospital & Institute, Beijing, CN

Purpose: To propose a proof-of-concept solution to real-time virtual visualization of target-in-motion based on in-treatment optical surface signals and pre-treatment images. A deep learning model was developed and validated to map body surface displacement to internal anatomy deformation. **Methods:** Body contours of 4DCT were segmented to simulate optical surface. Free-form deformable-image-registration (DIR) algorithm with isotropic variation regularization was used to register the end-of-exhalation (EOE) phase to other phases. Dimension of deformation vector field was reduced to the first two principal components (PC). A simple neural network composed of convolutional and fully connection layers was trained to predict the two PC scores of each phase from surface displacement with respect to EOE surface. The instant deformation field was reconstructed and used to warp EOE images to obtain real-time CT images. The approach was tested on three schemes: (1) Different respirations of 4D-XCAT digital phantom mimicking pre-treatment (training) and in-treatment motions respectively. (2-3) 4DCT images with annotated landmarks (5 patients) and with physician-delineated tumor contours (5 patients) from public DIR-Lab and TCIA 4D-Lung dataset respectively. The EOE-to-EOI (end-of-inhalation) pairs were excluded in training but used for validation. **Results:** Due to the relatively low complexity of respiration motion, the highest validation accuracy of tumor centroid trajectory ($0.04\text{mm} \pm 0.02\text{mm}$) was observed on XCAT phantom. For the 300 landmarks annotated on EOI images of DIR-Lab, the mean displacements between their predicted and reference positions were 1.05mm, 0.88mm, 1.18mm, 1.72mm and 1.53mm for the 5 patients respectively. The DICE-coefficients between predicted and reference tumor contours at EOI phase were 0.92, 0.84, 0.93, 0.85 and 0.71 respectively for the 5 patients from TCIA 4D-Lung dataset. **Conclusion:** The preliminary experiment displayed close relationship between surface geometry and internal anatomy, demonstrating the potential of using deep learning model to synthesize real-time 4D images out of in-treatment dose-free surface signals.

Evaluating the Clinical Impact and Accuracy of Real-Time KV Imaging in Liver SBRT

A Santoso^{1*}, Y Vinogradskiy¹, T Robin¹, K Goodman², T Scheffter¹, M Miften¹, B Jones¹, (1) University of Colorado Anschutz Medical Campus, Aurora, CO, (2) Mount Sinai, New York, NY

Purpose: In liver SBRT, high dose gradients and tumor motion make it challenging to accurately deliver dose. Real-time tumor tracking using on-board kV imaging can address intrafraction positional errors online. The purpose of this study was to evaluate the impact of real-time kV imaging on the delivery and accuracy of liver SBRT in a retrospective patient cohort. **Methods:** 33 patients treated with 41 courses of liver SBRT on a conventional linac were retrospectively analyzed. Patients were treated in 3-5 fractions with 6-18 Gy/fx, and kV images were acquired every 20° at the start of and during arc-based treatment to visualize the location of implanted fiducial markers as surrogate for tumor position. Corrections were made if markers were >3 mm from the expected reference position. Treatment interruptions and corrections were recorded from each fraction and the average interruption rate was calculated for each patient. Statistical analysis was performed using multiway ANOVA to evaluate interruption rate as a function of gating, compression, number of implanted fiducial markers, treatment time, and PTV volume. The elapsed time of pauses and shifts was recorded as well as the magnitude of shifts. **Results:** Treatment interruptions occurred at a rate of 0.69 per fraction. Gating threshold adjustment and patient re-alignment shifts occurred in 61% and 39% of interruptions, respectively. The interruption rate was significantly higher in patients with longer treatment times ($p < 0.01$). Average time per interruption was 1.9 ± 1.6 minutes. No significant difference was observed in the elapsed time for gating adjustment and re-alignment shifts. Median shifts for patient re-alignment were 1.4 mm (AP), 4.0 mm (SI), and 1.2 mm (LR). The median radial (3D) shift was 5.7 mm. **Conclusion:** Real-time imaging can correct for significant intrafraction positional errors with relatively minimal clinical impact and ensures accurate dose delivery in liver SBRT.

Convolutional Neural Network Based Fully Automatic Lesion Localization in Rectal Cancer

Y Zhang^{1*}, L Shi², X Sun², S Jabbour¹, N Yue¹, K Nie¹, (1) Rutgers Cancer Institute of New Jersey, New Brunswick, NJ, (2) Department of Radiation Oncology, Sir Run Run Shaw Hospital, Zhejiang Univ., Hangzhou, China

Purpose: To implement deep learning methodology involved in multi-modalities MRI imaging, to fully automatically localize and segment rectal tumors. **Methods:** A total of 54 patients with stage T3 and T4 colorectal cancer were studied. The imaging protocol included T2w, T1w DCE and DWI. All images were reviewed by a single experienced oncologist specialized in rectal MRI. Tumors were outlined as a region of interest (ROI) on the third-phase of DCE. As input to the neural network architecture, we choose image patches with size of 21x21 pixels which locate at the same position on one slice from all frames. Using these patches, a 7 layer Convolutional Neural Network(CNN) was established to test whether the middle of the patch belong to the ROI. The output can be interpreted as the probability that the central pixel in the input image patch is associated with a tumor. Five-fold cross-validation was used to evaluate the performance of the CNN classifier. For the training process, a large number of batches were employed and extracted from different areas inside and outside ROIs. For the validation set, all of the image pixels were tested in the trained network architecture to determine whether each pixel belongs to the ROI areas. **Results:** To evaluate the performance of the segmentation, the Dice Similarity Coefficient (DSC) was used to compare the results of the proposed algorithm and the ROI outlined by reader. Among all 54 patients, the mean of DSC is 0.76. **Conclusion:** Based on the results, CNN can be utilized to develop a rectal cancer segmentation method. This can provide helpful information for rectal cancer patients to assess their risk more accurately to choose an optimal strategy when designing radiation therapy planning.

Optimized Image Segmentation with An Interpretation Method

Z Chen¹, X Qi², S Tan^{1*}, (1) Huazhong University of Science and Technology, Wuhan, China, (2) UCLA School of Medicine, Los Angeles, CA

Purpose: A common challenge of deep-learning-based interactive segmentation methods is the need of retraining the original network after user's clicks. The retraining process is computationally expensive, and the labels that the user provides can be easily down-weighted during retraining, leading to inaccurate segmentation results. In this study, we propose a novel interactive method, instead of performing optimization over the weights of a neural network, to optimize the activation in the intermediate layer. Meanwhile, we introduce the gradient-based network interpretation method to guide our optimization. **Methods:** We use two types of operations to optimize the activation, namely Activation Replacement and Activation Reparameterization. We adopt the gradient-based interpretation method to find the spatial regions and feature channels in the activation that are associated with the target category. We replace the activation value in these spatial regions with the feature value corresponding to the category (called Activation Replacement). Besides, we introduce channel-wise scaling and bias to these associated feature channels as auxiliary parameters. The auxiliary parameters are optimized by the backpropagating refinement scheme (called Activation Reparameterization). Finally, we obtain the segmentation mask of the target object by updating the activation and performing the forward inference process again. The performance is evaluated over 120 MRI sequences for liver, kidney, and spleen segmentation. **Results:** We use the deep object selection (DOS) algorithm as the baseline, which is a conventional deep-learning-based method. The performance of the interactive segmentation algorithms is evaluated by the Number of Clicks when the segmentation mask achieves 90% IOU over the ground truth (NoC@90). The average NoC@90 scores are 3.20 and 5.60 for our proposed method and the DOS respectively. **Conclusion:** We propose an interactive segmentation algorithm by performing optimization over the activation in the intermediate layer. Experimental results suggest satisfactory performance achieved using our method, compared with the baseline.

Self-Supervised Deep Learning in the Assessment of Enteral Feeding Tube Positioning Based on A Small Dataset

G Liang^{1*}, D Steffey², H Ganesh³, J Zhang⁴, (1) Eastern Kentucky University, (2) University of Kentucky, (3) University of Kentucky, (4) University of Kentucky, Lexington, KY

Purpose: Enteral nutrition (EN) through feeding tubes serves as the primary method of nutritional supplementation for critically ill patients unable to feed themselves. The position of the Nasoenteric feeding tubes is routinely confirmed by plain radiographs after insertion and before the commencement of tube feeds. This work uses a self-supervised training strategy to improve the DCNN performance on an extremely small dataset. **Methods:** A self-supervised pre-training strategy called Comparing to Learn (C2L) was used as the backbone of our EN position DCNN model, which included a batch-level mix-up method for data augmentation and a novel teacher-student network for feature learning. The plain abdominal radiographs of 100 patients were retrospectively retrieved and used in this study. The images were resized to 256x256 and equally split into five folds for five-fold cross-validation. Different windows of pixel values (0-4095) were tested. Nine DCNN architecture were investigated. In total, over 100 models were trained and evaluated. Each model was trained five times. The accuracy and area under the receiver operating characteristic (ROC) curve (AUC) on the test data were used to assess the models. The ground-truth classification for enteric feeding tube positions was performed by a board-certified abdominal radiologist. **Results:** The preliminary results show that, by including a self-supervised pre-training strategy, DL provides an encouraging solution in the binary classification of the appropriate tube positioning vs. wrong positioning based on the extremely small dataset with an accuracy of 0.76 (95% CI 0.75-0.77) and AUC of 0.73 (95% CI 0.72-0.74), which is also an over 7% improvement of accuracy and over 5% improvement of AUC compared with the ImageNet pre-trained weights. Windowing setting (0-2750) helps improve the performance of DL models. **Conclusion:** Self-supervised DL based on a small dataset demonstrates promise in the assessment of appropriate vs inappropriate EN feeding tube placements.

Wavelet U-Net: Incorporating Wavelet Transform Into U-Net for Liver Segmentation

J Chang*, C Chang, California Protons Cancer Therapy Center / UCSD, San Diego, CA

Purpose: To incorporate the concept of wavelet transform into the U-net for the organ segmentation. The segmentation of organs in CT images is a crucial part of the overall treatment planning process in radiation oncology. While many automation packages, both atlas- and deep learning-based, are becoming available recently, current clinical practice for both organ-at-risks (OARs) and targets still relies almost entirely on human inputs. Here we incorporated the wavelet's multi-level spatially encoding characteristics into the U-net, and examined the clinical performance of the resultant automated segmentation system. **Methods:** A total of 50 liver cases are anonymized for this study. The liver contours are manually delineated in each case. Forty (40) cases are used for training, and ten (10) are reserved for validation. Dual-tree complex wavelet transform(DTCWT) are used in the deep learning U-net model. DTCWT provides multiresolution and sparse representation properties into the structure of an image. The deep convolution model provides the hierarchical structure to extract information from different feature levels. Similar to traditional U-Nets, we attempt to preserve information flow and details by interchanging maxpooling layers with discrete wavelet transformation and upsampling layers with inverse wavelet transformations. **Results:** The segmentation mask of the liver is generated by feeding CT images into the wavelet U-Net. Evaluation of the wavelet U-Net image segmentation model is done with dice and pixel-wise accuracy. The model achieved a dice score of 0.896 and the pixel-wise accuracy of 0.83% in the validation dataset. This model is found to have achieved comparable results as currently available commercial packages. Further adjustments of the model parameters are in progress and can potentially improve its performance. **Conclusion:** This Wavelet U-Net can currently be used as an automated quality assurance tool for commercial packages. Further development is in progress to extend its capability to segmenting liver targets.

Multi-Frequency-Based CXR Data Normalization for Deep-Neural-Network Classifier

H Kim*, KAIST, Daejeon, KR, W Sim, Radisen, Seoul, KR, D Cho, Radisen, Seoul, KR, S Cho, KAIST, Daejeon, KR

Purpose: While deep-neural-network (DNN) classifiers have arisen as promising tools showing state-of-the-art performances for detecting abnormalities in chest x-ray (CXR), one of the challenging problems that hampers the networks' performance is the data heterogeneity originated from a variety of sources such as devices, scan conditions, and image processing algorithms. We investigate the effect of a multi-frequency-based data normalization technique for the DNN-based diagnosis. **Methods:** The reference data set consists of hundreds of normal and abnormal CXR images collected from a single hospital. Each CXR image has been decomposed into various frequency bands by use of the Gaussian-Laplacian pyramids technique. We calculated five levels of Laplacian pyramids. Then, five images at the Laplacian pyramids and the highest level image at the Gaussian pyramids were used for data normalization. We calculated the standard deviation value of each frequency band image. The average value of the Gaussian pyramid image was calculated as well. After that, we set the reference values at each frequency band by averaging calculated values. Each image in the reference database has been normalized iteratively to meet a convergence condition. We trained a DNN classifier with the normalized reference dataset. In the testing phase, we collected another CXR database that has different frequency characteristics. We normalized the test dataset in the same way. **Results:** The inference of the non-reference dataset using the trained network combined with the data normalization resulted in an average precision score about 20% higher than that of the other trained network without data normalization. **Conclusion:** We have developed a multiscale data normalization algorithm to increase the performance of the deep-neural-network classifier. Our study is believed to play an important role in developing many DNN CXR classifiers.

Autosegmentation of Videofluoroscopic Swallow Studies Using U-Net for Improved Analysis of Radiation Induced Dysphagia in Head and Neck Cancer Patients

N Shaheen^{1*}, R Pena-Chavez², C Ulmschneider³, R Burdick^{2,4}, J Yee^{4,5}, A Kurosu⁶, N Rogus-Pulia^{2,4,5}, B Bednarz¹, (1)Department of Medical Physics, University of Wisconsin - Madison(2) Department of Communication Sciences and Disorders, University of Wisconsin - Madison(3) Department of Surgery, University of Wisconsin - Madison(4) Department of Medicine, University of Wisconsin - Madison(5) Geriatric Research Education and Clinical Center, William S. Middleton Memorial Veterans Hospital Madison, WI

Purpose: Radiation induced dysphagia is a common complication from head and neck cancer (HNC) treatment. Dysphagic patients will experience malnutrition and a large increased risk for aspiration pneumonia, leading to future hospitalizations. Current dysphagia diagnosis and treatment requires extensive manual analysis of a videofluoroscopic swallow study (VFS). Current methods are time consuming and solely qualitative. This work develops an auto segmentation algorithm for assisted analysis of VFS and further implementation of automated quantitative measures. **Methods:** 40 VFS were collected from a varying severity dysphagic cohort. Shielded edges of the images and non-swallowing related motion were cropped. Images were standardized and resized to 256 x 256 pixels. Hyoid, bolus, and C2 – C4 vertebrae contours were done on unprocessed images and underwent the same cropping and resizing. A 2D modified U – Net structure was used. The network was trained using 80% of available image slices (1386,4490, 2881) for the hyoid, bolus, and C2-C4 separately. A non-decaying learning rate and Adam optimizer in TensorFlow was used. **Results:** Dice coefficients on the remaining validation images were 0.87, 0.92, and 0.95 for the hyoid, bolus, and C2-C4, respectively. **Conclusion:** Resulting dice coefficients reflected accurate contours. The C2-C4 contours were most similar given the lack of motion and contrast in that region. With the Hyoid and C2-C4, edge pixels were most uniformly missed around the contour. The bulk of bolus contour was accurate, but small portions (residue) were missed in some cases. Identification of residue is debated with manual analysis leading to required further work for accurate bolus contouring.

Super-Resolution CT Image Via Convolution Neural Network with An Observer Loss Function

M Yu*, M Han, J Back, Yonsei University, Incheon, 28KR

Purpose: To enhance the CT image resolution, we proposed a convolutional neural network (CNN) based super-resolution (SR) technique. To train SR network, we proposed a perceptual loss function that uses the classifier learned by CT images as a feature extractor (i.e., observer loss). **Methods:** We used patient data authorized by Mayo Clinics for "the 2016 NIH-AAPM-Mayo Clinic Low Dose CT Grand Challenge". We used normal dose CT images of 10 patients. We acquired projection data using Siddon's algorithm in fan-beam CT geometry and applied 1x2 detector binning. High-resolution (HR) images and low-resolution (LR) images were generated by performing back-projection on original sinogram and binned sinogram, respectively. We implemented 13-layer CNN for CT classifier. The classifier was trained to classify lesion-present and lesion-absent. We randomly extracted 64x64 patches from the HR images and added Gaussian signal with various intensity, size, and location. After training, we extracted features from the 10-th convolution layer to calculate perceptual loss. For the SR network, we adapted RED-CNN based architecture, and bicubic interpolation was added at the beginning. We trained SR network to minimize the loss functions (i.e., mean-squared-error (MSE), ImageNet pretrained VGG, and proposed observer loss). We compared the results with different loss functions using peak signal-to-noise ratio (PSNR), structural similarity (SSIM), and visual information fidelity (VIF). **Results:** The quantitative evaluation results are best when using MSE loss but blurring occurs in the result images. On the other hand, when training the SR network using perceptual loss functions, structural details are preserved. In particular, the SR network with the observer loss represents more detailed textures than the network with VGG loss. **Conclusion:** In this work, we proposed observer loss to train SR network for CT images. SR network with proposed observer loss could preserve structural details and textures better than that with other loss functions.

A Realistic DRR Rendering Method Based on Cycle-GAN

R Wei^{1*}, B Liu^{2,3}, B Liang¹, J Dai¹, (1) National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, 100021, CN, (2) Image Processing Center, Beihang University, Beijing, CN, (3) Beijing Advanced Innovation Center for Biomedical Engineering, Beihang University, Beijing, CN

Purpose: In recent study, deep learning network trained with paired data was utilized to reduce the intensity inconsistency between DRR and x-ray projection. But for lung cancer patients, it is hard to obtain adequate paired data for network training due to respiration. In this work, we developed and validated a DRR rendering method based on Cycle Generative Adversarial Networks (Cycle-GAN), which could improve the similarity between DRR and x-ray projection using unpaired training data. **Methods:** In the proposed method, a Cycle-GAN was trained to generate synthetic x-ray projection from DRR, which was used to resemble real x-ray projection in tumor localization algorithms. Since respiratory motion made it hard to obtain paired data of DRR and x-ray projection, the Cycle-GAN was trained with unpaired data of DRR and x-ray projection from multiple patients. Wasserstein distance and gradient penalty terms were added to the loss function to improve the performance of the network. To apply to the new patient, the synthetic x-ray projection can be generated with DRR fed into the trained network. **Results:** The proposed method was evaluated with four patients' data. Three patients' data was utilized to train the Cycle-GAN, and the last one was used to test the network. The x-ray projections at angle ranging from 0° to 90° were sorted into different phases and DRR of corresponded CT was computed as the input to the network. For this experiment, the relative error between synthetic x-ray projection and realistic ones ranged from 0.04 to 0.11 with an average of 0.087, while the relative error between raw DRR and real x-ray projection ranged from 0.09 to 0.32 with an average of 0.163. **Conclusion:** We proposed a Cycle-GAN based DRR rendering method, which could greatly reduce the intensity difference between DRR and x-ray projection using unpaired training data.

This work was supported by the National Key R&D Program of China under Grant No.2018YFA0704100 and 2018YFA0704101, the National Natural Science Foundation of China under Grant No. 61601012

Angiogram-Free Intracranial Vessel Localization for Plaque Assessment

W Fan^{1*}, Y Sang¹, H Zhou¹, Z Hu², J Xiao², Z Fan^{2,3}, D Ruan^{1,4}, (1) UCLA, Los Angeles, CA, (2) Cedars-Sinai Medical Center, Los Angeles, CA, (3) Keck School of Medicine of USC, Los Angeles, CA, (4) UCLA School of Medicine, Los Angeles, CA

Purpose: Inspection of vessel morphology is important in assessing cardiovascular risks. Magnetic resonance (MR) vessel wall imaging (VWI) is routinely used with a companion MR angiogram (MRA) that localizes the vessel segments of interest. However, the acquisition of MRA prolongs scanning time, extra cost in clinical workflow, and is also subject to slight displacement with respect to the VWI. This study aims to investigate the feasibility to infer the vessel location directly from VWI. **Methods:** The (VWI, MRA) pair of images from 30 patients were included; and were randomly split into 25 cases for training doubled as atlas, and 5 cases for testing. To regulate vessel topology while preserving the target's specific appearance, such as plaque presentation, a novel atlas-based pipeline with deep correction was proposed. For each target VWI, all atlas VWI were first rigidly registered and the one with the highest mutual information was chosen to proceed to be deformable, generating an initial deformation vector field (DVF). An unsupervised error correction network was further introduced to improve the DVF, particularly in alignment and conformality to vessel defined via training MRA. The end-to-end inference applied the refined DVF to the reference MRA for final vessel extraction and localization. **Results:** The 90% Hausdorff distance on the vessel segment of interest is around 10mm, which is satisfactory for localization purposes. Close inspection shows that major vessels such as the internal carotid artery (ICA) agree well with the benchmark MRA, while vertebral arteries and basilar arteries showed inferior local match. **Conclusion:** Our method showed significant improvement, particularly in vessel structure integrity compared to the commonly used deep segmentation or deep synthesis. We are working on regulating the error correction network to better account for DVF heterogeneity and focal vessel performance.

Intelligent CT Reconstruction with Simultaneous Learning of Reconstruction Policy and Image Quality Assessment Using Quality-Guided Deep Reinforcement Learning

Y Gao*, C Shen, M Tsai, Y Gonzalez, L Chen, X Jia, The University of Texas Southwestern Medical Center, Dallas, TX

Purpose: Although iterative CT reconstruction methods can generate high-quality images by solving an optimization problem, it faces two challenges: to adjust regularization parameters to produce desired results and to define a proper image quality metric to guide regularization parameter adjustment. This study aims to employ a quality-guided deep reinforcement learning (QgDRL) framework to solve the two problems simultaneously. **Methods:** A parameter-tuning policy network (PTPN) and a quality assessment network (QAN) are constructed and jointly trained under a QgDRL framework. PTPN is trained to learn how to adjust regularization parameters for input image patches to improve reconstructed image quality via an end-to-end reinforcement learning process using an epsilon-greedy algorithm with experience replay. Intermediate results generated in the reconstruction process are stored to train QAN, which is trained to differentiate high-quality true CT image patches and low-quality generated intermediate image patches, as measured by a probability score for the input patch to be of high quality. The probability in turn serves as a reward function to guide the reinforcement learning process of PTPN training. We implemented the system in a problem of iterative CT reconstruction with pixel-wise total-variation regularization. **Results:** The effectiveness of QAN is demonstrated by being able to assign higher probability scores to patches of visually better quality. The trained PTPN can automatically decide regularization parameter adjustments in the reconstruction process to improve the resulting image quality. Relative errors of images with respect to the ground truth images reconstructed using a fixed regularization parameter, using the best PTPN-adjusted parameters, and using the best manually adjusted parameters are 19.6%, 9.1%, 9.5%, respectively. **Conclusion:** The QgDRL framework can simultaneously and spontaneously learn the policy on regularization parameter adjustment and image quality assessment in the iterative CT reconstruction problem.

Ortho2D: An Accurate, Memory-Efficient Framework for 3D Vertebrae Labeling

Y Huang^{1*}, A Uneri², C Jones³, X Zhang⁴, M Ketcha⁵, N Aygun⁶, P Helm⁷, J Siewerdsen⁸, (1) Johns Hopkins University, Department of Biomedical Engineering, Baltimore, MD, (2) Johns Hopkins University, Department of Biomedical Engineering, Baltimore, MD, (3) Johns Hopkins University, Department of Computer Science, Baltimore, MD, (4) Johns Hopkins University, Department of Biomedical Engineering, Baltimore, MD, (5) Johns Hopkins University, Department of Biomedical Engineering, Baltimore, MD, (6) Johns Hopkins University, Department of Radiology, Baltimore, MD, (7) Medtronic, Inc., Littleton, MA, (8) Johns Hopkins University, Department of Biomedical Engineering, Baltimore, MD

Purpose: Automatic labeling of vertebrae in CT is a valuable capability for more quantitative diagnostic analysis, interventional planning, and an independent check against wrong-level surgery or radiosurgery. We propose a novel neural network approach (Ortho2D) that operates on 2D orthogonal slices of a 3D image to aggregate, localize, and classify features of interest, thereby avoid memory bottlenecks associated with fully 3D networks and enabling operation on higher resolution datasets. **Methods:** Ortho2D uses two independent Faster R-CNN networks to label vertebrae in sagittal and coronal CT slices. The centroids of 2D detection bounding boxes are clustered in 3D to detect vertebrae centroids, identify the anatomical region (cervical, thoracic, lumbar, or sacral), and identify the individual vertebral levels therein. A post-process sorting method incorporates the confidence in network output to refine classifications and reduce outliers. Ortho2D was evaluated on a publicly available dataset containing 302 normal and pathological spine CT images. The labeling accuracy and memory requirements were assessed in comparison to other methods recently reported in literature. The approach was extended to higher resolution CT data to investigate potential improvements in accuracy. **Results:** Ortho2D achieved vertebrae detection accuracy of 97.1%, region identification accuracy of 94.3%, and individual vertebral level identification accuracy of 91.0%. Ortho2D met or exceeded the performance of previously reported 2D and 3D labeling methods and reduced memory consumption by a factor of ~50 (at 1 mm voxel size) compared to a 3D U-Net. Extension of Ortho2D to higher resolution datasets than normally afforded by fully 3D networks demonstrated a 15% boost in labeling accuracy by virtue of improved memory efficiency and the ability to operate on high-resolution data. **Conclusion:** The Ortho2D method achieved vertebrae labeling performance comparable to other recently reported methods with significant reduction in memory consumption, permitting further performance boosts via application to high-resolution CT.

Self-Supervised Learning Based CT Imaging with High Through-Plane Resolution

H Xie¹, Y Lei², T Wang^{1,3}, Z Tian^{1,3}, J Roper^{1,3}, J Bradley^{1,3}, X Tang^{2,3}, T Liu^{1,3}, X Yang^{1,3*}, (1) Department of Radiation Oncology, (2) Department of Radiology and Imaging Sciences, and (3) Winship Cancer Institute, Emory University, Atlanta, GA

Purpose: CT images for radiation therapy planning are usually acquired in thick slice to reduce imaging dose, especially for pediatric patients. However, this practice may degrade the quality of dose calculation and target delineation. In this work, a self-supervised deep learning workflow is proposed to synthesize high through-plane (sagittal and coronal planes) resolution CT images without requiring ground truth images for training, as patient images of thin slices are often not available for many tumor sites. **Methods:** The proposed workflow was designed to facilitate the convolutional neural networks to learn the mapping from low resolution (LR) to high resolution (HR) images in the in-plane (axial) direction. In the workflow, the through-plane LR CT images were sliced along the sagittal and coronal planes and fed through two parallel data flow paths. During the inference step, the through-plane HR images were generated by feeding the respective LR sagittal and coronal images to the trained networks. **Results:** The qualitative results show the capability of the proposed method for generating high through-plane resolution with data of 75 head and neck and 20 lung cancer patients' CT images. The image quality metrics can be all enhanced with the proposed method by from ~7% for structural similarity index measurement (SSIM) to ~130% for edge keeping index (EKI). All the improvements of the measure metrics are confirmed to be statistically significant with paired two-sample t-test analysis ($p=0.014$ for SSIM and $p<0.001$ for EKI). **Conclusion:** The proposed deep learning method for CT image generation with high through-plane resolution is self-supervised, which means it does not rely on ground truth

for network training. In addition, the assumption that the in-plane HR information can supervise the through-plane HR generation is confirmed and anticipated to potentially inspire more researches on this topic to further improve the through-plane resolution of medical images.

SU-lePD-TRACK 3-06

Squamous Cell Tumor Characterization in Head and Neck Cancer Patients Using Dual-Energy Computed Tomography

É Delisle^{1*}, H Bahig^{2, 3, 4}, H Bouchard^{1, 2, 3}, M Simard¹, C Larose², E Filion², P Nguyen-tâcn², S Bedwani^{1, 2, 3}, (1) Physics department, Université de Montréeal, Montreal, QC, CA, (2) Radiation Oncology Department, Centre Hospitalier de Université de Montréeal, Montreal, QC, CA, (3) Centre de recherche du Centre hospitalier de Université de Montréeal, Montreal, QC, CA, (4) Radiation Oncology Department, University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: To characterize contrast agent concentrations in head and neck squamous cell cancers (SCC) as a function of tumor subsite using contrast enhanced dual-energy computed tomography (CE-DECT) pre-treatment scans. **Methods:** Patients with larynx, hypopharynx and oropharynx SCC that underwent treatment planning with CE-DECT of the neck were studied. Primary and nodal gross tumor volumes (GTVp, GTVn) were contoured and their CE-DECT data were analysed. A two-material decomposition method was performed to extract iodine concentration (IC) maps. The IC distributions were grouped according to GTV (GTVp, GTVn) and tumor subsite (larynx-hypopharynx, oropharynx). The oropharynx and larynx-hypopharynx IC distributions were compared for both GTVp and GTVn subgroups. Both a Student's t-test and a Welch t-test were realized to compare the GTVp and GTVn IC distribution's average 90th percentile, mean, variance, skewness and kurtosis. A Welch t-test was used when the variances of the sample means were unequal. **Results:** 65 patients of which 57 had a GTVp and 30 a GTVn were analysed. 35%/65% of GTVp and 73%/27% of GTVn were in the oropharynx/larynx-hypopharynx subsites. There was a significant difference in the average 90th percentile, mean, variance, skewness and kurtosis of GTVp ICs between the larynx-hypopharynx ($p_0=9.97$, $M=2.00$, $VAR=8.80$, $SKEW=2.15$, $KURT=3.35$) and oropharynx ($p_0=7.85$, $M=1.53$, $VAR=7.78$, $SKEW=2.58$, $KURT=8.20$) subgroups: $p_{p_0}=0.0002$, $p_M=0.007$, $p_{VAR}=0.001$, $p_{SKEW}=0.004$, $p_{KURT}=0.002$. There was no significant difference in the average 90th percentile, mean, variance, skewness and kurtosis of GTVn ICs between the larynx-hypopharynx and oropharynx subgroups. These preliminary results suggest that IC maps have a better clinical resolving power for GTVp than for GTVn. **Conclusion:** This work implies that IC maps could be used as a biomarker to gain further insight into head and neck tumors. This information may be useful when investigating the prediction of locoregional recurrence using tumor IC distributions.

Using the Planning CT Scan for Pixel-To-Pixel Corrections of Cherenkov Intensity for Dose Imaging

R Hachadorian^{1*}, D Gladstone^{1,2}, M Jermyn³, P Bruza^{1,3}, R Zhang^{1,2}, L Jarvis^{1,2}, B Pogue^{1,3}, (1) Dartmouth College, Hanover, NH, (2) Dartmouth-Hitchcock Med. Ctr., Lebanon, NH, (3) DoseOptics LLC, Lebanon, NH

Purpose: The Cherenkov light emitted during radiotherapy provides a useful measure of the dose delivered to the patient's superficial tissues, yet variability between patients and treated sites contributes a substantial amount of nonlinearity to the Cherenkov light-to-dose relationship. This work developed a means of correcting for patient tissue properties and highly-attenuating features (localized vasculature, areola etc.) in breast cancer patients using the planning CT. A secondary application to correct for intra-fractional changes from erythema was examined. **Methods:** The average CT# was projected on a spatial mapping of the patient and co-registered to the Cherenkov image. Both 6MV/10MV beams were used in clinical treatment, and Cherenkov cameras mounted on the ceiling recorded emission images from all fractions of $n = 13$ patients. An updated correction model was generated to map the CT/Cherenkov light relationship, which was used to introduce point-to-point corrections of each Cherenkov image. The coefficient of variation (COV), σ/μ was used as a metric of success. **Results:** Variation diminished from 30.3% to 18.8% in 6MV beams, and in 10 MV beams was reduced from 30.5% to 12.6%. The linear regression for uncorrected Cherenkov intensities with respect to dose for 6 MV beams became stronger, from $R^2 = 0.59$ uncorrected, to a corrected value of $R^2 = 0.81$, and in 10 MV beams, uncorrected $R^2 = 0.72$ was corrected to $R^2 = 0.92$, gaining substantial linearity even in highly attenuating regions. It was also shown that the background image, acquired in tandem with the Cherenkov image, could be used to correct for signal loss from erythema. **Conclusion:** A substantial increase in light-to-dose linearity was introduced by calibrating for attenuation from surface-rendered CT scan image data. This was successful for both inter-patient tissue differences and challenging highly attenuating features. Lastly, a new means of correcting for inter-fractional optical changes was examined.

Simultaneous Dose and Dose Rate Optimization with Transmission Beams and Bragg Peaks for Proton FLASH Therapy

Y Lin^{1*}, B Lin^{1,2}, S Fu², M Folkerts³, E Abel³, J Bradley¹, H Gao¹, (1) Winship Cancer Institute of Emory University, Atlanta, GA, (2) Shandong University, Jinan, Shandong, China, (3) Varian Medical Systems, Palo Alto, CA

Purpose: With the radiation at ultra-high dose rates, the FLASH therapy (FLASH-RT) can substantially reduce normal tissue toxicities while maintaining tumor response. By far the only commercially available devices that can deliver ultra-high dose rates required for general-purpose clinical FLASH-RT are isochronous cyclotron based proton systems, for which high-energy transmission beams (TB) are needed to achieve ultra-high dose rates for deep-seated tumor targets. However, planning with TB alone does not fully leverage the degrees of freedom for dose shaping as traditional intensity modulated proton therapy (IMPT) via the Bragg peaks (BP) of multi-energy proton beams at the tumor targets. This work aims to develop a simultaneous dose and dose rate optimization (SDDRO) method with the joint use of TB and BP, namely SDDRO-Joint. **Methods:** Different from IMPT that only optimizes the dose distribution, SDDRO enables the dose rate optimization for the purpose of FLASH-RT, in addition to the dose optimization. During SDDRO-Joint, while TB primarily cover the tumor boundary in order to achieve ultra-high dose rate coverage of organs-at-risk (OAR) surrounding tumor targets, BP are placed inside tumor targets to further improve the target dose conformity and spare the normal-tissue dose, i.e., the FLASH sparing by TB and the dose sparing by BP. **Results:** SDDRO-Joint (both TB and BP) was validated in comparison with IMPT-BP (BP only), IMPT-TB (TB only), and SDDRO-TB (TB only). IMPT-BP serves as the gold standard for the dose distribution. SDDRO-TB serves as the gold standard for the dose rate distribution. The results suggest that SDDRO-Joint substantially increased the target dose conformity from SDDRO-TB, while preserving the dose rate coverage. Noticeably SDDRO-Joint had the best conformal index values, e.g., higher than IMPT-BP as well. **Conclusion:** A new treatment planning method SDDRO-Joint is developed to simultaneously optimize dose and

dose rate distribution for FLASH-RT.

Differential Dose-Rate Effects on Pancreatic Cell Survival from Proton Therapy: FLASH Versus Conventional Dose Rate

Y Lee, D Jiang, M Yang, X Wang, K Iga, X Zhu, A Koong, R Mohan, F Guan*, The University of Texas, MD Anderson Cancer Center, Houston, TX

Purpose: To compare the cell survival rates following proton irradiation at ultra-high FLASH vs. conventional dose rates. **Methods:** A synchrotron-based horizontal proton beamline (87 MeV) at our institution has been commissioned to deliver dose in either FLASH or non-FLASH mode. The dose rate within each beam delivery cycle was calculated based on the measured dose and its pulse width (~100 ms). A high-precision and high-efficiency experimental platform was developed by using a laser positioning system and a robotic arm. MIA PaCa-2 pancreatic cancer cells and HPNE normal pancreatic epithelial cells were seeded in a 96-well plate, then irradiated at the entrance region of the pristine Bragg dose curve. In the step-and-shoot irradiation mode, each well can have its specific dose (2, 4, 6 or 8 Gy in a single fraction) and dose rate (100 or 0.2 Gy/s). Post irradiation, the cells were re-plated into 6-well plates for colony formation. **Results:** For MIA PaCa-2 cells, from 0 to 6 Gy, there was no significant difference in cell surviving fraction (SF) between FLASH and conventional dose rates. However, at 8 Gy, there was a sharp increase of cell survival using the FLASH (SF = 0.02) compared with the non-FLASH (SF = 0.002). For the HPNE human pancreatic ductal epithelial cells, cell survival from the FLASH group is higher than that of the non-FLASH group at most of the dose levels. **Conclusion:** Our preliminary experimental data have shown that for pancreatic tumor cells, a dose threshold may exist for the differential effects in cell killing between FLASH and non-FLASH protons. However, for normal pancreatic cells, proton FLASH could increase their radio-resistance and protect cell survival. More experiments with additional conditions such as various oxygen concentrations are needed to further explore the clinical potential of proton FLASH in improving the therapeutic index.

Feasibility of SOBP Proton FLASH Beam Delivery Using a Gantry-Mounted Clinical Synchrocyclotron

A Darafsheh^{1*}, Y Hao¹, X Zhao¹, T Zwart², M Wagner², T Evans², F Reynoso¹, T Zhao¹, (1) Washington University School of Medicine, St. Louis, MO, (2) Mevion Medical Systems, Littleton, MA

Purpose: To demonstrate the feasibility of delivering a spread-out Bragg peak (SOBP) proton beam in ultra-high dose rate (FLASH) using a proton therapy synchrocyclotron as a major step toward implementing an experimental setup for preclinical studies. **Methods:** A Mevion HYPERSCAN synchrocyclotron was adjusted for the experiments. Protons with 230 MeV energy were delivered in pulses with temporal width ranging from 12.5 μ s to 24 μ s spanning from conventional to ultra-high dose rates. A boron carbide absorber and a slab of PMMA with arrays of holes, as the range modulator, were placed in the beam path for creating an SOBP profile. The radiation field was defined by a brass aperture with 11 mm diameter. The number of protons per pulse at various dose rates was determined by a Faraday cup. The response of two cylindrical (IBA CC04 and CC13) and two plane-parallel (IBA PPC05 and PTW Advanced Markus) ionization chambers were characterized. The dose rate was measured using the PPC05 chamber. The integral depth dose (IDD) was measured with a PTW Bragg Peak ionization chamber. The lateral beam profile was measured with EBT-XD radiochromic film. Monte Carlo simulation was performed in TOPAS as the secondary check for the measurements. **Results:** Faraday cup measurement showed 39.9 pC protons per pulse at 24 μ s pulse width. The measured IDD and beam profiles agreed with the simulation. The cylindrical chambers showed very high ion recombination and deemed not suitable for absolute dosimetry at ultra-high dose rates. The average dose rate measured using the PPC05 chamber showed 126 Gy/s at 1 cm depth in the SOBP beam. The beam range and modulation were 2.4 and 2 cm, respectively. **Conclusion:** It is feasible to deliver protons in an SOBP pattern with >100 Gy/s average dose rate in an ~1 cm³ volume using a clinical synchrocyclotron.

Commissioning a Fixed Field FLASH Pencil Beam Scanning Proton Therapy System in Support of the First In-Human Clinical Trial

A Mascia^{1,2*}, Y Zhang^{1,2}, E Lee^{1,2}, Z Xiao^{1,2}, J Speth^{1,2}, M Sertorio², E Abel³, M Folkerts³, A Lourenco⁴, N Lee⁵, A Subiel⁵, F Romano⁵, R Thomas⁵, R Amos⁴, J Breneman⁶, (1) University of Cincinnati Medical Center, Cincinnati, OH (2) Cincinnati Children's Hospital Medical Center, Cincinnati, OH (3) Varian Medical Systems, Palo Alto, CA (4) University College London, London, GB (5) National Physical Laboratory, Teddington, GB (6) University of Cincinnati, Cincinnati, OH

Purpose: Ultra-high dose rate radiotherapy, or FLASH radiotherapy (FRT), delivers therapeutic doses at dose rates exceeding 40Gy/s. With small modifications, some modern proton therapy systems are capable of treating deep-seated tumors with FRT. Pre-clinical and translational data shows potential for normal tissue sparing at ultra-high dose rates with no reduction in tumor control. FAST-01, the first in-human proton therapy FLASH clinical trial, began accruing patients in late 2020. **Methods:** For FAST-01, the pencil beam scanning proton therapy system delivers pre-defined FLASH treatment plans using a 250MeV transmission beam at a minimum of 40Gy/s. Commissioning and characterization of the delivery system was performed using, primarily, ion chamber and film. A treatment planning beam model was validated and end-to-end tests performed. The shielding was evaluated for the FRT trial doses and dose rates. A quality assurance program was adapted to include FLASH deliveries. **Results:** The parallel plate ion chamber was validated against a graphite calorimeter, with agreement within 1.0%. The radiochromic film dose-response curve was calibrated in the FLASH fields, cross-calibrated to the parallel plate ion chamber. A treatment planning beam model was created and validated for transmission FLASH fields. The machine trend analysis shows absolute dose variation within 1% and dose rate variation within 5% and always above 40Gy/s threshold. End-to-end tests and shielding evaluations all passed. Patient QA results meet a 90% passing rate at gamma criteria of 3%/3mm. Initial FLASH clinical treatments are performed with little modification to standard clinical workflow. In vivo dosimetry and log file analysis further confirms the accuracy and constancy of the FRT treatment delivery. **Conclusion:** While following a standard commissioning methodology while also adhering to a quality assurance program that includes special consideration with respect to dose rate, the proton therapy system is capable of safe and efficient FLASH radiotherapy.

Development and Validation of a FLASH Pencil Beam Scanning Beam Model for Treatment Planning and Verification in First In-Human Trial

Y Zhang^{1,2*}, E Lee^{1,2}, Z Xiao^{1,2}, J Speth^{1,2}, M Folkerts⁴, E Abel⁴, J Breneman³, A Mascia^{1,2}, (1) University of Cincinnati Medical Center, Cincinnati, OH (2) Cincinnati Children's Hospital Medical Center, Cincinnati, OH (3) University of Cincinnati, Cincinnati, OH (4) Varian Medical Systems, Palo Alto, CA

Purpose: State-of-art clinical proton accelerators can readily deliver scanning proton beam at ultra-high dose rate. While conventional PBS beam models were validated for dose accuracy in an SOBP, the purpose of this work is to develop and validate a dose calculation model in support of treatment planning and

verification under single-layer transmission mode. **Methods:** FAST-01, the first in-human clinical trial for proton FLASH, adopted a library of pre-defined 250MeV rectangular plans to cover a variety of field size, ranging from 7.5x7.5cm to 7.5x20cm. The required beam data, including depth dose, in-air spot and absolute dose, are acquired, processed and calculated to create a beam model in Varian Eclipse. Prior to validations, reference dosimetry was established using a calorimeter, and absolute dose was cross-validated using various detectors at both conventional and FLASH dose rate. The beam model was validated for the pre-defined library of plans delivered in the gantry in FLASH mode. Ion chamber measurements at different locations using a parallel plate chamber were compared to the calculation. Radiochromic film was also deployed to validate 2D dose distribution using gamma analysis in mock and real patients. **Results:** The measurement results were compared against dose calculations from FLASH beam model in Eclipse. For the plan library, the overall dose deviation was $0.2\% \pm 1.3\%$ at 1cm and 5cm depths. So far, FAST-01 has accrued four patients. For patient QA, the absolute doses were measured at 5cm using PTW Advanced Markus chamber. Cross-calibrated Gafchromic EBT3 film was used to acquire 2D dose distribution for gamma analysis. For these patients, the average dose difference was $1.8\% \pm 0.3\%$, and 2D gamma index all passed 90% at 3mm/3%. **Conclusion:** The validation results have demonstrated that the beam model is an accurate and indispensable tool for transmission flash planning and dose verification in support of trial.

SU-lePD-TRACK 5-06

Online Control of Micro-Beam Synchrotron Radiation Therapy Using Micro-Stripped Diamond Detectors

N Rosuel*^{1,2}, M Gallin-martel¹, L Gallin-martel¹, S KESHMIRI², M Krisch³, J Motte⁴, J Muraz¹, M Ruat³, L Tribouilloy¹, D Dauvergne¹, JF Adam², (1)Univ. Grenoble Alpes, Laboratoire de Physique Subatomique et Cosmologie, CNRS, 53 av. des Martyrs, 38000 Grenoble, France, (2)INSERM UA 7 STROBE, Grenoble France, (3) ESRF, Grenoble, France, (4) Universite Grenoble Alpes, CNRS, Grenoble INP, Institut Neel, 38000 Grenoble, France

Purpose: A diamond-based detector is being developed to solve the limitation of online monitoring in the case of Microbeam Radiation Therapy (MRT), a synchrotron-based technique using a micro-beam matrix of low energy photons (100 keV range) at very high dose rates (kGy/s range). **Methods:** To demonstrate the feasibility of using diamond materials for portal online monitoring in MRT, bulk diamond-based detectors (4.5x4.5 mm² area) have been tested under a single 50x800 μm^2 micro-beam with the same characteristics as MRT photons beam). Five repetitions of 2 s measurements were performed under a 4000 Gy/s photon flux to test the stability and repeatability of our detectors under those extreme conditions, and compare the quantitative response to simulations. As our detector will be used in a portal mode, measurements has been completed using absorbers of PMMA (0 to 47 cm thickness) to study the response of our detector as a function of the dose rate between 1 and 4000 Gy/s. **Results:** The study of our detector response exhibits a maximum difference within a 2 s pulse better than 0.2 % and a maximum difference on pulse mean response of 0.1 %. The reproduction of the measurement after approximately 500 kGy irradiation also shows middle term stability better than 0.3 %. **Conclusion:** This study shows the suitability of the diamond-based detector for the MRT portal beam monitoring. Linearity over a wide range of dose rates, allows us to measure micro-beam-irradiated and non-irradiated zones at the same time. These results lead us to proceed to the next stage. A multi-stripped diamond detector, read out with multi-channel analog charge digitizers, is being tested to perform each micro-beam and inter-beam flux measurement simultaneously. The first results will be presented.

Novel Plastic Scintillator for Online Dosimetry in Electron FLASH-RT

Y Poirier^{1*}, J Xu¹, A Ahmady¹, S Mossahebi¹, H Zhang¹, F Theriault-Proulx², A Sawant¹, (1) University of Maryland School of Medicine, Baltimore, MD, (2) MedScint, Quebec City, QC

Purpose: The accurate delivery of electrons at FLASH-RT dose rates in radiobiological experiments require new dosimeters that are capable of accurately measuring the radiation dose delivered at >0.55 Gy per pulse (>100 Gy/s) in real-time. We investigate the use of the novel Hyperscint RP100 plastic dosimeter as a direct pulse counter. **Methods:** A Varian 21EX clinac was converted to deliver 16 MeV electrons at FLASH-RT (100 Gy/s) dose rates. The linearity and reproducibility of the plastic scintillator at FLASH-RT dose rates was established by comparing with a pinpoint ionization chamber placed under 10 cm of solid water, where it acts as a relative dosimeter due to intense recombination effects. The plastic scintillator detector and to EBT-XD Gafchromic radiochromic film. were calibrated at conventional dose rates (1000 MU/min) and then irradiated at FLASH-RT Dose rate over a range of 3-20 Gy. **Results:** The plastic dosimeter response tracked with relative ion chamber measurements within $\leq 1\%$ over a wide range of delivered doses and dose rates, showing excellent response linearity and reproducibility. Plastic dosimeter dose measurements agreed with Gafchromic EBT-XD film measurements within $\pm 4-6\%$. Most importantly, the plastic scintillator system was able to detect the number of pulses delivered by the linac directly, allowing for instant verification of proper delivery of FLASH-RT beams. **Conclusion:** The plastic dosimeter was able to accurately measure the delivered radiation absorbed dose under characterization and biological experimental conditions, with a higher degree of reliability than conventional radiochromic film. Furthermore, it was shown to directly and accurately measure the number of pulses delivered in real time. This shows potential for use as a real-time in-vivo dosimeter during biological experiments, as well as potential clinical applications.

Real-Time Reduction in Isocenter Shifts During MR-IGRT Gantry Rotation

A Curcuru*, D Yang, H Gach, Washington University in St. Louis, St. Louis, MO

Purpose: To quantify imaging isocenter shifts due to fluctuations in the primary magnetic field (B_0) as a result of gantry rotation in a commercial 0.35T magnetic resonance image guided radiotherapy (MR-IGRT) system and to correct those shifts within the imaging sequence in real time. **Methods:** A hard pulse navigator (FA:90, dwell time = 8 μs , complex points = 64) was added to a sagittal 2D cartesian spoiled gradient echo (GRE) sequence (TR/TE: 20/3.7ms, FA: 20, rBW: 260 Hz/pixel) following each image on a commercial 0.35T MR-IGRT system. The gantry was rotated from 33° to 153° during imaging and measurements were acquired using a spherical 24 cm DSV phantom (T1/T2: 330/260 ms) using the system body coil. The resonant frequency offset was calculated by comparing the phase data from the first (reference) hard pulse navigator with each subsequent navigator. The calculated frequency offset was then fed back into the sequence from the image reconstruction computer as a real-time feedback object. This data was then used to modify the imaging pulse and receiver frequencies for the next image. Phantom images were acquired with and without the correction. Shimming was done at 33° for both image sets. Images were time aligned and the center of the phantom was calculated for each image using MATLAB. The phantom shifts in the frequency encoding direction were then compared. **Results:** RMS isocenter shifts in the frequency encoding direction were reduced using the resonance frequency correction (RMS = 2.70mm/1.14mm). Peak displacement in the frequency encoding direction was additionally reduced from 5.7mm without real time correction to 2.5mm with correction. **Conclusion:** This work provides a method for real-time reduction of imaging isocenter shifts due to B_0 fluctuations during gantry rotation in GRE

sequences. More precise gantry rotation data could yield further reductions.

Experimental Verification of Scanning Magnet with Distributed Winding Coils for Particle Beam Therapy

K Nagashima*, T Yamada, T Nomura, S Soeda, Hitachi, Ltd.

Purpose: Size of scanning system in particle beam therapy can be reduced by using a combined function scanning magnet compared to separated scanning magnets. We propose a combined function scanning magnet with distributed winding coils (DW-SCM). Its homogeneity of the dipole magnetic field and the correction method of the magnetic field are experimentally verified. **Methods:** DW-SCM can generate the rotating dipole magnetic field by the three-phase sinusoidal current. By changing balance of the three-phase current, the good field region (radius) of field homogeneity within $\pm 0.5\%$ can be expanded. We have made a prototype of DW-SCM with 30 mm bore diameter which is one-third the actual size of the actual one. It consists of 12 magnetic poles and 3 coils of hollow conductors. The magnetic field distribution in the scanning direction with respect to the central magnetic field has been measured to evaluate the good field region with and without the correction. **Results:** The measured magnetic field distribution of the prototype DW-SCM within the good field region is in agreement with the simulation results calculated by Poisson Superfish code by 0.01%. The good field region after applying the correction was 15 mm which is 50% of the bore diameter. **Conclusion:** We have made the prototype of DW-SCM and evaluated the good field region. After applying the magnetic field correction, the good field region reaches 50% of the bore diameter.

Response of Parallel-Plate Ionization Chambers and a Diode Detector on the Buildup Dose Measurement in Inline Magnetic Fields

N Anami*

Purpose: To investigate the response of parallel-plate ionization chambers and a diode detector on the buildup dose measurement in inline magnetic fields using Monte Carlo (MC) simulation. **Methods:** The ROOS, NACP-02 and MARKUS parallel-plate chambers and a PTW-60018 diode detector were modeled using the EGSnrc/cavity code. A 6 MV photon beam from a Varian Novalis Tx head was irradiated with a $10 \times 10 \text{ cm}^2$ field at a source-to-surface distance of 100 cm. The magnetic field strengths of 0, 0.35 and 1.0 T were applied parallel to the beam axis. The dose to water, $D(w)$, and the dose in sensitive volume of detector, D_{det} , were calculated at 0.1–1.5 cm depth in a water phantom. The overall perturbation correction factor, $P(Q,B)$, for the detectors was calculated with/without magnetic fields according to the Spencer–Attix cavity theory. The average restricted mass collision stopping-power ratio of water to air was calculated by the EGSnrc/SPRRZ code. In all dose calculations, photon and electron cutoff energies were set to 0.01 MeV and 0.521 MeV, respectively. The statistical uncertainty of the calculated dose was less than 0.1% in one standard deviation. **Results:** The dose to water at a 0.1 cm depth in inline magnetic fields was higher up to 37.4% than that of $B=0 \text{ T}$. The depth of the dose maximum in all inline magnetic fields was shifted 0.7 cm toward the surface compared to that of $B=0 \text{ T}$. The $P(Q,B)$ values for PTW-60018 were 0.814–0.889 at 1.0 T. Similarly, the $P(Q,B)$ values for ROOS, NACP-02, and MARKUS chambers they were 0.983–1.015, 0.960–1.022, 0.959–1.027 at 1.0 T, respectively, and larger than those of PTW 60018. **Conclusion:** The response of parallel-plate ionization chambers and a diode detector is affected by focusing electrons in the buildup dose measurement under the inline magnetic fields.

SU-lePD-TRACK 6-04

A Monte Carlo Characterization of Positional Accuracy of a Double-Focused and Double-Stack Multileaf Collimator On a 0.35 T MR-Linac

A Khan^{1*}, E Simiele², L DeWerd¹, P Yadav³, (1) Department of Medical Physics, School of Medicine and Public Health, University of Wisconsin-Madison, (2) Department of Radiation Oncology, Stanford University School of Medicine, (3) Department of Human Oncology, School of Medicine and Public Health, University of Wisconsin

Purpose: Characterization of a multileaf collimator (MLC) quality assurance (QA) technique for the positional accuracy of a double-focused and double-stacked MLC on a 0.35 T MR-linac using an ionization chamber array (ICA) is presented. As the experimental evaluation of the proposed QA technique may suffer from imperfect positioning of the ICA and gantry sag, Monte Carlo (MC) methods were employed. **Methods:** A previously benchmarked GEANT4 MC model of a 0.35 T MR-linac was used. Measured and simulated beam profiles for $10 \times 10 \text{ cm}^2$ and $24 \times 24 \text{ cm}^2$ field sizes were compared using gamma analysis for further model validation. Simulations were performed for the X1 and X2 banks of the MLC. The leaves of the bank under investigation occluded half of the inline detector array, creating a half-beam block, while the other bank created a 6.64 cm field size. Positional errors ranging from 0.5–2.5 mm along the crossline direction were introduced in 0.5 mm increments to correlate detector response with the MLC positional offset. **Results:** The measured and simulated beam profiles agreed with a 100% pass rate using a gamma criterion of 2%/2mm. A linear relationship was found between the introduced MLC offset and detector response with the coefficient of determination for the X1 and X2 banks being 0.9987 and 0.9991, respectively. The change in detector response with MLC offset was 22.7%/mm and 17.4%/mm for the X1 and X2 banks, respectively, where this difference in sensitivity was determined to be statistically significant ($p < 0.001$). **Conclusion:** The proposed QA method was found to be sensitive to MLC positional offset and has potential to be useful for routine machine QA. Furthermore, differences in sensitivity to MLC offset were found for each MLC bank, which could be the result of the 0.35 T magnetic field influencing the secondary electron trajectories.

Mechanical Wind-Up Motion Phantom for MR-Linac Daily Quality Assurance

M Snyder^{1*}, R Halford², D Yan¹, (1) Beaumont Hospital, Royal Oak, MI, (2) Beaumont Hospital, Dearborn, MI

Purpose: Visualizing organ motion in real-time is a primary advantage of combined MRI and linear accelerator treatment systems. However, the cine sequences used for motion visualization often trade image quality and spatial distortion for temporal resolution. Here we present a simple MR-safe phantom for evaluating daily consistency of such sequences. **Methods:** We designed the components of the phantom in AutoDesk Fusion 360TM. To avoid eddy currents, we utilized plastic for all moving components of the phantom. We made design choices for ease of 3D printing and simple laser cut production. We used glass bearings to reduce friction in the system, and leaded plastic (density of $\sim 4 \text{ g/cc}$) for counterweights and energy storage. **Results:** The phantom is 25cm in height and width, and 15cm in depth. A weighted tray is wound to the top of the phantom, and the stored energy is released via an escapement mechanism attached to an external oscillating arm. Attached to the oscillating arm is a 3cm diameter water-filled ball. The period of oscillation is adjusted via a slidable counterweight. The motion phantom produces an adjustable periodic oscillation in a frequency range of roughly 0.4 to 2Hz. This corresponds to a run time of between 15 to 3 minutes. This range allows enough time to setup the phantom and run a test of the cine sequences. **Conclusion:** It is possible to construct a simple, lightweight, MR-safe mechanical phantom that oscillates with a long enough period to provide a useful motion test for cine MR sequences. The phantom can be built with a combination of 3D printed components, laser-cut plastic, and inexpensive plastic/glass bearings. STL files for all pieces will be uploaded to facilitate others wishing to instantiate the phantom.

Evaluation of the Dosimetric Accuracy and Angular Dependency of the Novel SRSSMapCheck Design in the Magnetic Field

O Pen*, O Green, A Price, Washington University School of Medicine, St. Louis, MO

Purpose: SRS MapCheck (SRS-MC) developed by the SunNuclear Corporation is a commercial device used for small field patient-specific dosimetry. However, functionality in the presence of a magnetic field for the purposes of MRI-guided radiation therapy QA comes with certain challenges and requires novel engineering solutions, as well as rigorous testing to confirm the improved performance of the new design. **Methods:** Angular dependency of the central axis ion chamber reading was investigated for 2.5x2.5 cm and 5x5 cm fields. An additional set of measurements were taken at both the isocenter and at a 2.5 cm lateral offset for a SRS-MC detector plane parallel and perpendicular to the couch on the MRidian ViewRay Linac, which has constant background magnetic field of 0.35T. Control sets of measurements were taken on a Varian Edge Linac. Measurements were acquired for a traditional SRS-MC design and a proprietary novel engineering design. Several plans of varying complexity were planned in the ViewRay TPS and then measured on the ViewRay Linac, with acquired measurements being compared to the pre-planned and evaluated based on γ -analysis. Absolute dose calibration was performed with readings acquired with A1SL Extradin IC and PTW diamond detector in a solid water phantom. **Results:** Angular dependency observed in the traditional design of the SRS-MC was rectified with the new design. CAX readings matched were similar with and without the magnetic field. A γ -rate passing rate of 97.8% (3%/3mm) was achieved for all plans in relative dose mode. Absolute dose mode also reveals good agreement when properly calibrated for the dose at the StereoPhan center. **Conclusion:** Novel design of the MRI-compatible SRS-MC addresses previously discovered deficiencies and irregularities in the dose measurement introduced by the presence of the magnetic field and ensures the suitability of the SRS-MC as a tool for patient-specific QA in small field dosimetry.

Evaluation of MRI-Guided Linear Accelerator Based Stereotactic Radiosurgery for Brain Metastasis

M De Ornelas*, N Dogan, W Amestoy, H Guerrero, T Diwani, E Mellon, Sylvester Comprehensive Cancer Center, University of Miami, Miami, FL

Purpose: Assess the feasibility of an MRI-guided linac system in treating brain metastasis by comparing the plan quality to a frameless automated linac-based SRS system for treatment of brain metastasis. **Methods:** Ten patients with a single metastatic lesion were retrospectively planned using a frameless automated linac-based SRS planning system with HDMLC (2.5mm leaf-width) and an MRI-guided linac system with double-focused double-stacked multileaf collimator (4.15mm leaf-width). Lesion sizes ranged from 0.3cc to 27.1cc, with an average of 5.1cc. Energy for all plans was 6MV FFF and normalization set to cover 99.5% of the target volume with the prescription dose. The HDMLC plans utilized VMAT technique with 4-5 non-coplanar arcs at 1200 MU/min while the MRI-guided linac system used step-and-shoot technique with multiple coplanar beams at 600 MU/min. Plan quality was assessed by the following metrics: gradient index (GI), RTOG conformity index (CI(R)(T)(O)(G)), brain volume receiving 12Gy or more (V12Gy) and maximum dose (D(m)(a)(x)) for brainstem, optic chiasm, and optic nerves. Two-sided Wilcoxon sign-rank test (statistical significance at $p < 0.05$) was used to test differences between metrics. **Results:** All plans met OAR constraints. D(m)(a)(x) to the brainstem, optic chiasm and nerves were not significantly different between the plans. HDMLC-linac plans were statistically better in terms of GI ($p = 0.00$), CI(R)(T)(O)(G) ($p = 0.00$) and V12 ($p = 0.01$). **Conclusion:** Our study demonstrates that MRI-guided linac system can provide comparable organs-at-risk sparing to the HDMLC-linac for treatment of single metastatic lesions, although the HDMLC-linac plans had better GI, CI(R)(T)(O)(G), and V12. The GI for the MRI-guided plans improved with increasing target volumes, achieving acceptable values (< 4.0) for targets greater than 3cc, suggesting it could be used for SRS treatment of single metastasis targets larger than this size.

MO-A-TRACK 1-05

Audience Q&A

The relationship between the LGBTQIA+ community and the healthcare industry has historically been laden with fear and distrust. This persists today with access to care being denied or limited through policies including religious exemptions, discriminatory insurance requirements, and legislation targeting the LGBTQIA+ community. In addition, a lack of high-quality training for medical practitioners and supporting staff often results in a climate that fails to make LGBTQIA+ patients feel safe when they are at their most vulnerable. These barriers to care result in an inability and/or unwillingness to receive routine healthcare screenings, lower the likelihood of completing treatment, and ultimately lead to poorer outcomes among this population. The LGBTQIA+ community is multifaceted and varied; one's socioeconomic status and racial identity are key factors in dictating the level of severity of these health disparities.

While the challenges to reducing inequality can seem formidable, there are ways in which we, in the Medical Physics community, can begin laying the foundation for compassionate care for our LGBTQIA+ patients and provide support for our LGBTQIA+ colleagues. In this session, we aim to provide a brief historical background on this community's relationship to healthcare, tools that can be utilized to enhance both the patient and colleague experience, and examples pertaining to ongoing departmental efforts dedicated to promoting and championing inclusivity.

Learning Objectives:

1. Identify the historical and current healthcare disparities facing the LGBTQIA+ community.
2. Critically explore the intersection of race and LGBTQIA+ identities and its implications.
3. Identify and discuss steps being taken by clinics to enhance the comfort and safety of our LGBTQIA+ patients.
4. Demonstrate ways in which Members can ensure a welcoming and safe environment for LGBTQIA+ trainees and colleagues.

Prostate MRI Protocols

MO-A-TRACK 2-04

Audience Q & A

Speaker 1 (Ping Hou, PhD) – Brain MRI protocols

Magnetic resonance imaging (MRI) is a painless, noninvasive procedure that produces highly detailed images. Unlike X-rays or CT scans that use radiation to generate an image, MRI relies on hydrogen in the body to create images using a strong static magnetic field, RF waves, and spatially varying gradients. MRI brain scan can detect numerous diseases such as brain tumors and injuries, strokes, seizures, and developmental abnormalities as well as monitor treatment responses. Brain protocols share some common sequences which are tailored differently for unique diseases. This lecture will focus on the protocol of basic brain study, the physics of each pulse sequence, and image parameter optimizations. We will discuss several basic image artifacts and techniques to minimize them as well as introduce some new emerging techniques.

Learning Objectives:

1. To understand composition of common clinical MR brain protocols and their indications.
2. To understand pulse sequence selection, optimization and some basic artifacts.
3. To be able to implement some simple MR protocol for brain study.

Speaker 2 (Trevor J. Andrews, PhD) – Spine MRI protocols

MRI of spine is one of the most commonly clinical MRI studies. It is a powerful test for detecting anatomic abnormalities and assessing severity of pathology. This lecture will discuss several common indications for MRI of the cervical, thoracic, and lumbar spine. In addition several specific scanning techniques will be discussed as well as typical parameter choices which address these indications. Finally, we will address some of the key quality and safety issues physicists can address for MRI of the spine.

Learning Objectives:

1. To be able to list and discuss basic features of several common indications for spine MRI.
2. To be able to list and discuss the most common clinical MRI techniques used for the spine.
3. To be able to list and discuss the key image quality and MR safety issues for MRI of the spine.

Speaker 3 (Qing Yuan, PhD) – Prostate MRI protocols

Clinical prostate MRI protocols have evolved from robust anatomic T2-weighted (T2W) imaging to multiparametric MRI (mpMRI) with additional functional information from diffusion-weighted imaging (DWI) and dynamic contrast-enhanced (DCE) imaging in the management of patients with confirmed or suspected prostate cancer. Prostate Imaging Reporting and Data System (PI-RADS) adopted by medical communities not only serves as a guideline for standardized interpretation and reporting of prostate mpMRI data, but also defines explicitly minimal acceptable imaging acquisition parameters for prostate MRI protocols. This lecture will provide details of implementation and optimization of pulse sequences for prostate mpMRI protocols, and discuss emerging techniques for MRI-guided in-bore prostate biopsy and therapeutic interventions.

Learning Objectives:

1. To understand the pulse sequences in common clinical prostate MRI protocols.
2. To be able to implement and optimize pulse sequences tailored for specific clinical indications.
3. To be familiar with emerging MR techniques in prostate MRI applications.

B. Pogue, Thayer Engineering:

Macroscopic Biophotonics In-Vivo

MO-A-TRACK 3-03

Audience Q & A

Microscopic Biophotonics - One major objective of microscopic biophotonics technologies is to enable in vivo, in situ, and noninvasive or minimally invasive optical histology. This presentation will focus on the recent developments of two representative microscopic biophotonics technologies: optical coherence tomography and multiphoton endomicroscopy. These technologies are capable of imaging tissue microanatomy at a resolution from a few microns to the submicron level in real time and without the need for tissue removal, staining or processing. The basic physics principles, engineering challenges and solutions will be discussed. The performance of these imaging technologies for in vivo animal models, ex vivo human tissues, and translational in vivo human subject imaging will be presented.

Macroscopic Biophotonics – The major objective of macroscopic biophotonic technologies is to enable human physiological or pathophysiological study or clinical assessment. The presentation will focus on both research based and clinical tools for imaging tissue, guiding procedures, and measuring tissue function. Examples will be illustrated from endoscopy, surgery and radiation therapy, where innovations in procedure guidance are changing how delivery of care is achieved. More basic instruments that are portable, mobile or even implantable, make use of low cost innovations in light sources and detectors. The economic footprint of macroscopic optics is perhaps the largest single technology sector in medicine today.

Learning Objectives:

1. To learn about the recent developments and translational potential of microscopic biophotonics imaging technologies.
2. To learn about existing and emerging tools in surgical guidance, endoscopy, and radiation therapy as examples of medium to high cost macroscopic optical systems.

Pitfalls of Current Data-Driven Solutions and Pathways Toward XAI for Medical Physics

Artificial intelligence driven by deep learning have attracted much attention in the several years and is being increasing adopted in medical physics for various applications. The enormous success of deep learning stems from its unique capabilities of extracting essential features from big data and then making inferences. However, the data-driven process has many potential flaws, such as the demand for a large amount of annotated data and lack of interpretability. The purpose of this symposium is to summarize recent advances in deep learning techniques, in particular, unsupervised and semi-supervised deep learning, graphical neural networks, and technical tools that make AI more interpretable and trustworthy. Specific applications of the new generation of deep learning techniques in imaging, treatment planning, dose delivery, and clinical decision-making will be discussed in detail.

Learning Objectives:

1. Highlighting recent advances in deep learning techniques, such as unsupervised learning and interpretable AI.
2. Presenting new applications of these deep learning algorithms in quantitative imaging, image analysis and treatment planning.
3. Providing a comprehensive overview of the roles of the new generation of neural networks in imaging, treatment planning and therapeutic delivery.

First Human Clinical Trial on Treating Bone Metastases with FLASH

MO-AB-TRACK 5-06**Q&A & Panel Discussion**

Abstract: Ultrahigh dose-rate (FLASH) radiotherapy is on the forefront of radiotherapy with the potential to 'revolutionize cancer treatment'. There is a great interest as well as skepticism about this novel radiotherapy technique. The goal of this symposium is not to re-iterate the most known results to date, but to present the newest developments in terms of preclinical and clinical trials as well as technology developments.

The session will be opened by Sunil Krishnan, MD by discussing clinical challenges of FLASH in his talk entitled FLASH RT – the devil is in the details. Dr. Krishnan will speak about the conflicting data and focus more on the negative results to date. For balance, he will acknowledge that there are compelling positive results. Then he will discuss the recent results from Dresden, Australia, MDACC and MGH. He will wrap up by saying that it is critical to democratize FLASH and make it readily accessible to all so that more groups can perform benchmarking studies with appropriate controls and implore all groups to publish both positive and negative data and minimize publication bias.

Pierre Montay-Gruel, PhD, a radiobiologist, will present on the Benefits of hypo-fractionated FLASH-RT on the brain function. The advantages of single doses of FLASH-RT on the preservation of neurocognitive functions along with brain homeostasis has been intensively described. Recently, his group showed that FLASH-RT delivered with hypo-fractionated regimen was able to delay murine glioblastoma growth. Investigations of the impact of such hypo-fractionated doses to the normal brain are currently being performed, on the neurocognitive aspect but also on the preservation of the blood brain barrier and brain homeostasis.

Michelle Kim, PhD will present a talk entitled Implementation and Design of a Proton FLASH System for the First Canine Clinical Trial. Dr. Kim will talk about the initial experiences with our dedicated proton research room and talk about the efforts on the design and commissioning of the proton FLASH capabilities of our system. Additionally, she will discuss the current ongoing canine clinical trial for osteosarcoma.

Colleen Des Rossiers, PhD will present a talk entitled VHEE – rationale for therapy and FLASH potential. In her presentation, she will summarize the work on very high-energy electrons (VHEE), a candidate modality for clinical FLASH to large deep-seated tumors. The utility of very high energy electrons in the energy range from 150 MeV – 250 MeV (VHEE) in radiation therapy has been explored by many researchers in the last twenty years, but currently there are no commercially available medical accelerators producing electrons in this energy range. The FLASH effect has been most demonstrated with electron beams and data supporting the FLASH effect with photon beams is sparse. The dosimetric benefits of VHEE as compared with photons will be presented with the potential for FLASH therapy using VHEE. Additionally, the current state of the VHEE medical accelerator will be presented.

Anthony Mascia, PhD will conclude the session by presenting the technical and perhaps some clinical challenges of the first FLASH clinical trial with proton beams. Dr. Mascia's presentation will focus mostly on preparation, commissioning and delivery of FAST-01, the first FLASH clinical trial. The narrative is to present the pre-existing scientific literature then show some Cincinnati data that supported the clinical trial. Dr. Mascia will describe their animal irradiation systems that prepared them for commissioning a clinical gantry for a clinical trial. Most of the presentation will focus on the FAST-01: study design, technical challenge, planning, dosimetry, measurements, procedures and summary of data thus far available.

Learning Objectives:

1. To learn about the clinical barriers for translation of FLASH
2. To learn about the most current understanding of FLASH radiobiology
3. To learn about the technology developments potentially enabling clinical FLASH
4. To learn about the ongoing canine and clinical FLASH trials

Image-Guided Surgery and Interventions

MO-A-TRACK 6-01

Cardiac Radioablation: MRI-Guided Tracking of Cardiac-Induced Target Motion

S Lydiard^{1*}, B Pontre², N Hindley¹, B Lowe³, G Sasso⁴, P Keall¹, (1) ACRF Image X Institute, University of Sydney, Sydney, AU, (2) Department of Anatomy and Medical Imaging, University of Auckland, Auckland, NZ (3) Green Lane Cardiovascular Service, Auckland City Hospital, Auckland, NZ (4) Cancer & Blood, Radiation Oncology, Auckland City Hospital, Auckland, NZ

Purpose: Cardiac radioablation (CR) for atrial fibrillation (AF) presents one of the most challenging radiotherapy tracking scenarios: multiple small targets undergo rapid differentional cardio-respiratory motion and are near organs-at-risk. MR-guidance offers a solution for real-time target tracking. This work aims to develop and investigate MRI-guided tracking for cardiac-induced motion of CR targets. **Methods:** A tracking algorithm utilizing template-matching concepts, image manipulation optimized for target visualization and population-based target motion assumptions was developed. Tracking performance was characterized using breath-hold MRI images from six healthy and six AF participants. Multi-slice, ECG-gated, 2D cines were interpolated into 3D images for 18-30 cardiac phases, creating 4D datasets. Ground-truth targets were contoured on every cardiac phase. Retrospective tracking was performed on a single transverse slice of a 4D dataset. 3D geometric and volumetric tracking errors were calculated, defined as the difference between the ground-truth and tracked target centroids and volumes respectively. Single slice, transverse, ungated cines (50-60 images) were acquired at 4Hz in three healthy and three AF participants and used to characterize retrospective tracking performance on images more comparable to MRI-Linac acquisitions. Each image was visually assessed for critical tracking errors, defined as the tracked target overlapping an organ-at-risk. **Results:** The average 3D geometric tracking error was 1.6±1mm and 1.3±1mm for healthy and AF participants respectively. 90% of 3D geometric tracking errors were less than 3mm and 71% were less than 2mm. The average volume difference for all evaluated images and targets was 0.27±3cc and 0.02±2cc in healthy and AF participants respectively. 8.0±5% and 11±10% of the ungated images in healthy and AF participants respectively had critical 2D tracking errors. **Conclusion:** The feasibility of MRI-guided AF CR cardiac-induced target motion tracking has been demonstrated. The promising results warrant further investigation as a possible means to improve CR for AF treatment efficacy.

Deep Learning for Near Real-Time Image-Guided Focal Ablation

B Anderson*, B Rigaud, Y Lin, E Lin, G Cazoulat, E Koay, A Jones, B Odisio, K Brock, UT MD Anderson Cancer Center, Houston, TX

Purpose: Harness deep-learning based segmentation and registration capabilities combined with biomechanical model-based registration to train an outcome prediction algorithm for liver focal ablation outcomes. **Methods:** 129 patients with 204 lesions who underwent ablation therapy were retrospectively evaluated, including follow-up status of the ablated lesion. Liver, and disease segmentations were defined on pre-treatment and post-treatment CT images using a clinically validated AI-based algorithm. Lesions were separated based on patient MRN into a training/validation cohort, with 29 locally progressing and 24 non-progressing sites with > 6 month follow-up in the validation cohort. Image features from the pre-treatment CT were extracted via convolutions and fed into fully-connected layers for outcome prediction. Tuned hyper-parameters included dense layers, dense connections, convolutional layers, dropout, transition blocks, number of filters, unique loss functions (cosine/categorical cross entropy), and the images presented. We trained and evaluated the model using both rigid and deformable image registration (DIR), including liver segmentations, and/or disease segmentations based on validation area under the curve (AUC). **Results:** Qualitative assessment of our AI-based segmentation models showed immediate clinical usability or < 10 seconds editing in 96% (48/50) of liver, and 100% (24/24) of disease segmentations. AUC values were maximized when presenting the model with DIR images and the disease contour (AUC=0.75), and when presenting the model with rigid images, liver, and disease contours (AUC=0.74). **Conclusion:** Our fully automated outcome prediction model can provide the clinician with a likelihood of future tumor progression based on intra-procedural imaging in a clinically actionable timeframe (< 1 minute), providing feedback on ablation efficacy.

Funding was provided by the Society of Interventional Radiology Allied Scientist Grant, and the Dr. John J Kopchick Fellowship.

Head, Shoulders, Knees, and Toes: Towards Full Body Upright Cone-Beam CT Imaging

T Reynolds*, O Dillon, R O'Brien, ACRF Image X Institute, University of Sydney, Sydney, NSW, AU

Purpose: Limb realignment surgery is increasingly guided by preoperative 3D imaging to develop precise patient specific treatments. Current standard 3D imaging systems such as CT scanners require the patient be imaged supine, complicating surgical decisions attempting to improve limb performance under load. Here, we investigate the possibility of conducting weight bearing 3D imaging on a standard robotic cone-beam CT system, imaging the ankle, knee and hip in a single scan. **Methods:** A Siemens ARTIS pheno robotic cone-beam CT system (Siemens Healthcare) was used to image a synthetic ankle, knee and hip phantom (Sawbones) standing upright with a height of 110cm, mimicking stationary weight bearing conditions. The ARTIS pheno C-arm was manually manoeuvred away from the table

and positioned with the source and detector parallel to the floor. In this position, the C-arm was able to rotate around the phantom through an arc of 135°. The phantom was imaged (7.5 fps, 90 kV) from ankle to hip via a series of eight 135° arcs separated by approximately 17cm upward axial translations. The 3D images were reconstructed using a total variation regularised reconstruction. **Results:** The multi-arc acquisition enabled a total axial coverage of 100 cm, capturing the ankle, knee and hip joints in a single scan. The scan took ~120 seconds to complete, acquiring 1357 projections. The gantry movements were manually controlled via the pilot-joystick, limiting the gantry rotation velocity to 10°/s, elongating the scan time. **Conclusion:** This is the first-time upright 3D imaging of the ankle, knee and hip in a single scan has been implemented on a standard robotic angiography system. It represents the first step towards full body upright 3D imaging on a standard system, as well as 3D imaging of lower body limbs moving (i.e. bending and walking) for high quality preoperative planning and postoperative assessment.

This research was supported by G201166 IPA2 with Siemens Healthineers; ACRF grant G175269; Ricky O'Brien Fellowship CI NSW Fellowship G195559, NHMRC Project Grant G193048; Tess Reynolds USyd Postdoctoral Fellowship Scheme G200793.

MO-A-TRACK 6-04

Mechatronics-Assisted MRI-Guided Focal Laser Ablation of the Prostate: A Phantom Study

E Knull^{1,2}, C Park^{1,2*}, J Bax², D Tessier², A Fenster^{1,2}, (1) Western University, London, ON, CA, (2) Robarts Research Institute, London, ON, CA

Purpose: Magnetic resonance imaging (MRI)-guided focal laser ablation (FLA) is an emerging, minimally invasive treatment for prostate cancer, which involves the therapy and monitoring of localized regions to preserve critical structures and healthy tissues. Accurate needle delivery is pivotal to the therapeutic success of FLA. We present a mechatronic-assisted MRI-guided needle delivery system for prostate FLA allowing for in-bore needle positioning. This work aims to validate its free-space and in-bore needle positioning accuracy, and to demonstrate its utility in prostate phantoms. **Methods:** A compact MRI-conditional mechatronic system was developed with non-ferromagnetic components with actuation controlled by piezoelectric motors and optical encoders. It enables four degrees-of-freedom for transperineal positioning and an adaptable needle-guide. The needle-guide is remotely actuated, and needles are manually inserted for FLA to retain clinician expertise during the workflow. Needle positioning accuracy over the range-of-motion was assessed via free-space and in-bore MRI experiments (GE Discovery MR750 3T MRI) to virtual targets and the needle tip error was quantified. Prostate phantom experiments were performed to a 10.0cm needle insertion depth and needle tip error and needle trajectory error were quantified. Needle tracks were manually segmented on gradient recalled-echo (GRE) 3T-MRI images. **Results:** Free-space and in-bore needle positioning resulted in a mean needle tip error (SD) of 0.80±0.36mm (N=40) and 2.11±1.05mm (N=25), respectively. Preliminary phantom studies show a mean needle tip error and needle trajectory error of 2.61±0.62mm and 0.32±0.62° (N=10), respectively. This error enables an accurate FLA ablation radius of 3.02mm, within a 95% confidence interval and under the intended MRI acquisition parameters. **Conclusion:** We demonstrated the utility of a mechatronics-assisted system for MRI-guided prostate FLA. Preliminary prostate phantom studies show potential for accurate and precise MRI-guided needle delivery to localized focal zones, while maintaining manual needle insertion to improve safety with haptic feedback and optimizing MRI-guided FLA workflow.

This work was supported by the Ontario Institute for Cancer Research (OICR) Imaging Program, the Natural Sciences and Engineering Research Council of Canada (NSERC), and the Canadian Institutes of Health Research (CIHR).

MO-A-TRACK 6-05

An Investigation of Microwave Ablation Equipment Interference with Wireless Patient Monitoring

C Favazza*, A Ferrero, J Felmlee, Mayo Clinic, Rochester, MN

Purpose: To determine the extent of microwave ablation equipment interference with wireless patient monitoring in neighboring clinical spaces and estimate a shielding goal to allow simultaneous operation. **Methods:** Two Covidien Emprint microwave ablation units were clinically oriented in a space for a future procedure room, adjacent to an anesthesia induction bay where anesthetized patient vitals are wirelessly monitored with a Philips Expression MR400. One antenna per generator was inserted into an anthropomorphic water tank phantom at locations that represented worst-case clinical scenario for leakage microwave energy. Patient wireless monitoring devices were operated in the induction bay and interference was assessed with microwave generators set to different power levels. Ambient RF power (2.4–2.5 GHz range) was measured in the induction bay using a Tektronix RSA306B USB Spectrum Analyzer. The following measurements were performed 10 times over a 3-week span: (1)background, (2)MR400 communication, (3)full microwave antenna power (I(max)), (4)microwave antenna power level that preceded loss of vital trace (I(Edge)), and (5)power level that did not cause significant interference (I₀) with MR400. To assess the effect of room shielding, microwave units were operated inside an MRI scan room while wireless patient monitoring devices were operated in the adjacent induction bay. **Results:** Experiments demonstrated that microwave interference could result in complete loss of patient vitals data. Repeated RF power measurements showed: (1) significant overlap between MR400 communication and leakage microwave at I(max), (2) partial overlap at I(Edge) (3) and negligible overlap at I₀. From these results, a shielding design goal of 16dB was calculated. Lastly, MRI scan room shielding attenuated leakage microwave to power levels at or below background and prevented interference with MR400 in the adjacent room. **Conclusion:** Leakage radiation from microwave ablation devices can catastrophically interfere with wireless patient monitoring in nearby rooms. Proper room shielding can prevent such interference.

MO-A-TRACK 6-06

Micro-CT Enables Margin Assessment of Full Tissue Surface in Breast Conserving Surgery Without Impeding Clinical Workflow

B Maloney^{1*}, R Zuurbier², R Diflorio-alexander², S Streeter¹, W Wells², R Barth², K Paulsen^{1,2}, B Pogue^{1,2}, (1) Dartmouth College, Hanover, NH, (2) Dartmouth Hitchcock Medical Center

Purpose: Breast conserving surgery has a high positive margin rate leading to 15% of patients requiring a second surgery. Clinically accepted tools such as standard specimen x-ray have severe limitations. This study aims to show that micro-CT can improve malignancy detection across the entire surface of the resected specimen without significantly changing clinical workflow. **Methods:** Specimens from 33 patients undergoing breast conserving surgery were imaged as a part of a clinical trial at the time of surgery. Micro-CT scans were prospectively analyzed by two radiologists to determine margin status and tumor-to-edge distances for all six anatomic margins as well as the primary tumor diameter with a time-constraint of five minutes to mimic clinical conditions. **Results:** Micro-CT imaging of breast cancer specimens was done in 3-4 minutes and scans were analyzed in under five minutes. Sensitivity, specificity, and accuracy compared to pathology were 28.6-57.1%, 94.2%-90.1%, and 91.9-88.9% respectively. This can be compared to standard specimen x-ray imaging on the same data which gives values of 29%, 98%, and 95%. The primary tumor diameter obtained from the micro-CT scans compared to measurements in Pathology showed a Pearson Correlation Coefficient of 0.61 or 0.43 depending on the radiologist. **Conclusion:** This is the first study comparing micro-CT scans taken at the time of surgery to standard-of-care intraoperative tools. This study was designed to mimic clinical conditions, with imaging and analysis taking less than 10 minutes. This is comparable to the timing of current tools. The results are comparable to standard 2D specimen x-ray but with the ability to determine margin status across the entire tissue surface. There is inter radiologist variation in the analysis of these micro-CT scans. This could be due to a lack of training data for this novel modality.

MO-A-TRACK 6-07

Evaluation of Geometric Distortion in 7T MRI for Frameless Surgical Procedures

K Kirby*, K Welker, E Koons, A Fagan, Mayo Clinic, Rochester, MN

Purpose: To investigate the feasibility of using 7T MRI for image guidance during neurosurgical procedures that utilize skin-adhesive fiducials. These techniques require high spatial accuracy, which in MRI is limited by distortions due to inhomogeneity of the static field, nonlinearity of the applied gradients, susceptibility of tissues, and chemical shift artifacts. These distortion artifacts can affect targeting accuracy and are more pronounced in 7T MRI than at lower field strengths. **Methods:** A custom head-shaped phantom and 3 research subjects were imaged at 3T (Siemens Prisma) and 7T (Siemens Magnetom Terra). 10 skin-adhesive fiducials were placed on the phantom surface and on the exposed skin surface of the subjects, according to standard scanning procedures. Imaging sequences (MPRAGE, T2_SPACE, T2_SPACE_FLAIR) were optimized at 7T to reduce distortions, and all were corrected for gradient nonlinearity using the vendor distortion correction algorithm. The ground truth (GT) positions of the phantom fiducials were established via CT imaging (Siemens Somatom Force). Rigid registration of all image volumes was performed. Residual geometric distortions were quantified in phantoms via comparison with GT locations. Differences in fiducial positions in subjects between 3T and 7T were measured. **Results:** The phantom skin fiducial location error was 1.9 ± 0.6 mm for 7T MPRAGE, 1.3 ± 0.6 mm for T2_SPACE, and 1.6 ± 0.5 mm for T2_SPACE_FLAIR. Average subject fiducial location differences (3T compared to 7T) were 1.9 ± 0.1 mm for MPRAGE, 2.1 ± 0.1 mm for T2_SPACE, and 2.9 ± 0.5 mm for T2_SPACE_FLAIR. **Conclusion:** The data presented herein demonstrate that 7T-optimized imaging sequences can be used for neurosurgical planning applications where errors of up to 2 mm are acceptable, using standard skin-fiducial positioning procedures.

A Novel Formalism for Incorporating Professionalism, Interpersonal and Communication Skills into Medical Physics Residency Training

I Vergalasova*, N Yue, K Nie, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ

Purpose: The evolution of value-based healthcare and personalized medicine together with the rise of Medical Physics 3.0 has placed great emphasis on the importance of cultivating our skillset beyond science and analytics, to include professionalism, interpersonal and communication skills. Traditionally, these soft skills have been acquired indirectly via on-the-job training. However, it has become strikingly evident that formalized training of this skillset is a necessity for the success of medical physicists. Thus, a novel framework for incorporating formalized training of these soft skills into medical physics residency programs is proposed. **Methods:** The Accreditation Council for Graduate Medical Education (ACGME) provides a template of 5 milestone levels that can be applied to each of their required six core competencies, two of which are “Professionalism” and “Interpersonal and Communication Skills.” Given the success of the ACGME in training resident physicians over the course of decades, we decided to apply their milestone level template by customizing it to fit within each of the required medical physics residency clinical rotations. The formalism presents a framework for both the training that should be provided to the resident, as well as how to evaluate whether the resident has successfully mastered this training. **Results:** Five milestone levels were developed within each clinical rotation, as per CAMPEP standards. Along with each milestone template are guidelines for baseline assessment, formalized training and continuous evaluation for rotation leader(s) to follow their trainee’s progress attaining each of the milestones. Depending on the length of the rotation, a timeline was recommended for achieving each of the levels within the scope of that rotation. **Conclusion:** We believe the proposed framework is universal enough to be adapted into CAMPEP-accredited residencies nationwide. Although a significant time investment for both training and evaluation is required, the cultivation of successful medical physicists is rewarding beyond measure.

Career Preparation for Graduate Students: Preliminary Evaluation of An Introductory Course on the Profession of Medical Physics

S Leon*, B Schwarz, L Rill, M Arreola, University of Florida, Gainesville, FL

Purpose: Medical physics graduate students often receive an excellent education in academic topics but lack knowledge of what to expect after graduate studies. Students may be unfamiliar with career options available to them; the role of regulatory, accreditation, and certifying bodies; the residency application process; ethical and professional behavior; medical errors; and the role of professional societies. A one-credit course was created to address these topics. **Methods:** A new graduate course, featuring didactic lectures and practical, interactive assignments, was developed to address medical physics career awareness. Students learned about different subspecialties and work environments by holding and presenting interviews with practicing medical physicists across the country; they prepared for residency by writing a CV, personal statement, and participating in mock residency interviews with various program faculty; they engaged in small group discussions to debate real-world ethical issues; they performed a root-cause analysis; and they planned their own “career path”. Improvement in student career awareness and preparation was assessed by course evaluations and pre- and post-class surveys. **Results:** The course has been offered for two years and taken by 20 students. Course evaluations were completed by 15 students, with the educational value of the course rated as 4.3/5 (3.71 in year one, 4.75 in year two). In the second year, a pre-class and post-class survey was instituted to gauge the impact of the course on individual topics. Students reported increased awareness of career options, regulatory agencies, board certification, ethical and professional behavior, and professional societies. They reported a particularly strong increase in feeling prepared for the residency application process, with an initial score of 4.2/10 and a final score of 8.3/10. **Conclusion:** Medical physics students can benefit from a one-credit course dedicated to career preparation. Comments by students in course evaluations were overwhelmingly positive.

MO-AB-TRACK 7-03

Feasibility of Virtual Reality (VR) with Open-Source Software for Interactive Medical Physics Education

S Yoon*, T Li, University of Pennsylvania, Philadelphia, PA

Purpose: To investigate capabilities of an open-source-based VR tool for interactive multi-volume data presentation and medical physics education on a commercially available computer. **Methods:** VR headset and controller system (Samsung Odyssey+) was set-up with 3D-Slicer (v4.10.2) on a PC with modern graphics card (NVIDIA RTX 2080). Six VR scenes were constructed within 3D Slicer based on anonymized radiation therapy (RT) cases, including lung stereotactic body radiotherapy and head and neck proton therapy. Position and 6D motion data from headset and controllers were inputted into 3D-Slicer’s volume renderer to visualize multi-volumetric information in real-time. User could navigate freely within the VR scene using natural head and body movement. Stability and frame-rate (frames-per-second, or fps) of VR displays were qualitatively tested under various stressing conditions (e.g. multiple volume visualization, real-time re-slicing), and subjective experience such as motion sickness was tested on volunteers. **Results:** VR cases with less than 4 volumes simultaneously rendered in real-time had minimal perceptible loss in VR display fps~60. Performance suffered minimally with 4D-CT visualization involving 8 breathing phases (fps>50). Interaction with a single volumetric image decreased performance slightly while interaction with two simultaneously decreased performance significantly (fps<50 vs. <30), especially when real-time volume re-slicing was involved (fps<20). Performance increased significantly when images were rendered only on VR headset and not on the computer (50 vs. 35fps). Turning off shading also improved volume quality and performance substantially, while minimally impacting data visualization. Overall volunteers reported minimal motion sickness, except when frame-rate dropped below 20fps. **Conclusion:** VR scenes based on radiotherapy patient cases were created using open-source software. The ability to navigate and visualize complex 3D multi-volume information with intuitive body movements makes this a valuable tool for medical physics education. Various frame-rate optimization strategies can be employed to improved usability and reduce motion sickness of VR on this platform.

MO-AB-TRACK 7-04

Valued Discourse in Oral Examinations for Medical Physicists

A Cetnar^{1*}, (1) The Ohio State University - James Cancer Hospital, Columbus, OH

Purpose: Oral exams are commonly used as formative assessment for graduate programs and medical specialty certification and claim to assess problem-solving, probe depth of knowledge, recognize safe and competent clinicians, and assess professionalism and ethics. This study explores discourse between examiners and candidates during oral examinations to understand how these exchanges during the exam are related to the outcomes of the candidates in mock oral examinations.

Methods: Mock oral examinations were studied to examine discourse between examiners and candidates. Video recordings of the sessions (N = 53) were collected and transcribed. A mixed-methods design was used to inform a theory of questioning, justification, and the determination of acceptable responses. A grounded theory approach was used to analyze the discourse during these oral board examinations to understand how answers are assessed so that candidates can be more successful in how they present their responses during the examination. The scores of the exam questions, overall score, and examiner comments were provided correlation with the recordings. **Results:** After reviewing the data, examiners overwhelmingly asked questions involving requests for additional details or facts (74%). Candidates spoke more during the examination than the examiners with the average of $65\% \pm 13\%$ of the words being spoken by the candidate and $35\% \pm 13\%$ of the words from the examiner. **Conclusion:** Oral examinations can be a useful tool for evaluation if conducted with suitable assessment conditions. The questions should be well organized and examiners should receive appropriate training in asking valuable questions during the examination to be of greatest benefit to the candidate.

MO-AB-TRACK 7-05

Cooperative Education in a Medical Physics Masters Graduate Degree Program

A Riegel^{1, 2, 3*}, P Taylor^{1, 3}, (1) Northwell Health, Lake Success, NY, (2) Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY, (3) Hofstra University, Hempstead, NY

Purpose: Graduate medical physics education is often geared towards three career paths: Academic medical physics through post-doctoral research, clinical medical physics via board certification, or some weighted combination of the two. There are, however, many jobs where medical physics expertise may be useful. We developed a cooperative education or "co-op" course within our graduate program to connect employers to second year master's students. The purpose of the co-op was threefold: First, provide additional professional experience in our field; second, expose students to career pathways previously not considered; third, provide a means to financial support during graduate study. **Methods:** The co-op course was first offered in summer 2019. Students were eligible to participate after completing one year of study with a minimum cumulative GPA of 3.0. Three local companies agreed to offer a co-op: A medical physics consulting group, a radiation oncology software company, and an intellectual property law firm. Employers were required to sign a statement of understanding regarding educational expectations and minimum hourly wage. Student were hired directly by employers. Students and employers were asked to complete performance evaluations twice a semester to ensure a positive experience for both participants. Two graduates and two current students have participated in the co-op. **Results:** Survey results from participating students, alumni, and employers have been overwhelmingly positive with students saying they would recommend the co-op to other students and employers saying that having a co-op student was very positive for their company. One firm hired their co-op student full-time after graduation. **Conclusion:** Cooperative education is an innovative program that, in addition to providing much-needed funding to graduate students, yields invaluable professional experience to students that may illuminate career opportunities beyond traditional academic and clinical medical physics. We plan to expand the co-op program to include more local firms in the near future.

MO-AB-TRACK 7-06

Enhancing Brachytherapy Education with Immersive Virtual Reality (VR) Video Technology: Best Practice and Preliminary Outcome

T Li*, N Shah, E Hubley, S Anamalayil, N Taunk, University of Pennsylvania, Philadelphia, PA

Purpose: To develop and evaluate an education platform for brachytherapy using immersive video technologies. **Methods:** Immersive VR video technology uses a single 360-degree camera to record the entire 4-Pi space around the camera. When played back on supported devices, viewers can freely look around using their head movement when viewing on a head-mounted display or mouse when on computers. In this study, we compared cameras with different resolutions and features such as high-dynamic range videos. Different content delivery platforms were also compared. Finally, a gynecological brachytherapy immersive video simulation was delivered using VR headset to 14 medical residents. Enhancement of training outcomes was evaluated based on pre- and post-simulation surveys. **Results:** Consumer-grade VR cameras are preferred over professional VR cameras because of their smaller size and ease of use, which reduces interference with operating-room workflow and the chance of operator-related errors during video acquisition. If surgical light is used during procedure, it is important to use cameras capable of recording high-dynamic-range video. A minimal of 5.7k (5760x2880 pixels) resolution is required for brachytherapy immersive simulation due to the need to visualize small instruments such as applicator/needles, and ultrasound images/videos. 8k (7680x3840 pixels) resolution enhanced the visibility of small instruments and ultrasound but is not currently supported on mobile devices or headsets. VR brachytherapy training is best delivered using VR headset because it creates an immersive experience and reduce distractions. Applying VR simulation to medical residents increased their self-assessed scores in confidence, applicator assembling skills, insertion skills, and comfort with independent procedure from 1.5 to above 3 ($p < 0.001$). **Conclusion:** For creating VR video for brachytherapy education, a small camera with $\geq 5.7k$ resolution and high-dynamic-range video should be used. Preliminary results demonstrated substantially enhanced training outcome when VR simulation is used with high degrees of usability, engagement, and enjoyability.

This study is partially supported by McCabe Foundation and American Brachytherapy Society

The Toll of the Job: Burnout and the Medical Physicist

MO-B-TRACK 1-03

Audience Q&A

When clinics first began to care about patient incidents, punitive action was often taken against the healthcare worker. When safety experts recognized the environment's role, some clinics shifted to a blame free culture. We currently know however, that the Goldilocks "just right" clinical environment is one with a just culture. An organization with a just culture uses systems methodology when investigating an error or incident and evaluates the role of both the involved healthcare worker as well as the organization. Instead of focusing solely on the "sharp end", or the employee who made the mistake, a just culture looks to identify systematic factors that led to the error. The organization is responsible for a work environment that is fair to its staff while still endorsing personal accountability. Often, an organization with a genuine just culture environment also has a healthy work environment.

Burnout has recently been recognized by the World Health Organization as an occupational phenomenon that can manifest itself in a number of different ways. One of the current theories suggests that the probability of burnout increases as the mismatch between the individual's own value system and that of their organization diverges. One example of this potential mismatch is an employee's expectation of a just and fair work environment while the organization operates from a punitive stance. Based on data from a recent survey on burnout in medical physicists, the prevalence of burnout in our profession, and correlates to organizational features will be presented.

This session will provide an overview of just culture and explore ways to encourage a fair work environment in your workplace. An overview of burnout, its relationship with your work environment, and the potential implications of burnout will also be discussed.

Learning Objectives:

1. Understand just culture and ways to encourage a fair environment in your workplace.
2. Review the signs and potential causes of burnout.
3. Explore the prevalence of burnout in our profession and understand the potential implications of burnout on yourself and others.

Innovations in Medical Physics Education

MO-B-TRACK 2-06

Q&A

Dr. Edward F Jackson was a gentleman and a scholar. Ed's passing left a hole in our world and our hearts. His contributions to the field of medical physics, the science of magnetic resonance imaging (MRI) and quantitative imaging, MD Anderson Cancer Center, the University of Wisconsin, the AAPM and education were all impactful. In this symposium, we will attempt to convey the impact Ed had on these areas and on so many colleagues in medical physics around the world.

The landscape of MRI has changed substantially over the last couple of decades. MRI is an extremely versatile, non-ionizing modality with multiple soft-tissue contrast mechanisms for visualizing and characterizing anatomy, physiological function and metabolism. Constant technological advances are resulting in higher-performing and more reliable systems increasing the footprint of MRI in diagnostic and oncologic imaging. Additionally, MRI has also experienced rapid growth outside traditional diagnostic radiology departments and into hybrid interventional, intraoperative and radiation oncology suites. With these clinical and technical shifts, the role of the physicist in MRI has expanded to better meet the quality and safety needs of patients and practitioners for a rich variety of protocols and environments.

During the past few decades, remarkable advances in medical imaging technology have made it possible to obtain many anatomic, functional, metabolic, and physiological measurements from clinical images. With appropriate calibration, most of these imaging technologies can provide quantifiable information on properties of the materials from which the imaging signal emanated. We can combine quantitative imaging with the concept of objective biomarkers to define quantitative imaging biomarkers (QIBs), giving us objective measurements from clinical medical images. We will discuss the development and application of QIBs in clinical practice and clinical trials.

The experiences we have encountered over the last year as a result of COVID-19 have taught us the importance of adaptability. As educators, we were required to make radical changes in our approach to didactics and clinical training. However, adaptability is a hallmark of our continually evolving field. In this presentation will we discuss innovative educational approaches, as well as ways to educate, train, and prepare students and trainees for the future of our profession.

Learning Objectives:

1. Describe recent advances of MRI for diagnostic and oncologic imaging
2. Understand the development and application of QIBs in clinical practice and clinical trials
3. Describe methods to educate, train, and prepare students and trainees for the future of our profession

Q&A

Biophotonics in Radiation and Photodynamic Therapy - Therapeutic delivery can be enhanced by the synergy between non-ionizing and ionizing photons, where light-radiation interactions can inform about dose or amplify the clinical therapeutic value. In radiation therapy (RT), emerging trends include optical surface imaging, 3D Gel and water tank imaging, Scintillator detectors, and utilization of the interaction by scintillation or Cherenkov light to serve as molecular intermediates for imaging. In photodynamic therapy (PDT), emerging trends include direct measurements of light fluence, photosensitizer (PS) concentration, tissue oxygen concentration, blood flow, and their combinations leading to reactive oxygen species explicit dosimetry.

Computational Imaging: from X-ray Tomography to Biophotonics - Computational solution of inverse problems plays a critical role in a wide range of biomedical imaging modalities, ranging from human scale computed tomography to microscopic fluorescence tomography. In this overview, we will review common themes found across all these scales and give examples of algorithmic cross-fertilization between modalities. We will draw on examples from computed tomography, light-sheet microscopy, and hybrid x-ray/optical modalities.

Biophotonics Research Programs and Funding Opportunities at NIBIB - The NIBIB mission is to improve health by leading the development and accelerating the application of biomedical technologies. The Institute is committed to integrating the physical and engineering sciences with the life sciences to advance basic biomedical research and medical care. This presentation will provide an overview of the scientific programs and funding opportunities supported by NIBIB, highlighting the program priorities with the areas of particular importance to the field of Optical Imaging and Spectroscopy. Selected research awards with their potential clinical impacts and the National Centers for Biomedical Imaging and Bioengineering (NCBIB) in biophotonic will be highlighted.

Learning Objectives:

1. To learn common examples of applications of biophotonics in Radiotherapy and Photodynamic therapy.
2. To learn about the role of computational imaging and inverse problems in biomedical imaging and biophotonics.
3. To learn about existing funding opportunities and priorities at the National Institute of Biomedical Imaging and Bioengineering.

A Quantitative Analysis of Lung Elastography Performance Using Large-Deformation CT Scans Acquired at Residual Volume (RV) and Total Lung Capacity (TLC)

B Stiehl^{1*}, M Lauria¹, L Naumann¹, K Singhrao¹, I Barjaktarevic², J Goldin², M McNitt-Gray³, D Low¹, A Santhanam¹, (1) Department of Radiation Oncology, University of California, Los Angeles, Los Angeles, CA, (2) Division of Pulmonary and Critical Care, University of California, Los Angeles, Los Angeles, CA, (3) Department of Radiology, University of California, Los Angeles, Los Angeles, CA

Purpose: Lung elastography during normal breathing has proven to be a useful tool in characterizing regional lung function and has been shown to be an image-based biomarker for COPD patients. However, residual volume (RV) and total lung capacity (TLC) scans representative of deep breathing are often acquired for COPD patients. In this study, we systematically analyze the feasibility of performing lung elastography using large deformation breath-hold CT images acquired at RV and TLC. **Methods:** A quantitative analysis of biomechanical model performance for elasticity estimation was performed using 10 patient datasets with CT scans acquired at RV and TLC, retrospectively. Deformable image registration (DIR) was performed between RV and TLC image pairs with a published registration technique (pTVreg) to obtain ground-truth deformation vector fields (DVF). For each DVF, a well-validated inverse elasticity approach, which employs a lung biomechanical model, was performed to calculate elasticity estimations for each voxel. For validation of elastography performance, the percentage of voxels converging successfully in accordance with the ground-truth DVFs was calculated with convergence criteria of 5% and 10% of maximum observed deformation. Jacobian distributions were calculated for ground-truth DVF and displacement vectors produced by the biomechanical model during elasticity estimation and evaluated for convergence. **Results:** The mean convergence between ground-truth DVF values and displacement vectors output from the biomechanical model within

5% and 10% of the maximum deformation value were measured at 67.31% and 87.62%, respectively, with mean displacement error of 2.21 mm. Jacobian convergence within 0.3 (-0.3 mm³) of the ground-truth registration value was observed to be 80.15%. **Conclusion:** A high level of convergence demonstrates the feasibility of performing lung elastography using RV and TLC CT images. The ability to acquire elasticity estimation distributions for large deformation images allows for characterization of regional biomechanical phenomena observed in patients with lung diseases such as COPD.

MO-B-TRACK 6-02

Localized GBM Recurrence Prediction on Post-Operative Multi-Modal MRIs Through Stem Cell Niches Proximity Estimation Coupled SVM

Y Lao^{1*}, V Yu², A Pham³, T Wang³, D Ruan¹, E Chang³, K Sheng¹, W Yang³, (1) UCLA School of Medicine, Los Angeles, CA, (2) Memorial Sloan Kettering Cancer Center, New York, NY, (3) University of Southern California, Los Angeles, CA

Purpose: To provide early and localized GBM recurrence prediction, we introduce a novel post-surgery multi-parametric MR based support vector machine (SVM) method coupling with stem cell niches (SCN) proximity estimation. **Methods:** This study utilized post-surgery MRI scans ~2 months before clinically diagnosed recurrence from 58 GBM patients. The main prediction pipeline consists of a proximity-based calculation step, to identify regions with high risks of recurrence, and an SVM classifier training step, to further leverage voxel-wise prediction in the high-risk regions (HRR). The HRRs were estimated using the weighted sum of inverse distances to two possible origins of recurrence - SCN (PS) and tumor cavity (PT). Subsequently, multi-parametric voxels (from T1, T1 GD, FLAIR, T2, ADC MR) within the HRR were grouped into the recurrent subregions (warped from the time of clinical diagnosis) and non-recurrent subregions, and feed into a radial basis function SVM classifier. 49 patients were used for training and validation, and 9 patients were used for testing. Besides SVMPE, an SVM classifier using tumor margin as input high-risk regions (SVMTM) was also trained for comparison. **Results:** On pre-recurrence MRIs from 9 testing patients, the SCN proximity based HRRs achieved a maximized inclusion of recurrence, with a recall of 0.97. The fine-tuned voxel-wise prediction from the SVMPE classifier reached a recall of 0.84, a precision of 0.74, and an F1-score of 0.77. In contrast, performance from SVMTM was consistently lower (recall 0.66, precision 0.59, and F1 0.60). **Conclusion:** We introduced a novel voxel-wise early prediction method for brain GBM recurrence based on clinical follow-up MR scans using an SCN proximity estimation coupled SVM framework-SVMPE. The result shows promise in localizing subclinical traces of recurrence 2-month ahead of clinical diagnosis and may be used to guide early retreatment to a smaller target volume and individualized prescription.

MO-B-TRACK 6-03

Predicting PD-L1 Expression Level in Non-Small Cell Lung Cancer on Computed tomography Using Machine Learning

T Shiinoki^{*}, K Fujimoto, Y Kawazoe, Y Yuasa, M Kajima, Y Manabe, T Hirano, K Matsunaga, H Tanaka, Yamaguchi University

Purpose: Immune checkpoint therapy has been the research hotspot in clinical practice since new cancer therapy was discovered. Immune inhibitors which can hinder the combination between programmed death 1 (PD-1) and programmed death ligand 1 (PD-L1) may extend patients' progression-free survival or overall survival with lower side effects. The purpose of this study is to construct the model to predict the PD-L1 expression level in Non-small cell lung cancer (NSCLC) using CT images and machine learning. **Methods:** 203 patients who underwent CT scan were enrolled in this study. PD-L1 expression level was tested through the immunohistochemistry (IHC). Patients' data were divided into two parts (training and test data) by random selection during feature selection procedure. For each Tumor, Tumor-5 mm and Ring structures, 1130 radiomics features were calculated. Then, these features and 7 clinical features (age, sex, stage, histology, location, smoking, CEA) were used to construct the prediction model. Feature selections with Null importance and Lasso algorithms were performed. The prediction models were constructed using three machine learning algorithms (LightGBM, SVM: Support vector machine and LR: Logistic regression) with five-fold cross validation. For training and test data, AUCs were calculated to evaluate the accuracy of prediction model for each algorithm. **Results:** For training data of PD-L1 $\geq$ 50%, prediction models for LightGBM, SVM and LR resulted in an AUC of 0.95, 0.50, and 0.71, respectively. For test data, AUC were 0.79, 0.63, and 0.67, respectively. For training data of PD-L1 $\geq$ 1%, those resulted in AUC of 0.98, 0.69, and 0.68, respectively. For test data of PD-L1 $\geq$ 1%, AUC were 0.76, 0.59, and 0.58, respectively. **Conclusion:** The radiomic-based predictive approach may predict PD-L1 expression status in NSCLC patients relatively accurate. It may be helpful in guiding immunotherapy in clinical practice and deserves further analysis.

MO-B-TRACK 6-04

Principal Component Analysis of Quantitative Computed Tomography Features and Visual Emphysema Scores: Association with Lung Function Decline

M Koo^{1*}, W Tan², J Hogg², J Bourbeau³, C Hague², J Leipsic², and M Kirby^{1,2} for the CanCOLD Collaborative Research Group and The Canadian Respiratory Research Network, (1) Ryerson University, Toronto, ON, CA, (2) Centre for Heart Lung Innovation, St. Paul's Hospital, Vancouver, BC, CA, (3) McGill University Health Centre Research Institute, McGill University, Montreal, QC, CA

Purpose: Quantitative computed tomography (QCT) provides fully-automated measurements reflecting disease features in chronic obstructive pulmonary disease (COPD), yet visual scoring of emphysema remains the clinical standard and outperforms QCT for prediction of longitudinal outcomes, such as mortality. However, previous studies largely focus on only single QCT features. Our objective is to determine if multiple QCT features in combination are associated with COPD disease progression, independent of visual scoring. **Methods:** Participants with and without COPD from the Canadian-Cohort-Obstructive-Lung-Disease (CanCOLD) study were evaluated. CT images were visually scored by a radiologist for emphysema severity. 14 QCT features were extracted (VIDA software), including: low-attenuation-area<950 HU (LAA₉₅₀), wall-area-percent, total-airway-count, low-attenuation-cluster slope, disease-probability-map measures of emphysema and small airway disease, and vessel-volume. Principal component analysis (PCA) was performed for dimension reduction. Multiple linear regression models for annualized change in forced-expiratory-volume-in-one-second (Δ FEV₁) were constructed with linear combinations of features from each component along with visual emphysema score (VES), adjusted by confounding variables. **Results:** We evaluated 588 participants; never-smoker: n=145, ever-smoker: n=161; mild COPD: n=171; moderate-severe COPD: n=111. Three PCA components were extracted that explained 68% of the variance in Δ FEV₁; these components reflected airway, emphysema/vessels, and emphysema clustering/air trapping measurements. In a multiple linear regression model for Δ FEV₁, VES was significant (standardized estimate (SE)=-0.098, p=0.04). In a model for Δ FEV₁ with LAA₉₅₀ added, VES remained significant (SE=-0.094, p=0.04) but LAA₉₅₀ was not. In a model with the three PCA components added, the emphysema clustering/air trapping component was significant (SE=-0.233, p<0.0001), while VES and all other components were not. **Conclusion:** Linear combinations of QCT features increased the relative importance of QCT compared to visual scoring in terms of the association with FEV₁ change. These findings will motivate future studies to develop and investigate QCT measurements in COPD.

Dr. Kirby gratefully acknowledges support from the Parker B. Francis Fellowship Program and the Canada Research Chair Program (Tier II). We also acknowledge funding support from the Natural Sciences and Engineering Research Council of Canada (NSERC) Discovery Grant.

MO-B-TRACK 6-05

Quantitative Relaxometry for Ultra-Hypofractionated MR-Guided Radiotherapy to the Prostate and DIL: A Feasibility Study

E Subashi^{*}, E LoCastro, V Brennan, A Apte, M Zelefsky, N Tyagi, Memorial Sloan-Kettering Cancer Center, New York, NY

Purpose: Treatment of the prostate with an integrated boost to the dominant intra-prostatic lesion (DIL) using ultra-hypofractionated radiotherapy has been

implemented in a high-field MR-Linac. We study the feasibility of using quantitative relaxometry for response assessment during the course of this treatment regimen. **Methods:** Quantitative maps of the longitudinal (T1) and transverse (T2) relaxation times were acquired on the Elekta Unity MR-Linac using the variable flip-angle (VFA) and multi-echo spin-echo (MESE) method. Imaging parameters for the VFA method were: TR/TE=20/2.3ms, FA={4°,22°}, FOV=320x320x200mm, reconstructed voxel=0.7x0.7x3mm, acquisition time=1.5mins. For MESE: TR/TE/ΔTE=4000/22/11ms, 8 echoes, FOV=320x320x100mm, reconstructed voxel=0.5x0.5x3mm, acquisition time=5.5mins. The bias and uncertainty in the quantitative maps were first determined using a NIST-traceable phantom with known relaxation values. T1/T2 was measured at each fraction in eight patients undergoing ultra-hypofractionated therapy to the prostate with an integrated boost to the DIL. The prescription was 800cGy/900cGy x 5 to the prostate/DIL, respectively. The VFA, MESE, online-planning images, structure set, and dose were imported in CERR (Computational Environment for Radiotherapy Research) where the images from each relaxometry acquisition were rigidly registered to the online-planning dataset. T1 and T2 values were analyzed within the GTV and CTV as a function of fraction number. **Results:** In the NIST phantom, the measured bias and coefficient-of-variation for T1=[100ms–2600ms] was [-1.1%–12.3%] and [2.8%–9.6%] respectively. For T2=[30ms–1200ms], the measured bias and coefficient-of-variation was [-13.4%–5.1%] and [3.1%–16.5%] respectively. Across all patients and fractions, T1(CTV)=1775±102ms, T1(DIL)=1525±142ms, T2(CTV)=124±19ms, T2(DIL)=104±11ms. T1 and T2 were significantly longer in the CTV. Linear regression analysis showed that in the DIL there is a significant increase in T1 and a significant decrease in T2. This trend was also observed in the CTV but was not significant. **Conclusion:** Quantitative relaxometry may provide useful and complementary guidance as an imaging biomarker for therapy response assessment.

MO-B-TRACK 6-06

BEST IN PHYSICS (MULTI-DISCIPLINARY): Treatment Response Prediction Using Extracellular Volume Fraction Derived from Dual-Source DECT for Chemoradiation Therapy of Pancreatic Cancer

G Noid^{1*}, G Godfrey¹, E Paulson¹, W Hall¹, B Erickson¹, J Shah², X Li¹, (1) Medical College of Wisconsin, Milwaukee, WI, (2) Siemens Healthineers, Durham, NC

Purpose: Dual-source dual-energy CT (DECT) data can be used to calculate the extracellular volume fraction (ECVf) in tumors, which has been correlated with treatment outcome. In this work, we seek to find a correlation between ECVf and change in Carbohydrate Antigen (CA) 19-9 as a surrogate for treatment response for chemoradiation therapy (CRT) of pancreatic cancer. **Methods:** DECT data at the late arterial contrast phase acquired in the standard simulation on a dual-source DECT simulator for 22 pancreatic cancer patients, along with their CA19-9 and hematocrit data, were analyzed. Each patient underwent CRT with a prescription of 50.4Gy in 28 fractions. The patients were chosen based on the presence of a solid tumor in the pancreas which could be clearly delineated. A region of interest (ROI) was placed in the tumor and in the aorta. From the ratio of the Iodine density calculated from the DECT in the ROI and the hematocrit taken at the time of simulation, the ECVf was calculated. The ECVf was then compared to the change in CA19-9 before and after the CRT. Distant metastases as the cause of CA 19-9 elevation were ruled out on subsequent restaging studies prior to surgery. The DECT derived iodine ratio was validated using a phantom study. **Results:** The average hematocrit, ECVf, and change in CA19-9 during the treatment for the 22 patients was 35.6±5.4%, 7.3±4.9% and -4.6±21.8 respectively. We found a linear correlation between the ECV fraction and the change in CA19-9 with an R² of 0.7: ΔCA19-9 = 3.63×ECVf – 31.1. The correlation was statistically significant (P=0.006). The DECT derived iodine concentration agreed with the phantom measurements (R²=1.0). **Conclusion:** The pre-treatment ECV fraction obtained based on Iodine maps from dual-source DECT may be used to predict treatment response for adjuvant chemoradiation therapy of pancreatic cancer.

Use of Short Duration Dynamic [¹⁸F]DCFPyL PET and CT Perfusion Imaging to Localize Dominant Intraprostatic Lesions in Prostate Cancer: Validation Against Digital Histopathology

D Yang^{1,2,3*}, R Alfano⁴, G Bauman^{3,4}, J Chin^{3,4}, S Pantler^{3,4}, K Chung^{2,3}, A Ward⁴, T Lee^{2,3}, (1) Fox Chase Cancer Center, Philadelphia, PA, (2) Robarts Research Institute, University of Western Ontario, London, ON, CA, (3) Lawson Imaging Research Program, Lawson Health Research Institute, London Health Science Centre, London, ON, CA, (4) London Regional Cancer Program, London Health Science Centre, London, ON, CA

Purpose: Identifying the dominant prostate cancer nodule (dominant intraprostatic lesion, DIL) may enable more accurate diagnosis and therapy through more precise targeting of biopsy, radiotherapy, and focal ablative therapies. Our goal is to validate the performance of [¹⁸F]DCFPyL positron-emission tomography (PET) and CT Perfusion (CTP) for localizing DIL against digital histopathology images. **Methods:** Multi-modality image sets: in-vivo T2-weighted (T2w)-magnetic resonance imaging (MRI), 22-min dynamic [¹⁸F]DCFPyL PET/CT, 2-hr post-injection PET/MR, CTP were acquired in patients prior to radical prostatectomy. The explanted gland with implanted fiducial markers was imaged with T2w-MRI. All PET, CT, and MR images were co-registered to the pathologist-annotated whole-mount mid-gland prostatectomy histology using fiducial markers and anatomical landmarks. Regions of interest encompassing DIL and non-DIL tissue were drawn on the digital histopathology images and superimposed on PET and CTP parametric maps. Logistic regression with backward elimination of parameters was used to select the most sensitive parameter set to distinguish DIL from non-DIL voxels. Leave-one-patient-out cross-validation was performed to determine diagnostic performance. **Results:** 49,256 voxels from [¹⁸F]DCFPyL PET and CTP parametric maps of 15 patients were analyzed. 2-hr post-injection [¹⁸F]DCFPyL SUV (SUV_{late}) and a model combining K_i (net uptake rate constant) and k₄ (dissociation rate constant) of [¹⁸F]DCFPyL achieved the most accurate performance distinguishing DIL from non-DIL voxel. Both detection models achieved an AUC of 0.90 and an error rate of <10% from leave-one-patient-out cross-validation. Compared to digital histopathology, the detected DILs had a mean dice similarity coefficient of 0.76 for the K_i and k₄ model and 0.73 for SUV_{late}. **Conclusion:** We have validated using co-registered digital histopathology images that parameters from kinetic analysis of 22-min dynamic [¹⁸F]DCFPyL PET can accurately localize DIL in prostate cancer for targeting of biopsy, radiotherapy, and focal ablative therapies. Short duration dynamic [¹⁸F]DCFPyL PET was not inferior to SUV_{late} in this diagnostic task.

Evaluation of a Prototype Ratio 29:1 Grid for Large Patient Cardiovascular Angiography Imaging

K Fetterly^{1*}, B Schueler¹, D Miller¹, M Hindal¹ (1) Mayo Clinic, Rochester, MN

Purpose: This work assessed the performance of a high ratio (r29) 80 line cm⁻¹ grid under adult patient cardiovascular angiography imaging condition. Non-grid and the OEM r15 80 line cm⁻¹ grid were used as reference conditions. **Methods:** Plastic WaterTM phantom thickness in the range 20-44 cm was used to attenuate the primary beam and create scatter. X-ray source to detector (SID) distance 107 and 120 cm was used to match the 105 and 118 cm focus distances of the grids. Fields of view (FOV) 20 and 25 cm were tested. The X-ray technique was fixed to ensure equal phantom-specific dose for all conditions. Primary and scatter transmission (Tp and Ts) of the grids and non-grid scatter to primary ratio (SPR) was measured using a lead beam stop method. Object quantum SNR improvement factor (Ksnr) theory was expanded to consider variable geometric magnification of a hypothetical test object located at the X-ray system isocenter and used to assess the relative SNR across experimental conditions. **Results:** For equivalent imaging conditions, Tp of the r15 and r29 grids was 0.75 and 0.69 and Ts was 0.34 and 0.18, respectively. SPR was in the range 0.27-4.1; increased by 30-39% for FOV 25 versus 20 cm; and increased exponentially with phantom thickness. Ksnr increased approximately linearly with increasing phantom thickness. Ksnr of the 29 grid at SID 120 cm versus the r15 grid at SID 107 cm was in the range 1.0-1.17 for phantom thicknesses 20-44 cm. Predicted radiation dose reduction with preserved image quality ranged from 0-26%. **Conclusion:** Compared to the r15 grid, the very low scatter transmission properties of the r29 grid is expected to improve the relationship between image quality and radiation dose for adult patients. The predicted benefit of the r29 grid increased with increasing phantom thickness.

Clinical Performance of An AI Assisted Dose Reduction System for Fluoroscopic Guided Interventional Procedures

D Hintenlang*, N Quails, K Little, Ohio State University, Columbus, OH

Purpose: To evaluate the clinical performance of a dose reduction system utilizing AI guidance and a shuttered attenuator system to reduce radiation doses, to both patients and operators, during fluoroscopically guided interventional procedures. **Methods:** Two interventional fluoroscopy systems were retrofit with a shuttered attenuator system that intermittently attenuates the x-ray field outside of the primary focus area of the interventionalist. An integrated AI system adjusts the primary focus area based on interpretation of the tools and actions of the interventionalist to maintain high image quality in a dynamic, primary region of interest (ROI). Evaluation of the clinical performance of the system included characterization of entrance exposure, exposure from scattered radiation, high contrast resolution, low contrast resolution, and tracking performance of the AI system. **Results:** Dosimetry measurements demonstrate that the dose reductions of both DAP and exposure measurements scale in proportion to the relative areas of the attenuated and primary focus areas. However, the dose reduction algorithm is not immediately effective upon initiating an exposure. Fluoroscopists who utilize multiple short exposures are unlikely to realize the dose savings afforded by the system. High contrast spatial resolution in the peripheral region is reduced slightly compared to that in the primary ROI, but maintain spatial resolution of 2.36 lp per mm. CNR and contrast detail object detectability are more significantly affected by the increased noise present in the area outside of the primary ROI. The temporal response of the AI system is on the order of 1 s and can result in image discontinuities between the regions inside and outside of the primary ROI due to different refresh rates. **Conclusion:** The AI system generally performs as expected although subtle features of the system performance may require adjustments to operator technique to fully realize the dose reduction benefits of the system.

A Novel Integrating Proton Radiography System with a Monolithic Scintillator Detector

C Darne^{1*}, D Robertson², F Alsanea³, I Tendler⁴, L Perles⁵, C Collins-Fekete⁶, S Beddar⁷, (1) UT MD Anderson Cancer Center, Houston, TX, (2) Mayo Clinic Arizona, Phoenix, AZ, (3) UT MD Anderson Cancer Center, Houston, TX, (4) UT MD Anderson Cancer Center, Houston, TX, (5) UT MD Anderson Cancer Center, Houston, TX, (6) University College London, London, GB, (7) UT MD Anderson Cancer Center, Houston, TX

Purpose: In this work, we demonstrate the system design and preliminary images obtained using our novel integrating proton radiography system consisting of a monolithic volume of plastic scintillator and an optical camera. **Methods:** The system consists of a monolithic plastic scintillator volume (20 x 20 x 20 cm³) capable of capturing a wide range of proton beam energy depositions. The scintillator captures the slowed and scattered proton beam after it exits from the phantom, producing a scintillation light distribution. A charge-coupled device (CCD) placed along the beam's-eye-view direction captures an integral of the scintillation light along the beam axis to generate the radiograph. The imaging system was tested for uniformity, stability, linearity, and accuracy in measuring water-equivalent thickness (WET). A custom spatial and contrast resolution phantom was radiographed for qualitative assessment. **Results:** A coefficient of variation (CV) was calculated over 10 radiographs collected by the system and the resulting system stability was determined to be 0.37%. The system's ability to image the dose uniformly over a radiograph was evaluated by calculating the CV over a 5 x 5 cm area and was found to be 2.6%. The system response was found to be highly linear ($R^2 = 1$) over a range of two orders of magnitude in deposited dose (1 – 92 mGy). The WET was calculated for a Gammex solid water phantom insert with a relative accuracy of 0.25%. To improve contrast for the resolution phantom, radiograph image thresholding was applied by rejecting low pixel intensities (< 30% of the peak pixel intensity in the image). **Conclusion:** The preliminary images and studies conducted on the monolithic scintillator system design demonstrate its excellent linearity, uniformity, stability, and WET calculation accuracy. Our system therefore has the potential to be adopted clinically for proton radiography.

A Simulation Study of Quasi-Monochromatic X-Ray Source Based on Reflection Thin-Film Target

Y Tan*, Q Chen, S Zhou, and T Zhang, Washington University School of Medicine, St. Louis, MO

Purpose: Monochromatic X-ray sources are effective in contrast imaging, especially when their energy matches the contrast's K-edge. In this study, we evaluated the performance of the quasi-monochromatic X-ray source based on reflective thin-film Cerium oxide (CeO₂) target deposited on a diamond substrate. **Methods:** A thin-film target produces isotropic discrete k-lines and forward-distributed anisotropic white Bremsstrahlung x-rays. In the reflective direction, a quasi-monochromatic spectrum can be obtained when the Bremsstrahlung production is largely suppressed. Monte Carlo simulations were performed using Geant4 software to calculate the spectrum from the thin-film target of various thickness bombarded by electrons with energies ranged from 100-450keV. The absorbed dose in a water block was also simulated in Geant4 for each incident spectrum. The signal-to-noise ratio (SNR) and contrast to noise ratio (CNR) of a 4.5 cm water with iodine contrast were calculated based on the predicted spectrum and with that of conventional mammography x-ray sources under the same dose conditions. **Results:** Monte Carlo simulation shows that the Bremsstrahlung's production by the thin-film target decreases with electron energy and increases with the thin-film thickness. Comparing with conventional mammography sources, the same SNR and CNR of iodine images can be achieved by the quasi-monochromatic source with Cerium target but with 2 to 3 times lower x-ray exposure. **Conclusion:** The x-ray source with a CeO₂ thin-film target can produce a quasi-monochromatic spectrum that matches the K-edge of iodine to enhance the contrast. It may reduce x-ray exposure and increase CNR of iodine contrast in mammography.

Estimating Bone Densities Using a Cadmium Zinc Telluride Photon Counting Detector

J Nguyen^{1*}, D Richtsmeier¹, K Iniewski², M Bazalova-Carter¹ (1) University of Victoria, Victoria, BC, CA (2) Redlen Technologies, Saanichton, BC, CA

Purpose: The purpose of this work was to develop a technique to measure bone densities using a cadmium zinc telluride (CZT) photon counting detector (PCD). **Methods:** Seven bone phantoms were prepared by mixing a suitable amount of calcium perchlorate with water to achieve densities ranging between 1-1.45 g/cm³, which were pipetted into 600 μ L microcentrifuge tubes. A 10 cm diameter cylindrical polyethylene phantom with 18 cavities was used as a soft tissue equivalent material. Each bone tube was inserted in the same cavity and the phantom was imaged with a 120 kVp x-ray beam and CZT PCD while the remaining 17 cavities were filled with water. Energy thresholds of 38, 42, 68, 72, 98 and 102 keV were chosen to create 5 energy bins. Planar x-ray images were acquired at a tube current of 1 mA and the acquisition time was 25 ms. **Results:** A linear calibration curve was produced by plotting the ratio of the total number of counts in the bone phantom region of interest between two different energy bins as a function of bone density. Between all energy bins, the ratio of bins that resulted in the highest sensitivity was between bins 1 (38-42 keV) and 5 (98-102 keV), which resulted in a slope of 0.17 and an adjusted R² value of 0.976. Five additional bone phantoms with unknown densities were imaged and their densities were estimated from the calibration curve where the mean absolute error was 3.8% and 6.6% for the 40/70 and 40/100 keV ratios, respectively. **Conclusion:** It was demonstrated that measuring bone densities was possible by using a single image acquired with a PCD, a new technique that does not rely on dual-exposure imaging or a dual-layer detector. With further optimizations, future clinical applications to measure bone densities in vivo could be achieved.

This work was funded by Redlen Technologies, the NSERC Alliance Grant and Canada Research Chair program.

Implementation of Detailed Monte Carlo Simulation for Semiconductor Detectors Using the PENELOPE Code

H Mendes*, A Tomal, University of Campinas

Purpose: The modeling of radiographic detection can provide insight into the optimization strategies of the imaging system. This work aims to implement a detailed Monte Carlo (MC) simulation of DR digital detectors (semiconductor) considering pairs electron-hole creation and diffusion. **Methods:** The modeling was divided into two steps: radiation interaction and charge dispersion based on the penEasy Imaging code. The transport of photons and electrons is simulated using the PENELOPE code, with 50 eV as their cut-off energies. In each electron interaction, the absorbed energy was converted into electron-hole pairs, considering the Poisson distribution, modulated by the Fano factor of the sensor material. The electron-hole pair creation energy (W) depends on the absorbed energy and the electric field (F). The point of charge detection was sampled considering a two-dimensional Gaussian distribution, where the standard deviation was obtained from the Einstein equation for electron diffusion. The pulse-height spectrum (PHS) was obtained from the simulations for monoenergetic pencil beams with energy between 10 and 100 keV, considering a detector composed of amorphous selenium, 150 μ m thick, with 139 μ m pixel, and (F) equals to 3, 10, and 30 V/ μ m. The Swank factor was calculated from the PHS moments. **Results:** For energies lower than the K-edge the PHS consists of a single spectral peak. However, for energies above the K-edge, an additional peak is observed due to fluorescent photons. Moreover, the number of electron-hole pairs increases with F, resulting in a decrease in W. The Swank factor also increases with F, with the maximum difference of 2% between 3 and 30 V/ μ m cases. The Swank factor is up to 50% lower than the calculated without charge dispersion. **Conclusion:** The simulation presented includes the electron-hole pair dispersion in the detector providing a more detailed detector modeling and, consequently, insight into the imaging system's fundamental limitations.

Comparison of Ethiodol Contrast Media with Iodinated Microspheres for Use in 1000 Fps High-Speed Angiography (HSA) to Determine Blood Flow Details and Blood Velocity

X Wu*, A Shields, S Setlur Nagesh, D Bednarek, S Rudin, University at Buffalo (SUNY) School of Medicine, Buffalo, NY

Purpose: To compare the performance of Ethiodol, a non-water-soluble iodinated contrast agent, with iodinated microspheres in obtaining blood velocity distributions in order to achieve accurate blood flow evaluations important for diagnosis and outcome predictions in vascular disease. **Methods:** A 3D-printed patient-specific basilar bifurcation aneurysm phantom was placed in a constant flow loop, with a flow rate of 315 mL/min as measured at the phantom inlet. For each contrast media, 1500 images were acquired at 70 kV, 100 mA, and 1000 fps using the Actaeon photon counting detector (PCD), which has 100 micron pixel pitch. The respective contrast media were injected using an automated syringe pump through a 4 Fr catheter at a fixed rate of 60 mL/min. 1 mL of Ethiodol and 0.5 mL of 700-900 micrometer diameter iodine-coated microspheres were injected. The Ethiodol stream breaks up into droplets of similar size to that of the microspheres upon injection. X-ray Particle Image Velocimetry (XPIV) was performed using an automated particle tracking algorithm to obtain velocity distributions from the 1000 fps HSA sequences, which were then compared with each other. Contrast-to-noise ratios (CNR) of the two methods were evaluated for 10 different samples of tracked microspheres and 10 different samples of tracked Ethiodol droplets. **Results:** Similar velocity distributions were obtained around the aneurysm sac ROI for the Ethiodol and microspheres. The average CNR was 4.96 for the Ethiodol and 2.78 CNR for the iodinated microspheres. **Conclusion:** This work indicates that Ethiodol XPIV produces comparable velocity information to iodinated-microsphere XPIV for in-vitro applications. The Ethiodol droplets also produce a higher CNR than the iodinated microspheres, indicating a smaller radiation dose could be used for its particle tracking capability.

Dedicated Cone-Beam Breast CT with Offset-Detector: Estimates of Mean Glandular Dose (MGD) with Heterogeneous Tissue Distribution and Real Breast Shapes from Clinical Datasets

H Tseng*, A Karellas, S Vedantham, University of Arizona, Tucson, AZ

Purpose: We are developing a high-resolution CMOS detector-based cone-beam breast CT (CBBCT) system with offset-detector geometry. The purpose is to estimate the mean glandular dose (MGD) for offset-detector geometry using clinical datasets that provide for heterogeneous tissue distribution and real shape and compare it to the reference geometry using a centered detector. **Methods:** 30 clinical breast CT datasets acquired on a CBBCT system with a 40x30-cm centered (no offset) detector (1024x768 pixels) were reconstructed using Feldkamp-Davis-Kress (FDK) algorithm. The images were segmented into skin, adipose, and fibroglandular tissues. The segmented breast models were imported to a Monte Carlo simulation toolkit (GATE 8.0) and were assigned Hammerstein's elemental compositions. Three imaging geometries were considered: (1) 40x30-cm centered detector corresponding to acquisition geometry as reference; (2) 30x30-cm detector with 5cm offset; and (3) 25x30-cm detector with 7.5cm offset. MC simulations were conducted with 49kV (1.39mm HVL), 0.3x0.3-mm focal spot, and with 10E6 photons. The normalized glandular dose coefficient (DgNCT) was obtained for each geometry and breast. MGD was obtained as the product of DgNCT and the measured air kerma at the axis-of-rotation. **Results:** The coefficient of variation was less than 0.7%. For the 30 clinical breast CT datasets, the mean $\pm$ SD and the median (inter-quartile range) of the MGD (mGy) were 9.63 $\pm$ 2.84 and 8.99 (7.68–11.31) for the 40x30-cm reference geometry, 8.19 $\pm$ 2.62 and 7.70 (6.74–8.86) for

the 30x30-cm detector with 5cm offset, and 5.35 ± 1.39 and 5.15 (4.22–5.94) for the 25x30-cm detector with 7.5cm offset. The median computational time for MC simulations was approximately 40 minutes for each case. **Conclusion:** This study demonstrates the potential for dose reduction using offset-detector geometry with heterogeneous tissue distribution and real breast shapes. The estimated dose reduction for the 30x30-cm detector with 5cm offset and the 25x30-cm detector with 7.5cm offset were 14.8% and 44.4%, respectively.

MO-lePD-TRACK 2-02

Feasibility of Using Size-Specific Dose Estimate (SSDE) to Estimate Effective Dose of Individual Patients

A Abuhaimeid^{1*}, C Martin², C Lee³, (1) King Abdulaziz City for Science and Technology (KACST), Riyadh, , SA, (2) University of Glasgow, Glasgow, GB, (3) National Cancer Institute, Rockville, MD

Purpose: The aim of this study is to investigate the relationship between size-specific dose estimate (SSDE) and a derivative form of effective dose called size-specific effective dose (SED) for individual patients. **Methods:** Values of SED resulting from CT scans of six scan regions over the trunk were estimated for 193 adult phantoms using NCICT software. The library covers a wide range of adult patient sizes of different heights (150 – 190 cm) and weights (40 – 125 kg). The regions studied were: (1) chest, (2) abdomen, (3) pelvis, (4) chest-abdomen, (5) abdomen-pelvis, and (6) the whole trunk (CAP). SED values were assessed for 120 kV and a pitch of 1 using standard scan lengths similar to those used in the clinic. A MATLAB code developed in-house was employed to calculate the patient size in terms of water-equivalent diameter for the same phantom set used in NCICT software, which allowed values for SSDE to be calculated for CT scans investigated. **Results:** Good correlations between SED and SSDE values were observed for all scan regions studied, except the pelvis. The variations for the regions were all within $\pm 8\%$, but they reached 16% for pelvis scans due to differences in colon doses. These occurred because sections of the transverse colon lay inside the scan range for some phantoms and outside for others depending on the colon position for the individual. **Conclusion:** The strong correlations between SED and SSDE values suggest that coefficients of the best-fit for the correlations could be derived, from which risk of an individual patient could be assessed based on SSDE of a given scan taking into account the patient size and the gender. This may provide a simple and straightforward approach to assess SED in a manner similar to using size-based k-factors linked to dose-length product.

MO-lePD-TRACK 2-03

Fetal Dose in Body CT: Z-Axis Dose Profile Based Calculation Compared to Monte Carlo Simulation

X Li^{*}, K Yang, B Liu, Massachusetts General Hospital, Boston, MA

Purpose: In CT exams of pregnant women, fetus (or embryo) may be encompassed by, partly inside, or completely outside scan range. This study is to compare two fetal dose evaluation methods (Monte Carlo simulation, z-axis dose profile based direct calculation) for abdominopelvic, abdominal, and chest exams. **Methods:** This work considered three whole-body models of a pregnant patient (3, 6, 9 gestational months; 62, 67, 73 kg) undergoing chest, abdominal, and abdominopelvic exams on Siemens Somatom Definition CT with fixed mA, 120 kV, 19.2-mm beam width, helical pitch at 1, body bowtie filter, and CTDIvol of 15.6 mGy. Maternal water equivalent diameter (WED) at the fetus centroid was 30.7, 35.3, and 36.3 cm, respectively. A previously validated Monte Carlo simulation program (Geant4) was used to evaluate fetal dose, where helical scan was simulated with 360 projections and 360 patient table translations per gantry rotation, each translation by pitch $\times$ (collimator width)/360. In parallel, another previously reported method was used to evaluate z-axis dose profile of a water phantom, with inputs of scan range, CTDIvol and WED. Fetal average dose was calculated over the fetal volume in the cranial-caudal direction, and was compared with that of simulation. **Results:** Fetal dose from Geant4 simulation was 18.7, 18.3 and 17.7 mGy (3, 6, 9 months) in abdominopelvic exam; 0.69, 1.88 and 3.2 mGy (3, 6, 9 months) in abdominal exam; 0.10, 0.24 and 0.38 mGy (3, 6, 9 months) in chest exam. The results of profile-based evaluation were consistent with those of simulation, where their difference in magnitude was $(8.8 \pm 5.9)\%$ (maximum, 17.1%) for three exams. **Conclusion:** The dose profile based fetal dose calculation is easier to implement than Monte Carlo simulation and is suited for body CT of pregnant women at all gestational ages.

MO-lePD-TRACK 2-04

Implementation of Tube Current Modulation for Pediatric and Adult CT Patients with Various Body Sizes into NCICT2.0

C Lee^{*}, Y Yeom, National Cancer Institute, Rockville, MD

Purpose: To implement a prospective tube current modulation (TCM) feature into an organ dose calculation program for CT patients with various body sizes, NCI dosimetry system for CT (NCICT) 2.0, by using a library of body size-dependent computational human phantoms. **Methods:** We created a comprehensive library of TCM profiles for a total of 351 pediatric and adult body size-dependent computational human phantoms. We adopted a generic ray-tracing algorithm (Li et al. PMB 2014) to create TCM profiles: calculation of the attenuation at a given angle within a CT fan beam geometry for the energy spectrum of a reference CT scanner (Siemens Sensation 16). We averaged angular modulation in a single rotation to derive surrogate longitudinal modulation profiles with 1-cm intervals in each phantom. The resulting TCM profiles were implemented into the NCICT2.0 program. We compared organ doses for different scan protocols between fixed tube current and TCM scans. **Results:** A comprehensive library of TCM profiles were created from a total of 351 pediatric and adult computational phantoms with various body sizes and implemented into NCICT2.0. When the TCM strength was set 0.5, dose reduction from TCM was clearly observed in low to normal BMI phantoms but organ doses under TCM were greater than those under fixed current for high BMI phantoms. Lung dose for the 60-kg adult male phantom with the height of 175 cm reduced by 51% under TCM but that for the 100-kg phantom at the same height increased by 12% under TCM compared to fixed current scans. **Conclusion:** We established a library of generic TCM profiles from a library of body size-dependent computational phantoms and implemented the feature into NCICT2.0. The upgraded program should be useful to estimate organ doses for CT patients undergoing TCM-based CT scans.

Direct Measurement of CTDIw On Helical CT Scans

K DePew^{*}, R Boggs, M Yester, G Barnes, University of Alabama-Birmingham, Birmingham, AL

Purpose: In present day clinical practice the majority of CT exams employ helical scan protocols. Helical protocol CTDIvol is routinely determined by measuring CTDIw for axial scans. On some CT scanners axial scans with the same detector configuration employed on helical protocols are not available, and CTDIw cannot be measured directly with the standard CTDI phantom. Presented is a method to directly measure CTDIw on helical scan protocols. **Methods:** CTDIw is measured on helical scans by centering the CTDI phantom in the CT gantry as with axial CTDI measurements. The body CTDI phantom was modified by the addition of brackets to the sides of the phantom. The brackets support the phantom on the CT gantry shroud with the tabletop below. The phantom remains stationary during helical scans, and surface and axis doses measured. The measured doses are divided by the number of gantry rotations to determine values for one rotation, and CTDIw calculated. CTDIw for body and head helical scan protocols were measured and CTDIvol determined on a recently installed Siemens Somatom Drive CT Scanner that did not have axial scan protocols with the same detector configurations. CTDIw adult body measurements were made for helical and axial scans on a GE Discovery CT Scanner employing the same detector configuration and technical factors. **Results:** The body and head CTDIvol measured on the Siemens Scanner were 13.45 and 48.93 mGy. The corresponding displayed values were 12.80 and 47.78 mGy; 5% and 2.4% lower. The GE helical scan and axial body CTDIw measurements were 10.90 and 10.94 mGy. **Conclusion:** From the good agreement of axial and helical results for the GE scanner, the suspended phantom method is

viable and allows one to directly measure CTDI_w with helical scans. The results for the Siemens scanner show how the method can be applied.

MO-lePD-TRACK 2-06

Scanner-Independent Coefficients to Estimate Organ Doses of CT Pediatric Patients Based On Water-Equivalent Diameter

A Abuhaimeid^{1*}, C Martin², (1) King Abdulaziz City for Science and Technology (KACST), Riyadh, , SA, (2) University of Glasgow, Glasgow, GB

Purpose: This investigation aimed to study development of size-specific and scanner-independent dose conversion coefficients (DCCs) to assess organ doses of pediatric patients resulting from CT scans in the trunk based on the patient size, that was measured by water equivalent diameter (D_w). **Methods:** Organ doses of a wide range of pediatric patient sizes ranging from 1-15 years old were assessed using NCICT software based on Monte Carlo simulations. More than 150 pediatric phantoms with weights and heights in the range of 10–125 kg and 0.85-1.85 m, respectively, were involved. Organ doses were estimated using a 120 kV spectrum for CT scans performed in the body over six different areas, namely: chest, abdomen, pelvis, chest-abdomen, abdomen-pelvis, and all the trunk (CAP). In order to establish scanner-independent DCCs, organ doses of each patient were normalized with respect to the corresponding CTDI_{vol}. The patient size that was reported in terms of D_w was calculated using the same phantom set with a MATLAB software developed for this purpose using an equivalent spectrum. D_w was assessed for each phantom over the six areas studied. **Results:** The correlations between D_w values and DCCs of organs that were fully or largely inside the scan areas were good. Values of R² were more than 0.90 for the majority of organs. This would allow establishing size-specific and scanner-independent DCCs that could be utilized to assess doses of pediatric patients resulting from any CT scanner. **Conclusion:** The DCCs only depend on the patient size in terms of D_w, which takes attenuation of the scan area into account, and CTDI_{vol} that is given in the CT dose report. Most of DCCs published in the literature are based on patient sizes that depend on the patient dimensions, which are expected to lead to some uncertainties, especially for the chest area.

MO-lePD-TRACK 2-07

Variability of Water-Equivalent Diameter (D_w) with Tube Potential of CT Scans

A Abuhaimeid^{1*}, C Martin², (1) King Abdulaziz City for Science and Technology (KACST), Riyadh, , SA, (2) University of Glasgow, Glasgow, GB

Purpose: The aim of this work was to study variability of the patient size measure, which is reported by water-equivalent diameter (D_w) with the applied tube potential for given CT scans for pediatric and adult patients. **Methods:** A large library of 363 phantoms (168 pediatric and 195 adult) were used. The library was designed to represent characteristic of the whole patient population. It covers a wide range of ages from newborn baby to adult with various weights (10 – 125 kg) and heights (85 – 190 cm) for male and female phantoms. Values of D_w were assessed for each phantom using a MATLAB developed in house for this purpose. The values were calculated over six regions of the trunk that represent CT protocols applied in the clinic. The regions studied were chest, abdomen, pelvis, chest-abdomen, abdomen-pelvis, and the trunk (CAP). Five equivalent monoenergetic beams, which represented tube potentials of 80 – 140 kVp, were used to calculate D_w values. **Results:** The differences between D_w values assessed for the various spectra were found to be insignificant. For all phantoms, the differences were within ±2% over the scan regions, with the majority of differences being less than 1%. The differences were not be affected by size or gender of the patient. **Conclusion:** D_w is the metric that has been recommended by the AAPM to replace dimension-based metrics to estimate size-specific dose estimate (SSDE) for an individual patient resulting from a given CT. Although D_w values were affected by the area attenuation, results of this study showed that impact of tube potential on D_w of the trunk regions was minimal. Since, assessment of D_w requires advanced computational tools, the results suggest that energy-independent D_w values could be established and linked to effective diameter, which can be simply measured for an individual patient.

MO-lePD-TRACK 3-01

Comparison of CT-Guided and MR-Guided Adaptive Radiotherapy for Intramuscular Metastasis

S Prajapati^{1*}, Y Zhao^{1,2*}, C Tang¹, Z Yu¹, B Lee¹, P Castillo¹, A Sobremonte¹, R Kudchadker¹, J Yang¹, (1) UT MD Anderson Cancer Center, Houston, TX, (2) UT MD Anderson UTHealth Graduate School of Biomedical Sciences, Houston, TX

Purpose: An intramuscular tumor is not visible on CT but delineable on MR scans. We compared dosimetric differences between CT-guided radiotherapy (CTgRT) and MR-guided radiotherapy (MRgRT) to demonstrate the advantages of treating such tumor with MRgRT. **Methods:** A patient with a renal cell carcinoma gluteal intramuscular oligometastasis was treated with a 1.5T MR-Linac using daily adaptive MRgRT. The prescription was 60 Gy to GTV and 45 Gy to PTV delivered in 15 fractions. Fractional delivered dose of MRgRT was accumulated to the simulation MR scan by aligning the GTV on daily treatment MR scans to the simulation MR scan using rigid registration. In parallel, we developed an in-house cycle-consistent generative adversarial network (cycleGAN) model to generate synthetic CT for each daily MR scan. The synthetic CT was used to simulate daily CBCT alignment using rigid registration based on nearby bony landmarks because tumor is invisible in CT. The fractional dose based on CTgRT was accumulated to the simulation MR scan for comparison with MRgRT. **Results:** MRgRT D95% dose accumulation was 60.1 Gy and 47.5 Gy with average dose of 61.1 Gy and 55.0 Gy to GTV and PTV respectively. CTgRT D95% dose accumulation was 37.3 Gy and 24.4 Gy with average dose of 44.8 Gy and 38.8 Gy to GTV and PTV respectively. CTgRT dose accumulation resulted in >35% and >45% under-dose compared to the planned GTV and PTV D95% dose respectively. Qualitatively, the low-dose regions in CTgRT were comparable to MRgRT, however the high-dose regions were significantly different. The GTV was partially missed in 10/15 fractions and completely missed in 5/15 fractions to receive full planned dose in CTgRT simulated treatments. **Conclusion:** Treating intramuscular tumors using CTgRT can significantly under-dose the tumor without excessively generous margin. MRgRT is ideal for cases where tumor is not visible on CT.

MO-lePD-TRACK 3-02

Correction of Gantry Induced Geometric Image Distortion on MRgRT at Various Gantry Angles with Deformation Vector Field

B Lewis¹, J Shin^{1,2*}, B Quinn³, E Barber³, D Sievert¹, J Kim², T Kim¹, (1) Washington University in St. Louis, Saint Louis, MO, (2) Yonsei University College of Medicine, Seoul, KR, (3) Modus Medical Devices, London, ON, CA

Purpose: Geometric accuracy is vital for delivering high quality MR-guided radiotherapy (MRgRT). MR images acquired on 0.35T MR-linac systems are distorted when acquired at different gantry angles, requiring repositioning of the gantry for acquiring new volumetric images. This work investigates correction of distorted images acquired at different gantry positions using deformation vector fields (DVF) from reference images. **Methods:** Two phantoms were imaged on a 0.35T MR-linac using a clinical 3D TRUFI sequence. The phantoms included a cylindrical phantom, part of the QUASARTM MRID3D geometric distortion analysis system, and a QUASARTM 3D grid phantom. Acquisitions were performed at 30° increments, from 0° to 330°, with TR: 3ms, TE: 1ms, flip angle: 60°, FoV: 450x450x360mm³, imaging matrix: 300x300x240. Acquisitions were performed with the onboard Siemens distortion correction function turned on and off (DstOn and DstOff). The MRID3D phantom images were imported into the distortion analysis software to produce DVFs for each gantry angle with DstOn and DstOff. These DVFs were then applied to the 3D grid phantom images in the proprietary System Distortion Resampler software from ModusQA. Resampled images were compared to the original and resampled G0 distortion corrected images visually and with the structural similarity index measure (SSIM). **Results:** Significant

distortion was present in 3D grid phantom images with DstOff, and was partially corrected with DstOn. After resampling with DVFs the phantom appeared visually identical to the reference image. SSIM increased from a mean ($\pm$ SD) of 0.26 ± 0.001 and 0.06 ± 0.001 before resampling to 0.70 ± 0.004 and 0.69 ± 0.005 after resampling for DstOn and DstOff, respectively. **Conclusion:** The resampling software was successfully able to apply DVFs from one phantom to a second to correct for geometric distortion artifacts generated by imaging at different gantry angles on an MR-linac system. This gives the possibility of applying DVFs to patient images for accurate reconstruction during MRgRT.

MO-lePD-TRACK 3-03

Generative Adversarial Networks for Synthetic CT Generation from MR Scans with Truncated Anatomy

Y Zhao^{1,2*}, L Court^{1,2}, C Yu^{1,2}, C Cardenas^{1,2}, H Wang^{1,2}, X Wang², J Phan², J Yang^{1,2}, (1) University of Texas MD Anderson UTHealth Graduate School of Biomedical Sciences, Houston, TX (2) University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: MR scans in MR-guided radiotherapy can be partially truncated due to limited field of view, which could significantly affect dose calculation accuracy for MR-based online adaptive planning. We developed a cycle consistent generative adversarial networks (cycleGAN) based approach to create synthetic CT (sCT) images compensating the missing anatomy from the truncated MR scans. **Methods:** CT scans and T1-weighted MR scans with complete anatomy of 24 head and neck patients were used for this study. The MR scans were manually cropped 10-15 mm off at the posterior region of head to simulate truncated MR scans. Six patients were randomly chosen for testing and the rest were used for training. We proposed a modified cycleGAN using a residual-Unet as the generator to create sCT from MR. Truncated/complete MR scan pairs and CT scans were used to train the cycleGAN. The sCT pairs were generated for both truncated and complete MR scans. The mean absolute difference (MAD) of Hounsfield units (HU) was used to quantify the sCT performance. To evaluate the sCT in the truncated region, body contours were generated for each sCT pair. In the truncated region, the structural similarity index (SSIM), mean surface distance (MSD), and Dice similarity of body contours were calculated between sCT pairs to quantify the sCT performance in compensating the truncated anatomy. **Results:** The mean MAD were 83.2 ± 9.3 HU and 81.6 ± 9.2 HU for the sCT generated from truncated and complete MRI, respectively. In the truncated region, the mean SSIM was 0.86 ± 0.02 , the MSD was 1.91 ± 0.52 mm, and the Dice of body contour was 0.92 ± 0.02 , indicating a good performance in compensating the truncated anatomy. **Conclusion:** We developed a novel cycleGAN model that can create synthetic CT with complete anatomy from truncated MR scans, which could potentially benefit online MR-guided adaptive treatment planning.

MO-lePD-TRACK 3-04

3D Deep Convolutional Neural Network for Mapping MRI to Synthetic MVCT for Radiotherapy Planning

J Scholey^{1*}, A Rajagopal², E Vasquez³, A Sudhyadhom⁴, P Larson⁵, (1) University of California San Francisco, San Francisco, CA, (2) University of California San Francisco, San Francisco, CA, (3) University of California Berkeley, Berkeley, CA, (4) Harvard Medical School, Boston, MA, (5) University of California San Francisco, San Francisco, CA

Purpose: To synthesize MVCT (sMVCT) datasets from MRI using a 3D deep CNN. This is a novel solution for MRI-only treatment planning where MRI can be utilized for anatomical delineation and MRI-generated sMVCTs for more accurate electron density mapping versus synthetic conventional kVCTs. **Methods:** MVCT (3.5MV), kVCT (120kV), and T1-weighted MRIs for 120 head and neck cancer patients were retrospectively acquired and co-registered. MRI intensity values were normalized to standardize datasets acquired on different scanners. A deep neural network based on a fully-convolutional 3D residual U-Net architecture was implemented to map MRI intensity to sMVCT HU. Model inputs were volumetric patches generated from 100 paired MRI and MVCT datasets. The U-Net was initialized with random parameters and trained on a mean absolute error (MAE) objective function. Model accuracy was evaluated on 20 withheld test exams. For comparison, this method was applied to generate conventional synthetic kVCTs (skVCTs). sCTs were compared to respective actual CTs using MAE. To demonstrate clinical proof-of-concept, IMRT plans were generated on a MVCT then calculated with fixed plan parameters onto the corresponding sMVCT. Dose distributions were compared using gamma (3%/3mm local dose threshold) criteria. **Results:** The model produced MAE of 118.4 ± 17.3 and 127.7 ± 33.3 HU for MVCT and kVCT datasets, respectively. Overall, there was good agreement between sCTs and CTs. Distinguishing bone from air posed the greatest challenges. The retrospective dataset introduced additional deviations due to sinus filling or tumor growth/shrinkage between scans, differences in external contours due to variability in patient positioning, or when immobilization devices were absent from diagnostic MRIs. Dose-volume-histograms were in close agreement between sMVCT and MVCT datasets and the gamma value between dose distributions was 100%. **Conclusion:** sMVCT datasets can be generated from T1-weighted MRI using a 3D DCNN with dose calculation on a sample sMVCT in excellent agreement with the MVCT.

MO-lePD-TRACK 3-05

Diffusion Profiling Via a Histogram Approach in Locally Advanced Cervical Cancer Treated with Chemoradiotherapy: Challenges and Opportunities for Dynamic Targeting with MRI

M Jacobsen*, S Simiele, T Bruno, A Klopp, K Brock, R Stafford, L Lin, A Venkatesan, The University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: There is need for imaging biomarkers to identify radiation resistant tumors and guide radiotherapy of cervical cancer. As such, MR-guided adaptive radiotherapy has the potential to provide improvements to the therapeutic ratio. Parameters derived from diffusion-weighted MRI (DW-MRI) are appealing quantitative biomarkers because DW-MRI does not require exogenous contrast agents, has relatively short scan time, and is ubiquitous across systems owing to its role in diagnosis. Important histologic properties that correlate with apparent diffusion coefficient (ADC) include tumor proliferation index, tumor grade, presence of necrosis, and post-therapy tumor cell apoptosis. The purpose of this study was to evaluate cervical cancer ADC histograms prior to and following concurrent chemoradiotherapy (CCRT). **Methods:** Five cervical cancer patients who underwent a 4-week CCRT regimen with MRI prior to and following external beam radiotherapy (EBRT) were retrospectively analyzed. Histogram features were calculated from volumes of interest (VOIs) contoured by a radiologist on ADC maps. Tumor volume, surface area, and descriptive statistics for the ADC voxel data, including mean, median, standard deviation, quantiles, skewness, and kurtosis were compared using a paired t-test. **Results:** Post-EBRT scans were acquired an average of 41.4 days after baseline DWI. Tumor volume decreased by an average of 58.2 ± 55.2 cm³ ($p = 0.04$) and surface area decreased by 9823 ± 8011 mm² ($p = 0.03$) from baseline. Mean ADC was 1184.8 ± 169.5 10⁻⁶ mm²/s and 1342.0 ± 172.2 10⁻⁶ mm²/s ($p = 0.12$) pre-CCRT and post-CCRT, respectively. Skewness and kurtosis were 0.82 ± 0.16 and 4.56 ± 1.36 pre-CCRT and 0.50 ± 0.51 and 3.68 ± 0.38 post-CCRT ($p = 0.11$ and $p = 0.10$). **Conclusion:** Chemoradiotherapy resulted in increases in mean tumor ADC of locally advanced cervical carcinomas, with statistically significant decreases in tumor volume and surface area in this cohort. Future work will evaluate ADC of viable tumor subvolumes over time and correlate histogram features with treatment response.

Evaluation of Registration Accuracy for Online MR-Guided Adaptive Planning

R Wu*, Y Ding, P Castillo, M Pham, T Williamsom, L Bronk, A Liu, C Fuller, J Yang, MD Anderson Cancer Center, Houston, TX

Purpose: To quantify the accuracy of rigid and deformable image registration (DIR) by using an in-house -developed phantom for online MR-guided adaptive planning with a Unity MR-Linac. **Methods:** We developed a phantom to evaluate the registration accuracy between modalities (MR-CT) and within MR (MR-MR). This acrylic phantom consists of a rotational base and 3 inserts of different shapes (circle, oval, and irregular), which were filled with oil, agarose gel, and Styrofoam jelly to simulate fat, prostate, and lung tissues. Deformations and location changes were simulated by changing the inserts. One CT scan and 48 MR scans (T1-weighted short [2-min] and long [6-min], and T2-weighted [2-min and 6-min] scans) were imported into the Monaco treatment planning system for rigid and DIR tests. Contours of all inserts were manually drawn on each image for evaluation. After DIR, deformed contours were compared with manual contours in terms of Dice similarity coefficient (DSC), Hausdorff distance (HD), and mean distance to agreement (MDA). **Results:** Rigid registration accuracy was within 2 mm and 2 degree for all scans (CT-MR, MR-MR). For MR-MR, T1 images had better DIR accuracy than T2 images: DSC T1-T1=0.93, HDT1-T1=0.69 cm, and MDA T1-T1=0.12 cm (vs T2: DSC T2-T2=0.86, HDT2-T2=0.12 cm and MDA T2-T2=0.42 cm). For MR-CT, T1 was also more accurate than T2 (T1: DSC T1-CT=0.82, HDT1-CT=1.56 cm and MDA T1-CT=0.32 cm, compared with T2: DSC T2-CT=0.75, HDT2-CT=1.62 cm and MDA T2-CT=0.47 cm). No difference was found in DIR accuracy between the T1 short and long scans. **Conclusion:** Different MR sequences can greatly affect DIR accuracy. However, low-quality T1 scans [2-min] can be used without sacrificing DIR accuracy. This phantom allows end-to-end testing for online MR-based adaptive planning.

Real-Time Motion Tracking Based on Orthogonal Cine MRI for Abdominal Tumors On 1.5T MR-Linac

H Jassar^{1*}, A Tai¹, X Chen¹, T Keiper¹, E Paulson¹, F Lathuiliere², S Beriault², F Hebert², L Savard², D Cooper², S Cloake², X Li¹, (1) Medical College of Wisconsin, Milwaukee, WI, (2) Elekta, Stockholm, Sweden

Purpose: This work investigates the feasibility of real-time motion tracking (RMT) for abdominal targets using a template registration-based algorithm between real-time 2D-cine and 3D-MRI on MR-Linac. **Methods:** The RMT was evaluated using 9 sets of daily mid-position images (MidP) derived from an in-house 4D-MRI and balanced T2/T1-weighted bFFE cine images acquired with free breathing on a 1.5T MR-Linac for 8 patients with abdominal tumors. The cine images were acquired with a temporal resolution of 0.2 s for a total duration of about 10 minutes interleaved between coronal and sagittal orientations. A 2D-template was created in both orientations using data acquired over the first 20 s, followed by a rigid registration to the 3D-volume using a mask defined on the MidP. Motion tracking of the target was performed by registering the rest of the 2D-cine series with the corresponding template with a known relationship to the 3D-volume. Manually delineated contours on sampled cine frames were used as the ground truth. Tracking accuracy was defined as the standard deviation of the error (SDE) comparing the center-of-mass (CM) of the ground truth and the tracked motion. **Results:** The tracking algorithm was qualitatively validated by visual assessment of 9 abdomen sets for the 8 patients. It was quantitatively validated on 4/7 Pancreatic and 2/2 Renal Fossa cases. The mean SDEs (and ranges), were 1.08 mm (0.31-1.9 mm), 1.07 mm (0.33-1.68 mm), and 0.76 mm (0.37-1.24 mm) in superior-inferior, left-right, and anterior-posterior directions, respectively. For the three remaining pancreas cases, performing tracking with ROIs including a margin encompassing the target demonstrated the robustness of the algorithm to implant-induced image artefacts in two cases and suboptimal imaging plane selection. **Conclusion:** We have demonstrated the feasibility of accurate free-breathing motion tracking using the template registration for abdominal targets based on real-time orthogonal cine on MR-Linac.

Deep Learning Based Multiple-Arc VMAT MLC Sequence Prediction in Prostate Cancer

Y Lao^{1*}, N Tong², W Yang³, K Sheng⁴, (1) UCLA School of Medicine, Los Angeles, CA, (2) University of Southern California, Los Angeles, CA

Purpose: To predict sequential multileaf collimator (MLC) apertures and dose for multiple-arc volumetric modulated arc therapy (VMAT), we introduce a deep learning (DL) based model utilizing the beam eye's views (BEVs) of the given dose distributions in prostate cancer patients. **Methods:** Clinical dose distributions and VMAT plans for 70 prostate cancer patients were solicited. All VMAT plans consist of 4 half-arcs, each consisting of 98 control points. A 6-channel 7-level U-NET was used as the main network. The input was the 6 stacked 2D dose distribution slices in the BEV of each gantry angle, spanning from the isocenter to the source with 5mm intervals. The output was the 2 corresponding MLC apertures in each gantry angle, with the associated dose being the intensity. The dataset was divided into 80% for training, 10% for validation, and 10% for testing. 200 epochs were trained using an aggregated loss combining mean squared error and dice coefficient (DC), and the Adam optimizer. For comparison, networks using 4 and 8 input slices per gantry angle were also trained with the same hyperparameters. **Results:** On 7 test subjects, the predictions from the 6-channel model (6s-BEV) achieved an averaged MLC apertures DC of 0.73 (± 0.04) and a step-wise dose error (DE) of -4.89% ($\pm 7.98\%$), normalized to each arc. In contrast, models using fewer (4s) or more (8s) BEV slices as inputs resulted in compromised performance: 0.69 (± 0.04) DC and -10.96% ($\pm 8.35\%$) DE for 4s-BEV, and 0.71 (± 0.04) DC and -9.06% ($\pm 8.67\%$) DE for 8s-BEV. **Conclusion:** We successfully implemented a U-net for the prediction of multiple-arc prostate VMAT plans. The trained model predicted MLC apertures and the associated dose without involving the time-consuming planning process. The proposed DL model may thus facilitate online applications that benefit from fast planning.

Capturing Head-And-Neck Planning Trends with a Knowledge-Based Tradeoff Model

J Zhang^{1*}, Y Sheng², Y Ge³, Z Tian¹, X Yang¹, T Liu¹, J Wu², (1) Emory University, Atlanta, GA, (2) Duke University, Durham, NC, (3) University of North Carolina at Charlotte, Charlotte, NC

Purpose: Since the clinical implementation of inverse planning, treatment planning knowledge has developed substantially, yet the knowledge shift is not well-understood. This study's purpose is to analyze the progression of the clinical planning knowledge over time and investigate if knowledge-based planning (KBP) models built using historical data can represent the current planning practice. **Methods:** To evaluate how clinical knowledge has progressed, we retrieved 304 anonymized head-and-neck treatment plans and binned them into four cohorts based on treatment date: 2011-2012, 2013-2014, 2015-2016, and 2017. Planning parameters and anatomic features were extracted from the treatment planning system via scripting. The first three cohorts were used for model training and the 2017 dataset was reserved for evaluation. A recently-proposed knowledge-based tradeoff model was used to quantify planning tradeoff considerations. Tradeoff directions projected on the 2017 dataset were recorded. Model prediction errors after taking tradeoff considerations were also evaluated. Additional plan information, including optimization constraints and optimization structures were analyzed. **Results:** During the four time periods, the numbers of beams, structures with optimization constraints, and optimization constraints have not changed significantly ($p>0.05$). However, the standard deviations of these parameters have all decreased, indicating the planning practice has become increasingly standardized. Using the latest 2015-2016 dataset for model training reduces validation error by 26.0% for parotid, 21.9% for oral cavity, and 25.0% for pharynx, compared with models trained using cases from previous periods. However, the tradeoff decisions made clinically remain consistent: parotid and oral cavity have been involved in most tradeoff considerations. **Conclusion:** We have demonstrated that the planning trends can be captured by a knowledge-based tradeoff model. Our results suggest that clinical planning knowledge changes over time and care must be taken when using prior treatment plans to guide new planning efforts.

A Deep-Learning-Based Dual-Arc VMAT Plan Generation from Patient Anatomy for Prostate Simultaneous Integrated Boost (SIB) Cases

Q Zhu^{1*}, X Li², Y Ni³, C Wang⁴, Q Wu⁵, Y Ge⁶, F Yin⁷, Q Wu⁸, (1) Duke Kunshan University, Kunshan, 32, CN, (2) Duke University Medical Center, Durham, NC, (3), (4) Duke University Medical Center, Durham, NC, (5) Duke University Medical Center, Durham, NC, (6) University of North Carolina at Charlotte, Charlotte, NC, (7) Duke University, Chapel Hill, NC, (8) Duke University Medical Center, Durham, NC

Purpose: To develop a deep-learning algorithm to automatically generate dual-arc VMAT plans using a patient's 2D integrated CT attenuation coefficients for prostate SIB cases. **Methods:** A customized U-net were designed with 4-resolution-step analysis path and a 4-resolution-step synthesis path. The inputs are 2D integrated CT attenuation coefficients and associated structure contours at the gantry position projection. The output prediction of intensity maps generates two sets of MLC sequences for two VMAT arcs with the same collimator angle. The results were then sent to a commercial TPS for plan finalization. This study involves 140 prostate patients who received simultaneously-integrated-boost (SIB) treatment (PTV(58.8)/PTV(70) in 28fx). A total of 129 one-arc VMAT plans (library plans) were used for network training and validation. For the 11 test patients, the predicted intensity maps are divided into two parts from the isocenter. An empirical elliptical Gaussian distribution was multiplied with the predicted intensity maps. These intensity maps were then divided into upper and lower parts to calculate MLC positions. Key dosimetry metrics in the resulting dual-arc VMAT plans (DL plans) were compared against the one-arc AVP-DSP plans in network training. **Results:** After dose normalization (PTV(70) V70Gy=95%), some of 12 DL test case plans met institutional clinic guidelines of dose distribution for OAR and normal tissue sparing. The tested plans showed a high consistency. In an example DL plan, OAR parameters were comparable to one-arc library plan (Bladder V70Gy=5.6cc, V40Gy=15.5%; rectum V70Gy=3.9cc, V40Gy=35.9%). Single-arc: (Bladder (V70Gy=6.8cc, V40Gy=19.4%; rectum (V70Gy=2.8cc, V40Gy=26.3%). 3D max dose results in DL plans (D1cc=114.6% were lower than the one-arc library plan (D1cc=118.9%). On average, DL plan generation takes 30s/case in contrast to the current clinical practice. **Conclusion:** Compared to one-arc library plans, the proposed dual-arc VMAT plan generation algorithm has potentials to achieve higher modulation and lower maximum dose.

MO-lePD-TRACK 5-04

A Feasibility Study of Automated Inverse Planning Using Hyperparameter Tuning

M Kim*, K Maass, A Aravkin, University of Washington, Seattle, WA

Purpose: Inverse planning in current practice requires treatment planners to modify multiple parameters in the objective function to produce clinically acceptable plans. Due to the manual steps in this process, the quality of plans could widely vary depending on planning time available and treatment planner's skills. The purpose of this study is to automate the inverse planning process to maintain plan quality with reduced planning time. **Methods:** The parameters for tuning were the limit dose parameters of each organ-at-risk (OAR) objective. For given parameters, the treatment plan optimization was done in Raystation using the scripting interface to obtain the dose distributions deliverable. We investigated random and Bayesian searches with various forms of utility functions to achieve clinical goals. We also varied the range of dose parameters in the search space. We applied the framework developed to 5 patients who received SBRT to their peripherally located lung tumors with distinct clinical concerns. We constrained the dose to OARs according to RTOG0915. We normalized all plans to have PTV D95 equal the prescription dose and compared the OAR dose metrics in the clinically used plans with those in the automatically generated plans. **Results:** The number of iterations required to produce the satisfactory plan quality was 100 and the average planning time was 2.2 hours. The OAR doses achieved by the automatically generated plans were lower than the clinical plans by up to 76.8%. When the OAR doses were larger than the clinical plans, they were still less than the clinical goals by 3.6-98.9% indicating they were clinically acceptable. **Conclusion:** We successfully devised an automated inverse planning framework using hyperparameter tuning. We demonstrated that the plan quality could be improved, and the average treatment planning time (no planner intervention required) was 2.2 hours for SBRT lung cases.

MO-lePD-TRACK 5-05

Plan N Check: An Open-Source Tool for Automatic Head-And-Neck VMAT Planning in Varian Eclipse™

C Sample^{1*}, H Clark², (1) British Columbia Cancer Agency, Vancouver, BC, CA, (2) British Columbia Cancer Agency, Surrey, BC, CA

Purpose: To demonstrate the efficacy of a novel and open source tool, "Plan n Check," for automated creation of head-and-neck Volumetric Modulated Arc Therapy (VMAT) radiotherapy plans in Varian Eclipse™. **Methods:** The Eclipse Scripting Application Programming Interface was used to develop a binary script which runs within Eclipse™, reading and operating on patient data. Plan n Check creates dual concentric arcs centred on the primary target volume with a 60° collimator angle difference aligned with the patient's superior-inferior axis. Collimator jaws are automatically adjusted to adequately encompass target volumes. Standard institutional dose constraints are automatically applied to relevant structures which can be verified and overridden by the planner if needed. Optimization structures are automatically created where regions-of-interest overlap planning target volumes, excluding higher-priority tissues (e.g., nervous system). To fine-tune optimization objectives, N preliminary optimization cycle iterations followed by automatic constraint-checking and updating of objective penalties take place before proceeding with full VMAT optimization for 4 additional optimization cycles. **Results:** Plan n Check created treatment plans conforming to institutional best-practices and standards-of-care. Plans optimized with N = 1 and N = 2 met all institutional constraints, while plans optimized without preliminary iterations resulted in constraint violations for all but one patient (median: 2 violations per plan). **Conclusion:** Plan n Check is an open source tool for automating VMAT treatment planning in Varian Eclipse™. Use of preliminary optimization cycle iterations improves clinical constraint satisfaction without requiring any additional effort from the planner. Source code is freely available online.

MO-lePD-TRACK 5-06

A Fully-Automated Field-In-Field Algorithm Translatable to Multiple Disease Sites

K Huang^{1,2*}, D Rhee^{1,2}, A Olanrewaju², D Hancock², L Zhang², C Cardenas^{1,2}, P Das², S Beddar^{1,2}, D Fuentes^{1,2}, T Briere^{1,2}, L Court^{1,2}, (1) University of Texas MD Anderson UTHealth Graduate School of Biomedical Sciences, (2) University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: To develop an adaptive automated field-in-field technique compatible with various beam arrangements and treatment sites. **Methods:** We created an algorithm that automates the clinical workflow for creating field-in-field plans independent of treatment planning system. The algorithm automatically identifies a hotspot, creates a subfield, calculates dose, and optimizes beam weight without user intervention. This process is repeated until the hotspot is reduced. Parameters used in the algorithm are configurable and include the definition of hotspot, the target volume, the maximum number of subfields, the minimum MU per field, and the optimization solver, and so on. A sub-field is determined based on hotspot area. The beam weights are optimized based on user-configured physical constraints for DVH coverage and least-squared cost functions. The final plans were evaluated based on target volume coverage and the remaining hotspot dose. The algorithm was tested on 20 patients each for whole brain (2-field), rectal (3-field), and cervix (4-field-box) with the clinically delivered primary fields as inputs. **Results:** For whole brain plans, all plans achieved V98.5% with hotspot less than 108% of prescription dose. For rectal plans, all plans achieved V95% with hotspot less than 110% of prescription dose. For cervix plans, all plans achieved V97% with hotspot less than 109% of prescription dose. On average, the algorithm reduced the hotspots of the plans from 114% to 107%, 130% to 107%, and 111% to 107% for whole brain, rectal, and cervix, respectively. The average time to complete a plan is 8.5 mins, 22.2 mins, and 6.5 mins for whole brain, rectal and cervix plans, respectively. **Conclusion:** We automated the clinical workflow for generating FIF to reduce hotspots in 3D conformal plans. This algorithm successfully produced FIF plans for beam arrangements and multiple disease sites and can improve treatment planning efficiency when incorporated into automatic planning workflow.

Robust Lung SBRT Knowledge-Based Planning with Missing Data Management

A Kroshko^{1,2*}, L Archambault^{1,2}, O Morin³, (1) Université Laval, Quebec, Canada (2) CHUQ Pavillon Hotel-Dieu de Quebec, Quebec, Canada (3) University of California San Francisco, San Francisco, CA

Purpose: Lung SBRT is a complex site and treatment technique. A knowledge-based planning (KBP) technique is harder to implement because not all organs-at-risk in the thorax are delineated based on the location of the tumor and its size, which often results in a heterogeneous plan database. We developed a novel technique to predict dosimetric parameters for the lung SBRT effective even in the presence of missing data. **Methods:** A retrospective study was made of 399 lung SBRT patients (219 training, 30 validation and 50 test) treated with VMAT. Prescribed dose was 48 or 52 Gy in 4 fractions and 50 Gy in 5 fractions. Bayesian Stochastic Frontier Analysis (BSFA) with Markov Chain Monte Carlo (MCMC) algorithm were used to design a knowledge-based technique to predict achievable dose sparing to organs-at-risk. 95% Highest Density Interval (HDI) is also calculated within the MCMC framework and give us credible interval of dose prediction given a patient specific anatomy. Missing data for non-delineated OARs were estimated following a truncated normal distribution specific to each OAR. **Results:** In total, 16 dosimetric parameters were predicted for the spinal cord PRV, esophagus, heart, main bronchus, great vessels and chest wall. Mean difference between the observed and predicted values for the test group ranges between 1.5 (1.9) Gy for the D0.35cc of the spinal cord PRV and 4.9 (5.3) Gy for the D0.035cc of the main bronchus. Investigation of the missing data model shows that it is robust in our predictive model. **Conclusion:** BSFA for lung SBRT with missing data management shows convincing results in predicting dosimetric parameters for lung SBRT.

Patient-Reported Outcomes+ (PRO+) for Remote symptom Management, Featuring Automated Triage Pathways

X Tang*, N Hacker, A Danish, S Chen, Liye, Inc., New York, NY

Purpose: Despite the promising results, symptom monitoring is not widely implemented in the clinic. This is largely due to the additional staffing that is needed to triage the increased patients' symptom reporting. We herein propose a PRO+ platform for remote symptom management, where the plus sign represents automated triage pathways. This includes AI and evidence-based triage chatbot and severity classification algorithm, to reduce manual triage needs. **Methods:** 22 most common symptoms were included in the triage system. For each symptom, triage pathways were built in chatbot format. Three metrics were used for ongoing evaluation during development. 1) Patient engagement rate. Volunteer patients used the system to report symptoms. If a chatbot conversation was initiated and finished, it was counted as a successful engagement. 2) Chatbot triage efficiency. Nurses reviewed the reported symptom details and marked the situations that enough information was collected to provide patients clinical advice. Corresponding percentage was calculated. 3) Classification accuracy. The classification algorithm results were compared with manual results by nurses, and accuracy was reported. **Results:** The PRO+ platform was built. Patients can select any symptom to report. Once a symptom is selected, the chatbot will carry a conversation with patient to collect necessary information for triage. The chat bot conversation is adapted real-time to the reported symptoms and conversation. 150 volunteer patients reported symptoms, and the engagement rate was 91%. 80% of the time the chatbot had collected enough information for nurses to provide clinical advice. The severity classification discrepancy was 95%. **Conclusion:** A PRO+ platform was built for symptom management. It has automated triage pathways that can potentially allow clinics to provide remote symptom monitoring with reduced manual triage needs. More study is needed to examine the chatbot questions, severity classification performance, and staffing model required before wide adoption in the clinic.

MO-lePD-TRACK 6-02

Using in Vivo EPID Measurements to Model Acute Gastrointestinal Toxicity

C Bojcechko*, D Simpson, T Nelson, V Moiseenko, University of California San Diego, La Jolla, CA

Purpose: Currently for abdominal treatments, estimates of bowel toxicity are based on pre-treatment dose-volume histogram data. However, the actual dose the bowel receives can depend on intrafraction anatomy changes, such as weight loss and changes in bowel filling. We propose a method to model bowel toxicities, incorporating on-treatment patient information using in vivo transit electronic portal imaging device (EPID) images. **Methods:** For 63 patients treated to the lower thorax, abdomen, or pelvis on the Varian Halcyon, chart review was performed to measure incidences of toxicity. Twenty patients presented with acute gastrointestinal (GI) toxicity. For each treatment plan, the absolute volume dose-volume histogram of the bowel was exported and analyzed. The Halcyon collects in vivo EPID images for all treatments, which were downloaded and analyzed with an automated framework. Over the course of treatment, EPID measurements quantifying changes in radiation transmission in vivo were summed after every fraction. Logistic models were used to test correlations between acute GI toxicity and bowel dosimetric parameters as well as in vivo EPID measurements. **Results:** The incidence of toxicity versus the volume of 40 Gy fit with a logistic function was superior to an average model ($p < 0.0001$) and agrees with previously published models. The incidence of toxicity versus the sum of in vivo transmission measurements showed marginal significance after 15 fractions ($p=0.10$) and a significance of $p < 0.05$ is seen after 20 fractions when compared to an average model. **Conclusion:** This study agrees with other models that reducing bowel dose results in lower acute GI toxicity. Additionally, the study supports the hypothesis that in vivo EPID measurements can be used to monitor and model acute GI toxicity. From this study, it is unknown if the change in the patient's anatomy is a source of toxicity or just correlated.

Presenting Author receives grant funding from Varian Medical Systems.

MO-lePD-TRACK 6-03

Impact of Heart Irradiation on Survival (OS) in Two Patient Cohorts: Locally Advanced Non-Small Cell Lung Cancer (NSCLC) Patients (pts) Treated Conventionally and Early Lung Cancer Patients Treated with Lung SBRT

J Hu¹, J Li², S Schild³, J Anderson³, M Fatyga*, (1) Arizona State University, (2) Georgia Institute of Technology, (3) Mayo Clinic Arizona, Phoenix

Purpose: Recent evidence suggests that heart irradiation decreases OS in patients treated with radiation therapy (RT) for locally advanced (LA) NSCLC. Less is known about cardiac toxicity pts who receive SBRT to the lung. **Methods:** 134 pts treated for LA-NSCLC with conventionally fractionated RT and 197 pts treated for early stage cancer with lung SBRT at Mayo Clinic Arizona were included in this study. Each group was analyzed separately. We used a multivariate Cox model Akaike Information Criterion (AIC) to select patient specific covariates predictive for OS. We digitally subdivided each heart into 64 segments and used a multivariate Cox model with patient specific covariates V%_D for each segment to determine irradiated segments predictive for OS. We used a clustering algorithm to determine irradiated heart regions predictive for OS. **Results:** 134 patients were treated for LA-NSCLC (median dose: 62Gy, 1.8-2.0 Gy/fx) and 197 pts were treated with SBRT (48Gy in 4fx and 50Gy in 5fx). High doses delivered to the right-superior region of the heart were predictive for decreased OS in LA-NSCLC patients. The best predictive index was V%_55Gy (HR = 1.04/1%, $p<0.01$). Low doses to the inferior region of the heart were predictive for decreased OS in SBRT patients. The most predictive index was V%_2Gy (2Gy equivalent dose, HR = 1.01/1%, $p=0.01$). The LA-NSCLC model applied to SBRT patients did not predict a reduction of

OS because of significantly lower doses to the heart in SBRT treatments. **Conclusion:** Heart irradiation is associated with reduced OS in LA-NSCLC patients and in patients treated with lung SBRT. A comparison of the two patient cohorts suggests that different etiologies may be responsible for reduced OS in each.

MO-lePD-TRACK 6-04

Predictive Factors of Biochemical Failure Free Survival for Prostate Cancer Patients After External Beam Radiation Therapy

L Sun^{1,2*}, H Quon^{1,2}, V Tran¹, C Kirkby^{1,3}, W Smith^{1,2}, (1) University of Calgary, Calgary, AB, CA, (2) Tom Baker Cancer Centre, Calgary, AB, CA, (3) Jack Ady Cancer Centre, Lethbridge, AB, CA

Purpose: To identify external beam radiation therapy (EBRT)-related and diagnostic factors that predict biochemical failure-free survival (BFFS) for prostate cancer patients. **Methods:** Patients diagnosed with localized prostate adenocarcinoma (N0, M0) between January 2005 and December 2016 and treated with curative EBRT using a Varian linear accelerator at one of the four cancer centers in Alberta, Canada, were retrospectively included. Biochemical failure-free survival (Astro-Phoenix definition) was calculated using Kaplan-Meier estimator. Patient demographic and diagnostic factors, as well as EBRT treatment planning and delivery parameters, were collected. Cox proportional hazard model with LASSO regularization and random survival forest were used to identify the predictive factors. **Results:** This study included a cohort of 2827 patients with a median follow-up of 6.4 years (IQR: 4.0 - 9.1 years). The BFFS for this patient cohort was 85% at 5 years (CI: 83.5%-86.4%). The statistically significant factors in the Cox model with LASSO regularization were: Gleason score, prostate-specific antigen (PSA) at diagnosis, clinical T stage (increased risk of biochemical failure with worse diagnosis), PTV V98% (lower risk with better coverage), and irradiation technique (2-phase pelvic irradiation had a lower risk than seminal vesicles having lower dose than prostate). The five most predictive variables in random survival forest were, in order of decreasing importance: Gleason score, PSA at diagnosis, PTV V98%, clinical T stage, and CTV D99%. Variables including dose calculation algorithm, bladder volume, hip implant, PTV D99%, hormone treatment, PTV volume, age at diagnosis, image-guidance type, RT modality, number of malignancies, equivalent PTV margin, and fiducial marker usage were not predictive in either method. **Conclusion:** Using a large retrospective cohort of patients from multiple centers, we identified that dosimetric parameters including PTV V98% and CTV D99% were predictive of BFFS in addition to diagnostic factors including Gleason score, PSA at diagnosis, and clinical T stage.

This study is supported by Alberta Innovates Graduate Studentship in Health Solution.

MO-lePD-TRACK 6-05

Survival Prediction of Locally Advanced Non-Small Cell Lung Cancer Via Machine Learning Techniques Based On Multi-Region Radiomics Features and Clinical Risk Factors

R Nishioka¹, D Kawahara², N Imano², Y Nagata^{1,3} (1)Medical and Dental Sciences Course, Graduate School of Biomedical & Health Sciences, Hiroshima University, Hiroshima, JP(2)Department of Radiation Oncology, Graduate School of Biomedical Health Sciences, Hiroshima University Hiroshima, JP(3)Hiroshima High-Precision Radiotherapy Cancer Center Hiroshima, JP

Purpose: To develop and validate a nomogram for predicting overall survival(OS) in patients with locally advanced non-small cell lung cancer(NSCLC) using multi-region radiomics analysis that analyze CT image in the image-based segmentation and the dosimetric-based segmentation. **Methods:** From 2008 to 2018, 77 patients with locally advanced non-small cell lung cancer were included. A total of 66196 features were extracted from pretreatment computed tomography (CT) images. Rad-score was generated using Cox proportional hazards regression. The Clinical model was established by the use of clinical predictors which was selected by multivariable Cox regression model. The Nomogram model, combined with Rad-score and clinical predictors significantly associated with OS, compared with Rad-score and the Clinical model. The prediction model was evaluated by under the receiver operating characteristics curve, concordance index (C-index), calibration. Kaplan-Meier survival curve was calculated for OS comparing high-risk and low-risk cohorts based on nomogram scores. **Results:** Thirteen features were selected to construct Rad-score, significantly associated with OS. Univariable and Multivariate analysis showed that Rad-score and Histologic type were independent predictors of OS, with p values of <0.001 and 0.01, respectively. Nomogram model showed best performance (C-index: 0.87 [95%CI: 0.81-0.93], AUC: 0.88) compared with the Clinical model (C-index:0.76 [95%CI: 0.64-0.88], AUC: 0.63) and Rad-score (C-index:0.84 [95%CI: 0.77-0.91], AUC: 0.88). Additionally, participants could be classified into low- and high-risk groups by the nomogram. The calibration plots also showed good consistency between the prediction and the observation. **Conclusion:** A nomogram model, incorporate Rad-score and clinical predictors, is a useful tool for predicting OS in NSCLC patients which might facilitate clinical decision-making process.

MO-lePD-TRACK 6-06

Prediction of Therapeutic Outcomes of Patients with Non-Small Cell Lung Cancer for Stereotactic Ablative Radiotherapy Based on a Differential Model

E Mai^{1*}, A Hidetada², T Huy¹, Y Shirakawa³, N Kenta¹, Y Tadamas⁴, S Yoshiyuki⁵, (1) Division of Medical Quantum Science, Department of Health Sciences, Graduate School of Medical Science, Kyushu University, Fukuoka, JP (2) Division of Medical Quantum Science, Department of Health Sciences, Faculty of Medical Sciences, Kyushu University, Fukuoka, JP (3) Department of Radiation Oncology, National Hospital Organization Kyushu Cancer Center, Fukuoka, JP (4) Department of Radiology, Kyushu University Hospital, Fukuoka, JP (5) Kyushu International Heavy Ion Cancer Treatment Center, Saga, JP

Purpose: For unresectable non-small cell lung cancer (NSCLC) patients at a Stage 1 or 2, stereotactic ablative radiotherapy (SART) is the first treatment choice alongside surgery. A five-year survival rate for patients received SART is reportedly about 70%, whose patients may have been suitable for SART. Therefore, the evaluation approaches to choose suitable patients for SART could be needed. We aimed to predict radiotherapeutic outcomes of patients with NSCLC from computed tomography (CT) scans using a differential model. **Methods:** Five NSCLC patients receiving SART that had planning CT and follow-up CT images [total scans: 23 (4.6 scan/patient)] were employed for extraction of GTVs and calculation of tumor cell numbers. The number of tumor cells at a time (CT scan) for each tumor, except CT images with radiation pneumonitis, was calculated by multiplying the density of tumor cells with the tumor volume obtained from the CT images. The tumor growth trajectories with the time-variant number of tumor cells were predicted by a Gompertz model with a linear-quadratic model under the assumption that each tumor cell could be resistant or sensitive to radiation. Three parameters in the models (degrees of radiation resistance and sensitivity, and the ratio of two types of cells) were optimized by a Levenberg-Marquardt method. The proposed method was evaluated with the mean absolute percentage error (MAPE) between predicted and reference numbers of tumor cells. **Results:** The MAPE ranged from 6.09 to 83.10%, and the average MAPE was 29.3%. **Conclusion:** This study showed the potential of predicting the therapeutic effect after SART.

MO-lePD-TRACK 6-07

Dosimetric Predictors of Hematological Toxicity in Cervical Cancer Patients Using the Lyman Normal Tissue Complication Probability Model

D Wang^{1*}, J Zhu¹, Y Yin¹, D Li¹, B Li¹, T Bai¹, Y Yin¹, (1) Department of Oncology Physics and Technology, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Ji'nan, Shandong province, CN

Purpose: To identify dosimetric parameters associated with acute hematological toxicity(HT) and analyze HT in cervical cancer patients receiving helical tomotherapy(Tomo) and fix-field intensity-modulated radiation therapy(ff-IMRT) with concurrent chemo-radiotherapy using the Lyman-Kutcher-Burman (LKB) Normal tissue complication probability(NTCP) model. **Methods:** Data were collected from 269 cervical cancer patients who received Tomo or ff-IMRT from 2015-2018. Pelvis bone marrow (PBM) was contoured from the superior to the inferior boundary of the planning target volume (PTV). The cumulated dose of PBM was

evaluated by integrating two plans for each patient on the MIMTM system. The parameters (TD50(1), m, n) of the LKB model predicting $\geq$ grade 2HT (RTOG grading criteria) were determined using maximum likelihood analyses. Univariate and multivariate logistic regressions were enlisted to find the correlation between dose-volumetric parameters and the clinical factors of HT. **Results:** 202 (75%) patients experienced $\geq$ grade 2HT. The fitted LKB model parameters were: TD50(1)=30.23Gy, m=0.46, n=0.05. Per univariate analysis, NTCP (p=0.023), maximal PBM dose (p=0.064), V6-11Gy (p<0.100), and V46-55Gy (p<0.100) were associated with $\geq$ grade 2HT. NTCP (p=0.032; AUC=0.606), maximal PBM dose $\geq$ 54.5Gy (p=0.024, AUC=0.601), and V47 $\geq$ 11.5% (p=0.036; AUC=0.596) were significant predictive factors of $\geq$ grade 2HT from the multivariate logistic regression analysis. **Conclusion:** The volume of the PBM of patients treated with concurrent chemo-radiotherapy subjected to both low and high-dose irradiation was associated with HT. NTCP, maximal PBM dose $\geq$ 54.5Gy, and V47Gy $\geq$ 11.5% were strong predictors of toxicity. Hence, avoiding radiation hot spots on PBM could reduce the incidence of severe HT.

Q&A | Closing Comments

Over the past few decades, the field of medicine has undergone tremendous changes as new paradigms have altered the way in which we understand health and disease, and have accelerated the pace of innovation from laboratory to clinical practice. The speed with which the COVID-19 vaccine has been developed is a good example of modern medicine's increasingly molecular, prospective, and data driven nature. We can anticipate even greater advances over the next 10-20 years that will make medicine of the future very different than that practiced for the past century.

Where does physics fit into this evolving paradigm of contemporary medicine? How is our role in medicine likely to be different in the next few decades? What can and should we be doing to prepare for this change – and more importantly – to ensure that we contribute the greatest societal impact possible going forward? To answer these questions, we need to look at what drives innovation in science and medicine. In short: an essential element is creativity.

The suggestion that creativity is an essential element of our future as physicists may at first seem surprising, since we often associate creativity with scholars in the arts and humanities rather than the natural sciences. But science is indeed extraordinarily creative. The part of science that involves methodical collection of data and careful analysis may not seem creative at first glance – but the leaps in understanding that occur with new theories and approaches that have transformed how we understand the world inherently involve the highest levels of creativity. Creativity at its core is the ability to see what has not been seen, to imagine what has not been imagined, and to bring that into tangible expression. Key advances in science have involved exactly those kinds of creative leaps. And our ability to envision how we apply physics in new ways in medicine going forward will involve exactly that type of creativity.

We will begin our Symposium by looking at a brief history of creativity in the sciences in order to understand how essential it is to cultivate this important human endeavor. Our keynote speaker, Bruce Tromberg, PhD, Director of the National Institute of Biomedical Imaging and Bioengineering (NIBIB) at NIH will then describe areas in which he sees the greatest need for creativity in the application of physics and engineering to medicine today. He will describe some of the key areas that NIH views as essential drivers of medical advances and where creativity is needed in our discipline of medical physics. We will conclude our Symposium with a panel discussion among several of our distinguished colleagues who have embodied the best of creativity in their careers to create new areas of biomedical science, and will explore how they cultivated creativity in their work. We will also ask them to address those things that we should be doing as a community to ensure that we promote the creativity that will be needed to create our future.

Where exactly will medical physics go in the coming decades? We can anticipate that it might involve new emphases on big data, machine learning, and molecular diagnostics and therapeutics, as examples, and will involve increasing collaboration with our colleagues in other disciplines. While we may not know the exact form this future will take, we can be assured that it will take creativity to get us there. It is our hope that you will leave this Symposium inspired to bring your creative spark to this important effort.

Learning Objectives:

1. Understand how creativity has played an essential role in the history of science and medicine.
2. Understand areas in which creativity is needed today to create the future of physics in medicine.
3. Understand how individual innovators have cultivated creativity in their own careers and what needs to be done to ensure that we as a field lay the groundwork for creativity that will build our future.

Imaging: Rad/Fluoro Image Quality and Imaging Protocols

MO-lePD-TRACK 1-01

Using Exposure Index to Develop Thickness-Based Techniques for the Skull Views of a Pediatric Skeletal Survey

X Li^{1*}, K Hulme¹, E Park¹, (1) Imaging Institute, Cleveland Clinic, Cleveland, OH

Purpose: Skeletal survey is an important tool in evaluating suspected physical abuse in preverbal children (0-3 years). The need to demonstrate subtle injuries demands high contrast and spatial resolution. This is especially true for the imaging of infant skulls. The goal of this study was to develop radiographic techniques based on head thickness and the target exposure indices (EI_T) needed for clinical diagnosis. **Methods:** The study included skull radiographs of 30 patients (aged 0-32 months) who underwent pediatric skeletal surveys using one type of digital system. All images were taken table-top using manual techniques without grid. From these images, head thicknesses were measured. Exposure techniques and EI were also extracted. Most images were taken at 60 kV, with the rest at 65 kV. For the latter group, an equivalent mAs needed at 60 kV was calculated following the 15% rule. Because EI scales linearly with mAs, a new mAs was then calculated for each image to provide a hypothetical EI_T of 800 (mAs_800). Regression analysis was performed to relate mAs_800 to head thickness. From this relationship, the median head thickness of each age group was used to calculate mAs_800, which was then scaled to obtain the mAs needed for a clinically desired EI_T. **Results:** The natural logarithm of mAs_800 increased linearly with head thickness ($R^2=0.38-0.59$). For the same head thickness, a higher mAs was needed in the lateral direction. Evaluation of clinical image quality by experienced pediatric radiologists showed that EI_T of 2000 was desirable for newborns who have small and underdeveloped skulls, whereas EI_T of 1000 was adequate for toddlers. The relationship between mAs_800 and head thickness allowed a new technique chart to be developed to provide such age-dependent EI_T. **Conclusion:** The regression relationship between mAs_EI_T and anatomical thickness may be exploited to develop manual technique charts for children.

MO-lePD-TRACK 1-02

Development of a Size-Based Technique Chart for Portable Chest Images to Reduce Variability in Image Quality

J Moroz^{*}, M Hoerner, K Grizzard, Yale New Haven Health, New Haven, CT

Purpose: To use the patient height and weight, which are accessible from most Radiology Information Systems, to create a radiographic technique chart for portable chest images. By providing technologists with size-based imaging techniques, it is expected that diagnostic quality images may be captured for a variety of patient sizes without exposing the patient to excess radiation. **Methods:** Technique charts for portable chest images were derived from image data, over a period of three months (170 exposures). Patients were modeled as water-equivalent cylinders, having a diameter determined from their weight and assumed density of 1.00g/cm³, and length equal to their height. Technique charts were created through a two-step process: first calculating soft-tissue attenuation coefficients for x-ray spectra ranging from 50-120kVp using SPEKTR spectrum generating code, then estimating the patients' tissue-equivalent attenuation thickness based off the image technique. The kVp and mAs were then chosen to achieve the desired detector exposure for a range of patient heights and weights. **Results:** The relationship between the patients' tissue-equivalent attenuation thickness and the square root of their weight over height was linear, having a slope of 0.63 ± 0.03 , intercept of 0.59 ± 0.51 cm and R^2 of 0.701. The technique chart greatly improved the variability in EI values, reducing the range from 360 ± 200 to 300 ± 80 . The target EI for this technique chart was 300. Further, 90% of images (64 of 71) captured after implementing the technique chart had a DI between -2 and +2. The variability in EI values was significantly less in the proposed technique chart ($p < 0.001$) than the standard technique chart. **Conclusion:** Constructing a size-specific technique chart proved useful in maintaining a consistent image quality, as defined by the EI over a wide range of patient sizes. A size-based technique chart will guide technologists in adapting standard techniques to accommodate a wide range of patient sizes.

MO-lePD-TRACK 1-03

Evaluation of Exposure for High-Speed Angiography (HSA) with the 1000 Fps Aries Image Detector

J Collins^{1*}, A Shields², S Rudin³, D Bednarek⁴, (1) University at Buffalo, Buffalo, NY, (2) University at Buffalo, Buffalo, NY, (3) University at Buffalo (SUNY) School of Medicine, Buffalo, NY, (4) University at Buffalo, Buffalo, NY

Purpose: The Aries x-ray photon-counting detector (Direct Conversion Inc.) can image at 1000 fps and is being investigated to observe details of vascular blood flow. This study considers the input-exposure requirements of the imager and the radiation dose implications for clinical use. **Methods:** The Aries image receptor has 100-micron pixels and a 5x7.5 cm FOV. Image frames were captured using one millisecond acquisition times, an RQA5 phantom placed in the beam and technique parameters set to 70 kVp and 100 mA. A 6-cc PTW ionization chamber was used to measure exposure at the detector input. An idealized ICA saccular-aneurysm model was placed over the phantom and images of contrast flow taken at 1000 fps were evaluated. The image signal-to-noise ratio and the vessel contrast-to-noise ratio were calculated from the counts per pixel. The integrated input detector exposure was determined over the transit time of a contrast bolus through the vasculature of interest. **Results:** The RQA5 phantom images had a detector input-exposure-per-frame (EPF) of 38 μ R, with a signal-to-noise ratio (SNR) of 7.2 and contrast-to-noise ratio (CNR) for the aneurysm of 2.4. At this dose level, flow details could be clearly seen in images of the aneurysm model. Contrast-bolus transit times are typically under 200 ms, requiring less than 200 1-ms frames. The integrated detector exposure for the RQA5 phantom run would correspond to about 7.5 seconds of DSA (300 μ R/frame) at 3fps. **Conclusion:** The Aries imager has been shown to give high temporal and spatial resolution, providing visualization of detailed blood-flow patterns in vascular pathology previously unseen. Estimated exposure for HSA runs appear to be comparable to present DSA runs.

Adaptive Dual-Energy X-Ray Imaging with Pre-Calibrated Patient-Specific Weighting Factors

I Romadanov¹, M Sattarivand^{2*}, (1) Nova Scotia Health Authority, Halifax, NS, CA, (2) Nova Scotia Health Authority, Halifax, NS, CA

Purpose: In this work we developed a novel adaptive dual-energy (aDE) algorithm, which accounts for differences in beam attenuation within imaging plane allowing for enhanced material cancellation and noise removal compared to conventional log-subtraction dual-energy (DE) algorithm. **Methods:** Pre-calibrated weighting factors were obtained with a step phantom, which consists of overlapping slabs of solid water and bone with different thicknesses. Bone and solid water thickness were varied in [0-6]cm and [0-30]cm range respectively. Thicknesses varied in orthogonal directions forming 49 regions with overlapping materials of different thicknesses. Optimal material cancellation weighting factors for each region was determined by varying weighting factors to achieve zero contrast-to-noise (CNR) between regions with overlapping materials and corresponding target material (bone or soft tissue). The optimal weighting factors were fitted to average intensities of each region in low (LE) and high energy (HE) images. Image noise was suppressed with anti-correlated noise reduction (ACNR) algorithm. ACNR weighting factors were determined by maximizing signal-to-noise-ratio of each overlapping region, and then were fitted with corresponding LE and HE region intensities. To test the DE algorithm, HE and LE images of Rando phantom were fed as inputs to the optimal fitting functions to create patient-specific weighting factors maps. Soft tissue and bone only DE images of Rando phantom were obtained with different DE algorithms and CNR for several selected regions of interest within the Rando phantom were compared for different algorithms. **Results:** CNR values for aDE algorithm were higher compared to simple log-subtraction algorithm. Implementation of aACNR algorithm results in further reduction of image noise and improvements in CNR. **Conclusion:** A novel DE algorithm was developed, which has improved material cancellation and noise reduction compared to the conventional DE technique. This method can be easily implemented in a clinical environment for real-time DE image generation.

Theoretical Investigation of X-Ray Spectral Shape Impact on Dual-Energy Image Quality: Effects of Dose Allocation, Total Dose, and Energy Ratio

I Romadanov, M Sattarivand*, Nova Scotia Health Authority, Halifax, NSCA

Purpose: The aim of this study was to develop a theoretical framework for the investigation of the impact of x-ray spectral shapes and dependent parameters (dose allocation, total dose, energy ratio) on the resulting dual-energy (DE) image quality. **Methods:** Spectral shape incident on the object was described with an analytical fitting function, partially depicting the physical mechanisms behind the polychromatic x-ray beam generation such as Bremsstrahlung radiation and its attenuation. This function was written in terms of the physical parameters, such as x-ray tube potential Emax (kVp), parameter α (related to tube mAs), and parameter β (related to photoelectric absorption coefficient). Simple phantom was developed to evaluate image quality and this model was used in theoretical calculations. The contrast to noise ratio (CNR) between a tumor region (behind bone) and its background was used as a figure of merit to quantify image quality. Analytical CNR was derived and parametrically investigated in terms of spectral shape parameters, dose allocation, and total dose. Experimental verification of the derived equation as a function of dose allocation was performed. Various dose allocations for different energy ratios were achieved by varying beam filtrations and mAs with constant total dose. **Results:** Equation for DE CNR as a function of spectral parameters, total dose, and dose allocation was derived. It was parametrically investigated and experimentally validated. It was shown that the contrast is defined by material properties only, while noise depends on relationship between spectra. Expression for dose allocation corresponding to maximum tumor CNR function was derived. **Conclusion:** The derived analytical CNR function allows for investigation of the spectral parameters and their impact on the image contrast and noise. It was shown that dose allocation corresponding to maximum CNR has strong dependency on material composition of the imaged object and cannot be reduced to one near-optimal number.

A Fully Automated Algorithm for Accurately Analyzing Star Shot Images from Linear Accelerators

N Battaglia*, G Shastri, Radiological Imaging Technology, Inc., Colorado Springs, CO

Purpose: To design a robust and fully automated image processing algorithm for accurately analyzing star shot (also known as 'spoke shot') images, as recommended by the AAPM TG-142 guidelines. The proposed algorithm was specifically designed to eliminate external inputs (i.e., 100% automated) with a focus on generalizability for maintaining increased accuracy across a multitude of highly variable beam characteristics and image qualities, while also providing a significant time-save in the clinic. **Methods:** A fully automated ad hoc algorithm was designed for accurately and reliably analyzing star shot images without the need for external inputs. Performance of the algorithm was tested across a set of 29 star shot images. The images were comprised of a total of 165 beams. Analysis was performed on both a per-image and a per-beam basis. Generalizability was demonstrated with an array of gantry, collimator, and couch star shot configurations typically found in the clinical setting. In addition, because beam properties are likely to vary within the clinical settings, whether due to machine restraints, unique procedures, or preferences of the physicist themselves, the algorithm was designed to be invariant to beam widths, number of beams, and relative beam doses. **Results:** The proposed algorithm correctly analyzed all beams in 28 of the 29 star shot images (96.6%). Additionally, of the 165 beams, 163 (98.8%) were correctly identified. The single image that failed served as a test case for the resolution of the image processing algorithm as it could not resolve two beams with a large proportion of overlapping dose. **Conclusion:** This work demonstrated a robust solution for fully automating the star shot image analysis process with high accuracy and reliability, while also saving valuable time. Such automation provides a vastly improved workflow for medical physicists to perform necessary QA tasks more efficiently.

Impact of Flexible Noise Control (FNC) Processing Parameters on Image Quality: A Chest Phantom Study

L Ren*, T Daly, K Loewen, B Schueler, Z Long, Mayo Clinic, Rochester, MN

Purpose: To investigate the impact of flexible noise control (FNC) processing (Fujifilm, Tokyo, Japan) on digital radiography chest imaging. **Methods:** An anthropomorphic chest phantom was imaged using a clinical chest protocol with 85 kV and five radiation dose levels (0.7, 1.0, 1.4, 1.8, and 2.2 mAs) at 40'' source-

to-image distance with scatter removal image processing applied. All images were processed without and with FNC. Selected options for the four processing parameters of FNC included filter control FFC (C and F), frequency balance FNB (A, C, E, and G), density control FNT (A, B, and C), and strength control FNE (0.1, 0.5, and 0.9), resulting in 72 combinations. Subtractions were performed between images without and with FNC from the same setting to assess noise and grayscale changes. Noise-only images were generated by subtracting two identical acquisitions and two regions-of-interest (ROIs), one over lung field and the other over liver area, were drawn to quantify the noise level for each setting. Texture analysis was performed in the liver ROI using the gray-level co-occurrence matrix (GLCM). Edge-preserving capability was evaluated using a line profile through a lung/rib interface. **Results:** Use of FNC resulted in 15-70% noise reduction depending on the dose levels, parameter choices, and ROI selections. Options in FNB and FNE parameters did not show performance difference. Option F for FFC and A for FNT demonstrated the highest noise reduction compared to other options. Information measure of correlation from GLCM demonstrated the largest difference among the parameter combinations, with CGC the closest to baseline and FGA/B the most different. The appearance of edge interfaces was also affected, with FGB and CGB providing better edge-preserving capabilities. **Conclusion:** The impact of FNC on chest imaging was demonstrated using a phantom. Noise suppression and edge-preserving capability depend on radiation dose level and FNC parameter choice.

Development of 3D Rosette K-Space Trajectory in Ultra-Short Echo Time MRI Applications

X Shen^{1*}, M Chiew², U Emir³, (1) Purdue University, West Lafayette, IN, (2) Oxford University, UK, (3) Purdue University, West Lafayette, IN

Purpose: Ultra-short echo time (UTE) MRI is the promising imaging modality for the direct measurement of tissues with short transverse relaxations (T₂), e.g., myelin in the white matter, globus pallidus, sodium imaging, and lung imaging. The most common k-space patterns for UTE applications are the 2D and 3D radial trajectories. The purpose of this study is to develop 3D rosette k-space pattern for UTE applications. Since rosette k-space pattern shares the advantages of radial acquisition, and it is capable of combining compressed sensing for acceleration, rosette trajectory may be a better choice for UTE MRI. **Methods:** The equations and figures of 3D rosette trajectory are shown in the supporting document. The performance of 3D rosette and 3D radial k-space patterns with different sampling strategy was compared based on the reconstructed image quality from a simulated phantom, in terms of the signal-to-noise ratio (SNR) and accuracy. In addition, the 3D UTE sequence using rosette trajectory was simulated on the JEMRIS software (<http://www.jemris.org/>). The parameters were: FOV=240mm, matrix size=120x120x120, hard RF pulse for excitation with duration of 0.1ms, 15 degree flip angle, TE=0.05ms, and TR=5ms. **Results:** The SNR of 3D rosette k-space trajectory is larger than the SNR of 3D radial, regardless of sampling pattern (11.86 > 9.10 with full k-space acquisition, 12.39 > 7.85 with undersampling pattern of 25% spokes). In addition, 3D rosette k-space provided more accurate reconstructed images than 3D radial. The simulation results of 3D UTE sequence with rosette trajectory were shown in the supporting document. The reconstructed images captured most of the properties in original images. **Conclusion:** The performance of 3D rosette k-space trajectory is generally better than 3D radial, in terms of SNR and accuracy. In addition, the feasibility of using rosette trajectory in UTE MRI has been demonstrated by simulation.

Characterization of Diffusion Tensor Parameters in Normal-Appearing White Matter

M Barrera Esparza¹, (1) Hospital Angeles Lomas, Mexico City, MEX, MX

Purpose: To quantify the fractional anisotropy (FA), the apparent diffusion coefficient (ADC) and the radial diffusivity (RD) in normal-appearing white matter (NAWM) surrounding focal brain lesions in patients with multiple sclerosis (MS) and to establish a change gradient of these 3 factors over the distance to the focal lesion. Then, by comparing the gradient between patients with several stages of MS, evaluate the possibility of predicting new focal lesions. **Methods:** A diffusion tensor (DT) post processing was completed to magnetic resonance images (MRI) of MS patients. The FA, ADC and RD values in focal lesions were obtained using the software toolkit. Then, a color map in the images was constructed to better visualize the lesion limits, also 2 regions of interest (ROI) of different sizes were defined surrounding the focal lesions. Once these 3 variables were measured in the lesions and in every ROI, an analysis of change gradient was determined along the distance to the focal lesion. This was done in 7 different patients. **Results:** In an early stage of the disease (relapsing-remitting MS), the patients showed a significant decrease in ADC and RD values as the ROI moved away from the lesion, being bigger in the lesions than in the ROIs. In contrast, the FA had its greatest increase in this early disease stage as the ROI was further away from the lesion. New lesions were shown in cases where there was a greater change gradient. **Conclusion:** This work helps to provide an accurate prognosis of the disease and the possibility to analyze the use of early treatment to prevent the development of clinically definite MS.

Effects of MLC Motion on B₀ in 0.35 T MRI-Linac

H Gach*, D Yang, O Green, T Kim, Washington University in St. Louis, St. Louis, MO

Purpose: Currently, commercial MRI-Linacs only turn on the beam when the gantry and MLCs are stationary. However, treatment times could potentially be reduced by allowing the beam to be on during MLC motion (e.g., Sliding Window IMRT or VMAT). The purpose of this study was to quantify the effects of MLC motion on B₀ for a 0.35 T MRI-Linac (ViewRay, Mountain View) and determine their effect on image quality. **Methods:** B₀ center frequencies and field homogeneities were measured in a 24 cm diameter spherical volume (DSV) water phantom doped with 5 mM NiSO₄ (T₁ = 330 ms at 0.35 T) during MLC sweeps. Free induction decays (FIDs) were acquired every 0.29 s while the gantry was static at gantry angles 0-330° in increments of 30°. The spectra were calculated from the FIDs. The peak offset and full width at half maximum (FWHM) were calculated after fitting the spectra to a Lorentzian function. Measurements were conducted without gradient shimming. MRIs were also acquired during MLC sweeps using the 2D cine radial (8 fps) and Cartesian (4 fps) balanced steady state free precession (bSSFP) acquisitions normally used during treatment. MRIs were inspected for presence of artifacts. **Results:** Variations in the mean center frequency and FWHM between gantry angles are within expected ranges. B₀ and field homogeneity standard deviations from MLC motion were <2.0 and <1.3 Hz, respectively. No conspicuous image artifacts were observed during the MLC sweeps. **Conclusion:** MLC motion had a minimal effect on image quality and B₀. Therefore, dynamic beam shaping using MLCs could potentially be performed without an impact to image quality and target tracking.

Exploration of the Predictive Value of Delta Radiomics Texture Features Extracted from Low-Field Magnetic Resonance Images in Pancreas Stereotactic Body Radiotherapy Patients

G Simpson*, W Jin, B Spieler, J Ford, L Portelance, E Mellon, D Kwon, F Yang, N Dogan, University of Miami, Miami, FL

Purpose: Magnetic resonance-guided radiotherapy (MRgRT) provides radiation oncology departments a modality that acquires high contrast images ideal for anatomical visualization for target localization, motion tracking, and gating. The purpose of this work is to explore the predictive potential of delta radiomics texture features (i.e., changes in radiomic texture features over time) extracted from daily set up images of pancreas patients treated with MRgRT. **Methods:** The gross tumor volume (GTV) was delineated on daily set up images of 27 pancreas patients treated with 33-50 Gy in 5 fractions. Gray level intensities for each GTV were quantized to 64 levels using the histogram equalization method and 39 second order texture features were extracted. Two sets of delta radiomics features were calculated: absolute change (DF(ABS)) and normalized change (DF(NORM)). DFABS is the absolute difference between fraction 1 and fractions 2-5. DF(NORM) features are DF(ABS) normalized by fraction 1 feature values. Delta radiomics features were ranked by predictive importance using the Gini Index obtained during training of a random forest (RF) model. The RF models constructed using DF(ABS) and DF(NORM) from fraction 1 and 2 produced in the highest area under (AUC) the receiver operating characteristic curve and selected the same two DF(ABS) and DF(NORM) features as most important. Gray level co-occurrence matrix-based sum average and gray level size zone matrix-based large zone low gray level emphasis were used to construct RF models for evaluation of predictive performance using leave-one-out (LOO) analysis to obtain AUC. **Results:** The RF using DF(ABS) features achieved an AUC, with a 95% confidence interval, of 0.77(0.58–0.96) and the RF with DF(NORM) achieved an AUC = 0.78(0.59–0.97). **Conclusion:** Delta radiomics texture features calculated from fraction 1 and 2 set up images during SBRT may provide valuable prediction of treatment response with time to modify the treatment and improve outcomes.

MO-lePD-TRACK 2-05

Improved Myelin Water Imaging Using 3D GRASE and Orthogonal Matching Pursuit Reconstruction

R Gabr*, J Lincoln, K Hasan, J Wolinsky, P Narayana, University of Texas Health Sci. Center at Houston, Houston, TX

Purpose: Noninvasive MRI-based quantification of myelin provides valuable information for the study of neurological and neuropsychiatric disorders. Multi-echo spin echo MRI data are analyzed using multi-exponential T2 relaxation to assess myelin by computing the fraction of myelin water (usually assumed as 10<T2<40 ms) to the total signal. This approach for myelin water fraction (MWF) is challenged by the fast decay of the myelin water signal and the need for high resolution and signal-to-noise ratio. Three dimensional GRASE imaging accelerates image acquisition for whole-brain application. However, data fitting is sensitive to noise due to the ill-conditioned nature of the problem, which is conventionally addressed using regularized non-negative least-squares (NNLS) analysis. Here we investigate the application of orthogonal matching pursuit for improving the quality of MWF maps. **Methods:** 3D GRASE data were acquired from one patient with multiple sclerosis in four different session in a study of oral acetazolamide over a period of 5.5 month using a 3.0 T Philips MRI system with a multi-channel head coil. Acquisition parameters were TR/TE/ΔTE = 747/7/7 ms; number of echoes, 32. Non-negative least squares reconstruction was used as reference. Orthogonal matching pursuit was implemented with nonnegativity constraint (NNOMP). The number of components (sparsity) was empirically optimized and four components was found to yield the best results. **Results:** The NNOMP-reconstructed MWF maps consistently showed improved visual quality in all scans. Figure 1 shows a comparison between NNLS and NNOMP in one scan. White matter MWF values calculated from NNOMP were approximately 10-15% higher than those obtained from NNLS. **Conclusion:** NNOMP produces MWF maps with improved quality. The improved performance is attributed to the regularization imposed by the sparsity constraints in NNOMP. No spatial regularization was imposed on either of the techniques. Analysis on a larger sample is underway to assess NNOMP both qualitatively and quantitatively.

MO-lePD-TRACK 2-06

Development of a Clinical Protocol to Rapidly Determine the Potential Impact of Radiofrequency Induced Heating in Patients with Abandoned Epicardial Leads During MRI

O Aboyewa¹*, J Vonk², L Kammann³, J Haggstrom², M Nichols¹, (1) Creighton University, Physics Department, Omaha, NE, (2) Creighton University, Department of Radiology, Omaha, NE, (3) Imaging Services, Creighton University Medical Center Bergan Mercy, Omaha, NE

Purpose: In the 2017 Heart Rhythm Society consensus statements, scanning of MR nonconditional CIEDs in the presence of epicardial leads were classified as contraindications. While there are numerous studies on transvenous leads, there is insufficient data to comment on the safety of patients with epicardial leads during MRI. This study seeks to clarify safety concerns in patients with epicardial leads owing to the sensitivity of its applications. **Methods:** a tissue-equivalent phantom was designed according to the ASTM standard for measurement of radiofrequency (RF) induced heating on or near passive implants. The polycarbonate phantom and was filled with a polyacrylic acid (PAA) gel-saline that has similar electrical and thermal properties with the human body tissue. Forms fabricated to hold the lead and fluoroptic temperature probes permits easy localization and configuration (lead length and shape) within the gel. An initial thermometric study was performed on a 3T Siemens Tim Trio MRI system with routine clinical pulse sequences on a straight 58.4cm bipolar epicardial lead positioned in the phantom at a depth of 5cm below the surface. **Results:** Preliminary data shows no significant heating above the background in presence of the lead for all pulse sequences examined. **Conclusion:** The design of the phantom, lead, and temperature probe holder permits a rapid determination of the potential heating that may occur during an MRI study given the specific presentation of the lead within the patient. The system is relatively easy to setup and use within the clinic and can provide additional information to better evaluate safety concerns with border-line cases where the potential benefit of MRI may outweigh the risks. Further investigation on the variation of induced RF heating with lead type, insulation, lengths, and presentation within the body are underway and will be discussed.

MO-lePD-TRACK 2-07

Characterization of a Tissue-Equivalent Phantom for Thermometric Studies in MRI

O Aboyewa¹*, H Akinleye², J Wrubel¹, M Nichols¹, (1) Physics Department, Creighton University, Omaha, NE, U.S.A. (2) Physics Department, Federal University of Technology, Akure, Nigeria

Purpose: To measure the complex permittivity and thermal properties of a gel-saline phantom designed for thermometric studies in a 3T MRI scanner. **Methods:** A gel-saline phantom was designed according to the ASTM International standard for measurement of radiofrequency (RF) induced heating on or near passive implants during magnetic resonance imaging. The dielectric constant and electrical conductivity of the phantom was obtained using an open-ended coaxial probe permittivity measurement method that relies on changes in the complex reflection coefficient of an optimized probe due to the material under test. A simple implementation of this method was achieved with a basic RF electronic circuit consisting of a signal generator, power splitter, circulator, and oscilloscope, as opposed to the widely used Vector Network Analyzers (VNA). The non-ideal behavior of the coaxial probe due to spurious reflections and ohmic losses were accounted for by a scattering matrix that relates the measured reflection coefficient to the reflection coefficient at the probe tip. The probe was calibrated with three standard terminations including a short circuit, an open circuit, and a saline solution with a similar permittivity to that of the phantom. Assessment of the thermal conductivity and specific heat capacity of the phantom is underway and will be discussed. **Results:** A dielectric constant of 82.1 ± 1.4 and electrical conductivity of 0.47 ± 0.04 S/m was measured at a frequency of 127.8 MHz. This agrees with the recommended values of the ASTM standard of 80 ± 20 and $0.47 \pm 10\%$ S/m, respectively, for the phantom. **Conclusion:** A novel equivalent circuit for open-ended probe permittivity measurement has been developed and verified in the electrical characterization of a tissue-equivalent phantom. The complex permittivity of the phantom agrees with recommended values and indicates its usability for safety assessment in MRI.

A Hybrid Approach for Correcting CBCT by Exploiting Individual Strength of Deep Learning and Deformable Registration

J Uh*, C Wang, S Acharya, C Hua, St. Jude Children's Research Hospital, Memphis, TN

Purpose: To propose a novel hybrid approach, which utilizes prior planning CT (pCT) with deep learning, for correcting daily pretreatment CBCT to facilitate online verification of proton range. **Methods:** Previously proposed methods for correcting CBCT using CycleGAN are often limited in suppressing image artifacts, while maintaining a high geometric fidelity. In contrast, classic methods of deforming pCT onto CBCT provide more accurate intensities but suffers from geometric uncertainties. In the proposed method, high and low spatial-frequency components in each CBCT and pCT image are separated via Fourier transform. Then, CycleGAN and deformation are respectively used to correct geometry-weighted (high frequency) and intensity-weighted (low frequency) components which are subsequently combined, thereby each process deals with only the component weighted toward its strength. The CycleGAN was trained with 50 high-frequency image pairs of abdominopelvic CBCT/CT. A fast deformation algorithm followed by a threshold-based internal air correction was employed to process pCT. Additional datasets of 4 and 7 CBCT/pCT image pairs were used respectively to tune meta-parameters and evaluate the mean absolute error (MAE) performance of the proposed method against the same-day CT. **Results:** Correcting a CBCT dataset took less than a minute including the CycleGAN and deformation processes. The proposed method produced more accurate intensities than using CycleGAN alone (MAE, 37 ± 4 vs. 42 ± 4 ; $P<0.001$, paired t-test) and significantly reduced artifacts. When comparing with the deformation-alone method, the improved accuracy was pronounced in bony structures (defined by HU > 200; MAE, 73 ± 12 vs. 87 ± 19 ; $P=0.045$, paired t-test) reflecting robustness against misregistered bones in the deformed pCT. **Conclusion:** In the proposed hybrid approach, CycleGAN and deformable registration complemented each other to perform better than either individual method. The improvement in bony structure fidelity has implications for estimating proton range which is sensitive to geometric errors in those structures.

CBCT Air Artifact Reduction Using a Simulation-Based Image Translation Model

S Olberg^{1,2*}, J Chun^{1,3}, K Wang¹, J Wang¹, Y Zhang¹, J Kim³, S Jiang¹, J Park¹, (1) Medical Artificial Intelligence and Automation (MAIA) Laboratory, Department of Radiation Oncology, University of Texas Southwestern Medical Center, Dallas, TX, (2) Department of Biomedical Engineering, Washington University in St. Louis, St. Louis, MO, (3) Department of Radiation Oncology, Yonsei University College of Medicine, Seoul, KR

Purpose: Cone-beam computed tomography (CBCT) has long been an established standard for patient setup. With the growing focus on adaptive radiotherapy (ART) and the rise of purpose-built ART platforms, the importance of CBCT-based guidance in facilitating adaptive workflows is only rising. A primary challenge in this reliance on CBCT is the persistent issue of image quality in scans that are marred by artifacts, especially streak artifacts caused by the motion of intestinal gas during CBCT acquisition. We present preliminary results of a simulated reconstruction image translation model dedicated to artifact reduction for CBCT-guided abdominal ART. **Methods:** The image-to-image translation approach employed here relies on a training data set consisting of paired CT images and simulated reconstructions derived from these images ($n = 35$ patients, 20 pairs per patient). To simulate gas motion-induced artifacts in a reconstructed image, deformations of the air containing regions in the source CT image were introduced during projection acquisition every 36 projections over a total of 360 projections. The trained model, which maps from an input reconstruction to a synthetic CT output, was tested on unseen simulated reconstructions as well clinical CBCT data. **Results:** When applied to unseen simulated reconstructions, the trained model achieves a notable reduction of streak artifacts and accurate HU values in the synthetic CT outputs. Preliminary tests on out-of-domain clinical CBCT data demonstrate a general smoothing effect that similarly acts to reduce the presence of artifacts. **Conclusion:** Results achieved with the simulation-enabled image translation model explored here demonstrate the promise of a fast, image-to-image translation model in the CBCT artifact reduction task, which is a topic of special relevance to an abdominal ART workflow.

MO-lePD-TRACK 3-03

Deformable Image Registration Using Spatial Transformation-Based Network for CBCT-Guided Radiotherapy

H Xie¹, Y Lei¹, Y Fu¹, T Wang^{1,3}, J Roper^{1,3}, X Tang^{2,3}, J Bradley^{1,3}, P Patel^{1,3}, T Liu^{1,3}, X Yang^{1,3*}, (1) Department of Radiation Oncology, (2) Department of Radiology and Imaging Sciences and (3) Winship Cancer Institute, Emory University, Atlanta, GA

Purpose: Longitudinal CBCTs from image guided radiation therapy reveal volumetric changes in patient anatomy that may warrant plan changes or be predictive of outcomes. However, quantitative assessments are challenged by poor CBCT image quality, especially in the abdomen, and by the need for fast and accurate deformable registration to make real-time clinical decisions. To address these challenges, we propose a deep learning-based CBCT-CBCT deformable registration method. **Methods:** The proposed deformable registration workflow consists of training and inference stages that share the same feed-forward path through a spatial transformation-based network (STN). The STN consists of a global generative adversarial network (GlobalGAN) and a local GAN (LocalGAN), which capture the overall motion and the local motion respectively. The network was trained by minimizing the losses combining image similarity with the deformable vector fields (DVF) regularization without the supervision of ground truth DVFs. In the inference stage, the global DVF and patches of local DVF were predicted by the trained GlobalGAN and LocalGAN. The local DVF patches were subsequently fused to generate a local whole-image DVF, which is summed with the global DVF to obtain the final DVF. The proposed method was investigated using 100 abdominal CBCTs from 20 radiotherapy patients. Each patient was treated in five fractions over 1 to 2 weeks. **Results:** The resulting images show that the deformably registered CBCT images are visually similar to the target CBCT image. Additionally, quantitative assessment shows that the target registration error (TRE) across all patients and fractions is 2.91 ± 1.16 mm after registration with the proposed method. An accurate CBCT-CBCT deformable registration took less than 3 seconds. **Conclusion:** We developed a deep learning-based CBCT-CBCT registration method and investigated its feasibility and performance in fractionated radiotherapy. This registration tool could provide fast and straightforward image registration for CBCT-guided radiotherapy.

This research is supported in part by the National Cancer Institute of the National Institutes of Health under Award Number R01CA215718, and Pilot Grant by the Winship Cancer Institute of Emory University.

High-Quality CBCT Reconstruction from Sparse and Limited-Size Projections Using a Joint Deformable Registration and Reconstruction Network (Reg-ReconNet)

Y Zhang*, UT Southwestern Medical Ctr at Dallas, Dallas, TX

Purpose: To develop a joint deformable registration and reconstruction network (Reg-ReconNet) to reconstruct high-quality, field-of-view (FOV)-extended CBCT images from sparse and limited-size projections. **Methods:** Reg-ReconNet leverages prior CT/CBCT information to reduce the number of cone-beam projections needed for on-board CBCT reconstruction, and to extend the effective FOV. It starts with an unsupervised 2D-to-3D deformable registration network (2D3D-RegNet), which deforms prior images to estimate on-board CBCT images by matching digitally-reconstructed-radiographs (DRRs) of the deformed prior images to acquired on-board cone-beam projections. The 2D3D-RegNet was followed with a deep cascaded CBCT reconstruction network, which features recurrent inputs of cone-beam projections at each cascade level, repeated data fidelity enforcement layers composed of embedded forward/backward projection operators, and task-specific convolutions and residual connections to correct aliasing, streaking and truncation artifacts from reconstruction. We used 14 patient cases from a TCIA lung library to train and evaluate Reg-ReconNet, each of which has multiple 4D-CT image sets acquired throughout the radiotherapy treatments. For each patient, we extracted one phase image from the first 4D-CT set as prior information, and simulated cone-beam projections from all intra-fractional/inter-fractional 4D-CTs for training/testing (10/4 patients, corresponding to 400/200 image volumes). The reconstructed images were compared against the 'ground-truth' original 4D-CTs using

the relative-error (RE) metric. **Results:** Using 5 projections, the average($\pm$ s.d.) REs of reconstructed CBCTs by the Feldkamp-Davis-Kress (FDK) algorithm, iterative algebraic-reconstruction-technique with total-variation regularization (ART-TV), 2D3D-RegNet (without following ReconNet), ReconNet (without preceding 2D3D-RegNet), and Reg-ReconNet were $198.4\pm 37.8\%$, $44.2\pm 3.8\%$, $20.3\pm 5.1\%$, $17.8\pm 6.8\%$, and $16.9\pm 3.8\%$, respectively. Corresponding results were $112.8\pm 21.8\%$, $27.6\pm 1.8\%$, $18.1\pm 4.8\%$, $11.5\pm 4.3\%$, and $10.4\pm 2.6\%$ for 20 projections, and $78.9\pm 14.3\%$, $19.7\pm 3.2\%$, $16.8\pm 4.4\%$, $9.1\pm 3.2\%$ and $7.6\pm 1.8\%$ for 60 projections. **Conclusion:** Reg-ReconNet incorporates prior information into new CBCT reconstruction through joint deformable registration and image reconstruction. It can reconstruct high-quality images from sparse projections and extend the effective FOV by merging and updating prior information.

The study was supported by funding from the National Institutes of Health (R01CA240808) and from the University of Texas Southwestern Medical Center.

MO-lePD-TRACK 3-05

Physics-Based Motion Artifact Simulation in CT/CBCT Images Using 4DCT Phases

S Alam^{1*}, T Li¹, S Zhang², P Zhang¹, S Nadeem¹, (1) Memorial Sloan Kettering Cancer Center, New York, NY, (2) Peking University Cancer Hospital & Institute

Purpose: To realistically mimic motion and scatter artifacts in lung CT and cone-beam CT (CBCT) using 4DCT phases and physics-based simulation. In our recent paper [1], we presented a new data augmentation pipeline for physics-based simulation of baseline CBCT scatter artifacts on planning CT to allow utilization of more accurate contouring. Here, we extend our pipeline to include motion artifacts. **Methods:** 600 projections equivalent to a 60 second (10 projections/second) 4DCT scan were used for generating motion plus scatter/noise artifact induced synthetic CBCTs. First scatter artifacts/noises were extracted from week1 CBCTs using power-law adaptive histogram equalization method and induced to each 10 phases of 4DCT. Four projections/phase were repeated 15 times to reconstruct a 60 second scan. Hence, we reconstructed [4 projections/phase x 10 phases] x 15, equivalent to 600 projections for a 60 sec scan. Eventually, corresponding motion plus scatter artifact induced synthetic CBCT was reconstructed using CBCT reconstruction parameters using iterative Ordered-Subset Simultaneous Algebraic Reconstruction Technique. The geometric parameters used for reconstruction were taken directly from the clinical practice for CBCT reconstruction. Synthetic CBCTs were evaluated against their ground-truth CBCT using histogram comparison and structure similarity index (SSIM) & root mean square error (RMSE). **Results:** The histogram of motion-artifact simulated data via our pipeline aligned very well with histogram against their ground-truth CTs and achieved RMSE and SSIM of 0.04 and 0.83, respectively. **Conclusion:** We show that we can realistically simulate motion artifacts using our pipeline for CT as well as CBCT images using 4DCT phases. The augmented motion and scatter-artifact simulated data will allow to segment OAR/GTV structures across CT and CBCT images using the same 3D deep learning segmentation model we presented in [1].Ref:[1] Alam SR, et al. Generalizable cone beam CT esophagus segmentation using physics-based data augmentation. Physics in Medicine & Biology, 2021

MO-lePD-TRACK 3-06

Synthetic CT Generation from Contrast Enhanced Planning CT and Low-Quality Treatment CBCT Using a Novel Dual Convolutional Neural Network

Y Cao*, A Vassantachart, S X Bian, D C Ling, Z Fan, E Chang, W Yang, University of Southern California, Los Angeles, CA

Purpose: The study aims to produce quantitative cone-beam computed tomography (CBCT) by learning HU features from planning CT while maintaining the structural integrity of on-treatment CBCT using a dual convolutional neural network (CNN) architecture. **Methods:** The study included paired CT and CBCT images from 49 patients (33 training, 8 validation, and 8 testing). A primal-dual 3D CNN architecture was built based on a loop, which contains a primal network and a dual network. For the primal network, CBCT was treated as initial synthetic CBCT (S-CBCT) to obtain the synthetic CT (S-CT), aiming to capture the HU information from planning CT. In the dual network, the S-CT were treated as input data to generate S-CBCT using another CNN, aiming to capture the geometry information from CBCT. The energy function was computed by a combination of the pixel intensity loss of S-CT with CT, and the pixel+texture loss of S-CBCT with CBCT. Thus, the full objective was: $E_T = aE_{CT}(SCT-CT) + bE_{CBCT}(SCBCT-CBCT)$, where a and b are weightings to control the contribution of each network. Mean absolute error (MAE), peak signal-to-noise ratio (PSNR), normalized cross-correlation (NCC), and structural similarity index (SSIM) were used to evaluate the model performance. **Results:** The dual CNN model performed better when the total loss was close to the loss between S-CT and CT using unequal weightings ($a=0.9$ and $b=0.1$). The visual inspection of S-CT showed improved image quality. All parameters tested were improved from CBCT to S-CT (equal weightings) and S-CT (unequal weightings). The results for the 4 abovementioned images are: MAE (78.88, 65.45, and 59.97); NCC (0.89, 0.92 and 0.95); PSNR (24.28, 26.30 and 28.65); SSIM (0.58, 0.67, and 0.75), respectively. **Conclusion:** In this study, a primal-dual CNN was built to generate synthetic CT with more accurate HU, reduced noise, and organ structure integrity for the treatment day.

Thoracic CBCT-Based Synthetic CT for Lung Stereotactic Body Radiation Therapy

Y Lei*, L Qiu, A Kesarwala, J Roper, K Higgins, J Bradley, T Liu, X Yang, Emory University, Atlanta, GA

Purpose: Cone beam CT (CBCT) has been widely implemented to guide the daily delivery of lung radiotherapy including Stereotactic Body Radiation Therapy (SBRT), however, clinical applications that depend on quantitative CBCT are limited by poor tissue contrast, image artifacts, and instability of Hounsfield Unit (HU) values. The purpose of this study is to develop a deep learning-based approach to improve CBCT image quality for quantitative analysis during radiotherapy. **Methods:** A deep learning-based model, which integrates histogram matching and perceptual supervision into a cycle-consistent adversarial network (Cycle-GAN), was trained to learn the mapping between paired thoracic CBCT and planning CT images. Cycle-GAN was introduced due to its ability to learn a mapping between CBCT images and paired planning CT images. Perceptual supervision was adopted to suppress interface blurring. Histogram matching was introduced into Cycle-GAN to force the synthetic CT (sCT)'s intensity distribution to be close to that of planning CT. The proposed deep learning-based algorithm was evaluated using 80 thoracic breath-hold CBCT images from 20 lung SBRT patients, each with 3-5 CBCTs. Planning CT images were used as the ground truth for evaluating the sCTs derived from co-registered CBCTs. **Results:** The mean absolute error (MAE), peak-signal-to-noise-ratio (PSNR) and normalized cross-correlation (NCC) indexes calculated between the sCTs and planning CTs were 63.2 HU, 30.2 dB, and 0.96, respectively. The proposed sCT method outperforms other current deep-learning methods and can generate a quantitatively accurate sCT in seconds. **Conclusion:** We developed a new CBCT correction method to generate a quantitatively accurate thoracic sCT from a CBCT and demonstrated that this method could significantly improve CBCT image quality. This method has the potential to enhance the accuracy of CBCT-guided radiotherapy, in particular for online adaptive applications that depend on accurate, real-time HU values for dose calculations.

Evaluation of Cone-Beam Computed Tomography-Based Radiomic Features Reproducibility: A Phantom Study

T Adachi^{1,2*}, M Nakamura^{1,2}, H Iramina², T Mizowaki², (1) Division of Medical Physics, Department of Information Technology and Medical Engineering, Human Health Sciences, Graduate School of Medicine, Kyoto University, Kyoto, Japan, (2) Department of Radiation Oncology and Image-Applied Therapy, Graduate School of Medicine, Kyoto University, Kyoto, Japan

Purpose: To explore the most influential factors on the reproducibility of cone-beam computed tomography (CBCT) radiomics features. **Methods:** Three sphere materials (acrylic, rubber, and cork: 30 mm ϕ) were placed at three different locations (upper-central, lower-central, lower-peripheral) in an anthropomorphic chest phantom. The CBCT images were acquired using Halcyon (125 kV, 168 mAs, CTDI(vol): 3.36 mGy) and TrueBeam (125 kV, 225 mAs, CTDI(vol): 3.46 mGy; Half-fan). The images were reconstructed using following three algorithms: (i) Feldkamp-Davis-Kress (FDK) algorithm in Halcyon (FDK(Halcyon)), (ii) FDK algorithm in TrueBeam (FDK(TrueBeam)), and (iii) iterative CBCT (iCBCT) algorithm with medium noise suppression level in TrueBeam (iCBCT(TrueBeam)). The targets were manually delineated in Eclipse treatment planning system version 15.6 by three medical physicists under the lung window setting. A total of 93 radiomics features, including 18 first order and 75 texture features, were extracted from the inside region of interest for each material using PyRadiomics (version 2.2.0). The effects of the inter-observer, target location and reconstruction algorithm variability on radiomics features were evaluated using coefficient of variation (CV). Features with CV value less than 5% were considered highly reproducible. **Results:** For inter-observer and inter-target location comparison, the median percentage of reproducible features in FDK(Halcyon), FDK(TrueBeam) and iCBCT(TrueBeam) were 51.6% (range: 38.7-62.4), 51.6% (range: 43.0-76.3) and 55.9% (range: 45.2-69.9), and 35.5% (range: 28.0-48.4), 33.3% (range: 26.9-40.9) and 33.3% (range: 24.7-38.7), respectively. For inter-reconstruction algorithm comparison, the median percentage of reproducible features were 20.4% (range: 11.8-29.0). **Conclusion:** Inter-reconstruction algorithm variability may have a greater influence on the reproducibility of CBCT-based radiomic features than the inter-observer and target location variability. Even with the same FDK algorithm, reconstruction device differences have a large effect on the radiomics features reproducibility. It is recommended that the reconstruction algorithm should be unified for CBCT-based radiomics analysis.

Graph Theory-Based Radiomics Features: Application of Tumor Network Structures On CT-Based Radiomics for Prognostic Prediction

M Umeda*, N Kadoya, S Tanaka, S Tanabe, Y Sugai, T Ishida, H Ohashi, S Dobashi, K Takeda, K Jingu, Tohoku University, Sendai, JP

Purpose: We developed graph theory-based features and tested their feasibility for predicting prognosis in non-small cell lung cancer (NSCLC) using computed tomography (CT)-based radiomics. **Methods:** We used CT images and gross tumor volume contours of 304 patients treated with radiotherapy for NSCLC at our hospital. Patients were divided into training (n = 213) and test (n = 91) datasets. Graphs were constructed with pixels as vertices and the difference in CT values between pixels as weights given to the edges. Thresholds were set for the weights, and edges lower than each threshold were removed. Several graphs were constructed with different thresholds, and features based on graph theory concepts, such as 1 vertex feature, 51 edge features, 20 degree features, 40 minimum spanning tree features, and 40 Laplacian matrix features, were extracted. Next, we developed graph theory histogram-based features for each of these features with 45 gradients and 15 y-axis intercepts of approximate curve features, 1 peak feature, 1 kurtosis feature, and 1 skewness feature. Then, we extracted 215 graph theory-based features. Univariate cox regression analysis was used to assess each feature's prognostic power and the C-index was calculated to evaluate predictive performance. The least absolute shrinkage and selection operator cox regression model and the Kaplan-Meier method were used to assess the performance of the prognostic prediction, and results were evaluated by comparing C-index of 107 standard features (14 shape features, 18 statistical features, and 75 texture features). **Results:** C-indexes for graph theory-based features in the training and test datasets were 0.624 and 0.667, respectively, whereas those for standard features were 0.642 and 0.625, respectively, showing that, in test dataset, graph theory-based features had higher C-index than standard features. **Conclusion:** Graph theory-based features may be useful for improving the performance of radiomics-based prognostic prediction.

Explainable AI Model for COVID-19 Diagnosis Through Joint Deep Learning and Radiomics

D Yang*, G Ren, M Ying, J Cai, Hong Kong Polytechnic University, Hong Kong, 91

Purpose: Deep learning based computer-aided diagnosis is a promising and efficient tool for the early detection of the Coronavirus Disease 2019 (COVID-19). However, the "black box" characteristic makes it difficult for clinicians to comprehend. This study aims to develop an explainable automatic COVID-19 detection system by combining deep learning classification and radiomics feature analysis. **Methods:** A dataset of 4671 Chest X-rays from multiple public datasets was used in this study. A deep learning model was developed by inserting deformable convolutional layer into the last denseblock in DenseNet121. During training, data augmentation was applied to training data to prevent overfitting. The proposed deformable convolutional neural network predicted the category of the input Chest X-ray and output a series of visualization results with Grad-CAM++ method. A mask for the region of interest (ROI) was generated via element-wise multiplication between lung region mask and visualized attention mask. Pyradiomics was then used to extract the features of the ROI. Correlation between each feature and category was calculated by using statistical methods. Ten features were selected and evaluated to describe the variance between categories based on statistical scores and random forest modeling. **Results:** The proposed network obtained an overall test accuracy of 95.0%. The recall and precision of COVID-19 were both above 0.95. Meanwhile, saliency maps with bounding boxes were provided for interpretability. In radiomics feature analysis, all selected features had a p-value less than 0.01. The feature based classifier achieved 79.6% on testing set, which proved the validity and consistency of using selected features to represent different categories. **Conclusion:** We have developed an explainable deep learning based COVID-19 Chest X-ray diagnosis method. To the best of the author's knowledge, our method is the first of its kind to combine class activation map and radiomics features to achieve the interpretability of convolutional neural network.

Treatment Response Prediction for MRI-Guided Adaptive Radiation Therapy of Pancreatic Cancer Using Multiscale Wavelet-Based Delta-Radiomics

H Nasief*, W Hall, X Chen, E Paulson, B Erickson, X Li, Medical College of Wisconsin, Milwaukee, WI

Purpose: To investigate whether delta radiomics (change of radiomic features) based on daily MRI acquired during MR-guided adaptive radiation therapy (MRgART) of pancreatic cancer can predict treatment response. **Methods:** Daily motion-average MRI sets derived from 4D-MRI acquired on a 1.5T MR-Linac during MRgART for 18 pancreatic cancer patients undergoing chemoradiation therapy (CRT) with 30-35 Gy in 5-fractions were acquired. CA19-9 response, pathological response for the cases treated with pre-operative CRT, and metastasis status were correlated with radiomic data. Wavelet decompositions were utilized to overcome challenges with inter- and intra-patient MRI intensity variations and to provide a robust way to extract radiomics data. On each daily MRI set, 438 wavelet-based delta-radiomics features (WDRF) were calculated from multiscale features extracted from different decomposition levels. Good or bad response groups were defined based on either pathological treatment response or distant metastasis free progression, and 50% reduction in CA19-9. Spearman correlations were applied to rule out redundant information. T-test, regression models, and linear mixed effect model were used to identify independent WDRFs with significant changes that correlate to response. Bayesian classifier with a leave-one-out cross validation method was used to determine WDRF combination with highest outcome predictions. The performance of the model to predict response was measured using AUC of ROC curve. **Results:** Spearman correlation showed that 67 features from different wavelet decomposition were not highly correlated and can be used for the analysis. 30 WDRFs showed trends correlating to response, with 8 WDRFs passing t-test and linear mixed effect (p<0.05) and demonstrated significant changes by 3rd or 4th fraction during treatment. Best performing model was a 3-feature combination that can predict response with an AUC of 0.94. **Conclusion:** Machine learning identified wavelet delta-radiomics features from daily MRI in MRgART that can predict treatment response during chemoradiation therapy for pancreatic cancer.

Exploratory Unsupervised Structure-Learning Based Radiomics Approach for Brain Metastases Treatment Response Modeling of Stereotactic Radiosurgery

Z Yang^{1*}, L Wang², M Chen¹, R Timmerman¹, T Dan¹, Z Wardak¹, W Lu¹, X Gu¹, (1) UT Southwestern Medical Center, Dallas, TX, (2) University of Texas At Arlington, Arlington, TX

Purpose: Stereotactic radiosurgery (SRS) has been shown to reduce neurocognitive decline for patients with multiple (>4) brain metastases (BMs). Early, accurate and noninvasive treatment response diagnosis is essential for SRS management to assist subsequent therapy decision making. In this study, we develop a novel unsupervised structure learning-based radiomics approach for BMs treatment response modeling. **Methods:** The study cohort includes 14 BMs SRS patients (307 BMs) with planning MRIs and dose distribution available. BMs segmentations are generated via our En-DeepMedic segmentation platform. For each BMs, 791 features are collected from MRI and dose distribution including clinical parameters, geometry features, first-order and texture features, using 7 types of ROI masks with different dilation margins. An unsupervised structure learning algorithm integrating both global and local information of the input is implemented. After optimization, a tree graph with skeleton and clusters on branches is learned to represent the intrinsic structure of the dataset in a reduced dimension, where similar subjects are clustered together and the main trajectory of the graph represents the inherent data structure. In addition, the algorithm can also perform clustering task based on input features. **Results:** This unsupervised algorithm can discover a stable latent tree structure suggesting a linear progression trajectory starting from no size-change BMs towards size-changed BMs. The main skeleton diverges into three sub-branches in size-changed group, suggesting that possible responses subtypes can be further distinguished in that group. The algorithm can also cluster size-changed and no-change BMs into different subsets with F-measure score and Rand index as 0.70 and 0.65 respectively without any supervision. Specifically, no size-change group is clustered with only 6 misclassification. **Conclusion:** This proposed unsupervised structure learning-based radiomics approach can reveal a tree structure with clusters associated with BMs treatment responses. This indicates that BMs treatment responses are separable only utilizing treatment images and dose.

CT-Based Deep Learning Radiomics for Predicting Chemoradiation Treatment Response in Locally Advanced Rectal Cancer

J Fu^{1*}, Z Wang¹, K Singhrao¹, J Lewis², X Qi¹, (1) Department of Radiation Oncology, UCLA, Los Angeles, CA, (2) Department of Radiation Oncology, Cedars-Sinai Medical Center, Los Angeles, CA

Purpose: Many studies have used the conventional handcrafted radiomic features to predict neoadjuvant chemoradiation treatment (nCRT) response in patients with locally advanced rectal cancer (LARC). The goal of this study is to investigate deep learning (DL)-based features for nCRT response prediction based on the planning CT. **Methods:** 86 LARC patients treated at a single institution were retrospectively enrolled. All patients received preoperative nCRT, with a prescription dose of 50.4Gy in 28 fractions, before total mesorectal excision. Patients were split into a responder group (n=45) and a non-responder group (n=41) based on pathological tumor regression grades. Each patient had a planning CT along with the manually delineated gross tumor volume. Handcrafted features and DL-based features were extracted from the planning CT using PyRadiomics and a pre-trained convolutional neural network (VGG19), respectively. Two logistic regression models with LASSO regularization were constructed using handcrafted and DL-based features, respectively. The model performance was evaluated with the stratified 5-fold cross-validation using receiver operating characteristic (ROC) curves. **Results:** The model constructed using handcrafted features achieved an area under the ROC curve (AUC) of 0.63±0.13, while the one constructed using DL-based features yielded an AUC of 0.76±0.04. **Conclusion:** Deep learning-based features extracted from planning CT achieved more accurate nCRT response prediction for LARC patients, as compared to handcrafted features. Deep learning-based features selected by the LASSO regularization are potential biomarkers for outcome prediction and personalized therapy.

Can Unified Data Improve the Performance of Radiomics-Based Prognostic Prediction in Lung Cancer Patients?

Y Sugai^{*}, N Kadoya, S Tanaka, S Tanabe, M Umeda, T Yamamoto, K Takeda, S Dobashi, H Ohashi, K Takeda, K Jingu, Tohoku University, Sendai, 04JP

Purpose: We investigated the radiomics-based survival prediction of non-small-cell lung cancer (NSCLC) patients by focusing on subgroups with identical characteristics. **Methods:** 304 NSCLC (Stages I-IV) patients treated with radiotherapy in our hospital were used. We extracted 107 radiomic features (14 shape features, 18 first-order statistical features, and 75 textural features) from the GTV drawn on the free-breathing treatment-planning CT image. Three feature selection methods [test-retest and multiple-segmentation (FS1), Pearson's correlation analysis (FS2), and a method that combined FS1 and FS2 (FS3)] were used to clarify how they affect survival prediction performance. The radiomic features selected by each selection method were combined with clinical features to form the explanatory variables in this analysis. A least absolute shrinkage and selection operator cox regression was used for subgroup analysis including each histological subtype and each T stage, where the most accurate feature selection method was adapted. Five-fold cross-validation was used to ensure the reliability of the model, and the predictive performance was evaluated with the Concordance-index (C-index) and Kaplan-Meier methods. **Results:** In all data, the C-index were 0.64 (FS1), 0.65 (FS2), and 0.64 (FS3) for the training dataset and 0.62 (FS1), 0.63 (FS2), and 0.62 (FS3) for the test dataset. The subgroup analysis indicated that prediction models based on specific histological subtypes and T stages had higher C-index than prediction model based on all data, especially for model based on T4 (training dataset, 0.72; test dataset, 0.70). Moreover, prediction models based on each T stage in adenocarcinoma (ADC) had a higher C-index than prediction model of ADC. **Conclusion:** Our results showed that feature selection methods moderately impacted the survival prediction performance. In addition, prediction models based on specific histological subtypes and T stages may improve the prediction performance. These results may prove useful for determining the optimal radiomics-based predication model.

A Functional Dosimetry-Based Prediction Model for Radiation Pneumonitis

B Liang^{*}, Y Tian, R Wei, J Miao, P Huang, Z Liu, W Xia, J Dai, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, Beijing CN

Purpose: Ventilation image (VI) reveals the presence of functional heterogeneity within lungs. This study adopted the omics method to mine the heterogeneous information to better predict the incidence of radiation pneumonitis (RP). **Methods:** VI was derived from the 4-dimensional computed tomography (4DCT). The functional dose (FD) distribution was obtained by weighting OD with VI. The omics features were extracted, and then selected by the minimum redundancy maximum

relevance (mRMR) method. The prediction models were constructed with the logistic regression (LR), support vector machine (SVM), k-nearest neighbors (KNN), and random forest (RF) classifiers. Cross validation, bootstrap and nested sampling and methods were adopted for model training and classifier parameter hyper-tuning. The prediction models based on the omics features extracted from OD and the dosimetric factors (V5, V20 and mean lung dose, DF) based model were constructed for comparison. **Results:** 217 thoracic cancer patients treated with radiotherapy were used to train and validate the prediction model. The 4DCT-based VI showed the heterogeneous pulmonary function of the lungs. 19 first-order, 27 gray level (GL) co-occurrence matrix (GLCM), 16 GL run length matrix (GLRLM) and 16 GL size zone (GLSZM) features were extracted from the ipsilateral, contralateral and total lungs, separately. In total, 234 (78×3) features were extracted for each patient. The FD-omics and OD-omics models achieved optimal performance when 5 features were selected using the LR classifier. And the area under curve (AUC) were 0.755 (0.753-0.757), 0.716 (0.713-0.718), respectively. In comparison, the AUC of the DF model was 0.680 (0.675-0.684). **Conclusion:** The FD-omics model outperformed the OD-omics and DF modes for RP prediction due to the use of more data points and the data-mining in greater depth. It also indicates that the heterogeneity of pulmonary distribution revealed by VI helps to better model the dose response of radiation.

Prediction of Glioblastoma Patient's Survival After Radiation Therapy with Random Survival Forest Model

Y Kim^{1*}, KW Kim², H Yoon², W Sung¹, (1) The Catholic University of Korea, Seoul, KR (2) Yonsei University College of Medicine, Seoul, KR

Purpose: To predict the outcome of radiation therapy (RT) in patients with glioblastoma from parameters before and after RT and to identify predictive variables using a machine learning. **Methods:** We assessed 336 glioblastoma patients treated between 2006 and 2017. A random survival forest was trained to predict survival from baseline values of total 16 parameters including tumor, demographic, immunologic, and treatment factors. The feature importance was determined using the amounts of increased predictive power by adding each parameter. **Results:** The trained model achieved concordance index (c-index) of 0.628 in cross-validation, comparable to the one (0.629) in the similar published study with cox proportional hazard regression. The importance analysis identified methylation of the MGMT gene promoter, the extent of resection, and sub-ventricular zone involvement as the most important variables (permutation importance = 0.082, 0.034, and 0.021 respectively), followed by gross target volume (0.018), age (0.008), and acute severe lymphopenia (0.004, lymphocyte counts of < 500 μ L). More number of variables did not necessarily guarantee the predictive power of the trained model. The model achieved the maximal concordance index (0.658) by including the most important 3 or 4 parameters. **Conclusion:** Random survival forests were an explainable machine-learning approach for prediction of an entire patient's survival curve. Only three or four baseline parameters were necessary to achieve comparable predictive power of the trained model. Those parameters were the methylation of MGMT gene promoter, extent of resection, sub-ventricular zone involvement, or gross target volume, for the glioblastoma patients.

Moving Beyond Dose: The Role of HPV Status in Predicting Normal Tissue Toxicity for Head & Neck Cancer Patients

X Ray^{*}, W Sumner, L Sutton, I Deichaite, V Moiseenko, UC San Diego, La Jolla, CA

Purpose: Planning objectives used in radiotherapy plan optimization are driven by population-based studies, however patient-to-patient variation in tumor and normal tissue response is well established. Various patient characteristics have been explored as potential biomarkers to personalize treatment planning for this variance. The objective of this study was to evaluate if HPV status is a significant, independent factor affecting normal tissue toxicities for head-and-neck cancer patients treated with radiotherapy. **Methods:** HPV status, radiation treatment doses to organs-at-risk, and reported early and late dysphagia were retrospectively obtained for 101 patients treated at our clinic. Mean doses were extracted for the entire pharynx, superior/middle/inferior pharyngeal constrictor muscles (PCM), and cricopharyngeus. Early and late dysphagia grades were collected on the 0-5 CTCAE scale and binarized to 0-2 versus 3-5. T-tests were used to evaluate relationships between outcome and dose, and chi-squared tests to evaluate associations between outcome and HPV. Multivariate logistic regression models were built to predict outcome as a function of HPV status, sex, age, and dose metrics. P-values < 0.05 were considered significant. **Results:** Significant dose metrics for early dysphagia included mean dose to the Pharynx (p=0.032), middle PGM (p=0.020), inferior PGM (p=0.015), and cricopharyngeus (p=0.022) with respective increased dose differences of 7.0, 7.1, 12.1, and 11.4 Gy. No dose metrics were significantly associated with late dysphagia; however, HPV-negative status was significantly associated with late dysphagia (p=0.028). HPV-negative status was not significantly associated with early dysphagia. In logistic models, results were consistent: all four organ mean doses remained significant covariates for early dysphagia while HPV was the only significant covariate for late dysphagia. **Conclusion:** HPV status was a significant predictive covariate for late dysphagia in our cohort. While further investigation is warranted to evaluate the root cause of this association, these results may be useful for assessing an individual patient's toxicity risk and personalizing their treatment or follow-up.

Analysis of Time Dependency of NTCP Modeling and Dose-Volume Correlations of Patient Reported Xerostomia After HPV Associated Oropharyngeal Cancer

P Mavroidis^{1*}, A Tzikas², E Lavdas², R Amdur³, W Mendenhall³, N Sheets¹, R Green¹, L Marks¹, S Das¹, B Chera¹, (1) University of North Carolina, Chapel Hill, NC, (2) University of West Attica, Department Of Biomedical Sciences, Athens, Greece, (3) University of Florida Hospitals, Gainesville, FL

Purpose: This study aims at analyzing the time dependency of dose-volume correlations with patient reported (PRO) xerostomia after radiotherapy and the corresponding normal tissue complication probability (NTCP) modeling. **Methods:** 151 patients with favorable risk, HPV-associated oropharyngeal squamous cell carcinoma were treated with radiotherapy. A dose of 60Gy delivered with IMRT was prescribed to the patients. Xerostomia was assessed based on the PRO-CTCAE score and it was defined as a ≥ 2 point increase from baseline at 6, 12, 18 and 24 months post-RT. The dose volume histograms (DVH) of the contralateral parotid and contralateral glands (parotid and submandibular glands combined) of each patient were exported and correlated with the follow-up data of xerostomia. The clinical data was fitted by the Relative Seriality (RS) NTCP model. **Results:** Xerostomia was observed in 59%, 38%, 29% and 31% of the patients at 6, 12, 18 and 24 months, respectively. The AUC values of the correlations ranged between 0.59-0.66. For the contralateral parotid, the values of the D50, γ and s parameters of the RS model were 24.4Gy, 0.46 and 0.01 at 12 months and 31.5Gy, 0.34 and 0.01 at 24 months post-RT. Statistically significant Odds Ratios (ORs) of 3.1 (1.2-7.9) and 2.9 (1.3-6.6) were found for the contralateral parotid for biological doses < 23Gy and 21Gy at 12 and 24 months post-RT, respectively. Similarly, for the combined contralateral glands ORs of 2.3 (1.1-5.0) and 2.8 (1.1-6.8) were found for biological doses < 27Gy and 31Gy at 12 and 24 months post-RT, respectively. **Conclusion:** The dose-response curve of PRO xerostomia at 6, 12, 18 and 24 months post-RT could be determined by the RS NTCP model. Keeping the biological dose to the contralateral parotid < 21Gy or to the combined contralateral glands < 27Gy was found to significantly reduce the risk for patient reported xerostomia.

MO-lePD-TRACK 5-05

Identifying Correlations Between Radiation Dose and Blood Counts Drops After Radiotherapy of Prostate Cancer

P Papanikolaou^{1*}, G Swanson², S Stathakis³, P Mavroidis⁴, (1) Long School of Medicine, UT Health San Antonio, San Antonio, TX, (2) Baylor Scott & White Health, Temple, TX, (3) UT Health San Antonio MD Anderson Cancer Center, San Antonio, Texas, (4) University of North Carolina, Chapel Hill, NC

Purpose: The purpose of this study is to determine dose-response relations regarding the endpoint of hematocrit level drop after pelvic irradiation in patients undergoing external beam radiotherapy for prostate carcinomas. **Methods:** A retrospective analysis was conducted on 221 patients treated between 2014 and 2016 at a single institution for prostate cancer. Patients received either 78Gy to primary prostate or 70Gy post-prostatectomy. All patients had complete blood counts collected at baseline (pre-RT) and 3 months post-RT, which were analyzed in conjunction with dose volume histograms corresponding to eight different pelvic structures. **Results:** Pelvic structures that upon irradiation correlated with significant decreases in hematocrit were the following: the bone volume of os-coxae bilaterally superior to the acetabulum (OCUB), the bone volume of the entire os-coxae bilaterally (OCTB), and the bone volume of the whole pelvis (BVWP). The structure showing the highest correlation was OCUB with a maximum AUC of 0.74. For V20Gy < 30% the odds ratio was 9.8 with 95% confidence interval (CI) of 2.9-32.9. For mean dose to OCUB, an AUC of 0.73 was observed where the dose threshold was 23Gy and the odds ratio was 2.7 and 95%CI 1.3-5.6. For OCTB, AUC was 0.69 with a V20Gy < 50% showing an odds ratio of 9.3 (95%CI 2.7-31.8). For BVWP, AUC was 0.71 with a V20Gy < 40% demonstrating an odds ratio of 7.5 (95%CI 2.2-25.4). Further, mean dose < 24Gy had an odds ratio of 2.6 (95%CI 1.1-6.1) showing an AUC of 0.72. **Conclusion:** These findings confirm the association of damage to pelvic bone marrow with blood counts drop. The doses to OCUB, OCTB and BVWP were found to correlate with a significant drop of hematocrit. A threshold of V20Gy < 30% or mean dose < 23Gy to OCUB may reduce almost ten-fold the risk for this endpoint.

MO-lePD-TRACK 5-06

Association Between Dosiomics-Based Index with Radiation Pneumonitis Induced by Radiation Therapy of Breast Cancers

Z Yang^{1,2*}, X Chen², M Chen³, C Wang¹, F Yin^{1,2}, (1) Duke University Medical Center, Durham, NC (2) Duke Kunshan University, Kunshan, Jiangsu, China (3) Kunshan First People Hospital, Kunshan, Jiangsu, China

Purpose: To investigate the feasibility of predicting the occurrence of radiation pneumonia (RP) in patients after radiation therapy (RT) of breast cancer using dosiomics index. **Methods:** A pilot retrospective study of 42 breast cancer patients was performed under an institutional IRB protocol. 11 of 42 patients were observed with RP complications based on CT scans 3-5 months post RT. We hypothesize that the dosiomics features can better characterize the occurrence of RP than the traditional volume-based dosimetric metrics (such as V5, V20, and mean dose). To test, we first evaluated the potential dosimetric deviations due to inter-fractional mispositioning and intra-fractional patient respiratory motion using daily cone-beam CT (CBCT). The actual dose distribution within the lung was re-calculated by incorporating the CBCT images taken before each fractional treatment. 91 dosiomics features were extracted from both the whole lung dose and the high dose region (>20 Gy), respectively. T-test was performed to find the optimal features as potential indexes for RP. The comparison of p-value between the dosiomics features and the traditional dosimetric indexes was also conducted to evaluate the overall performance. **Results:** Dosiomics feature GLCOM-based Sum Variance extracted from whole lung dose presents the significant statistical difference between 11 RP patients and rest 31 patients (p-value = 0.0487), and feature GLCOM-based Cluster Shade extracted from high dose region gives lower p-value (0.0316). While the traditional dose constraints are insufficient to characterize the dose distribution differences between two groups of patients (p-value for mean dose = 0.5447, p-value for V5 = 0.7926, and p-value for V20 = 0.4058). **Conclusion:** This pilot work verified the feasibility of evaluating the occurrence of RP in patients after breast cancer RT with dosiomics features. The dosiomics-based indexes, feature GLCOM-based Sum Variance and Cluster Shade, showed the potential to replace the traditional dosimetric indexes in predicting RP.

MO-lePD-TRACK 5-07

Principal Component Analysis of Dose Clustering Patterns for Parotid Toxicity Modeling in Head and Neck Radiation Therapy

M Chao^{1*}, I El Naqa², Y Lo¹, J Penagaricano², (1) Mount Sinai Medical Center, New York, NY, (2) Moffitt Cancer Center, Tampa, FL

Purpose: To develop a predictive model using principal component analysis (PCA) and logistic regression (LR) for parotid complication based on 3D dose clustering in head-and-neck cancer irradiation. **Methods:** Spatial dose distribution inside the parotid gland was incorporated into the percolation-based cluster model for 155 patients receiving intensity modulated radiation therapy from three institutions. Radiation induced complication was classified into two categories for patients who never developed xerostomia and those who developed xerostomia with grade 1 and above, respectively. For each patient, forty bins of the normalized largest size of dose clusters were formed with cutoff dose ranging from 11-50 Gy in 1 Gy step size. PCA was applied to these 40-column variables from all enrolled patients. The principal components (PCs) were determined and subsequently input into a multinomial logistic regression model for quantitative analysis of toxicity correlation. The returned fitting parameters were examined to establish the correlation between the principal components and parotid gland toxicity. In addition, three cluster connectivity options representing cluster formation were evaluated for the association of optimal morphological clustering patterns with the gland toxicity. **Results:** PCA analysis revealed that first three PCs are the most important ones with the first PC explaining over 91% for all three connectivity variances. The scatter plots between the dominating PCs show distinct clustering patterns among the two groups of patients. These first three PCs were input into the LR model and the p values (<0.05) were found for the first and the third principal components. No significant difference was observed among three cluster connectivity choices. **Conclusion:** The PCA-LR model can reveal correlations between the percolation-based cluster model and parotid toxicity. Thus, it can be a valuable tool to augment normal tissue complication modeling and facilitate treatment planning decision making in the head and neck radiation therapy.

Application of Random Forest Algorithm for Dose Reconstruction Based on Classification of Clean-Up Workers of the ChNPP Accident

K Chizhov^{1*}, V Kryuchkov², V Chumak³, C Lee¹, V Drozdovitch¹, E Cahoon¹, V Vij¹, R Zhang¹, V Kryuchkov², I Golovanov², E Bakhanova³, N Gudzenko³, Bazyka D³, M Little¹, (1) National Cancer Institute, Rockville, MD, (2) State Research Center Burnasyn Federal Medical Biophysical Center of Federal Medical Biological Agency, Moscow, Russia, (3) National Research Centre for Radiation Medicine, Kyiv, Ukraine

Purpose: As a result of the accident at Chernobyl Nuclear Power Plant a heavy contamination of the environment occurred. Thousands of workers took part in cleanup work, and only few percent of them have sufficient dosimetry. Thus, methods are required for dose reconstruction for large groups of liquidators based on a limited set of data. **Methods:** A dosimetry method was developed based on random forest algorithm. It was applied to a cohort of 11105 liquidators from Clinical and epidemiological registry of Ukraine. Neural network was trained (70%) and tested (30%) on database of 1807 liquidators, whose doses were reconstructed according to detailed questionnaires using the Realistic Analytical Dose Reconstruction with Uncertainty Estimation (RADRUE) method. The developed algorithm was based on the date of the mission and duration, occupation, place of work and residence, affiliation to the organization. Dose reconstruction for study cohort was made in 2 steps: reconstruction of the specific group (contingent) of the liquidator and then dose assessment within the contingent. Rules for division into continents described in RADRUE method. **Results:** Liquidators from study cohort were divided into 9 contingents. The contingents were also divided by year from 1986 to

1990. Based on RADRUE database the dose distribution for each contingent any year was calculated. The developed method determines with an accuracy of 91.5% whether the liquidator was a military or civilian. For other contingents, the correctness of the method was from 73.7% to 99.8%. **Conclusion:** Developed algorithm applicable for contingent and dose range reconstruction for liquidator if the training dataset contains all possible variants from the studied dataset. Results of the study and the cohort will be used as a resource to investigate novel hypotheses about the radiation-related risk of cancer and benign outcomes by combining historical dose records, epidemiological data and medical records.

An Experimental Study of Intrabeam IORT Dosimetry Accuracy

H Zhang*, I Das, Northwestern Memorial Hospital, Northwestern University Feinberg School of Medicine, Chicago, IL

Purpose: The INTRABEAM (IB) System has been reported to have a large dosimetric difference between the vendor provided and user measured data. This study is aimed to verify the dosimetric accuracy by performing ionization chamber measurements of absorbed dose in a water phantom and comparing with the annual calibration data for past 10 years. **Methods:** Ionization chamber measurements were performed with a PTW 34013 parallel-plate chamber at source to detector distances of 2 to 30 mm with and without a spherical applicator. The experimental output dose rates were derived by using the formula recommended by the manufacturer. The source calibration data, taken from the annual certificate files provided by manufacturer from 2011 to 2020, were reviewed and compared with the experimental results. **Results:** It is found that the source data format was changed in 2017, from one dataset to two distinct datasets: one is Calibration V4.0, and other is TARGIT. The dose rate fluctuation from 2011 to 2016 at the same distance was within $\pm 12\%$, from 2017 to 2020 was within 5%. However, the dose rates of 2017 certificate file increased up to 210% and 58% respectively for Calibration V4.0 and Target datasets comparing to the previous years. Experimental data with and without a spherical applicator taken in 2017 and after were found to still agree with 2011 certificate data within $\pm 5\%$ uncertainty, but a difference up to 200% was seen comparing with the Zeiss 2017 source data. **Conclusion:** Comparing with our experimental data, the source output was found to remain almost the same from 2011 to 2020, therefore TARGIT trial dosimetry is still accurate. The large dosimetric difference is attributed to the lack of updated Zeiss QA water phantom conversion factor. We provided a new conversion factor to account for the change of calibration standard in Zeiss dosimetry laboratory.

Liver Segmentation Workflow Development for Pre-Treatment Hepatic Y90 Resin Microspheres Therapy Using a Commercially Available Software

D Alvarez^{1,2*}, N Ridha³, A Gutierrez^{1,2}, M Chuong^{1,2}, R Gandhi^{1,2,4}, (1) Miami Cancer Institute, Baptist Health South Florida, Miami, FL, (2) Florida International University, Herbert Wertheim College of Medicine, Miami, FL, (3) MIM Software Inc., Cleveland, OH, (4) Miami Cardiac & Vascular Institute, Miami, FL

Purpose: Liver segmentation for the purpose of pre-treatment planning of hepatic Y90 resin microspheres therapy is not a standardized practice. To that end, a semi-automatic, customizable workflow has been developed within MIM Sureplan® that enables standardization within a clinical practice. **Methods:** The clinical workflow at Miami Cancer Institute (MCI) for pre-treatment planning of hepatic Y90 resin microspheres therapy was re-created in the MIM SurePlan platform. Briefly, the original steps were performed manually, utilizing a segmentation software where the liver was drawn on the non-contrast CT of the MAA mapping SPECT/CT. Early and late arterial phase CBCTs for left and right hepatic lobes were then registered to the non-contrast CT. The early phase CBCTs, which determine perfusion paths, were used to delineate left/right lobes, while late phase CBCTs were used for GTV delineation. For select cases, a recently acquired diagnostic contrast CT or MRI may be used for GTV delineation. After these five image registrations, the RT/LT lobe and RT/LT GTV volumes were segmented and their volumes used to calculate the prescribed activity of Sirspheres® for each hepatic lobe. This manual process was designed into a streamlined, semi-automated workflow. **Results:** The MIM workflow was designed to standardize the MCI pre-Y90 treatment process. It is robust enough to accommodate several scenarios to best serve the unique needs of the patient, including pauses, stop gaps between major processes, and editing points, as well as flexibility as to which image studies to use for segmentation. An auto-generated volume statistics table is ultimately rendered for activity calculation. **Conclusion:** A clinically robust, semi-automated workflow process for pre-treatment of hepatic Y90 resin microspheres therapy has been created in MIM SurePlan. Streamlining the workflow should achieve time-savings and standardization in clinical practice. Consideration should be given to this workflow as a means for standardizing the pre-treatment planning method.

Dr. Chuong reports receiving honoraria from Sirtex. Dr. Gandhi is a consultant and proctor for Sirtex.

Demonstration of An Automatic Segmentation Method for Evaluating Cardiac Structure Doses in Support of Research on Cardiovascular Morbidity Subsequent to Breast Radiotherapy

M Mille¹, J Jung^{2*}, B Ky³, W Kenworthy³, C Lee⁴, Y Yeom¹, A Kwag⁵, W Bosch⁶, S MacDonald⁷, O Cahlon⁸, J Bekelman⁹, C Lee¹, (1) National Cancer Institute, Bethesda, MD, (2) East Carolina University, Greenville, NC, (3) University of Pennsylvania, Philadelphia, PA, (4) University of Michigan, Ann Arbor, MI, (5) Vanderbilt University, Nashville, TN, (6) Washington University, Saint Louis, MO, (7) Massachusetts General Hospital, Boston, MA, (8) Memorial Sloan Kettering Cancer Center, New York, NY, (9) University of Pennsylvania, Philadelphia, PA

Purpose: To develop an automatic segmentation algorithm to contour heart substructures on a planning CT for estimating doses in support of research on cardiovascular morbidity subsequent to breast radiotherapy. **Methods:** We collected DICOM-RT data for 100 breast cancer patients enrolled in the Radiotherapy Comparative Effectiveness clinical trial who were treated using photons. For each CT, a cardiology team provided a manual segmentation of the whole heart (WH), left/right atria, left/right ventricles and left anterior descending artery (LAD). A cardiac atlas library was developed for the automatic segmentation using 30 patients and the remaining 70 patients (40 left-side, 30 right-side) were used for performance testing. The input to the algorithm was the manual contouring of the WH which is drawn at time of treatment planning. The automatic segmentation consists of a selection of a most similar heart from the atlas library followed by a structure-guided B-spline transformation. The automatically contoured results were then compared with manual delineations to evaluate geometric and dosimetric similarity. **Results:** The median dice similarity coefficient (DSC) for the four chambers ranged from 66% to 84% and the average surface distance (ASD) was ~4 mm. Performance for the LAD was worse with a mean DSC of 6% and median ASD of ~6 mm which can be explained by the difficulty segmenting such a small structure. The doses calculated using the manual and automatic delineations showed excellent correlation within expected variability of manual segmentation. For left-sided (right-sided) treatments, the mean dose difference for the chambers and LAD was <0.7 Gy (<0.4 Gy) and 1.8 Gy (0.4 Gy), respectively. **Conclusion:** Cardiac structure doses based on our automatic segmentation agree with that of manual segmentation. When applied to large patient datasets our automatic segmentation method should facilitate the development of better prescriptive criteria for mitigating cardiovascular morbidity following breast radiotherapy.

Improving Workflow Efficiency and Safety for RefleXion X1 Treatment Planning Process Via Eclipse API Scripting

E Simiele*, N Kovalchuk, Stanford University Cancer Center, Palo Alto, CA

Purpose: The RefleXion™ X1 system is the first biology-guided radiotherapy machine that can target cancer in real-time using on-board PET imaging in combination with a 6MV FFF beam. The current version of the system is not yet integrated with any record and verify system, has limited contouring, dose evaluation, and isocenter placement tools. To improve efficiency and safety of the treatment planning process, application programming interface (API) scripting was utilized to overcome these limitations. **Methods:** Eclipse, the primary treatment planning system (TPS) at our institution, is used to perform all contouring and plan dose

evaluation for the RefleXion treatment plans. Therefore, two scripts were developed using the Eclipse API scripting framework. The first script, RefleXion Assistant, focuses on preparing structure sets for import and planning in the RefleXion TPS. Such preparation includes checking all structures are within the body contour, inserting a special couch contour, and verifying the proposed isocenter placement in outside the collision zone. The second script, Automated Plan Check (APC), generates the shift note and focuses on physics plan checks and plan quality evaluation of the treatment plans. **Results:** RefleXion Assistant can check several planning failure-modes in the RefleXion TPS within 30sec, e.g., if a structure is outside the body, the RefleXion TPS will throw an error preventing optimization and requiring the planner to identify the offending structure, fix it, export/import the new structure, and adjust the plan setup. Example items checked with the APC include high-severity failure-modes, i.e., physician's prescription dose/fractionation in Aria match the RefleXion plan, shift note accuracy, cardiac device policy compliance, etc. Plan quality is evaluated by computing DVH metrics and comparing them to institutional/clinical trials planning constraints. **Conclusion:** Two API scripts were developed and implemented to prevent failure-modes with the RefleXion TPS, resulting in significant improvements in planning efficiency and safety.

Optimal Combination of Spatial and Temporal Fractionation for the Treatment of Multiple Brain Metastases

N Torelli^{1*}, D Papp², J Unkelbach¹, (1) University Hospital Zurich, Zurich, ZH, CH, (2) North Carolina State University, Raleigh, NC

Purpose: Stereotactic radiosurgery (SRS) is a standard treatment modality for intracranial metastases. While small lesions are preferably treated in a single fraction, large metastases must be temporally fractionated to reduce dose toxicities in normal tissues. In this work, an algorithm for determining the best trade-off between single-fraction and hypofractionated SRS for the treatment of multiple brain metastases is developed and demonstrated. **Methods:** Non-coplanar IMRT plans are created to obtain spatial dose distributions for the treatment of each metastasis. We then assume that each metastasis is either treated to the full dose in one of the fractions (spatial fractionation) or is fractionated uniformly over all fractions (temporal fractionation). The optimal fractionation scheme is obtained by solving a binary quadratic optimization problem, which, for a fixed tumor BED, minimizes an equally weighted sum of the mean cumulative biologically effective doses (BED α/β) to the whole brain and to a 5 mm-thick rim structure around the metastases. The algorithm is demonstrated for a clinical case consisting of twenty-nine brain metastases of varying sizes to be treated with a BED10Gy of 45 Gy. **Results:** A four-fraction SRS plan is computed with the proposed fractionation optimization algorithm and compared to two SRS plans treating all metastases with one and four uniform fractions, respectively. The optimal fractionation scheme suggests the temporal fractionation of large metastases and the spatial fractionation of smaller lesions, leading to mean BED2Gy of 14.90 Gy and 74.96 Gy in the healthy brain and rim structure, respectively. Single-fraction and hypofractionated SRS plans achieve mean BED2Gy in the healthy brain and rim structure of 20.18 Gy and 90.59 Gy, and 18.48 Gy and 72.17 Gy, respectively. **Conclusion:** The proposed algorithm allows to optimally combine spatial and temporal fractionation for different lesions, potentially outperforming current state-of-the-art uniform fractionation schemes for the treatment of multiple intracranial metastases.

This work was supported by grant Spatiotemporal fractionation in radiotherapy (310030_189285/1) of the Swiss National Science Foundation. This material is based upon work supported by the National Science Foundation under Grant No. DMN-1847865.

MO-lePD-TRACK 6-07

Effective Organs-At-Risk Dose Sparing in Volumetric Modulated Arc Therapy Using a Half-Beam Technique in Whole Pelvic Irradiation

H Park^{1*}, J Park^{2,3}, M Artz^{2,3}, Y Zhang^{2,3}, J Ricci⁴, H Jang⁵, S Huh^{2,3}, (1) Ajou University School of Medicine, Suwon, South Korea, (2) University of Florida College of Medicine, Gainesville, FL, (3) University of Florida Health Proton Therapy Institute, Jacksonville, FL, (4) Orlando Health UF Health Cancer Center, Orlando, FL, (5) Dongguk University College Of Medicine, Gyeongju, South Korea

Purpose: To effectively spare organs-at-risk (OAR) doses using multi-leaf collimator (MLC)'s optimal segments, volumetric modulated arc therapy (VMAT) using a half-beam technique (HF) was devised for whole pelvic radiation therapy (WPRT). The potential dosimetric benefits of VMAT-HF were suggested for clinical application with statistical analysis. **Methods:** Fifteen eligible patients diagnosed with anal, vaginal, and cervical cancer were selected. Dosimetric benefits of VMAT-HF, presented with dose conformity and dose-volume parameters in terms of modulation complex score, were compared to those of VMAT optimized using a fully opened field (FF). The left or right side of FF was alternatively opened in VMAT-HF by using a pair of arcs rotating clockwise and counterclockwise. Consequent normal tissue complication probability (NTCP) by reducing the irradiated volumes and delivered doses for OAR were evaluated as well as dose-volume parameters. **Results:** Compared to VMAT-FF, VMAT-HF showed superior conformal dose distribution, where the 75% isodose line compactly surrounded the separated regional lymph nodes. Dose conformity was comparable between VMAT-HF and VMAT-FF; however, VMAT-HF achieved the conformal dose distribution using 60%–70% less intensity modulation complexity than that used by VMAT-FF. The small intestine and colon showed a noticeable reduction in the irradiated volumes of up to 35% and 15%, respectively, at an intermediate dose of 20–45 Gy. The small intestine showed statistically significant dose sparing at the volumes that received a dose every 5 Gy from 15 to 45 Gy. Such a dose reduction for the small intestine and colon in VMAT-HF presented significant NTCP reduction than that in VMAT-FF. **Conclusion:** VMAT-HF provided more optimal composition of MLC segments to deliver conformal doses without excessive intensity modulation. It achieved distinguishable dose sparing for gastrointestinal OAR in WPRT without sacrificing the target dose conformity. VMAT-HF can be usefully used in reducing OAR toxicities associated with WPRT.

Audience Q&A

Professionalism education is one of the six main categories required of CAMPEP-accredited programs. Often, professionalism is taught in an ad hoc manner or in the course of on-the-job training. Several graduate programs and residency programs have recently formalized professionalism education. This session will begin with an introduction of professionalism and how it's taught in other allied health fields. Next, graduate and residency programs will describe their professionalism curricula and motivation for selecting topics, which vary widely from business acumen to communicating with patients. They will describe at least one way in which formalizing professionalism training has benefited their trainees and one way in which it has directly benefited the educational program. The session will conclude by discussing how professionalism training can be formalized and unified across Medical Physics.

Learning Objectives:

1. Present concrete examples of residency professionalism training and education currently incorporated by several medical physics programs
2. Discuss the advantages to trainees of formalized professionalism education
3. Discuss the advantages to programs of formalized professionalism education

Audience Q & A

Equipment testing is a key component of the life of a clinical medical physicist. For some imaging systems, this process is straightforward and well-established. Some systems, however, have unique characteristics that require adaptation of traditional testing methods. This session will feature active clinical medical physicists, each of whom will reveal how to tackle testing some of these "misfit" systems that fall outside of the norm among imaging systems. The discussion will include what QC evaluations one should consider, how these may be adapted for "non-standard" systems, and how to approach QC for technically advanced equipment that does not yet have clearly-defined, accepted testing methods. Speakers will specifically address breast ultrasound, color displays, digital dental units, O-arms, mini c-arms, and DXA units.

Learning Objectives:

1. Obtain practical tips for successfully evaluating less common imaging systems.
2. Understand some of the unique characteristics of these less common systems.
3. Understand how to incorporate adapted/new QC practices when evaluating technologically advanced equipment.

Audience Q & A

Temporal resolution and spatial resolution present competing demands in MRI. Several new techniques have been developed in recent years to accelerate MR image acquisition, some of which have been introduced commercially and others still in the research realm. This session will review some of these techniques. The first talk will provide an overview of the combined spin and gradient echo imaging (SAGE) technique and introduce spatial and temporal acceleration strategies for application in dynamic susceptibility contrast MRI and fMRI. This talk will also highlight the advantages of a multi-echo acquisition approach over the current clinical implementations. The second talk will discuss dynamic contrast-enhanced MRI reconstruction of undersampled k-space data using compressed sensing and deep learning.

Learning Objectives:

1. Understand the basic implementation the SAGE pulse sequence
2. Understand the advantages of multi-echo acquisition vs. conventional EPI acquisition for DSC-MRI and fMRI
3. Understand the requirements of DCE-MRI in clinical practice
4. Discuss DCE-MRI reconstruction from undersampled k-space data using compressed sensing and deep learning methods

Design and Performance of the ARIEL X-Ray FLASH Irradiation Platform at TRIUMF

N Esplen^{1,*}, L Egoriti², B Paley³, T Planche³, C Hoeft³, A Gottberg³, M Bazalova-Carter¹, (1) University of Victoria, Victoria, BC (2) University of British Columbia, Vancouver, BC (3) TRIUMF, Vancouver, BC

Purpose: To optimize, build and commission a novel Bremsstrahlung target and megavoltage irradiation platform for delivering ultrahigh dose-rate radiation to small-animals in an exploration of X-ray FLASH radiotherapy at TRIUMF. **Methods:** The design of a tantalum-aluminum (Ta-Al) explosion-bonded conversion target has been optimized using Monte Carlo (MC) and Finite Element Analysis (FEA) simulation methods. The water-cooled Ta-Al target facilitates conversion of a 10MeV, 1kW electron beam at the ARIEL e-linac into an ultrahigh dose-rate ($>40\text{Gy/s}$) x-ray source with $<1\text{s}$ pulse-lengths and 0.05%-100% Duty Factor (FLASH mode) while preserving routine beam-dump capabilities in a lower power steady-state. Dose rates in water-phantoms were calculated in slab and CAD geometries using EGSnrc and TOPAS MC codes, respectively, to inform the design of the Ta-target, Al-flange and W-shield thicknesses and geometry. Thermo-mechanical FEA simulations in ANSYS subsequently informed the stress-strain conditions and fatigue life of the target assembly under prescribed conditions resulting in the re-design, and thus revised dose-rate capabilities, of the final prototype. Erosion tests and commissioning will be followed by dosimetric characterization ahead of FLASH treatment planning in small-animal models. **Results:** Simulated water-phantom irradiations demonstrate that surface dose-rates of 128Gy/s may be achieved for a $1\times 1\text{cm}^2$ field size and 7.5cm source-to-surface distance using the treatment-beam configuration ($E=10\text{MeV}$, $2\sigma=5\text{mm}$, $P=1\text{kW}$). Dose rates $>40\text{Gy/s}$ are maintained to a depth of 5cm in water. Modular collimation and SSD flexibility allows for $>200\text{Gy/s}$ to be achieved at larger field sizes. Assembly temperatures are maintained below the Ta, Al and cooling-water thresholds of 2000, 300 and 100°C , respectively, while the Al strain behavior remains everywhere elastic. **Conclusion:** The ARIEL x-ray FLASH experimental platform achieves ultra-high dose-rates within the thermo-mechanical constraints of the system. Target cooling, mechanical robustness and failure mitigation have culminated in a design intended for FLASH and steady-state applications with installation and commissioning planned for May 2021.

This work was partially funded by the National Sciences and Engineering Research Council of Canada (NSERC) Discovery Grant, Canada Research Chair program and the New Frontiers in Research Fund (NFRFE)

MO-EF-TRACK 4-02

Electron FLASH in Clinical Setting: LINAC Conversion, Commissioning and Treatment Planning

M Rahman^{1,*}, M Ashraf¹, D Gladstone^{1,2,3}, P Bruza¹, L Jarvis^{2,3}, P Schaner^{2,3}, X Cao¹, B Pogue^{1,3,4}, J Hoopes^{1,2,3,4}, R Zhang^{1,2,3}, (1) Thayer School of Engineering, Dartmouth College, Hanover, NH, (2) Department of Medicine, Radiation Oncology, Geisel School of Medicine, Dartmouth College, Hanover, NH, (3) Norris Cotton Cancer Center, Dartmouth-Hitchcock Medical Center, Lebanon, NH, (4) Department of Surgery, Geisel School of Medicine, Dartmouth College, Hanover, NH

Purpose: Clinical use of ultra-high dose-rate (UHDR, $>40\text{Gy/s}$) electron FLASH radiotherapy (eFLASH-RT), a modality demonstrating greater normal tissue sparing than conventional radiotherapy with equivalent tumor control, is constrained by the availability of FLASH systems that include minimally modified clinical settings, well-defined beam characteristics and FLASH-enabled treatment planning system (TPS). In this study, we present a potential solution with rigorous commissioning of a modified common LINAC and implementation of an electron FLASH beam model in a widely-adopted TPS. **Methods:** A Varian Clinac 2100C/D was converted to deliver UHDR electron beams by withdrawing the target and scattering foil while running in 10MV x-ray mode. Beam characteristics and stability were quantified by film, Cherenkov and scintillation imaging. The eFLASH beam model, established in Geant4 and implemented in Varian Eclipse TPS, was validated by comparing calculations with film measurements. eFLASH plans were generated for representative canine and human patient cases to demonstrate the planning and delivery capability in minimally modified clinical settings involving complex geometries and anatomical inhomogeneities. **Results:** The surface average dose rate at the isocenter was $>230\text{Gy/s}$ for all measured fields with adequate long-term stability (deviations of output $<10\%$, symmetry/flatness $<2\%$, spatial shift and shape $<2\text{mm}$). The Geant4 beam model and its Eclipse implementation were validated to clinical accuracy (absolute average error was $<1.5\%$ for lateral profiles, and $<2\%$ for percent-depth-dose profiles). An eFLASH-RT plan was generated and accurately delivered to a canine patient with a malignant melanoma tumor in the posterior oral cavity. By utilizing routine accessories, oblique gantry angle and couch kick, a human eFLASH-RT plan comparable to a conventional electron plan was achieved. **Conclusion:** Treatment planning and accurate delivery of eFLASH-RT were demonstrated feasible in minimally modified radiation oncology clinical settings. The presented solution and its open-source beam model are readily transferable to facilitate the clinical translation of eFLASH-RT.

MO-EF-TRACK 4-03

Fast 4D-CBCT Reconstruction Using a Novel Feature-Compensated Deformable Convolutional Network (FeaCo-DCN)

Z Jiang^{1*}, Y Chang², Z Zhang³, F Yin⁴, L Ren⁵, (1) Duke University, Durham, NC, (2) Duke University, Durham, NC, (3) Duke University, Durham, NC, (4) Duke University, Durham, NC, (5) Duke University, Durham, NC

Purpose: 4D-CBCT is valuable for localizing targets affected by respiratory motion in radiotherapy. However, it is limited by long scanning time, high imaging dose, and degraded image quality due to the under-sampling in each respiratory phase. Compressed sensing-based methods suffer from severe blurriness, while motion-compensated methods are limited by their slow speed and compensation errors. In this study, we proposed a novel feature-compensated deformable convolutional network (FeaCo-DCN) to realize the fast 4D-CBCT with high image quality. **Methods:** The proposed FeaCo-DCN consists of (1) encoding networks which extract features from each phase of 4D-CBCT reconstructed by the FDK method, (2) deformable convolutional networks which align features of other phases to those of the target phase, and (3) a decoding network which combines and decodes features from all phases to yield high-quality images of the target phase. Different phases of 4D-CBCT are reconstructed in parallel using FeaCo-DCN. We trained and tested FeaCo-DCN on 9 fast (1-minute) 4D-CBCT scans in the AAPM SPARE Challenge using the leave-one-out strategy. Results were compared to the top-ranking methods in the Challenge in both image quality and tumor localization accuracy. **Results:** FeaCo-DCN generated high-quality 4D-CBCT while reducing about 90% of the conventional scanning time. Images reconstructed by FeaCo-DCN showed accurate and clear structures and achieved 3D tumor localization accuracy within 2.5 mm, considerably outperforming the compressed sensing-based and motion-compensated algorithms. Additionally, FeaCo-DCN took only about 2.5 seconds to reconstruct images of one respiratory phase. **Conclusion:** FeaCo-DCN showed effectiveness in realizing fast and high-quality 4D-CBCT while reducing about 90% of the acquisition time. The proposed feature-compensated reconstruction can be applicable for other 4D imaging modalities beyond 4D-CBCT, such as 4D-MRI and 4D-PET. FeaCo-DCN can become a valuable tool for 4D imaging for motion management in radiotherapy.

Imaging Based Prediction of Proliferative Foci as a Target for Surgical Intervention Across Glioma Grades

E Gates^{*}, A Celaya, D Suki, J Weinberg, S Prabhu, D Fuentes, D Schellingerhout, University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: True proliferation of gliomas can only be measured by biopsy and is prone to sampling error due to tumor heterogeneity. We estimate tumor proliferation using MR imaging then demonstrate the ability for predictions to inform prognosis and guide surgical treatment. **Methods:** 52 image-guided(sub-millimeter accuracy) biopsy samples from 23 patients were used to train a random forest model to estimate proliferative index(%Ki-67 expression). Model inputs were routine MRI sequences: T1w (pre- and post-contrast), T2w, and FLAIR. This model was applied to a glioma patient cohort from our institution containing 207 grade II, 246 grade III, and 728 grade IV tumors. MR images for these patients were co-registered and normalized using normal tissue intensities. The random forest was applied voxel-wise through the automatically segmented tumor volume to estimate the pointwise proliferative index. We then calculated the maximum estimated proliferative index with at least 0.1cc volume in each tumor. For 811 cases with postoperative imaging available we also calculated the maximum postoperative proliferative index within unresected tumor. Maximum estimated proliferation was correlated with survival using univariate and multivariate(including mental status, age, grade) Cox models. **Results:** The root-mean-square-error for predicting Ki-67 with the random forest was 5.4%. A threshold of 11.6% on maximum preoperative proliferative index showed strong survival differences between patients with high and low proliferation tumors: univariate hazard ratio of 2.18(log-rank $p < 0.05$), multivariate hazard ratio 1.38($p < 1E-4$). Furthermore, reduction in highly proliferative disease postoperatively was associated with improved survival. Patients with high maximum postoperative proliferation had significantly worse survival($p < 0.05$) than patients where highly proliferative disease was removed. **Conclusion:** MR imaging non-invasively predicts pointwise proliferative activity. Estimated proliferation also predicts survival in glioma patients independently of clinical factors and tumor grade. Changes after surgery are prognostic, supporting the use of estimated proliferation to both guide and assess surgical intervention.

MO-EF-TRACK 4-05

Intentional Deep Overfit Learning (IDOL): A Novel Deep Learning Strategy for Adaptive Radiation Therapy

J Chun^{1*}, J Park^{2*}, S Olberg^{2,3}, Y Zhang², D Nguyen², J Wang², J Kim^{1**}, S Jiang², (1) Department of Radiation Oncology, Yonsei University College of Medicine, Seoul, KR, (2) Medical Artificial Intelligence and Automation (MAIA) Laboratory, Department of Radiation Oncology, University of Texas Southwestern Medical Center, Dallas, TX, (3) Department of Biomedical Engineering, Washington University in St. Louis, St. Louis, MO

Purpose: Applications of deep learning (DL) are promising to realize an effective adaptive radiotherapy (ART) workflow. Despite the promise demonstrated by DL approaches in several critical ART tasks, there remain unsolved challenges to achieve satisfactory generalizability for a trained model in a clinical setting. Foremost among these is the difficulty of collecting a task-specific training dataset with high quality and consistent annotations. In this study, we propose a tailored DL framework for patient-specific performance that leverages the behavior of a model intentionally overfit to a patient's available prior information – an approach we term Intentional Deep Overfit Learning (IDOL). **Methods:** Implementing the IDOL framework in any task in radiotherapy consists of two training stages: 1) training a generalized model with a diverse set of n patients, just as in the conventional DL approach, and 2) intentionally overfitting this general model to the patient of interest ($n+1$) using perturbations and augmentations of the available task- and patient-specific prior information to establish a personalized IDOL model. The IDOL framework itself is task-agnostic and is thus widely applicable to many components of the ART workflow, three of which we explore here. **Results:** In the replanning CT auto-contouring task, the Dice similarity coefficient for the parotid glands improves from 0.865 with the general model to 0.939 by adopting the IDOL model. In the case of MRI super-resolution, the mean absolute error (MAE) is improved by 28% using the IDOL framework over the conventional model. Finally, in the synthetic CT reconstruction task, the MAE is reduced from 68 to 22 HU by utilizing the IDOL framework. **Conclusion:** In this study, we demonstrate the wide applicability of the IDOL framework to common ART tasks. We expect the IDOL framework to be especially useful in creating personally tailored models in situations with limited availability of training data.

MO-EF-TRACK 4-06

Joint Optimization of Subsampling Pattern and Reconstruction of DCE MRI for Pharmacokinetic Parameter Estimation

J Zou^{*}, J Balter, Y Cao, University of Michigan, Ann Arbor, MI

Purpose: To optimize a deep neural network (NN) that incorporates k-space subsampling pattern selection and pharmacokinetic (PK) parameter estimation for reconstruction of dynamic contrast-enhanced (DCE) MRI. **Methods:** 2D Cartesian phase-encoding subsampling patterns in a 3D Cartesian acquisition are modeled as independent and identically distributed samples from a multivariate Bernoulli distribution which is jointly learned within a convolutional recurrent reconstruction NN. A PK parameter estimation layer which produces PK parameters from the extended Tofts (eTofts) model using linear least-squares fitting follows the reconstruction network. The PK parameters of 25 real DCE-MRI scans were used to generate simulated dynamic image time series using the eTofts model which were then used for network training and testing. Gaussian noise with CNR=20 was added to the simulated data. 15 scans were used for training, 5 for validation, and

5 for testing. Loss functions investigated included combinations of 1) image reconstruction L_2 loss and 2) PK parameter estimation L_2 loss. An undersampling acceleration rate of 9 was used in all experiments. PK parameter estimation accuracy was evaluated by root mean squared error (RMSE). Performance was compared to a dictionary learning-based (DL) method. **Results:** The combined image reconstruction and PK parameter loss yielded the lowest RMSE for all 3 eTofts model parameters, followed by the image reconstruction loss alone, and finally the DL method which demonstrated the largest deviation from ground truth. The combined loss reduced the RMSEs by 38.5%, 54.5%, and 41.0% for K^{trans} , $k(ep)$, and $v(p)$, respectively, compared with the DL method, with corresponding improved SSIM of reconstructed images (.98 vs .69). **Conclusion:** A NN that jointly optimizes image subsampling patterns and reconstruction yields images and quantitative model parameters from undersampled MR scans that outperform DL techniques. Different subsampling pattern parameterization strategies and application on real DCE data will be investigated in the future.

MO-EF-TRACK 4-07

Latent Space Arc Therapy Optimization

N Bice^{1*}, N Kirby¹, D Nguyen², C Kabat¹, P Myers¹, N Papanikolaou¹, M Fakhreddine¹, (1) UT Health San Antonio MD Anderson Cancer Center, San Antonio, Texas, (2) UT Southwestern Medical Center, Dallas, TX.

Purpose: Volumetric modulated arc therapy (VMAT) planning is a challenging problem in high-dimensional, non-convex optimization. Current arc therapy optimization algorithms favor solutions near the initialization point and are slower than necessary due to plan overparameterization. In this work, we reduce the effective dimension of arc therapy plans with unsupervised deep learning and navigate the learned low-dimensional coordinates during VMAT optimization. **Methods:** We collected a dataset of 1,874 clinically delivered VMAT arcs from historical treatments documented in ElektaVersaHD log files. Multileaf collimator (MLC) leaf positions are represented at 80 evenly-spaced control points for 80 leaves on 2 banks (12,800-dimensional parameterization) over the duration of the arc. A family of 2D convolutional variational autoencoders (VAE) is used to reduce the dimension of the arc data (embedding dimensions $d \in \{32, 64, 128\}$). For comparison with linear machine learning dimensionality reduction, principal component analysis (PCA) is used. Trained models are used to search for held-out arcs with a leaf-position-based objective function and simulated annealing. For comparison with a traditional routine, stochastic global direct aperture optimization with geometry-based segment initialization is implemented. **Results:** VAEs can compress arcs into 32, 64, and 128 dimensions and reconstruct them with median absolute leaf position errors of 1.59, 1.43, and 1.58 mm, respectively. PCA with the same embedding dimensions returns median errors of 7.99, 6.83, and 5.55 mm. When allowed the same number of maximum iterations, we find that the latent space algorithms converge in significantly fewer iterations compared to traditional methods. Given the same optimization problem, latent space optimization approaches a solution significantly faster (2.5 minutes) compared to conventional DAO (7.5+ minutes). **Conclusion:** Learned latent spaces provide a setting for efficient VMAT optimization. While global DAO can reach lower objective scores given enough time, optimization in learned latent spaces can achieve similar accuracy much faster.

MO-EF-TRACK 4-08

MR Multitasking-Based Dynamic Imaging for Cerebrovascular Evaluation (MT-DICE): Development and Feasibility Study on Brain Cancer

Z Hu^{1,2*}, A Christodoulou^{1,2}, N Wang¹, Y Xie¹, M Maya¹, M Shiroishi³, W Yang³, D Li^{1,2}, Z Fan^{1,3}, (1) Cedars-Sinai Medical Center, Los Angeles, California, USA (2) University of California, Los Angeles, California, USA (3) Keck School of Medicine of USC, Los Angeles, CA

Purpose: Dynamic contrast enhanced MRI (DCE-MRI) and dynamic susceptibility contrast MRI (DSC-MRI) provide permeability- and perfusion-related parameters, respectively, and are evolving as increasingly common modalities for evaluating a variety of brain cancers. However, acquiring both in one exam requires two separate scans and multiple contrast injections. In this work, we developed an MR MultiTasking-based Dynamic Imaging for Cerebrovascular Evaluation (MT-DICE) technique for simultaneous high-temporal-resolution, distortion-free DCE-MRI and leakage-insensitive DSC-MRI in one scan with a single-dose injection. **Methods:** MT-DICE employs a 3D Cartesian acquisition with periodic non-selective saturation recovery (SR) preparations followed by multi-echo FLASH readouts. Image reconstruction is performed based on MR multitasking framework with an SR time dimension and an echo time dimension for dynamic T_1/T_2^* quantification, respectively, and a contrast phase dimension for contrast dynamics imaging. DCE- and leakage-insensitive DSC-MRI metrics are computed by tracer kinetic modeling with tracer concentrations derived directly from the dynamic T_1/T_2^* values. The technique was tested on 8 healthy subjects and 5 patients with known brain tumors at 3-T with a 7.6-minute scan ($1.5 \times 1.5 \times 4.0 \text{ mm}^3$ spatial resolution, 1.2s temporal resolution). Inversion-recovery TSE and multi-echo GRE were performed in healthy subjects to provide T_1/T_2^* references, respectively. Three healthy subjects were returned for a second session for reproducibility assessment. **Results:** MT-DICE T_1/T_2^* values showed excellent quantitative agreement with references with all intraclass correlation coefficients (ICC) ≥ 0.85 . The permeability and perfusion parameters demonstrated good inter-session reproducibility, with the ICCs of v_p , K^{trans} , CBV, and CBF at 0.822, 0.694, 0.872, and 0.857, respectively. Derived values of the kinetic parameters in all healthy subject and patient cases were within the literature range. **Conclusion:** MT-DICE simultaneously quantifies permeability and leakage-insensitive perfusion parameters in a single 7.6-minute scan with a single-dose injection. Such a spatially matched multiparametric evaluation would potentially improve the performance of tumor characterization and treatment response monitoring.

MO-EF-TRACK 4-09

Non-Circular Orbits on a Clinical Robotic C-Arm for Reducing Metal Artifacts in Orthopedic Interventions

Y Ma^{1*}, T Reynolds², G Gang³, O Dillon⁴, T Russ⁵, W Wang⁶, T Ehtiaty⁷, C Weiss⁸, N Theodore⁹, J Siewerdsen¹⁰, R O'Brien¹¹, J Stayman¹², (1) Johns Hopkins University, Baltimore, MD, (2) University of Sydney, Eveleigh, AU, (3) Johns Hopkins University, Baltimore, MD, (4) University of Sydney, Sydney, NSW, AU, (5) Johns Hopkins University, Baltimore, MD, (6) Johns Hopkins University, Baltimore, MD, (7) Siemens Medical Solutions USA, Baltimore, MD, (8) Johns Hopkins University, Baltimore, MD, (9) Johns Hopkins Hospital, Baltimore, MD, (10) Johns Hopkins University, Department of Biomedical Engineering, Baltimore, MD, (11) University of Sydney, Eveleigh, AU, (12) Johns Hopkins University, Baltimore, MD

Purpose: Metal artifacts pose a challenging problem to cone-beam CT (CBCT) in image-guided orthopedic interventions. Highly attenuating metal implants effectively create a missing-data problem and this incomplete data yields reconstruction artifacts. Previous work has demonstrated that non-circular orbits can improve data completeness and potentially avoid missing data. In this work, we present the first implementation of continuous non-circular orbit acquisitions on a clinical robotic C-arm for reduction of metal artifacts. **Methods:** A Siemens ARTIS pheno robotic C-arm with a Siemens Test Automation Control System (TACS) was used to image a 3D-printed (copper/PLA blend) cervical spine phantom implanted with four stainless steel pedicle screws using two non-circular orbits: a sawtooth orbit and a double-circle orbit. The sawtooth orbit rotated 360° continuously in the LAO/RAO direction tilted between $+25^\circ$ and -25° in two cycles in the CRAN/CAUD direction. For the double-circle orbit, two 360° LAO/RAO rotations were conducted with fixed 30° and -30° CRAN/CAUD tilt. To accommodate the irregular projection data, model-based iterative reconstruction was applied using a penalized-likelihood approach. Comparisons between orbits including a conventional circular scan are presented. Additionally, we analyze the effect of precision of system geometry on image quality. **Results:** Both non-circular orbits significantly reduce the artifacts surrounding the implants, permitting better visualization of pedicle screws and the surrounding anatomy. In extreme cases where two screws coincide in the same axial plane, the anatomical structures are highly obscured in the conventional scan, while the non-circular orbits preserve anatomical details of the vertebrae, surrounding soft tissue, and threads on the screws. Moreover, by further refining the machine recorded geometry, we reduce the noise level by 40.67%. **Conclusion:** This is the first continuous acquisition of non-circular orbits on a clinical imaging system. In an emulated cervical spine scan, we demonstrate the ability of non-circular orbits to dramatically reduce metal artifacts.

Tumor Dosimetry and Radiobiological Modeling of Combined Radiopharmaceutical Therapy and External Beam Radiotherapy for Recurrent Head and Neck Cancer

D Adam*, I Marsh, J Grudzinski, T Bradshaw, P Hill, S Cho, C Hullett, A Burr, P Harari, B Bednarz, University of Wisconsin, Madison, WI

Purpose: Radiopharmaceutical therapy (RPT) in combination with external beam radiotherapy (EBRT) shows promise as a method to offer disease control and mitigate potential high-grade toxicities associated with re-treatment for patients with recurrent head and neck cancer. This work establishes a patient-specific dosimetry framework that uses radiobiological models to combine the dosimetry from RPT and EBRT and applies it to a first-of-a-kind clinical trial where patients are treated with a ^{131}I -based RPT compound (CLR 131) and reduced fractionation EBRT. **Methods:** Serial SPECT/CT patient scans performed at approximately 24-, 48-, 72-, and 168-hours post-injection of 15.6 mCi/m² CLR 131 were used as input to a GEANT4 based RPT dosimetry platform named RAPID. Phantom-based recovery coefficients were applied to physician delineated tumor volumes to account for partial volume effects. Separately, EBRT treatment plans were created using standard of care (SOC) clinical practices (prescribed doses of 60-66 Gy in 2 Gy fractions). For treatment, the total number of EBRT fractions delivered was reduced accordingly to achieve the SOC total dose when including the CLR 131 RPT mean absorbed dose to the PTV. Radiobiological models (BED, EUD, EQD2) were used to compare the two radiation modalities. **Results:** The RPT mean absorbed dose to the PTV reduced EBRT treatments by 3-4 fractions. The RPT BED to the PTV was nearly equivalent to the absorbed dose yet the RPT EUD indicated dose heterogeneity in two patients. The EBRT EUD indicated the absorbed dose was largely homogeneous and the EBRT BED was greater than the EBRT absorbed dose. **Conclusion:** RPT proffers a method to reduce the EBRT dose from current SOC treatments. Incorporating RPT dose during the optimization of EBRT plans could further reduce normal tissue toxicities. The framework employed here is extendible to other permutations of EBRT and RPT treatments.

This work is supported by NIH SPORE CA196513-01. BB and JG are co-founders of Voximetry, Inc., a nuclear medicine dosimetry company in Madison, WI.

Prostate HDR and Utilization of MR

The ability of magnetic resonance imaging (MRI) to create distinct images of the body's soft tissues and the tumors that arise amid them is helping Brachytherapy Radiation Oncologists to precisely shape doses to cervical and prostate tumors, while at the same time avoiding exposure to critical healthy organs and tissues. Conforming brachytherapy doses closely to the tumor's shape and position is important in order to apply the highest possible dose to the tumor while limiting the dose to critical structures, such as the bladder rectum, and urethra thereby decreasing the likelihood of treatment side effects.

To achieve the above, comprehensive quality assurance and safety considerations need to be put in place prior to clinical use of MRI is Radiation Oncology imaging and treatment planning.

There are three approaches to incorporating MRI into the brachytherapy workflow. They are: MR-informed MR-guided, and MR-based brachytherapy. Workflows for MR based HDR brachytherapy will be discussed, however, many of these processes apply to MR-guided techniques as well. Safety consideration will be reviewed and their implications to applicator, and workflow selection.

Implementation of MR-based HDR gynecologic and prostate brachytherapy will be discussed, including development of an imaging protocol, applicator commissioning and reconstruction, simulation techniques, contouring, treatment planning and dose adaptation.

Learning Objectives:

1. To understand the advantages of having MR based brachytherapy
2. To understand the safety considerations when using MR based brachytherapy
3. Clinical considerations when utilizing MR for GYN and prostate brachytherapy

Weighing the Risks and Benefits of Imaging Guidance with Ionizing Radiation

MO-E-TRACK 6-03

Q&A Panel

Image guided radiation therapy (IGRT) has become the standard of care in radiotherapy. Modern day IGRT, first introduced in late 1990s, has evolved over the past two decades by introduction of new techniques, often involving multiple modalities. During a daily treatment fraction, the patient may be imaged more than once in order to position the patient and to confirm repositioning if necessary. Image guidance is also employed for intrafraction motion management and adaptive radiotherapy. These imaging procedures, if x ray based, expose additional radiation dose to healthy tissues outside radiotherapy targets. Therefore, understanding the magnitude of this extra dose and the risks associated with these doses are important. Both AAPM TG-75 and TG-180 reports were developed to address the concerns and to provide guidelines and strategies for minimizing imaging dose while improving treatment delivery.

This lecture reviews advances in image guidance during the radiotherapy procedures with emphasis on x ray-based modalities. The evolution of IGRT and currently available IGRT tools and techniques will be reviewed with emphasis on x ray-based ones. Newer specialty radiation delivery units like proton therapy often employ customizable IGRT devices that may need attention, especially with regard to radiation dose. These devices will also be reviewed during this session. The session also provides an overview of the AAPM TG-180 report as well as the recommendations of the report on managing image guidance doses.

The session further discusses techniques for reducing the imaging dose and explains the recommended threshold beyond which imaging dose should be considered in the treatment planning process. It addresses the techniques and methods that can be used in clinical practice to estimate imaging dose resulting from different kV and MV imaging procedures. It explains two recommended methods of estimating patient imaging dose during treatment planning. The lecture also presents a perspective view of radiation dose to healthy tissues resulting from the sources such as leakage, out-of-field dose, etc. and from image-guidance procedures. While the commonly adopted radiation protection safety philosophy of As Low As Reasonably Achievable (ALARA) is applicable to imaging guidance dose, minimizing imaging doses by employing reasonable methods should not compromise target localization. Therefore, balancing ALARA principles with the requirement for effective target localization requires that imaging dose be managed based on the consideration of weighing risks and benefits to the patient.

Learning Objectives:

1. Learn the latest advances in IGRT modalities and techniques
2. Learn the applications of IGRT in specialty delivery units
3. Learn the magnitude of typical organ doses resulting from different imaging procedures and modalities
4. Learn available techniques to reduce the imaging dose in daily clinical practice and how to account for kV and MV imaging dose.
5. Develop a perspective view of radiation to sensitive organs between imaging dose and unintended dose from therapeutic beams.
6. Understand weighing the risks and benefits of imaging guidance for effective target localization.

Audience Q&A

AAPM and its individual members have been engaged in global outreach efforts for some time. AAPM's imaging physics community is involved in projects with several intergovernmental and non-governmental international organizations (e.g., the IAEA and RAD-AID). However, some imaging physicists - especially those early in their career - may find it difficult to break into global health work. Even once actively involved, they may have difficulty making meaningful, effective contributions. In some regions, physicists' work is hindered by a lack of regulations, enforcement of regulations, and resources needed to comply with regulations. Often, the work of individual physicists is not part of a concerted, continuous effort and would benefit from more organized partnerships. With the formation of the International Council, AAPM's global activities have been centralized to allow for more efficient use of resources and greater collaboration between individual efforts. To foster participation at a global level, this session will highlight AAPM's current contributions to global health initiatives in radiology and will discuss challenges and areas of growth. We will demonstrate the need for radiology and imaging physics services in regions with limited resources, provide examples of successful partnerships, and illustrate opportunities for continued growth.

Learning Objectives:

1. Learn about challenges faced in regions with limited access to radiology and imaging physics services

2. Increase awareness of opportunities for imaging physicists to contribute to global health initiatives
3. Learn about creating successful, effective partnerships with institutions in low-resource regions

Concluding Discussion

Physics is the fundamental science of many modern diagnostic and therapeutic medical procedures. For over 135 years physical principles have been applied in the development of technologies and methods to enhance the practice of clinical medicine with two major goals, more effective diagnostic imaging procedures and applying radiation for the treatment of diseases, especially cancer.

This continues to be a dynamic process with the evolution of technology throughout society and especially the impact of digital science, technology, and applications. Our current medical physics activities and clinical applications are built on the foundation of the research and developments by many of our medical physics pioneers that are our history and heritage.

The International Organization for Medical Physics (IOMP) in collaboration with the AAPM has an extensive project for documenting and publishing elements of this history, often by physicists who were active participants in the developments during the recent half-century. These are published at: <http://www.mpjournal.org/history.aspx> and selected ones presented at the AAPM History Symposium.

Learning Objectives:

1. Follow the events and contributions of individuals in the development and evolution of computed tomography (CT).
2. Explore the Role of Cobalt-60 in Cancer Treatment Around the World.
3. Appreciate the contributions of Harold Johns to the medical physics profession and practice.

MRI Homogeneity Testing

In MRI, main magnetic field (B0) homogeneity is an important factor in performance. Annual testing of B0 homogeneity is required by the ACR accreditation program and Joint Commission standards. However, many physicists are uncertain as to how to conduct this test and interpret the results, and each vendor has their

own accepted methods for testing B0 homogeneity and corresponding tolerance levels.

This session will explain the main methods of homogeneity testing and provide specific instructions on how to perform these tests on individual vendor platforms. Advice on interpreting the results will also be discussed. Resources to assist the physicist with homogeneity testing will be identified.

Learning Objectives:

1. Learn vendor-specific methods for testing homogeneity.
2. Understand how to set performance criteria.
3. Identify resources to assist the physicist with homogeneity testing.

Q&A

Purpose: To provide guidance on quality management for electronic brachytherapy.

Materials and Methods: The task group used the risk-assessment approach of Task Group 100 of the American Association of Physicists in Medicine. Because the quality management program for a device is intimately tied to the procedure in which it is used, the task group first designed quality interventions for intracavitary brachytherapy for both commercial electronic brachytherapy units in the setting of accelerated partial-breast irradiation. To demonstrate the methodology to extend an existing risk-analysis for a different application, the task group modified the analysis for the case of post-hysterectomy, vaginal cuff irradiation for one of the devices.

Results: The analysis illustrated how the TG-100 methodology can lead to interventions to reduce risks and improve quality for each unit and procedure addressed.

Conclusion: This presentation on this report provides a model to guide facilities establishing a quality management program for electronic brachytherapy.

Learning Objectives:

1. To become familiar with the contents of the report of TG 182.
2. To see how the TG-100 approach can be applied to the design of QM for an electronic brachytherapy unit.
3. To understand why the design of a QM program is customized to a clinic's procedure.

A. Bush:

Radiology Administrator's Perspective: 2

MO-F-TRACK 6-05

Audience Q & A

Radiology administrators are not likely eager to pay for physicists to engage in activities outside of accreditation and regulatory compliance roles. Physicists, however, have a skill set that is aptly suited to tackle problems outside of these traditional roles. This symposium will teach the physicist how to bring additional value to a

radiology department. Our speakers are split 50/50 between physicists and administrators. Topics will include non-traditional physics tasks like: building scanner/indication based scheduling template rules, contrast administration/timing/uniformity across scanners and sites, scan speed optimization in CT for pediatrics to mitigate motion and sedation, monitoring exam timeliness in the setting of rapid imaging needs, and monitoring protocol selection and dose consistency across an enterprise. Examples will be presented in a manner which does not require on-site physics support. Therefore, our examples should resonate with the consulting physicist or the off-site academic physicist in addition to onsite physics support.

Learning Objectives:

1. Learn how to quantify potential time and contrast agent savings and provide opportunities for increased efficiency to support physics time spent outside of traditional roles.
2. Walk away with references and examples of non-traditional physics projects you can implement.

Mentoring Activities Within the AAPM

MO-F-TRACK 7-05

Discussion

The importance of mentorship within health care settings is well recognized and serves as a key component of training to build clinical, teaching and research knowledge, and to advance interpersonal, communication and leadership skills. Usually, this involves an experienced, well-regarded, empathetic person (the mentor) who guides another (usually less experienced and possibly younger) individual (the mentee) in the development of their clinical, teaching, and research skills, as well as their personal and professional growth. Formalized mentoring has been promoted in the academic world for many years to advance an individual's career development and improve teaching and research. Virtual mentoring is a more recent phenomenon enabled with expansion of broadband internet, together with a variety of tools that allow easier communication across the world. Virtual mentoring has the further potential of providing professional training and education support to under-resourced regions. Virtual mentoring activities were significantly escalated in the last year with the COVID-19 pandemic and the additional emphasis on remote instruction.

Both the mentor and mentee benefit from the mentoring process. A challenge for the medical physicist who is mentoring someone from an under-resourced region is to truly understand the local circumstances of the mentee's environment including the institutional, societal, economic, cultural, political, clinical, and technological perspectives. Additional challenges relate to time-zone differences, insufficient internet bandwidth, and limitations in time and availability. A further challenge relates to mentoring associated with practical hands-on activities in a clinical environment, especially in the context of medical physics residency programs.

There is evidence that mentorship works the best when the mentor and mentee have explicitly shared their values, interests, expectations, and goals. During the past year, research and practice in remote mentoring have further highlighted the need to reassess, re-evaluate, and reconnect intentionally between mentor and mentee. We will demonstrate mentoring approaches that extend best practices of shared understanding and trust building to remote mentoring.

This session will provide: (1) an overview of global mentoring, in healthcare and academic contexts, and at multiple levels (e.g., graduate student, medical physics resident, early career medical physicist, mid-career medical physicist, academic medical physicist), (2) a discussion of the foundational frameworks of successful mentoring methods, with an emphasis on virtual mentoring, (3) a discussion of factors influencing the success of virtual mentoring in medical physics, and (4) a summary of AAPM mentoring activities, particularly those aimed at trainees and early careers.

Learning Objectives:

1. Describe an overview of global mentoring in the clinical and research settings and the benefits that it provides.
2. Define the characteristics of successful approaches to virtual mentoring.
3. Explore and self-reflect on virtual mentoring methods, i.e., techniques and technologies and identify strategies to apply to their practice.
4. Describe AAPM mentoring activities.

Multi-Scale Residual Network for Tumor Segmentation in Pancreatic Cancer

S Gou^{1*}, S Chen², B Cui³, Z Zhou⁴, J Lu⁵, (1), Xi'an, , CN, (2) Xidian University, (3) (4) University of Central Missouri, Warrensburg, MO, (5)

Purpose: Accurate segmenting tumor is of great importance on effective diagnosis and treatment for pancreatic cancer. We aim to develop a new multi-scale residual network (MSRN) for accurate and automatic tumor segmentation. **Methods:** Totally 71 positron emission tomography (PET) and 71 MR images are used in this study. In each scan, the tumor was contoured by an experienced radiologist and used as ground truth. Due to the heterogeneity of pancreatic components and unclear tumor boundaries, achieving segmentation of pancreatic tumors may present challenges. Accurately and automatically segment the tumor can greatly help the diagnosis and treatment of pancreatic tumors. The model is designed based on multi-modal feature fusion network. In order to fuse information in the multi-modal image, the feature maps of PET and MRI were extracted through two parallel multi-scale networks respectively and were fused. And then the squeezing-and -excitation block (SE-block) was used to automatically improve the valid features in the fused feature map and suppress the invalid features. The registered training images are input into the multi-modal feature fusion network to train the segmentation model, and the lesion features are extracted through the multi-scale residual network. The testing phase includes two steps: (1) tumor segmentation through trained multi-modal fusion network; (2) the distance regularized level set evolution (DRLSE) method is applied to post-processing. The segmentation results are evaluated through dice similarity coefficient (DSC), sensitivity (SEN) and specificity (SPE). **Results:** Five-fold cross validation was performed in this study. The average results on quantitative analysis for DSC, SEN, and SPE are 0.742, 0.771, and 0.993, respectively. **Conclusion:** A new multi-scale residual network (MSRD) was developed for tumor segmentation in pancreatic cancer in this study. The experimental results demonstrated that MSRD can obtain promising segmentation results.

MO-lePD-TRACK 1-02

Quantitative Evaluation of Intra- and Inter-Modal Deformable Image Registration of CT and MR Images for Heart, Left-Ventricle and Thoracic Aorta

A Omid^{1*}, E Weiss², J Wilson^{1,3}, M Rosu-Bubulac², (1) Biomedical Engineering Department, Virginia Commonwealth University, Richmond, VA, (2) Radiation Oncology Department, Virginia Commonwealth University, Richmond, VA, (3) Pauley Heart Center, School of Medicine, Virginia Commonwealth University, Richmond, VA

Purpose: The first step in correlating local radiation dose and regional cardiac magnetic resonance (CMR) findings is mapping CT-derived radiation doses onto CMR via image registration. This is the first study to evaluate the accuracy of intra- and inter-modality deformable image registration (DIR) for heart, left ventricle (LV), and thoracic aorta (TA), using paired longitudinal CT and pre/post contrast MR imaging. **Methods:** 0% (INH) and 50% (EXH) breathing-phases from 4DCT, and inspiratory/expiratory pre-/post-contrast MR image sets were acquired from five lung cancer patients twice during radiotherapy treatment. DIR was performed for the following comparisons: Different time points - (C1) intramodal CT, (C2) intramodal MR, (C3) intermodal CT/MRI; Same time point - (C4) intermodal CT/MR, (C5) intramodal MR pre/post contrast. Registration performance was assessed using HD, MDA, and DICE for the original and deformed contours. **Results:** Mean MDA ranged 1-2 mm, except for the two intermodality comparisons of the LV (2.6mm for both). Mean HD ranged 8-17 mm. Mean DICE ranged 0.85-0.95. Overall, all metrics performed better intramodality, with/without contrast. Contour comparisons via HD and MDA were least favorable for LV, and similar for TA and heart. DICE was best in heart, with LV and TA performing similarly. The following scenarios had statistically significant differences ($p < 0.05$): HD: (C2), (C4), (C5) for LV_vs._TA; MDA: (C1), (C2), (C4), (C5) LV_vs._heart (C2)-(C5) LV_vs._TA; DICE: (C1)-(C5) for TA_vs._heart and LV_vs._heart. When the various modalities were compared, the differences were found significant mainly between (C1) vs. (C4), and (C2) vs. (C4), for almost all structures of interest. **Conclusion:** Though intramodal registration remains slightly superior, both intramodal and intermodal DIR are within TG 132 recommended range for the structures of interest, suggesting that quantitative regional analyses of CT and MR images from patients undergoing radiotherapy may be spatially correlated without significant error following registration, even across modalities.

MO-lePD-TRACK 1-03

Spatial Transformation Network-Based MRI-CBCT Deformable Registration for CBCT-Guided Prostate Radiotherapy

S Momin^{*}, Y Lei, T Wang, Y Fu, J Roper, P Patel, A Jani, J Bradley, T Liu, X Yang, Department of Radiation Oncology and Winship Cancer Institute, Emory University, Atlanta, GA

Purpose: Radiotherapeutic dose escalation to dominant intraprostatic lesions (DIL) in prostate cancer could potentially improve tumor control. This study aims to propose an unsupervised method to accurately register multiparametric MRI to CBCT images for improved DIL delineation, treatment planning, and dose monitoring in CBCT-guided prostate radiotherapy. **Methods:** Our proposed spatial transformation network (STN) consists of two consecutive networks: zoomed-out and zoomed-in feature networks. Both networks have adversarial learning integrated to further force the realism of derived deformation vector field (DVF). The network begins with MRI and CBCT as inputs to the zoomed-out network to predict an overall approximation of DVF, which is transferred to spatial transformer to generate zoomed-out version of deformed MRI. For subsequent zoomed-in network training, 3D patches are extracted from zoomed-out version of deformed MRI. Zoomed-in network learns smaller changes within the extracted patches to generate more local DVF, which is transferred to spatial transformer for generating deformed patch. We performed leave-one-out cross-validation experiment on 30 pelvic cancer patients to evaluate the proposed registration method. The target-registration-error (TRE) as the Euclidean distance of the identified landmarks was used to quantify the accuracy of the proposed MRI-CBCT registration. **Results:** Overall results of this work showed feasibility of our proposed network architecture to accurately register multimodal images with good spatial alignment of different structures. An average TRE of 2.9mm (range 2.1-3.7mm) was achieved after registration for all patients, compared with 5.7mm (range 4.9-8.3mm) before registration. The proposed network can generate a final DVF in a single forward prediction, which is faster than the conventional iterative registration algorithms. **Conclusion:** We developed a new framework to accurately register the prostate on MRI to CBCT images for external beam radiotherapy. The proposed method could be used to aid DIL delineation on CBCT, treatment planning, dose escalation to DIL, and dose monitoring.

MO-lePD-TRACK 1-04

To Design and Construct Customized Multimodal Imaging Phantoms by 3D Printing

J Qiu^{1*}, (1)Shandong First Medical University & Shandong Academy of Medical SciencesH Zhang^{2*}, (2) Duke Kunshan Medical Physics Program, Department of Duke Graduate School

Purpose: To develop a method for constructing customizable, multimodal quality control (QC) imaging phantoms based on 3D printing technology **Methods:** Four

phantoms were designed and constructed through 3D-printing technology using three unique printing materials. Physical parameters of the 3D-printed materials were evaluated, including density, shore hardness, porosity, deformation temperature, computed tomography (CT) number, absorption coefficient, and printing accuracy. Imaging performance of the phantoms was studied using MRI, CT, PET/MR, and PET/CT, and compared with conventional/commercial phantoms. Imaging assessments included high contrast resolution, low contrast resolution, uniformity, deformation, SNR, slice accuracy/slice thickness, location accuracy/laser alignment, CT number, relaxation time, and registration. **Results:** All three printing materials have a shore hardness of 90. The physical densities of these materials are 1.15 g/cm³, 0.76 g/cm³ and 1.27 g/cm³, respectively. The porosities are 9.09%, 6.81%, and 18.56%, respectively. The threshold temperature of deformation for the three materials is greater than 105°C, which is higher than that of PMMA and silica gel. Imaging scans of the constructed phantoms for single modality scanners (MRI and CT) and dual-modality scanners (PET/MRI and PET/CT) were compared with those of the commercial phantoms. The standard deviation of the HU value uniformity test was less than 3 HU for CT scans. **Conclusion:** 3D-printed medical imaging phantoms allow for rapid, customized phantom fabrication for clinical situations across single and dual modality imaging platforms. Further imaging parameter analysis is underway to provide more quantitative evaluation of the proposed phantoms.

MO-lePD-TRACK 1-05

Effects of Permanent Magnet Shapes Used in Halbach Cylinders On FFL-MPI

M Ergor¹, N Dogan², A Bingolbali^{1*}, (1) Yildiz Technical University, Istanbul, TR, (2) Gebze Technical University, Gebze/Kocaeli, TR

Purpose: Selection field, which contains a field-free line (FFL), is used in Magnetic Particle Imaging (MPI) to allow spatial selection of a specific region to achieve spatial encoding along a line. Since permanent magnets can generate a static magnetic field, there is no need to consider the issue of power consumption. Studies show that the shape and performance of permanent magnets affect the quantity of the magnetic field generated. In this study, FFL was formed by using dipole Halbach cylinders and the effects of magnet shapes on FFL performance were investigated. **Methods:** Dipole Halbach rings consist of six different shapes of permanent magnets (square, hexagon, octagon, dodecagon, hexadecagon, circle) were used for generating FFL. NdFeB (neodymium-iron-boron) was chosen as the magnet material. For each model, magnetic flux density and gradient field strength were simulated using COMSOL Multiphysics 5.4. **Results:** Magnetic flux density and gradient field strength increase on the y-axis from the rectangular magnet shape to the cylindrical shape. Gradient values obtained from the permanent magnets (square, hexagon, octagon, dodecagon, hexadecagon, circle) are 3.6 T/m, 4 T/m, 4.4 T/m, 4.6 T/m, 4.7 T/m, 4.8 T/m, respectively. The homogeneity of the gradient for each design was above 95% and did not change according to the shapes of the magnets used. Also, the gradient values were stable along 35 mm. **Conclusion:** The outcomes show that Halbach magnet systems formed with different magnet shapes have a significant impact on FFL performance. Polygons were used to improve the square-shaped permanent magnets. Gradient has been increased by 25% using the polygonal magnet shapes. Future studies will be continued to increase the stability and bore size of the system.

Autosegmentation On Low-Resolution T2-Weighted MRI of Head and Neck Cancers for Off-Line Dose Reconstruction in MR-Linac Adapt-To-Position Workflow

B McDonald¹, C Cardenas², N O'connell³, S Ahmed⁴, M Naser⁵, J Xu⁶, D Thill⁷, R Zuhour⁸, S Mesko⁹, A Augustyn¹⁰, S Buszek¹¹, S Grant¹², B Chapman¹³, A Bagley¹⁴, K Wahid¹⁵, R He¹⁶, A Mohamed¹⁷, A Dresner¹⁸, J Christodouleas¹⁹, K Brock²⁰, C Fuller²¹, (1) UT MD Anderson Cancer Center, Houston, TX, (2) UT MD Anderson Cancer Center, Houston, TX, (3) Elekta Inc., (4) UT MD Anderson Cancer Center, (5) UT MD Anderson Cancer Center, Houston, TX, (6) Elekta Inc., St. Charles, MO, (7) Elekta Inc., St. Charles, MO, (8) University Of Texas Medical Branch, (9) UT MD Anderson Cancer Center, (10) UT MD Anderson Cancer Center, (11) UT MD Anderson Cancer Center, (12) UT MD Anderson Cancer Center, (13) UT MD Anderson Cancer Center, (14) UT MD Anderson Cancer Center, (15) UT MD Anderson Cancer Center, (16) UT MD Anderson Cancer Center, Houston, TX, (17) UT MD Anderson Cancer Center, Houston, TX, (18) Philips Healthcare, (19) Elekta Inc., (20) UT MD Anderson Cancer Center, Houston, TX, (21) UT MD Anderson Cancer Center, Houston, TX

Purpose: To compare autosegmentation methods on low-resolution T2-weighted on-board setup MRIs from a 1.5T MR-linac for off-line reconstruction of delivered dose. **Methods:** 7 organs-at-risk (OARs) (parotids, submandibulars, mandible, cord, brainstem) were contoured by 7 observers each in 43 images. Ground truth (GT) contours were generated using STAPLE. 20 autosegmentation methods were evaluated in ADMIRE: 1-9) atlas-based autosegmentation using a population atlas library (PAL) of 5/10/15 patients with STAPLE, patch fusion (PF), random forest (RF) for label fusion; 10-19) autosegmentation using images from a patient's 1-4 prior fractions (individualized patient prior (IPP)) using STAPLE/PF/RF; 20) deep learning (DL) (3D ResUNet trained on 43 GT structure sets plus 45 contoured by one observer). Autosegmentation methods were evaluated on 5 images using Dice similarity coefficient, mean surface distance, Hausdorff distance, Jaccard Index against GT. Execution time was measured for each method. Inter-observer variability was quantified using pairwise comparison. For each metric and OAR, performance was compared to inter-observer variability using Dunn's test with control. Methods were compared pairwise using Steel-Dwass test for each metric pooled across OARs. Further dosimetric analysis was performed on contours from DL (fastest), IPP_RF_4fractions (best performance), and PAL_STAPLE_5atlases (worst performance): Delivered doses from clinical plans were recalculated on setup images with each structure set. Percent differences in Dmean and Dmax were measured between GT and each method. **Results:** DL and IPP methods performed best, all significantly outperforming inter-observer variability and with no significant difference between methods in pairwise comparison. Most PAL methods were not significantly different from inter-observer variability or each other. DL was the fastest and PAL methods the slowest. Execution time increased with number of prior fractions/atlas. Dosimetric differences were minimal (median<6%) for DL and IPP_RF_4fractions but greater for PAL_STAPLE_5atlases (median<16%). **Conclusion:** Autosegmentation using DL or IPP is superior to PAL considering both geometric and dosimetric criteria.

MO-lePD-TRACK 3-02

Dosimetric Benefits of MR Guided Adaptive Radiation Therapy

A Sethi^{*}, S Hoffman, J Ingram, B Lee, J Roeske, T Refaat, Loyola University Medical Center, Maywood, IL

Purpose: To quantify dosimetric gains achieved with MR guided adaptive radiation therapy (MRgART) for pancreas cancer patients treated with stereotactic body radiotherapy (SBRT). **Methods:** This IRB approved study evaluated SBRT plans of 15 pancreas cancer patients treated with MRgART on a 0.35T MR linac in our department between 2018 and 2020. Prescription dose was 40Gy to PTV and 50Gy to GTV in 5 fractions with 6MV FFF X-rays. For each fraction, a reference treatment plan was re-computed on the daily MR image for dose predictions. If OARs exceeded dose tolerance, the treatment plan was re-optimized and adapted.

The decision to adapt was driven by an iso-toxicity approach: $V36 \leq 0.5\text{cc}$ for stomach, duodenum, small and large bowels (SB, LB). We looked at adapted plan specifications, reasons for adaptation, and dosimetric gains with adaptation for each OAR (Dmax and V36Gy) and PTV coverage (V40Gy) by comparing predicted vs. re-optimized plans. **Results:** Based on a review of 72 treated fractions (42 adapted), duodenum was the most common reason for plan adaptation (38.1% fractions) owing to its close proximity to pancreas, followed by stomach (31%), SB(26.2%), and LB(9.5%). For 14.3% of fractions, PTV coverage was the decisive factor. For adapted fractions, average improvements in V36Gy (cc) for stomach, duodenum, SB, and LB were (mean $\pm$ s.d.) 1.7 ± 1.2 , 2.3 ± 1.2 , 1.1 ± 0.7 , and 4.0 ± 3.2 cc respectively. The corresponding dose reductions in Dmax for Stomach, Duodenum, SB, LB were $18.1 \pm 7.0\%$, $16.7 \pm 10.3\%$, $15.0 \pm 10.8\%$, and $37.0 \pm 37.8\%$ respectively. For target coverage driven MRgART, V40Gy for PTV improved on average by $5.0 \pm 4.7\%$. **Conclusion:** Intra-abdominal OARs undergo significant motion due to soft-tissue deformation, patient weight loss, respiration, and peristalsis. MRgART can be effective in mitigating the dose impact of these anatomical variations.

MO-lePD-TRACK 3-03

Improving DWI Spatial Resolution with Respiratory Motion Modeling on An Interleaved BSSFP-DWI Sequence

J Charters^{1*}, D O'Connell¹, Y Gao¹, Y Yang¹, J Ginn², J Lamb¹, (1) University of California, Los Angeles, Los Angeles, CA (2) Washington University, Saint Louis, MO

Purpose: Diffusion-weighted imaging (DWI) may serve as a biomarker for lung and pancreatic tumors undergoing magnetic resonance imaging (MRI)-guided radiotherapy (MRgRT). However, obtaining DWI with sufficient signal-to-noise ratio (SNR) and resolution for biomarker use is challenging for these tumors due to substantial respiratory motion. Furthermore, direct co-registration and summation of DWI frames of moving tumors is difficult due to lack of anatomic information. Here we demonstrate a motion deblurring technique based on interleaving high-resolution, high SNR balanced steady-state free precession (bSSFP) images with low-resolution, low SNR DWI images. **Methods:** Studies on a dynamic thorax phantom and one volunteer were performed on a 0.35T MRgRT machine. The subjects experienced a sequence of bSSFP and DWI multislice scans, which repeated 100 times over approximately 17 minutes in order to adequately capture respiratory motion. A respiratory bellows surrogate was processed in LabVIEW and served as the motion surrogate. The bSSFP images and respiratory bellows were used to extract a motion model which related tissue motion to the bellows trace. The model coefficients were resampled from the bSSFP grid (2mm x 2mm spacing) to the DWI grid (2.73mm x 2.73mm spacing). The warped coefficients, together with bellows surrogate values corresponding to the DWI images, were used as estimated DWI deformation vector fields (DVF). Signal averaging across all DWI images was compared to averaging across the model-registered DWI images. Resolution enhancements were evaluated visually and quantified by fitting a sigmoid function to line profiles across intensity edges. **Results:** Model-estimated DVF accuracy on the bSSFP phantom images was subpixel for nearly every image. Line profile sigmoid widths for the phantom were 8.3 and 3.6 pixels for non-registered and phantom-registered images. Visually, motion blurring was reduced. **Conclusion:** Our work demonstrates the feasibility of motion de-blurring of DWI images using a motion model built from interleaved bSSFP images.

MO-lePD-TRACK 3-04

Optimizing Site-Specific Diffusion Weighted Imaging in an MR-Linac

H Nusrat^{1,2*}, L Lawrence^{3,4}, R Chan³, A Lau^{3,4}, A Elzibak¹, B Chugh^{1,2,5}, A Sahgal², B Keller^{1,2}, (1) Department of Medical Physics, Odette Cancer Centre, Sunnybrook Health Sciences Centre, Toronto, ON, CA, (2) Department of Radiation Oncology, University of Toronto, Toronto, ON, CA, (3) Sunnybrook Research Institute, Toronto, ON, CA, (4) Department of Medical Biophysics, University of Toronto, Toronto, ON, CA, (5) Department of Physics, Ryerson University, Toronto, ON, CA

Purpose: Diffusion weighted imaging (DWI) is sensitive to changes in tumor microstructure and can be used to non-invasively monitor radiotherapy treatment response. Despite being clinically available in MR-scanners, DWI can be further optimized in MR-guided radiotherapy systems. Maximum b-value is an important sequence parameter that controls the amount of diffusion weighting; high diffusion weighting leads to noise and less accurate apparent diffusion coefficient (ADC) estimates. MR-Linac users follow the recommended maximum b-value of 500 s/mm², however, higher maximum b-values are routinely used for DWI in sites such as the brain. The goal of this work was to optimize DWI in an MR-Linac using a standardized phantom. **Methods:** DWI sequences for brain, prostate, and abdomen were optimized with respect to maximum b-value and number of signal averages (NEX). DWI scans of the NIST-QIBA phantom (High Precision Devices, Boulder, USA) were conducted in the Elekta Unity MR-Linac's (Elekta AB, Stockholm, Sweden) Philips Marlin 1.5T MR scanner. ADCs were estimated by fitting with offline reconstruction (MATLAB). Maximum b-value and NEX were varied and differences between measured and manufacturer-specified ADC were reported. The impact of varying NEX on scan duration was also quantified. **Results:** For the brain sequence, maximum b-value achieving accurate ADC was 3,000 s/mm² ($\pm 4.0\%$ of standard across all diffusion vials). For all three sites, fitting with a subset of b-values below 400 s/mm² reduced ADC accuracy ($\pm 17.6\%$, 22.3% , 24.1% for brain, prostate and abdomen, respectively). Reducing NEX from clinical protocol to the scanner's minimum resulted in underestimation of ADC by $14.3\% (\pm 1.7\%)$, $18.4\% (\pm 5.1\%)$, and $17.5\% (\pm 4.3\%)$ for the brain, prostate, and abdomen sequences, respectively but reduced average scan duration from 5.8 to 1.1 minutes. **Conclusion:** Site-specific DWI sequences were optimized for ADC accuracy with respect to maximum b-value and scan time using a standardized phantom. Future work involves repeating this methodology in vivo.

MO-lePD-TRACK 3-05

Reduced Field-Of-View Diffusion Weighted MRI On An MR-Guided Radiotherapy System

J Pham^{*}, Y Gao, D Low, P Hu, Y Yang, University of California, Los Angeles, Los Angeles, CA

Purpose: Longitudinal on-board diffusion MRI (DWI) using MR-guided radiotherapy (MRgRT) system has the potential to monitor localized treatment response throughout treatment course. Clinically, DWI is acquired together with an anatomical MRI with a large field-of-view (FOV), while the DWI focuses primarily on the tumor within a smaller FOV. Accordingly, reduced FOV (rFOV) DWI has been introduced to remove artifacts from motion, flow and other signal interferences from the surrounding regions. In this study, a rFOV DW-single-shot echo planar imaging (DW-ssEPI) using saturation bands was implemented on an MRgRT system and its performance was evaluated with phantom studies. **Methods:** Full FOV DW-ssEPI (fFOV-EPI) and rFOV DW-ssEPI (rFOV-EPI) were evaluated on a 0.35T MRgRT system using a diffusion phantom and a spatial integrity phantom. Both scans used the same resolution ($2.7 \times 2.7 \times 6\text{mm}^3$), TE (120ms), and TR (3200ms). The FOV of fFOV-EPI and rFOV-EPI was $350 \times 350\text{mm}^2$ and $225 \times 225\text{mm}^2$, respectively. Saturation bands were placed immediately outside of the rFOV in the phase encoding direction to minimize aliasing artifacts. Signal-to-noise ratio (SNR) compensation was introduced for the rFOV-EPI to equalize SNR between the two scans. As a result, fFOV-EPI and rFOV-EPI used 6 and 9 averages for a scan time of 1:46 and 2:34min, respectively. Apparent diffusion coefficient (ADC) measurements were evaluated relative to the reference values by the manufacturer. Spatial integrity was evaluated using an open-source toolbox to quantify spatial distortion. **Results:** Both fFOV-EPI and rFOV-EPI provided accurate ADC quantification on the diffusion phantom ($p < 0.05$). rFOV-EPI had similarly low levels of distortion as fFOV-EPI at 50, 75, and 100mm radius of the spatial integrity phantom. **Conclusion:** rFOV-EPI is a feasible method to generate rFOV DWI and is comparable to conventional fFOV-EPI on phantom scans. Future work will focus on patients and volunteers to test the efficacy of rFOV-EPI for image quality and ADC quantification improvements.

MO-lePD-TRACK 3-06

Dosimetry Impact of Gating Threshold Selection in Cine-MR Image Guided Breath-Hold Pancreatic Cancer Radiotherapy

Y Dong^{1*}, P Hu¹, F Yang², Y Yang¹, (1) University of Science and Technology of China, Hefei, China, (2) University of Miami, Miami, FL

Purpose: To investigate the dosimetry effects of gating threshold selection in cine-MRI guided breath-hold pancreatic cancer radiotherapy. **Methods:** Seventeen pancreatic cancer patients underwent MRI guided breath-hold stereotactic body radiation therapy. The sagittal cine-MRI was used to monitor tumor motion and gate radiation beam. Gross tumor volume (GTV) was set as the tracking target, and a margin of 3-5 mm was used as gating boundary. Beam-off event would not be triggered until the target-out percentage exceeded a predefined gating threshold. We re-generated VMAT plans using 33Gy prescription. We calculated the GTV displacement in each MRI frame that satisfied the gating threshold, shifted the isocenter by the displacement, and then added up all iso-shift plans to create the motion plan. The coverage for GTV and PTV and dose to nearby organs at risk (OARs) were compared between motion plans and original plan. **Results:** The GTV V33Gy was 89.34%±12.58% in the original plan, and 88.53%±12.27%, 88.39%±12.16%, 88.30%±11.91% and 88.26%±11.82% for motion plans generated with 0%, 1%, 3% and 5% gating threshold. ($p>0.05$ for all motion plans). The PTV V33Gy was 97.63%±1.33% in the original plan, and 92.87%±3.16%, 92.32%±3.27%, 91.64%±3.38% and 91.27%±3.34% for motion plans generated with 0%, 1%, 3% and 5% gating threshold. ($p<0.05$ for all motion plans). The duodenum V12.5Gy ($p<0.05$) and V18Gy in the motion plan increased significantly when gating threshold was greater than 2% ($p<0.05$). No significant difference was found for other OARs. No significant difference was found for all parameters between motion plans. **Conclusion:** The dose parameters deteriorate with increasing gating threshold but rendered no difference among thresholds 0-5%. But the efficiency gradually improves with increasing thresholds. A threshold of 3-5% was deemed a reasonable selection considering the tradeoff between effectiveness and efficiency.

Optimization of the imaging Plane for Real-Time Tumor Tracking in MR-Guided Radiotherapy of Moving Targets

K Traeuble¹, P Palaniappan¹, C Gianoli¹, C Paganelli², G Baroni^{2,3}, F Kamp^{4,5}, C Belka^{4,6}, C Kurz⁴, G Landry⁴, M Riboldi^{1*}, (1) Department of Medical Physics, Ludwig-Maximilians-Universität München, Munich, DE (2) Department of Electronics, Information and Bioengineering, Politecnico di Milano, Milano, IT (3) Bioengineering Unit, Centro Nazionale di Adroterapia Oncologica, Pavia, IT (4) Department of Radiation Oncology, LMU University Hospital, Munich, DE (5) Department of Radiation Oncology, University Hospital Cologne, Cologne, DE (6) German Cancer Consortium (DKTK), Munich, DE

Purpose: To provide a patient-specific optimization of the 2D cine-imaging plane in MR-guided radiotherapy with respiratory gating, based on pre-treatment 4D information. **Methods:** The sampling directions in MR imaging can be selected arbitrarily, thus leading to different imaging planes in 2D cine-MR. Our method performs a multi-threaded grid search of candidate planes for cine-MR imaging, whose orientation can be adjusted at user-defined angular steps and total range. The optimization maximizes the peak-to-peak motion amplitude over the tumor trajectory, as depicted in the treatment planning 4D-CT. The GTV contours delineated on the 4D-CT motion phases are processed to create the corresponding ITV. Candidate planes are centered in the center of mass of the ITV, whose cross-sectional area is assumed to be proportional to the motion amplitude sampled with cine-MR. The imaging plane orientation is defined by rotation angles about the principal direction of the ITV, which provide the grid search initialization. The algorithm has been tested on artificial images (ellipsoids and cuboids), where the ground truth motion trace allows determining the optimal plane unambiguously. Finally, the algorithm has been applied to 16 clinical 4D-CT datasets including lung, liver and pancreas tumors. **Results:** The algorithm checked up to 4275 planes, with a computational time proportional to the angular range in the grid search procedure. Optimal planes in the artificial images were returned as expected. In clinical cases, motion in the optimal plane was larger (10.3 mm on average, range [4.1, 17.4] mm) compared to the clinically used sagittal orientation (8.5 mm on average, range [2.3, 13.8] mm). **Conclusion:** An algorithm for the optimization of the cine-MR imaging plane based on pre-treatment 4D-CT images has been implemented and tested. The optimal plane consistently provides a larger motion amplitude compared to the sagittal plane, thus effectively minimizing effects due to out of plane motion.

Automatic Liver Tumor Localization Using a Combined Deep Learning and Biomechanical Model (DL-Bio)

H Shao^{1*}, X Huang², M Folkert³, J Wang⁴, Y Zhang⁵, (1) The University of Texas Southwestern Medical Center, Dallas, TX, (2) Northwestern Memorial Hospital, Chicago, IL, (3) The University of Texas Southwestern Medical Center, Dallas, TX, (4) UT Southwestern Medical Center, Dallas, TX, (5) UT Southwestern Medical Ctr at Dallas, Dallas, TX

Purpose: Liver tumor localization is challenging for X-ray-based image-guided radiotherapy, due to the low tumor contrast against neighboring normal tissues. We developed a liver tumor localization technique through combining 2D-3D deformation, deep-learning, and biomechanical-modeling (DL-Bio) to automatically localize liver tumors through solved deformation-vector-fields (DVF). **Methods:** DL-Bio solves DVFs between planning CT images and new on-board cone-beam projections for tumor contour propagation and localization. It initializes the DVFs through 2D-3D deformation, which solves DVFs by intensity-matching digitally-reconstructed-radiographs of the deformed prior image to on-board cone-beam projections. DL-Bio further applies a deep-learning model to fine-tune the 2D-3D DVFs at the liver boundary, especially for the caudal liver side where lacks sufficient intensity contrast for 2D-3D deformation. The deep-learning model corrects the DVFs at the caudal liver boundary, using a liver surface ring structure, 2D-3D DVFs at the high-contrast cranial liver boundary, and liver boundary motion correlations learnt through model training. Final intra-liver DVFs, including those around the tumor region, were derived with a biomechanical model using the deep-learning-optimized liver boundary DVFs as the boundary condition for finite element analysis. We trained and validated the deep-learning model of DL-Bio using 24 liver patients, and evaluated the combined DL-Bio framework using an independent set of 10 patients. The tumor localization accuracy of DL-Bio was evaluated using the tumor DICE coefficient and center-of-mass-error (COME). **Results:** On a total of 90 evaluation images and tumor contours, the average(±s.d.) liver tumor COMEs of the 2D-3D deformation (2D-3D), 2D-3D deformation with biomechanical-modeling (2D-3D-Bio), and DL-Bio were 4.7±1.9 mm, 2.9±1.0 mm, and 1.7±0.35 mm, respectively. The corresponding average(±s.d.) DICE coefficients were 0.60±0.120, 0.71±0.072, and 0.78±0.028, respectively. **Conclusion:** The deep-learning model of DL-Bio successfully captures the motion correlations at the liver boundaries for DVF correction, and generates more accurate boundary conditions for biomechanical modeling to improve liver tumor localization accuracy.

The study was supported by funding from the National Institutes of Health (R01CA240808) and from the University of Texas Southwestern Medical Center.

Deformable MRI-CT Image Registration Using Self-Similarity Network for Head and Neck Cancer Radiotherapy

Y Fu^{*}, Y Lei, T Wang, J Zhou, M McDonald, J Bradley, T Liu, X Yang, Emory University, Atlanta, GA

Purpose: To propose an unsupervised deep learning-based image registration method for MRI-CT head neck (HN) image registration using image self-similarity descriptors. **Methods:** The MRI and CT images were first separately processed to extract self-similarity descriptors for MRI and CT, respectively. The self-similarity descriptors were obtained by constructing normalized local intensity differences, which was used as local structural descriptors. The self-similarity descriptor for MRI and CT could effectively represent the local image features using the same gray scale, which enables traditional similarity metrics to be used for similarity calculation. An unsupervised network takes the concatenated similarity descriptors and the original images as input and directly predict the deformation vector field (DVF). The network was trained by minimizing the normalized cross correlation loss between the deformed MRI and fixed CT and an additional DVF regularization loss. The network was trained using 20 patients' datasets and evaluated on a separate 10 patients' datasets. **Results:** Our results show that the image alignment at the shoulder region and the image boundaries has greatly improved after registration. Landmarks located at the center of the humeral head and tip of the axis vertebra dens were manually selected to calculate the landmark distance errors. The average landmark distance errors were reduced from 6.13 to 2.92 mm at the center of humeral head, and from 3.98 to 2.62 mm at the tip of the axis dens. **Conclusion:** We have developed a novel unsupervised multimodal image registration method for MRI-CT HN image registration. Taking the combined MRI and CT image and their respective self-similarity descriptors as input, the network performs direct DVF prediction to deformably align the MRI HN images to the CT images for facilitating HN cancer treatment planning.

MO-lePD-TRACK 4-03

Investigation of the Sensitivity of Ventilation Accuracy to the Deformable Image Registration Regularization Parameter

H Byrne^{1,3*}, J Kipritidis², O Dillon¹, J Booth^{2,3}, P Keall¹, (1) ACRF ImageX Institute, Faculty of Medicine and Health, The University of Sydney, Australia, (2) Northern Sydney Cancer Centre, Royal North Shore Hospital, Australia, (3) Institute of Medical Physics, School of Physics, University of Sydney, Australia

Purpose: To investigate the sensitivity of producing accurate ventilation information from deformable image registration (DIR) to the regularization parameter, λ , by comparing DIR-derived ventilation with Galligas PET images for a range of values of λ . **Methods:** Paired inhale/exhale breath hold CT scans and Galligas PET ventilation images were obtained from 8 patients. The exhale CT was deformably registered to the inhale CT for a range of λ from 0.05 to 1.5. Two previously described methods were used to produce ventilation maps: first the Hounsfield unit change between the deformed inhale and exhale image to infer lung density change, second the Jacobian determinant of the deformation vector field to infer air volume change. Three assessment metrics were used (1) Spearman correlation between the CT ventilation maps and the Galligas PET images, (2) percentage of negative values in the Jacobian determinant (indicating singularities in the motion field, see AAPM report TG132) and (3) mean square error between the exhale and deformed inhale CT images. **Results:** Spearman correlations between CT ventilation maps and the Galligas PET images generally increased as λ increased from 0.05 to around 0.75, with the gains stabilizing as λ was increased further. Image match accuracy measured by mean square error increases with smaller λ as expected. However, $\lambda < 0.5$ created motion models implying up to 6.3% of the lung contracted during inhale, and derived ventilation maps using the Jacobian determinant had Spearman correlations as low as 0.20, implying non-physiological deformation. The dependence of the Spearman correlation on λ was more marked for the Jacobian determinant method than the Hounsfield unit method. **Conclusion:** Physiological ventilation information derived from deformable image registration using two ventilation algorithms was benchmarked against Galligas PET as the regularization parameter was varied. The Hounsfield unit algorithm proved robust across the range of λ tested.

This work was supported by two government grants: a Cancer Institute NSW Translational Program Grant and an NHMRC Investigator Grant. Paul Keall is an inventor of a US patent on CT ventilation (#7668357). This patent is owned by Stanford University and is unlicensed.

Learning-Based Multiscale Self-Similarity Descriptors for Non-Rigid MRI-CT Liver Image Registration

Y Fu*, Y Lei, T Wang, J Zhou, M McDonald, J Bradley, P Patel, T Liu, X Yang, Emory University, Atlanta, GA

Purpose: To propose a multi-scale image self-similarity descriptor for non-rigid MRI-CT liver image registration using deep learning-based network. **Methods:** The lack of multimodal image similarity metric is one of the challenges in multimodal image registration. We propose to use multiscale image self-similarity descriptors together with deep learning networks for MRI-CT liver image registration. To capture both the global and local descriptors, a multiscale deep learning network was used. The original MRI and CT images were down-sampled by factors of 8, 4, 2 in a pyramid network architecture. CT and MRI image self-similarity descriptors were calculated by normalizing the image intensity differences in the superior-inferior, anterior-posterior and lateral directions. The normalization of the image similarity descriptor enables the calculation of cross-modality image similarity measure since they share the same gray scale levels for MRI and CT. Normalized cross correlation was maximized between the fixed CT and the deformed MRI using their respective multi-scale image similarity descriptors. We evaluated the proposed network on 40 patients' datasets using five-fold cross validation. The trained network was able to predict the deformation that aligns the MRI to CT in a single shot. **Results:** For evaluation purpose, the MRI liver contours were deformed using the predicted deformation to obtain the liver contours of the deformed MRI. For all patients, the average dice similarity coefficient of liver has increased from 0.89±0.04 before registration to 0.95±0.03 after registration. The alignment of hepatic vessels and liver boundaries have both improved after the proposed non-rigid image registration. **Conclusion:** We have proposed a novel multiscale image self-similarity descriptor for MRI-CT liver image registration. Integrated into an unsupervised registration network, the proposed image similarity descriptors enable direct alignment of the MRI to CT images with high accuracy. This image tool may have a great potential on facilitating the liver radiotherapy treatment planning.

MO-lePD-TRACK 4-05

Training an Unsupervised Deformable Image Registration Model with Thoracic Fast, Low-Dose Helical CT Acquisitions

R Savjani^{1,3*}, P Paysan², D O'Connell¹, J van Heteren³, S Scheib², D Low¹, (1) University of California Los Angeles, Los Angeles, CA (2) Varian Medical Systems Imaging Laboratory, Baden - Daettwil, CH (2) Varian Medical Systems Imaging Laboratory, Baden - Palo Alto, CA (3)

Purpose: Monitoring respiratory motion is critical while patients are undergoing thoracic radiotherapy. Low-dose, fast helical CT scans can capture the variability in respiratory motion while patients are free breathing. These scans have been used previously to fit a model (5DCT) to derive CT volumes from a baseline CT volume, as well as the tidal volume and air flow derived from an external surrogate marker. Here, we leverage these data to apply an unsupervised deep-learning based deformable image registration algorithm (VoxelMorph) to build towards a motion management model. **Methods:** We obtained data from 32 retrospective patients (27 for training, 5 for validation) each scanned with 25 fast, low-dose helical CT acquisitions. A VoxelMorph model was trained at 2-mm resolution using mean square error for image similarity loss with regularization. A random pair of images within each patient served as input, training randomly across patients for a total of 25,000 pairs. The generated deformation vector fields from the model were used to warp each structure to a selected reference volume for each patient. Dice scores between the warped structure and an autosegmentation were computed and also compared to a state-of-the-art algorithm, deeds. **Results:** Median Dice scores were higher than that of deeds on the 5 independent test sets for 19 of 20 structures (stomach was lower). Median Dice scores ranged from 76.2% in the duodenum to >95% in the right and left lungs. On inference, deformations could be generated on the 5DCT VoxelMorph model in less than 1 second on a GPU, whereas deformations for deeds took approximately 10 minutes on CPUs. **Conclusion:** Fast, helical free breathing scanning provides a rich dataset to train deep-learning based image deformation models. Together, this framework is being developed towards developing a rapid motion model to help predict respiratory motion in real-time for radiotherapy.

Using Automatic Segmentation to Improve Deformable Image Registration

K Shah^{1*}, J Shackleford¹, N Kandasamy¹, G Sharp², (1) Drexel University, Philadelphia, PA, (2) Massachusetts General Hospital, Boston, MA

Purpose: Deformable image registration (DIR) aims to find a geometric transformation between corresponding image data and brings them into a common coordinate frame. DIR accuracy can be improved using a hybrid image similarity metric which matches both image intensities and the location of known structures. This work evaluates the application of the point-to-distance map (PD) hybrid similarity metric for DIR when the segmented structures have been created using a deep learning segmentation method. **Methods:** The approach was evaluated using a publicly available head and neck dataset. Brainstem, mandible, larynx, and parotid glands were segmented automatically using a 3D UNet model. Pairs of images with segmented structures were registered using a hybrid similarity metric, which penalizes the distance between structure boundaries. Cubic B-splines were used for the registration transform and sum of squared difference for the intensity similarity. **Results:** Accuracy of the deformable registration was quantified using the Dice Similarity Coefficient (DSC) and 95% Hausdorff Distance (95% HD), with and without the PD metric. Results demonstrate much improved overlap between the fixed and warped contours once the PD metric is applied. For example, with a grid spacing of 40 mm, mean DSC for the larynx increases from 0.72 to 0.8 with the PD metric. The computational overhead associated with adding the PD metric is minimal. **Conclusion:** A PD hybrid similarity metric was found to improve DIR accuracy when the segmented structures were created by deep learning. This means that a significant improvement in terms of registration accuracy can be achieved without resorting to manual contouring.

This material is based upon work supported by the National Science Foundation under Grant Nos. 1553436, 1642345 and 1642380 and the National Institutes of Health under NCI R01CA229178.

Using Neural Networks to Extend Cropped Medical Images for Deformable Registration Among Images with Differing Scan Extents

E McKenzie^{1*}, N Tong², D Ruan¹, M Cao¹, R Chin¹, K Sheng¹, (1) UCLA, Los Angeles, CA, (2) Xidian University, Xi'an CN

Purpose: To improve deformable image registration (DIR) among images with different scan extents, we train a neural network that fills the missing volume of head-and-neck CT's. **Methods:** We trained a generative adversarial network on a dataset of 409 head-and-neck CT's to predict anatomy in the missing volume using the cropped 3D images as input. The network used a U-Net generator with VGG deep feature losses. To test the DIR improvement, we deformably registered combinations of a randomly cropped, full, and predicted full volume on 53 unseen test volumes to a single cropped, full, and predicted full target. We tested our method's robustness by performing the same registration combinations with progressively increasing the amount of cropping. Registration performance was measured using 95% Hausdorff distance across 16 contours. **Results:** We successfully trained a network to recover large missing volumes of incomplete images. Registration with predicted full images was not significantly different from registration using original full images. The average contour matching error for full image registration was 9.9mm, while our method was 11.6mm, 12.1mm, and 13.6mm for predicted-to-full, full-to-predicted, and predicted-to-predicted registrations, respectively. Registration of the cropped images had errors of 31.7mm and higher. Plotting the registered image contour error as a function of the initial error shows that our method is robust to registration difficulty. Predicted-to-full registration was statistically independent of cropping extent up to 18.7cm superiorly cropped. Predicted-to-predicted registration was robust, with a -0.04mm change in average contour error for every millimeter of cropping. **Conclusion:** Differences in scan extent is a major contributor to inaccuracies in deformable image registration. We address this by training a network to complete cropped 3D images. Predicted full images can be registered to the same accuracy as full images and are robust to differences in crop extent.

Neuro-Fuzzy Guided Objective Function Parameter Optimization of Inverse Treatment Planning

E Cisternas Jimenez*, F Yin, Duke University, Chapel Hill, NC

Purpose: IMRT is a complex, multi-criteria issue, which contains various non-linear relationships. The tuning for the weighting factors in the objective function for an IMRT plan is driven by humans to achieve an ideal dose distribution. This is done manually in a tedious and time-consuming process based on trial and error and user experience. This work aims to develop a neuro-fuzzy guided system to automate the tuning process. **Methods:** A machine learning technique, based on an adaptive network fuzzy inference system (ANFIS), was used. It integrates both fuzzy inference systems (FIS) and neural network (NN) principles. FIS logic theory has been widely used for IMRT optimization. There are criticisms that most studies use pre-defined simple linear membership functions and fuzzy rules, which are derived from experts' knowledge. However, IMRT contains various non-linear relationships. This study explores a new approach using ANFIS to tune parameters of the FIS model to increase the exactness of the AI model. The capability and the accuracy of FIS and ANFIS were analyzed and compared against each other. **Results:** The algorithm's performance was examined using the C-Shape TG119 IMRT phantom. The experimental results showed that ANFIS is an effective way to build an optimal FIS, and analysis of ANFIS showed improvement on both DVH and dose distribution. Using ANFIS, the OAR volume encompassed by characteristic percentages of isodose was reduced by 15%. The ANFIS guided inverse planning system is capable of finding the optimal combination of weighting factors for different structures, finding an optimal balance between the target and the critical organ dose by finding an optimal set of weighting factors. **Conclusion:** It is feasible to automatically tune the weighting factors for an IMRT plan under the guidance of an optimized FIS without human intervention other than providing the treatment plan parameters and set of constraints.

Solving the Non-Convex Volumetric Modulated Arc Therapy (VMAT) Problem Via a Sequence of Convex Optimization Problems

P Dursun*, G Jhanwar, J Deasy, M Zarepisheh, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: Volumetric modulated arc therapy (VMAT) optimization problem is a complex and highly non-convex problem and existing algorithms suffer from local optimality. We propose a novel sequential convex programming (SCP) algorithm that directly optimizes aperture shapes and promotes delivery efficiency and global optimality. **Methods:** We propose an algorithm for VMAT that conducts an effective global search by solving a sequence of convex local approximations. The algorithm starts with optimizing the aperture weights of 72 evenly distributed beams using the beam's eye view (BEV) of the target from each direction. Thereafter, a convex approximation problem is solved to optimize the leaf positions and the aperture weights within a search space where the leaves can move in and out within a pre-defined step-size. There are both local and global search strategies in the algorithm to ensure a high-quality plan. The complexity of the apertures is constrained, to exclude highly irregular aperture shapes, and is also penalized in the objective function to increase shape regularity. The algorithm is tested on paraspinal, prostate and oligometastasis sites. The VMAT plans are compared against ideal 72-beam IMRT plans. Also, the performance of aperture regularization strategies is analyzed.

Results: The DVHs of the optimized VMAT plans are similar to 72-beam IMRT plans. Due to the convexity of the resultant sub-problems, the algorithm is computationally tractable, converging in less than an hour on average on a regular Windows workstation. Significant reductions in aperture complexity at a reasonable cost of plan quality are observed after adding constraints and the aperture complexity regularization term in the objective function. **Conclusion:** We developed a computationally efficient algorithm for VMAT which finds a near-global optimal solution by alternating large (global) and small (local) search steps. Aperture complexity is effectively constrained (hard constraint) and penalized (objective function) to produce efficient delivery plans.

MO-lePD-TRACK 5-03

Characterization and Optimization of GRID Treatment Planning

Y Cho*, S Chao, B Guo, J Suh, Cleveland Clinic Foundation, Cleveland, OH

Purpose: Spatially fractionated radiation therapy or GRID is known to be effective to treat bulky mass in breast and head & neck tumors. Biological mechanism includes abscopal effect, escalated damage to endothelial cells and immune system activation. Difference in radiation damage to healthy tissue and tumor cell due to the heterogeneous dose distribution in GRID treatment can be evaluated using therapeutic ratio (TR) defined by the surviving fraction (SF) in normal tissue with GRID dose distribution to the equivalent uniform dose (EUD) with which SF of tumor is maintained. In this study, the efficacy of GRID dose distribution is characterized as a function of collimator design, beam energy, depth of tumor, dose fraction size and tumor type. **Methods:** Dose distribution in water phantom was acquired in the treatment planning system, Pinnacle, using three different GRID collimators of 10mm, 12mm, and 14mm with separation of 21mm as well as fluence pattern of 10mm by 10mm segments with 17mm separation using MLCs. Three different beam energies of 6MV, 10MV and 15MV were used with the GRID field size of 10cm x 10cm. Dose was prescribed at depth of 5cm. Dose volume histogram (DVH) in the phantom was collected in every 1cm depth. Three different tumor type (radio-resistance, semi-resistance, and radiosensitive) were considered. **Results:** The maximum TR was found at the depth of dose maximum in each beam energy for all collimator design. For the same prescription dose of 15Gy, TR at depth of 5cm increased by 12%-21% and 13-26% from 6MV-to-10MV and 6MV-to-15MV, respectively. EUD for tumor also increased by 22%-32% and 24%-33%. To maintain the same EUD of 5.5Gy for tumor, the low energy photon of 6MV required 27%-59% and 28%-65% more prescription dose compared to 10MV and 15MV, respectively. TR increased with the ratio of collimator opening in the order of 10mm, 12mm, 14mm and MLCs. **Conclusion:** The TR and EUD of tumor is characterized to optimize the efficacy of GRID planning.

Development of Plan Complexity Mitigation Algorithm for VMAT

T Ono*, M Nakamura², T Mizowaki¹, (1)Department of Radiation Oncology and Image-applied Therapy, Graduate School of Medicine, Kyoto University, Kyoto, Japan, (2) Division of Medical Physics, Department of Information Technology and Medical Engineering, Human Health Sciences, Kyoto University Graduate School of Medicine, Kyoto, Japan

Purpose: The purpose of this study was to develop an algorithm to mitigate plan complexity in volumetric-modulated arc therapy (VMAT) and to evaluate its usefulness. **Methods:** Twenty patients who underwent VMAT (including seven Dynamic WaveArc plans) between September 2015 and December 2020 were enrolled in this study. Clinical sites included the brain (n=6), head and neck (n=2), lungs (n=3), esophagus (n=3), whole pelvis (n=3), and prostate (n=3). Patients with less than 85% gamma passing rate (GPR) of 3%/2mm were arbitrarily selected. Using the GPR prediction model we previously developed, we identified the leaf positions responsible for the decrease in GPR. Using a limited nonlinear algorithm, the multi-leaf collimator (MLC) positions were optimized within the mechanical limitations. The dose prescription for the target was re-normalized, and the monitor unit (MU) was modified. The Modulated Complexity Score (MCS), average aperture area (AA: mm²), and MU/Gy were evaluated to determine the difference in plan complexity between the optimized and original plans. The calculated doses were evaluated for the target and surrounding organs. Additionally, the ArcCHECK cylindrical diode array was used to measure the dose, and GPR (5%/1 mm) and GPR (3%/2 mm) were evaluated to determine the difference between the optimized and original plans. Differences were presented as means $\pm$ standard deviations. **Results:** The differences in plan complexity parameters between the optimized and original plans were $4.3 \pm 2.7 \times 10^{-3}$ for MCS, 67.6 ± 113.3 mm² for AA, and -0.3 ± 1.3 MU/Gy, respectively. For the calculated dose, dose volume histograms were within 1% for the target and surrounding organs. The difference of GPR between optimized and original plans were $0.9 \pm 1.1\%$ point (%p) for GPR (5%/1 mm) and $1.0 \pm 1.8\%$ p for GPR (3%/2 mm). The GPRs were slightly improved with the optimized plans. **Conclusion:** The developed algorithm could mitigate plan complexity and improve GPR with minor leaf position modifications for VMAT.

IMRT Treatment Planning Study for the First Clinical Biology-Guided Radiotherapy System

D Pham*, D Breitkreutz, E Simiele, D Capaldi, L Vitzthum, M Gensheimer, H Bagshaw, B Han, M Surucu, L Xing, D Chang, N Kovalchuk, Stanford University School of Medicine, Stanford, CA

Purpose: The first clinical biology-guided radiotherapy (BgRT) system – RefleXion X1 - is installed and being commissioned for clinical use at our institution. RefleXion X1 is a 6MV-FFF linac mounted on a ring gantry rotating at 60 rpm while the couch advances in 2.1mm increments. The modulation is achieved via 50 firing positions with 64 binary MLCs (6.25mm at 85cm SAD) with either 1cm or 2cm jaws. This study was conducted to compare the treatment plan quality for IMRT cases without PET-guidance. **Methods:** Nineteen patients previously treated with VMAT on C-arm linacs were selected for this retrospective study including 8 prostate cancer patients (80Gy/40fx), 6 lung cancer patients (66Gy/30fx) and 5 post-surgical parotid cancer patients (60Gy–66Gy/30fx). For each VMAT plan, a corresponding plan was generated on the RefleXion treatment planning system (TPS) using our institutional planning constraints. All clinically relevant metrics in this study, including plan PTV D95%, PTV D1%, Conformity Index (CI), and organs at risk constraints were analyzed and compared between the VMAT and RefleXion plans using paired t-tests. **Results:** Clinically acceptable plans were obtained with both techniques. For the prostate, lung, and head and neck sites, no statistically significant difference was observed in PTV D95%, PTV D1%, or CI between the VMAT and RefleXion treatment plans. Due to inherent OAR dose penalties in the RefleXion optimizer, dose reduction to certain critical structures was observed in RefleXion plans: brainstem Dmax (-4.8Gy, p<0.008), contralateral cochlea Dmean (-4.8Gy, p<0.01), lips Dmax (-3.5Gy, p<0.007) for head and neck cases; esophagus Dmean (-2.3Gy, p<0.039), spinal cord Dmax (-3.6Gy, p<0.001) for lung cases; femurs left and right Dmax (-4.8Gy, p<0.003 and -5.0Gy, p<0.01) and rectum V75% (-1.6%, p<0.01) for prostate cases. **Conclusion:** The RefleXion TPS provided comparable plan quality to VMAT plans with slightly superior OAR sparing.

NYU Clinical Experience with Total Body Irradiation: From 3D Laterals to Image-Guided VMAT

P Galavis*, C Hitchen, A McCarthy, M Malin, S Taneja, S Ayyalasomayajula, Y Yuan, N Gerber, D Barbee, J Teruel, NYU Langone Medical Center, New York, NY

Purpose: Patients receiving myeloablative total body irradiation (TBI) doses ≥ 12 Gy are at risk of developing interstitial pneumonitis. At our institution, TBI transitioned from extended distance opposed Laterals to image-guided VMAT, in an effort to improve coverage while sparing lungs and kidneys. This work presents a dosimetric comparison between 3D Laterals and VMAT. **Methods:** Nine patients were treated with VMAT as part of an ongoing phase II single-arm clinical trial. VMAT patients were CT-simulated supine, with thermoplastic masks for head/neck, chest/abdomen/pelvis and feet. VMAT planning (12Gy (n=6) or 13.2Gy (n=3) in 8-BID fractions) utilizes 6MV multi-isocentric arcs and AP/PA beams to treat the upper and lower body, respectively. Ten 3D Lateral patients were CT-simulated supine with arms positioned/immobilized for lung shielding, with rice compensation between legs/feet. Laterals plan (12Gy in 8-BID fractions) uses 15MV, beam

spoiler, head compensation, and subfields to maintain coverage and mean-lungs dose <10.5Gy. Target (Body-5mm, extending 3mm into lungs and kidneys for VMAT; Body-2cm for Laterals) coverage was evaluated at V100%, and D98% (percentage of Rx). Absolute dose to lungs and kidneys were reported. **Results:** Median Target V100% and D98% for VMAT was 93.2% (Range: 95.6% to 92.1%) and 90.2% (94.3% to 88.3%), whereas for Laterals V100% and D98% was 57.3% (66.5% to 46.3%) and 80.6% (75.5% to 84%). The median Lung mean dose was 7.6Gy (7.3Gy to 7.9Gy) for VMAT. The median mean dose to kidney was 10.4Gy (10.1Gy to 10.7Gy) for VMAT, and 12.5Gy (11.9Gy to 13.5Gy) for Laterals. **Conclusion:** We have established a VMAT-TBI program for patients requiring myeloablative irradiation. Improvement in target coverage is demonstrated by V100% and D98%, while reducing the mean dose to the lungs significantly from 10.5Gy to 8Gy.

MO-lePD-TRACK 5-07

Using the Pareto Optimal Projection Search (POPS) Algorithm for Fully Automated Treatment Planning

C Huang*, Y Yang, Y Nomura, L Xing, Stanford University, Stanford, CA

Purpose: Radiation therapy treatment planning has traditionally been a time-consuming process with potentially high inter-planner variability. The Pareto optimal projection search (POPS) algorithm, which produces Pareto optimal and clinically acceptable plans, provides a fully automated framework for treatment planning without requiring any active planning. **Methods:** The POPS algorithm searches the feasibility boundary for desirable plans, as defined by a scoring function. Overall, POPS has two main components—gradient-free search in the decision variable space and projection of decision variables to the Pareto front using the bisection method. As treatment plan evaluation is highly nuanced with many candidate scoring functions available in literature, we evaluate the performance of the POPS automated plans under the following two conditions: 1) when POPS performs plan scoring using a normalized equivalent uniform dose (NEUD) metric and 2) when POPS performs plan scoring using a scoring function (SF) based on dose-volume histogram (DVH) limits. **Results:** Treatment plans were generated automatically using the POPS algorithm for a dataset of 21 prostate cases collected as part of clinical workflow. Dose conformity, dose homogeneity, and sparing of organs-at-risk are assessed using a Wilcoxon signed-rank test. In general, plans generated using the POPS algorithm were of high quality. Plans scored using the NEUD metric had improved conformity and comparable homogeneity as compared to plans scored using the SF score. Sparing of organs-at-risk for POPS generated plans was also comparable when using either of the scoring functions. **Conclusion:** The POPS algorithm allows for fully automated treatment planning and produces plans that are Pareto optimal and clinically acceptable. We anticipate that POPS will substantially improve treatment planning workflow.

Quantifying of the Afterglow Effect from a Chromium-Doped Alumina Scintillator Following Proton Irradiation

T Geoghegan^{1*}, K Patwardhan¹, B Smith¹, R Flynn¹, J Yu², A Gutierrez², D Hyer¹, (1) University of Iowa Hospital and Clinics, Iowa City, IA, (2) Miami Cancer Institute, Baptist Health South Florida, Miami, FL

Purpose: The purpose of this work was to investigate the afterglow effect, which refers to continued light emittance post-irradiation, of a chromium-doped alumina scintillation screen (Chromox) when irradiated with a proton beam. To our knowledge, the afterglow effect has not previously been quantified in the literature. **Methods:** Chromox is a desirable scintillation material for visualization of proton beam profiles due to its high light yield and radiation hardness. The afterglow effect was studied using a clinical IBA Proteus Plus delivery system to irradiate a 1 mm thick 10x10 cm² Chromox scintillation screen. A uniform planar dose (7x7 cm²) with a single energy (150 MeV and 9125 total monitor units) was delivered to the screen. Following the irradiation, the afterglow images were acquired every 3 minutes for 18 minutes. **Results:** The afterglow was still detectable after 10 minutes using an IR-filtered camera with the exposure time set to 7 seconds. The afterglow half-life was calculated to be approximately 110 seconds. **Conclusion:** While Chromox appears to be very suitable for static beam diagnostics, the afterglow will be present if consecutive, varied images are acquired. Ideally, use of a Chromox scintillation screen should be limited to applications that require a high light output for single static exposures. In some applications, the afterglow could be viewed as an advantage as imaging can be completed post exposure rather than in real time.

Research reported in this abstract was supported by the National Cancer Institute of the National Institutes of Health under award number R37CA226518. Hyer and Flynn are co-inventors on a patent that has been licensed to IBA.

Investigations of a Novel Hyperscint™ Plastic Scintillator Detector and Hyperspectral Analysis Approach in a 74 MeV Proton Beam

C Duzenli^{1*}, C Hoehr², C Belanger-champagne², C Penner², V Strgar², (1) British Columbia Cancer Agency, Vancouver, BC, CA, (2) TRIUMF, Vancouver, BC, CA, (3) University of British Columbia, BC, CA

Purpose: A novel plastic scintillator and spectral analysis approach (Hyperscint™) was investigated in a 74 MeV proton beam for stem effect, dose and dose rate response, and suitability to provide a Cerenkov-free reference spectrum for use in MV x-ray dose calibrations. **Methods:** Irradiations were performed in a passively scattered 74 MeV horizontal proton beam line with a 2.5 cm circular field aperture. The plastic scintillator detector (PSD) was 1 mm in diameter and 1 mm in length, coupled to the spectrometer with PMMA optical fibre. The probe was positioned at the centre of a 2 cm spread out Bragg peak in polystyrene phantom 7 cm distal to the proton nozzle. Doses from 200 cGy to 5000 cGy were delivered using the nominal 6 nA beam current, followed by comparison with 1 nA, 2 nA, and 10 nA beam currents. The optical emission spectrum in the proton beam was compared with that acquired in a 150 kVp ortho-voltage x-ray beam, to assess suitability for use as a Cerenkov-free reference spectrum. Stem effect was further investigated in the proton beam by irradiating the fibre cable alone. **Results:** The 74 MeV proton beam and 150 kVp x-ray beam produced indistinguishable Cerenkov-free optical emission spectra in the PSD. Integrated area under the spectral curve was linear with dose and independent of dose rate. Optical fibre emission was observed to increase with length of cable irradiated at 0.1 % of the PSD signal per cm of irradiated cable. **Conclusion:** The Hyperscint™ dosimetry system shows potential for dose measurement in a 74 MeV proton beam with negligible stem effect. The Cerenkov free spectrum may be used to facilitate calibration of the device in MV x-ray beams to improve Cerenkov removal and performance in small field dosimetry.

Development of a Novel Hybrid Scintillation-Cerenkov Detector for Simultaneous Dose and Irradiation Angle Measurements

E Jean<sup>1^{2*, S Lambert-girard³, F Theriault-Proulx³, L Beaulieu¹, (1) CHU de Quebec - Universite Laval, Quebec, QC, (2) CHAUR, Trois-Rivieres, QC, (3) Medscint Inc., Quebec, QC}

Purpose: This study introduces a novel hybrid detector capable of simultaneous dose and direct irradiation angle measurements based on Cerenkov angular dependency. **Methods:** A Cerenkov probe composed of a 10-mm long sensitive volume of clear PMMA fiber separated by an absorptive filter from a 1-mm diameter

transport fiber was built. Filtered and raw Cerenkov signals respectively from the sensitive volume and the transport fiber were collected using the Hyperscint RP-200 scintillation dosimetry platform (Medscint, Quebec, QC). An independent scintillation probe composed of 10-mm BCF12 scintillating fiber (Saint-Gobain, Hiram, OH) was also used for simultaneous dose measurements. Dose calibration of each detector signal was accomplished with repeated irradiations of 200 cGy (6 and 18 MV) and the total signal was deconvolved using a hyperspectral approach. Using a solid-water phantom, measurements at fixed incident angles covering a wide range of doses, dose rates as well as output factors were realized. A cylindrical phantom was then used to obtain an angular calibration curve for fixed dose irradiations and perform irradiation angle measurements. **Results:** For fixed incident angle, signal characterization of the Cerenkov detector displays a linear dose-light relationship for the whole range of doses and dose rates tested. The sensitive volume signal shows a discrepancy with the predicted dose that reaches 1.1 % for the lowest dose rate. Output factors were accurately measured within ± 0.8 % for field size up to 25×25 cm². Irradiation angle measurements using various doses exhibit an absolute mean error of 1.86° and 1.02° at 6 and 18 MV, respectively. **Conclusion:** The ability to measure both irradiation angle and dose from a clinical photon beam using novel hybrid scintillation-Cerenkov detector was shown. These results offer promising perspectives for future applications in external beam radiotherapy, especially for stereotactic radiosurgery (SRS) and magnetic resonance image-guided radiotherapy (MR-IGRT).

This work was supported by the Natural Sciences and Engineering Research Council of Canada (NSERC) and the Fellowships Program of the Ministère de la Santé et des Services Sociaux du Québec (MSSS). MO-lePD-TRACK 6-04

Output Constancy of the W2 Scintillator in Flattening Filter Free Fields in a Medical Linac

S Thrower^{1*}, S Holmes², S Prajapati¹, E Schueler¹, S Beddar¹, (1) UT MD Anderson Cancer Center, Houston, TX, (2) Standard Imaging, Inc., Middleton, WI

Purpose: Ion chambers are prone to saturation effects at the dose rates delivered by modern flattening filter free (FFF) beams. The purpose of this work is to characterize the dose linearity and dose rate constancy of an Exradin W2 scintillator in a FFF beam as a potential alternative to ion chambers for FFF beam dosimetry. **Methods:** An Exradin W2 scintillator detector was placed at reference conditions (100cm SSD, 10cmx10cm field, depth of dmax). All measurements were taken in a 10MV FFF beam calibrated to deliver 1cGy/MU at reference conditions according to AAPM-TG51 protocol. Cerenkov light ratio corrections were computed according to the manufacturer's instructions. The W2 output was calibrated by defining the reading from 100MU at the reference point as 100cGy. To test the linearity of the response with delivered dose, 200, 400, 600, and 800cGy were delivered at dose rates of 800 and 2400MU/min. To test the detector's constancy with dose rate, 100MU was delivered at nominal dose rates of 400, 800, 1200, 1600, 2000, and 2400MU/min. The measurements were repeated at 90cm and 80cm SSD, where the inverse-square adjusted dose rates are higher than the nominal rates, reaching a maximum of 3750cGy/min. The dose rate constancy was quantified by evaluating the standard error (std/expected value) of the measurements at each dose rate. **Results:** At 800 and 2400 MU/min, the difference between measured and delivered dose was <0.15%; and the slope of the linear fit of the data was 0.99 and 1.00, respectively. The standard error across dose rates were 0.04%, 0.04%, and 0.06% for measurements at 100cm, 90cm, and 80cm SSD, respectively. **Conclusion:** The W2 produces consistent readings up to 3750cGy/min without showing any saturation effects, and therefore may be a better choice than an ion chamber for dosimetry of FFF beams.

The authors would like to thank Standard Imaging for their guidance and for providing the W2 detector so that we could perform this study.

Geometry Optimization and Optical Sectioning for In-Water Cherenkov Dosimetry of Large and Small Photon Beams

Y Zlateva^{1*}, B Muir², I El Naqa³, J Seuntjens⁴, (1) Duke University, Durham, NC, (2) National Research Council, Ottawa, ON, (3) Moffitt Cancer Center, Tampa, FL, (4) McGill University, Montreal, QC

Purpose: Cherenkov emission (CE)-based dosimetry is an emerging technique that is especially promising for small-field measurements. Here, we present Monte Carlo (MC) simulations and relative experimental validation of photon-beam CE, optimize detection angle geometry, and simulate optical sectioning in a small field with added noise. **Methods:** Additional photon beam experimental validation is provided for a previously-published MC code. Both large and small fields are measured at 90° to beam in water with lenses focusing into a fiber+CCD. Small field measurements are 1D with field size varied only transverse to the optical axis (10x10 to 0.5x10 cm²), pending detector development. Optimization of polar angle (relative to beam) and aperture is performed for a 10 MV photon beam MC model, on percent-depth dose-CE (PDD-PDC) root-mean-squared error and Gamma index, with consideration of convenience. In addition, we simulate 1D (along optical axis) optical sectioning of a 5x5-cm² small-field Matlab model, assuming diffraction-limited optics and using the theoretical PSF with added Poisson noise. Based on these findings and the literature, the achievable detection system specifications and potential costs are laid out. **Results:** Measurements and simulations were in agreement within uncertainty (<1% for 10x10 cm², <7% for 0.5x10 cm²). Optimal detection included multiple angles, but a sufficiently accurate single-angle compromise was 57.5° $\pm$ 5.0° [uncertainty (k=1): 1.2%/0.3mm in build-up and 0.2% in drop-off, with <1mm upstream shift in build-up and <0.5% correction in drop-off]. The optical sectioning test case and accompanying analysis revealed that shot-noise limited detection should be possible and reasonably priced, with expected system quantum efficiency >90%, $\pm 2.5^\circ$ polar angle resolution, short acquisition times (~seconds), sensitive volume of 0.0013 mm³ (5 μ m along optical axis), and traceable calibration uncertainty of 0.5%. **Conclusion:** These findings indicate that, especially for small fields, optical sectioning may be an attractive (viz. accurate and affordable) dosimetry alternative, unique to CE.

Effects of Shipping and Handling On a DNA-Based Detector

T Schulze^{1*}, H Nusrat², G Pang³, M Tambasco⁴, (1) SDSU, San Diego, CA, (2) Sunnybrook Health Sciences Center, Toronto, ON, (3) Odette Cancer Centre, Toronto, ON, CA, (4) San Diego State University, San Diego, CA

Purpose: Our lab has developed a DNA-based detector that uses plasmid DNA as a biosensor of DNA damage from ionizing radiation. We aimed to quantify the effects of shipping and handling on the stability of DNA detector readings to assess radiobiological damage. **Methods:** DNA detectors were constructed by pipetting plasmid DNA, pBR322 (Thermo Fisher Scientific, Inc.), into nine 6.28 mm³ cylindrical wells drilled into biocompatible near tissue equivalent material (polycarbonate). Each well contained 3 μ l of DNA solution with a concentration of 12 ng/ μ l for a total of 27 μ l per detector. Each detector was sealed using aluminum foil seals. One control and two detectors to be irradiated to 20 and 30 Gy, respectively, using the XStrahl 300 orthovoltage unit, were shipped on ice in an insulated box via FedEx airmail from San Diego State University (SDSU), San Diego, USA, to Odette Cancer Centre Sunnybrook, Toronto, Canada following biomaterials shipment guidelines. A stationary control was kept at -20 °C at SDSU. The detectors were shipped back to SDSU via FedEx airmail. Agarose gel electrophoresis was used to separate the plasmid DNA open circular, linear, and supercoiled isoform bands corresponding to single strand breaks (SSBs), double strand breaks (DSBs), and no strand breaks, respectively. The gel band intensities were imaged to quantify the relative SSBs and DSBs. **Results:** Total shipment distance and time was 8300 km in ~3.6 days. The shipped controls resulted in mean increases of 18.3 $\pm$ 3.0% and 1.64 $\pm$ 0.30% in the SSBs and DSBs, respectively. Adjusted for these changes, the 20 and 30 Gy irradiated samples showed DNA DSB damage of 4.73 $\pm$ 1.10% and 8.26 $\pm$ 0.67%, respectively. **Conclusion:** Increases in SSBs and DSBs occurred with shipping and handling of the DNA. However, relative damage between the shipped and stationary control can be used to quantify DNA damage in the irradiated detectors.

MO-lePD-TRACK 6-07

Evaluation of a New High-Resolution Digital Detector Array for SRS and SBRT Quality Assurance

A Rusnak^{1*}, C Collins², Z Saleh^{1,2}, G Cardarelli^{1,2}, E Klein^{1,2} and Y Yang^{1,2}, (1) Brown University, Providence, RI, (2) Rhode Island Hospital, Providence, RI

Purpose: The myQA SRS device is a recently developed 2D digital detector array dedicated for patient specific quality assurance (QA) and commissioning of stereotactic radiosurgery (SRS) and stereotactic body radiation therapy (SBRT). A preliminary investigation was performed to evaluate the performance of this high-resolution device for clinical use. **Methods:** The myQA SRS device came with the SRS phantom and three different inserts for film and ion chamber measurements. It provided an active area of 120x140mm² and exploited complementary metal-oxide-semiconductor (CMOS) technology. Five clinically treated SRS/SBRT plans were randomly selected and evaluated. All treatment plans were originally planned in RayStation (V8.0A) treatment planning system (TPS) with VMAT using 6FFF. The QA plans were then generated on scanned CT images of the myQA SRS device within the SRS phantom and delivered on a Varian Truebeam linac equipped with HD MLCs. The same QA plans were also measured with EBT3 radiochromic film using the film insert for absolute dosimetry comparison. Gamma index analysis was performed with 1mm distance to agreement (DTA) and 3% absolute global dose difference (DD) using myQA Patient software. **Results:** The large active area allowed myQA SRS to measure dose to multiple targets in one measurement. The CMOS technology provided a spatial resolution of 0.4mm. With 1mm DTA and 3% DD criteria and 10% threshold, the average gamma passing rate of TPS compared to myQA SRS and EBT3 film was 99.5% and 99.1%, respectively. The average gamma passing rate of myQA SRS measurement compared to EBT3 film was 96.0%. **Conclusion:** The myQA SRS device was evaluated for patient specific QA with both SRS and SBRT treatment plans. Gamma analysis demonstrated that myQA SRS provided accurate dose measurements for small field. The large active area and high resolution improved the VMAT QA efficiency for single isocenter multiple targets SRS plans.

TU-A-TRACK 1-01**Introduction****TU-A-TRACK 1-02****G. White, Medical Physics Services:****Ethics in Medical Physics: The AAPM Perspective****TU-A-TRACK 1-03****G. Loreti, International Atomic Energy Agency:****Ethics in Medical Physics: The IAEA Perspective****TU-A-TRACK 1-04****C. Skourou, Beaumont Hospital:****Ethics in Translation****TU-A-TRACK 1-05****Discussion and Audience Q&A**

The AAPM has developed a code of ethics to guide professional conduct, as well as a published curriculum to educate medical physics residents in ethics. This symposium seeks to promote a conversation in the field of ethics as it pertains to global medical physics practice and outreach. The IAEA has identified a lack of awareness of the importance of ethics and its potential to strengthen professional behavior, e.g. the need for competencies to encourage medical physics professionals to question and raise ethical dilemmas in daily practice. Wider recognition of medical physics as a health profession and more exposure to ethics in medical physics education, are key to addressing challenges in ethical behavior.

Learning Objectives:

1. Realize the extent to which ethical principles can be applied to practice, procedures and tools
2. Explain the importance of awareness of ethics in global activities and cooperation
3. Explore what the AAPM and IAEA can do to promote education in ethics for medical physics worldwide by sharing experiences and supporting international initiatives

Imaging Scientific Session**TRACK 2****Radiography and Fluoroscopy****TU-A-TRACK 2-01****BEST IN PHYSICS (IMAGING): 3D Assessment of Complex Spine Deformity Using Linear Tomosynthesis and Statistical Shape Model Registration**

C Zhao^{1*}, M Herbst², T Weber², S Vogt², L Ritschl², S Kappler², A Margalit¹, A Jain¹, J Siewerdsen¹, W Zbijewski¹, (1) Johns Hopkins University, Baltimore, MD, (2) Siemens Healthineers, Forchheim, Germany

Purpose: Spine deformities (e.g. pediatric scoliosis and kyphosis) are conventionally evaluated using anteroposterior (AP) and lateral (LAT) long-view radiography or slot-scans. However, the evaluation of vertebral axial rotation is not possible in two-view planar imaging. We investigate the feasibility of comprehensive 3D assessment of spine deformity using linear unidirectional tomosynthesis (AP only) augmented with 3D-2D registration of a vertebral statistical shape model (SSM). **Methods:** We consider an imaging protocol involving a longitudinal linear scan (1cm translation/view) of the x-ray source and flat-panel detector (varied collimation: 5x40 cm to 20x40 cm, 0.3 mm pixel) to acquire AP projections of the entire spine (180 - 60 views depending on collimation). Such scans can be implemented using a variety of robotic x-ray systems. To obtain 3D pose of an individual vertebra, its SSM was 3D-2D registered to the tomosynthesis projections. Feasibility studies utilized a previously validated high-fidelity x-ray system simulation framework. A digital pediatric anthropomorphic phantom with the capability to introduce spine deformations was developed. The accuracy of the 3D-2D SSM registration was tested on 120 instances with randomized initialization errors (± 10 mm in translations and $\pm 10^\circ$ in rotations, 60 instances each for normal and deformed spines). Radiation dose was varied 1 - 5 mAs/view. **Results:** The 20x40 cm collimation (60 views covering 60 cm length) provided sufficient depth information to accurately estimate 3D vertebral pose. For both normal and deformed spine, coronal plane translations and rotations were measured with less than ± 1 mm and $\pm 2^\circ$ errors. Vertebral axial rotation errors were $< \pm 3^\circ$; AP translation errors were within ± 5 mm. The registration was robust down to 2 mAs/view exposure, corresponding to ~ 0.11 mGy mean dose to the spine (estimated by Monte Carlo simulation). **Conclusion:** 3D-2D SSM registration using AP linear tomosynthesis achieves reliable 3D quantification of lumbar spine deformity with modest radiation dose.

Work supported by academic-industry collaboration with Siemens Healthineers, XP Division

TU-A-TRACK 2-02**A Framework for Calculating 2D Wall Shear Stress (WSS) In-Vitro Using 1000 Fps High-Speed Angiography (HSA)**

A Shields*, D Bednarek, S Rudin, University at Buffalo (SUNY) School of Medicine, Buffalo, NY

Purpose: There is evidence that wall shear stress (WSS), or the frictional force of flowing blood on the vessel wall, is involved in the pathogenesis of aneurysms and vessel stenoses. The objective of this investigation was to create a framework for calculation of 2D WSS using velocity distributions extracted from high-speed angiography (HSA) sequences. The impact of different parameters on WSS estimation was explored. **Methods:** A 3D-printed patient-specific basilar-aneurysm model was imaged under constant-flow conditions using 1000-fps HSA. The average/maximum velocity values were determined pixelwise over the flow sequence to create velocity-mapping distributions. At each coordinate position along the vessel wall a normal vector was defined, along which the X/Y-components of velocity vectors were indexed with increasing distance from the wall. It was assumed that there is no flow through the vessel wall, i.e. the velocity at the wall was forced to zero. The shear rates were obtained from the spatial gradients of fitted curves, or the rate of change of tangential-velocity values along the direction of the normal. The effect

of tangential-velocity curve fitting parameters was investigated. **Results:** The proposed framework for calculating 2D WSS allows for manipulation of parameters such as the number and spacing of points used along the normal vector. Finer resolution of data points allows for truer estimation of velocity nearest the wall, the tradeoff being increased noise. Smoothing splines produced the best fit for tangential-velocity curves. The highest WSS values were found along the aneurysm dome, as well as the bifurcation region between the outflow vessels and aneurysm sac where the flow impinges on the wall. **Conclusion:** A method to obtain average and peak WSS per pixel from in-vitro HSA sequences was described. The application of this method to HSA sequences has the potential to provide clinically useful information during a vascular intervention.

Development of a Hybrid Direct-Indirect Active Matrix Flat Panel Imager for Digital Radiography

A Howansky^{1*}, A Mishchenko², S Leveille², S Dow¹, C Orlik¹, J Stavro¹, A Goldan¹, J Scheuermann³, A R Lubinsky¹, W Zhao¹, (1) Stony Brook University Department of Radiology, Stony Brook, NY, (2) Analogic Canada Corporation, Saint-Laurent, Quebec, (3) Siemens Healthineers, Malden, MA

Purpose: Recent work has proposed “hybrid” direct-indirect active matrix flat panel imagers (AMFPIs) for x-ray imaging. Hybrid AMFPIs comprise an amorphous selenium (a-Se) direct AMFPI which is optically coupled to a turbid scintillator, such that a-Se acts as both an x-ray and optical sensor. This work investigates how beam quality and x-ray converter parameters influence the sensitivity, spatial resolution, noise characteristics, and detective quantum efficiency (DQE) of Hybrid AMFPIs. **Methods:** A prototype Hybrid AMFPI was constructed by modifying a commercial direct AMFPI (AXS-Screen+v2, 85 μ m pitch). Its active matrix was fixed upright to permit imaging in a back-irradiation (BI) geometry, wherein x-rays first expose the detector through the pixel array. Gd₂O₂S:Tb (GOS) scintillators were coupled to the a-Se to compose different Hybrid AMFPIs. Their x-ray sensitivity, presampling modulation transfer function (MTF), quantum-noise-limited noise power spectrum (NPS), and DQE were measured at RQA5 and RQA9 beam qualities using conventional methods. Phantom imaging experiments were performed to evaluate differences in their imaging characteristics. **Results:** Hybrid configurations had greater sensitivity than the direct AMFPI alone; the largest improvement was observed at RQA9 with the thickest GOS due to the increased x-ray quantum efficiency provided by scintillator. Hybrid MTFs were between the direct AMFPI and scintillator MTFs across all configurations and beam qualities. Hybrid NPS featured correlated and white noise components, and an overall noise reduction at low spatial frequencies compared to the direct AMFPI NPS. Hybrid DQEs were accordingly enhanced at low frequencies without penalty at higher frequencies. Phantom images demonstrated more favorable tradeoffs in spatial- and low-contrast resolution with Hybrid AMFPIs than with their constituent direct and indirect imaging components. **Conclusion:** Hybrid AMFPIs leverage the favorable x-ray imaging characteristics of direct and indirect AMFPIs, which may improve tradeoffs between spatial- and low-contrast resolution in digital radiography.

TU-A-TRACK 2-04

Dual-Energy Reduces Severity of Motion Artifacts in Free-Breathing 2D Pulmonary Angiography

E Nikolau^{1*}, M Wagner¹, S Schafer², T Hacker¹, E Temme¹, P Laeseke¹, M Speidel¹, (1) University of Wisconsin-Madison, Madison, WI, (2) Siemens Healthineers, Malvern, PA

Purpose: To quantify the severity of motion artifacts in 2D pulmonary angiography using conventional digital subtraction angiography (DSA) and dual-energy (DE) subtraction angiography in a free-breathing animal model. **Methods:** Real-time dual-energy pulmonary angiography was performed in three free-breathing porcine subjects on an interventional C-arm system equipped with 30 Hz fast-kV switching capability. Tissue-subtracted dual-energy images were generated by weighted log subtraction of low and high kV image pairs. The relative size and intensity of respiratory-induced motion artifacts over a single respiratory cycle were quantified and compared between dual-energy and conventional DSA images. Severity of motion artifacts was measured from image profiles placed across the diaphragm boundary. Deformable image registration was implemented to correct inter-frame respiratory motion in the 1/30 s period between low and high kV images. Additionally, dual-energy images were generated after application of a machine-learning based denoising algorithm. Dual-energy images with one or both algorithms applied were subjected to the same artifact analysis and compared with regular dual-energy. **Results:** For dual-energy acquisitions, the areas of diaphragm motion artifact profiles were reduced by 93.2% to 96.8% compared to DSA. Application of deformable registration further reduced artifact areas (98.1% to 98.7%). Artifact profile intensity was reduced by 32.2% to 74.6% using dual-energy, and by 80.3% to 90.3% for registered dual-energy. Noise reduction in dual-energy images across all porcine subjects ranged from 58.5% to 67.4%. **Conclusion:** Motion artifacts in dual-energy and conventional DSA on an interventional C-arm have been evaluated in an animal model of free-breathing pulmonary angiography. Dual-energy imaging with 30 Hz kV switching enables a large reduction in diaphragm motion artifacts seen in DSA images. Application of a deformable registration algorithm further reduced residual inter-frame motion artifacts seen in dual-energy subtraction images.

TU-A-TRACK 2-05

In-Vitro 1000 Fps High-Speed Angiographic (HSA) Evaluation of the Hemodynamics in the Ascending Aorta Resulting from the Graft of a Left Ventricular Assist Device (LVAD)

A. Shields^{1*}, S.V. Setlur Nagesh², V. Chivukula³, D.R. Bednarek⁴, S. Rudin⁵, (1) University at Buffalo, Buffalo, NY, (2) University at Buffalo, Buffalo, NY, (3) Florida Institute of Technology, (4) University at Buffalo, Buffalo, NY, (5) University at Buffalo (SUNY) School of Medicine, Buffalo, NY

Purpose: Implantable left ventricular assist devices (LVAD) can restore blood circulation for patients with end-stage heart failure. However, significant complications such as stroke may occur due to the unfavorable hemodynamic environments produced by suboptimal implantation configuration. High-speed angiography (HSA) was performed at 1000 fps to resolve previously unseen vascular flow dynamics in-vitro for one LVAD outflow graft configuration. **Methods:** Flow detail was evaluated within a 3D-printed aortic vascular model. The imaging ROI focused on the anastomosis of a 10-mm diameter LVAD graft with the wall of the ascending aorta, at an insertion angle of 90 degrees with respect to the centerline of the aorta. The model was connected to a constant flow loop, with a system flow rate set to 5 L/min, as measured at the graft. The aortic valve was assumed to remain closed, so all flow into the aorta originated from the LVAD graft mimicking complete LVAD support. Iodine-based contrast media was slowly injected with an automated syringe injector and imaged at 1000 fps with the new 5cm x7.5cm FOV CdTe-based Aries photon-counting detector. **Results:** Examination of the image sequences illustrates detailed flow dynamic patterns made available through use of the high-frame-rate-enabled, larger-FOV detector. The iodine contrast-labeled fluid can be seen exiting the LVAD graft as a high-velocity jet, which directly impinges on the aortic wall opposite the graft. The 90-degree configuration causes a strong recirculation pattern to form inferior to the anastomosis zone. **Conclusion:** This investigation presents a novel HSA application, where the severe hemodynamic conditions produced by the high velocity jet from a 90-degree LVAD graft configuration are directly visualized in-vitro. This initial study sets the groundwork for further investigation into other LVAD graft configurations, where better alignment of the outflow graft anastomoses with the aortic axis may produce more favorable flow patterns in the aorta.

Multiparameter Dense Neural Network (DNN) to Estimate Patient Eye-Lens Dose During Neuro-Interventional Procedures

J Collins^{1*}, C Guo², A Podgorsak³, S Rudin⁴, D Bednarek⁵, (1) University at Buffalo, Buffalo, NY, (2) , Chicago, IL, (3) University at Buffalo, Buffalo, NY, (4) University at Buffalo (SUNY) School of Medicine, Buffalo, NY, (5) University at Buffalo, Buffalo, NY

Purpose: Fluoroscopically-guided neuro-interventional procedures can result in high patient radiation dose to the eye lens with associated deterministic risks such as cataract formation. Deep learning (DL) models were investigated to determine if the patient lens dose for given exposure conditions could be estimated in real-time hence better controlled. **Methods:** Monte-Carlo simulations were done using NCICT computational phantoms to create a dataset of lens dose values for the right and left eyes to train the DL models. The dataset was obtained for a range of geometric and exposure parameters used in neuro-interventional procedures including entrance-field size, kVp, filter type, gantry angulation, patient head size, and patient x, y, z head position relative to the beam isocenter. The dose for each combination of parameters was expressed as lens dose per entrance air kerma (mGy/Gy). Data was split into training, validation and testing sets. Stacked models and median algorithms were implemented to create more robust models. The parameters to be input into the DNN during a procedure are obtained from our dose-tracking system (DTS) which is interfaced to the imaging system. Model performance was evaluated using the mean-absolute-percentage error (MAPE). **Results:** Using the median and stacked algorithms both led to a MAPE of less than 10% for prediction of the testing set. The lens dose prediction time for a single-exposure projection was 8 ms and 6 ms for the median and stacked algorithms, respectively. **Conclusion:** A DNN method is able to accurately predict the patient eye lens dose based on the geometric and exposure parameters that would be used in a fluoroscopic neuro-interventional procedure. This work shows that using a DNN is a viable option to be implemented in the DTS to predict patient eye-lens dose in real time and eliminate the need to have a large database of pre-calculated factors.

Authors receive research support from Canon (Toshiba) Medical Systems. The dose tracking system (DTS) software is licensed to Canon Medical Systems by the Office of Science, Technology Transfer and Economic Outreach of the University at Buffalo.

Single-Shot Quantitative X-Ray Imaging Using Primary Modulation and Dual-Layer Detector: A Simulation Study

L Shi^{*}, N Bennett, A Wang, Stanford University, Stanford, CA

Purpose: Conventional x-ray imaging provides limited quantitative information due to scatter, beam hardening, and overlaying tissues. A single-shot quantitative x-ray imaging (SSQI) method proposed in this work quantifies material-specific densities in x-ray imaging by combining the use of a primary modulator (PM) and a dual-layer (DL) detector. **Methods:** The PM features a checkerboard arrangement of alternating unattenuated and partially attenuated squares. Conceptually, the PM performs scatter correction for the DL images, while the DL images remove beam hardening from the PM. The DL detector further generates low- and high-energy images with superior registration, which are used to create material-specific images. In this work, a simulation study was performed for chest x-ray to test the feasibility of SSQI. We first simulated the x-ray images of a digital phantom (Lungman, Kyoto Kagaku) by incorporating a 120 kV spectrum, PM, and DL detector, and including scatter. The DL images contained four measurements that were obtained behind the hole (unattenuated) and fill (partially attenuated) regions of the PM of each layer. Using the low-frequency property of scatter and a pre-calibrated material decomposition (MD), four unknowns (i.e., two scatter images and two material-specific images) were jointly recovered by directly solving four equations given by the four measurements. **Results:** SSQI accurately performed MD to separate soft tissue from bone. Its performance improved with a smaller PM pitch and reduced focal spot blur. A pitch of 457 μ m and source-to-modulator distance of 36.3 cm can be an optimal combination for practical use, reducing the RMSE by 80% and 96% for PMMA and copper MD images, respectively, as compared to without scatter correction. **Conclusion:** We demonstrated the feasibility of SSQI to perform MD that is robust against scatter. The simplicity of SSQI may enable its widespread adoption beyond x-ray imaging to real-time image guidance and cone-beam CT.

Q&A

Despite its long history and established clinical utility, X-ray Computed Tomography (CT) remains an area of active research and innovation. In the recent years, significant progress has been made in scanner hardware, reconstruction algorithms, and dose reduction techniques. The technical development is paralleled by continuous expansion of diagnostic applications of CT. In this session, we will present an overview of some of these important advances, including (1) high-resolution CT systems, (2) personalized CT dosimetry, (3) new clinical capabilities in assessment of lung disease and (4) learning-based reconstruction algorithms.

One of the areas of major current progress in CT hardware has been in improving the spatial resolution of whole-body CT. The first talk will present comprehensive measurements of technical and clinical performance of one of the recently introduced high-resolution CT scanners. The system has six user-selectable focal spots, and three different detector configurations for acquisition. The MTF measurements in both the in-plane (x, y) and longitudinal (z) axes demonstrate a true doubling in spatial resolution. Clinical applications which benefit from the resolution of this scanner include thoracic, small vessel, pediatric, and musculoskeletal imaging. Advances in computational and deep learning technologies are enabling rapid, patient-specific CT organ dose estimation. Patient-specific organ dose estimation uses the CT images from the patient's scan to develop a personalized phantom model and to accurately model patient-specific aspects of the CT scan that affect dose,

such as tube current modulation and patient positioning. Patient-specific organ dose estimation is typically performed through two steps: (1) estimating a dose distribution map and (2) determining organ boundaries that are then applied to the dose map. Monte Carlo, Linear Boltzmann Transport Equation (LBTE) solver, and deep learning methods have been developed for rapid dose map estimation. Deep learning methods have also been applied in organ segmentation. The second talk will present an overview of patient-specific CT organ dose estimation methods and potential applications. The development and validation of a specific tool, using a rapid LBTE solver and deep learning segmentation methods, will be described.

The third talk will focus on recent advances in clinical application of CT. With careful attention to image protocol details, CT and Dual Energy CT now provides for a detailed map of parenchyma, vessels and airways along with a characterization of pathophysiology. Image matching between multiple lung volumes yields regional metrics related to lung mechanics and provides a marker of underlying functional small airways disease. Dual Energy-based material decomposition of contrast enhanced images provide a measure of regional perfused blood volume which serves as a surrogate for regional perfusion. With regional Jacobians from image matching providing regional measures of ventilation and DECT-PBV providing regional measures of perfusion, one can now assess the matching of ventilation and perfusion which is the primary function of the lung, required for gas exchange. The application of these CT metrics to the understanding of the etiology of smoking-associated lung disease will be discussed.

The session will conclude with a presentation of the emerging learning-based methods that exploit datasets of regular-dose and/or low-dose CT scans for improved image reconstruction. The talk will first review an approach based on model-based image reconstruction (MBIR), where the sparsity-based regularizer parameters are learned in an unsupervised manner from a dataset of high-quality CT images. A union of sparsifying transforms is pre-learned to cluster CT image patches into multiple groups, with a specific transform well-matched to each group. When incorporated as a data-driven regularizer in MBIR, the learned transforms provide much better image reconstruction than conventional filtered backprojection and non-adaptive regularization methods especially at low X-ray doses. Next, an extension of this approach to a unified supervised-unsupervised (SUPER) learning scheme will be discussed. This scheme combines classical MBIR optimization and unsupervised transform learning together with recent supervised deep learning in a common framework. Multiple interpretations of this unified framework will be discussed and shown to provide much better image reconstructions than the constituent models with limited training data.

Learning Objectives:

1. Understand the performance characteristics of high-resolution whole-body CT
2. Understand the computer modeling techniques that enable personalized CT dose estimation
3. Understand the advanced CT techniques used in assessment of lung function
4. Understand the unsupervised and supervised-unsupervised approaches for learning-based CT image reconstruction.

Q&A & Panel Discussion

Function-guided radiation therapy using various imaging modalities such as CT, MRI, PET, and SPECT, may play a role in reducing toxicity as well as improving local control by targeting resistant disease and enabling treatment planning that can use a normal tissue regional function map in order to minimize the probability of radiation-induced toxicity or maximize the probability of post-treatment function. This session is focused on efforts to develop and clinically translate various functional image-guidance technologies across a variety of disease sites and disease stages.

In the first talk, we will discuss functional avoidance lung radiotherapy, which uses 4DCT to map regional lung ventilation. These maps are used to generate radiotherapy plans that reduce doses to functional regions of the lung. We will present early findings from a phase II, two-center, study that evaluated 4DCT-ventilation functional avoidance radiotherapy. The talk will report on the primary trial outcome of radiation pneumonitis. Secondary outcomes reported include non-pneumonitis thoracic clinical toxicity and functional avoidance dosimetric results.

In the second talk, we will highlight recent work on function guided treatment planning using multiple imaging modalities in liver, lung, and head and neck. We will discuss in detail the clinical workflow and preliminary results from recent, prospective clinical trials on response-based adaptive therapy using FDG-PET and V/Q SPECT in advanced stage lung cancer and gadoteric acid MRI for liver SBRT

In the third talk, we will discuss the first clinical experience with a novel biology-guided radiotherapy (BgRT) system equipped with PET imaging, Reflexion X1. We will discuss beam QA and commissioning procedures following the TG-148 protocol. We will report on performance characterization of the PET subsystem following the NEMA NU-2 2018 standard. We will also report on the imaging performance in CT mode and on the dosimetric and geometric accuracy of the system. We will report on the design of an early-phase clinical trial to quantify and evaluate the FDG dose for daily PET guidance, expected to start in April 2021.

In the fourth talk, we will discuss a novel lung functional avoidance strategy that accounts for serial (central and peripheral airways) and parallel (parenchyma)

components of lung function. We will discuss a virtual bronchoscopy-based technique to spatially map the airway tree and connect the air supply pathways with functional sub-lobe lung regions. We will discuss the development of a radiation response model for individual airway segments and the incorporation this model with NTCP models for lung parenchyma to create functional avoidance plans that minimize post-radiotherapy ventilation loss in lung cancer patients.

In the last part of the symposium, we will have a Q&A session for discussions between session organizers, speakers, and the audience.

Learning Objectives:

1. Understand the motivation and the basic concepts of functional guidance in radiotherapy
2. Keep up to date on the latest functionally-guided RT clinical trials
3. Understand the clinical requirements and technical characterization of a novel biologically-guided radiotherapy system
4. Understand the current challenges in functional-image-based guidance and novel strategies to address these challenges

Q&A & Panel Discussion

Advances in radiation therapy (RT) have been driven mainly by technologic developments that enable precise delivery of ablative radiation doses to tumors while sparing adjacent critical structures. Substantial advances in RT technology, particularly in image-guided RT, over the past decade have paved the way for escalating radiation doses to levels that were historically inconceivable. However, dose escalation is subject to physical limits, and it cannot combat radioresistance in many tumors. The current "brute force" approach, in which delivering higher radiation doses to tumors creates more DNA damage and thus kills more tumor cells, neglects the vast knowledge accrued on the biology and immunology of tumors and normal tissues in response to radiation. This session highlights new advances with a focus on the biological rather than the physical aspects of radiation. Topics covered include mechanisms of proton-induced bone fractures; minibeam therapy using protons and heavy ions; combinations of radiation and DNA-repair inhibitors for radiosensitization and for antitumor immunity; and radio-immunotherapy dose-painting. The hope is that this session will encourage, motivate, inspire, and guide physicists to assume leading roles, rather than secondary ones, with regard to biological research applied to radiotherapy.

Learning Objectives:

1. Understand and discuss opportunities for physicists in biological research applied to radiotherapy.
2. Highlight how original physics ideas can help to create biological hypotheses.
3. Encourage, motivate, inspire, and guide physicists to take a leading role rather than a secondary one on applying biological research to radiotherapy.

Compact Neural Network to Predict Radiation-Induced Lymphocyte Depletion

Y Kim^{1*}, I Chamseddine², A Saraf³, Y Cho⁴, F Keane⁵, W Sung⁶, H Yoon⁷, H Paganetti⁸, J Kim⁹, S Cho¹⁰, C Grassberger¹¹, (1) KAIST, Daejeon, , KR, (2) Harvard Medical School/Massachusetts General Hospital, Quincy, MA, (3) Massachusetts General Hospital, , (4) Yonsei University College of Medicine, Seoul, , KR, (5) Massachusetts General Hospital, , (6) The Catholic University of Korea, Seoul, , KR, (7) Yonsei University College of Medicine, Seoul, , KR, (8) Mass General Hospital and Harvard Medical School, Boston, MA, (9) Yonsei University College of Medicine, Seoul, , KR, (10) KAIST, Daejeon, , KR, (11) Massachusetts General Hospital, Cambridge, MA

Purpose: Radiation-induced lymphopenia (RIL) is known to be associated with survival after radiotherapy (RT). We investigate the correlation of dose distributions with RIL in lung and liver cancer patients and develop a compact neural network to predict RIL in this study. **Methods:** We investigated dose distributions in 84 lung

cancer patients and 63 liver cancer patients treated at two institutions, and investigated RIL directly after RT and the lymphocyte recovery 3 months later. Dose distributions were deformably registered to a common target coordinate system for spatial normalization, and non-parametric correlation tests were used to study local effects of dose to specific regions. A compact multi-path neural network was designed that integrates clinical patient data in fully connected layers with the dose distribution in convolutional layers for predicting the post-RT absolute lymphocyte count of lung cancer patients. We used relatively a small (less than 3) number of convolutional layers, a limited number of kernels, and extensive max-pooling for a light-weight network. Training and validation were performed separately on data from different institutions. **Results:** Clear correlation of RIL with dose was observed around large vessels - pulmonary vessels and heart in lung cancer patients and large hepatic vessels in liver cancer patients. When focusing on lymphocyte recovery, these correlations shifted to bone marrow. Keeping the neural network structure compact enabled convergence of the network in both training ($n=63$) and validation sets ($n=21$), and the network predicted the post-RT lymphocyte count (average $0.9/\mu\text{l}$, range $[0.1-2.2]/\mu\text{l}$) with a mean square error of $0.06-0.08$. **Conclusion:** Dose to large vessels is strongly correlated with RIL directly after RT in liver and lung cancer patients, while dose to bone marrow correlates with the recovery from RIL. The developed neural network integrates 3D dose information directly with clinical data and successfully predicts RIL.

From Person-Specific to Population-Based Colorectal Models: An Age-Scalable Computational Anatomical Colorectal Model for Radiation Dosimetry in Late Effects Studies of Childhood Cancer Survivors

C Owens^{1,2*}, B Rigaud¹, E Ludmir¹, A Gupta^{1,2}, S Shrestha^{1,2}, A Paulino¹, C Peterson^{1,2}, S Kry^{1,2}, S Smith¹, K Brock^{1,2}, R Howell^{1,2}, (1) The University of Texas MD Anderson Cancer Center, Houston, TX, (2) The University of Texas Graduate School of Biomedical Sciences at Houston, Houston, TX

Purpose: To develop, validate and integrate into an age-scalable computational phantom an “average” colorectal model that incorporates anatomical variations of pediatric patients. **Methods:** Whole-body non-contrast CT scans of fifty-five male pediatric patients (age range: 2.1-21.6years) were retrospectively selected. Manual colorectal contours were reviewed and approved by two radiation oncologists. Forty-five and ten patients were used for training and testing, respectively. All contours were spatially normalized using median colorectal length and registered to an anatomical template using the constrained symmetric thin-plate spline robust point matching (sTPS-RPM) method. Deformed contours were used to generate a principal component analysis (PCA)-based statistical shape model (SSM) of the colorectum to extract the dominant deformation modes of the population. The sTPS-RPM inter-patient registration was evaluated using Dice similarity coefficient (DSC), distance-to-agreement (DTA), and Hausdorff distance (HD). To validate the generalizability of the PCA model to represent unseen shapes, we computed the DSC between the original and PCA reconstructed contours for ten test patients. The population PCA-based colorectal model was integrated into our phantom, which can be scaled to any age (infant-to-adult). Additionally, the length and mass of the model was matched to ICRP reference data within 5% across the age range. **Results:** The sTPS-RPM inter-patient registration mean(min-max) DSC, DTA and HD was $0.96(0.93-0.98)$, $1.5\text{mm}(1.2-2.0)$, and $6.0\text{mm}(3.2-19.7)$, respectively. On the training set, the PCA-based SSM was able to describe 95% of inter-patient colorectal variance with 11 of the 45 dominant principal components. Using the PCA-based SSM on the unseen 10 test patients, the mean(min-max) DSC between the validation and reconstructed colorectal contours was $0.80(0.76-0.84)$. **Conclusion:** We developed, validated and integrated a population PCA-based SSM of the colorectum into our phantom. The model will be used to reconstruct colorectal doses for a study of subsequent colorectal cancers in childhood cancer survivors treated in the pre-CT era of RT.

TU-A-TRACK 6-03

MRI-Based Multi-Region Delta-Radiomics for Prediction of Recurrence After Chemoradiotherapy in Locally Advanced Cervical Cancer

M Kawamura^{1*}, D Kawahara², I Nishibuchi², A Saito², T Yoshida³, Y Nagata^{2,4}, (1) Graduate School of Biomedical & Health Sciences, Hiroshima University, Hiroshima, JP, (2) Department of Radiation Oncology, Institute of Biomedical & Health Sciences, Hiroshima University, Hiroshima, JP, (3) School of Medicine, Hiroshima University, Hiroshima, JP, (4) Hiroshima High Precision Radiotherapy Cancer Center, Hiroshima, JP

Purpose: The aim of this study is to predict the recurrence of locally advanced cervical cancer after radiotherapy from delta-radiomics features using magnetic resonance imaging (MRI). **Methods:** This study included 61 patients with locally advanced cervical cancer treated with chemoradiotherapy between 2003 and 2017. Region of interest(ROI) were created with the uterus as the clinical target volume(CTV). In addition to the ROIs that expanded and shrunk from CTV were created, the inner and shell regions were analyzed. The inner region was defined as the region that the voxels excluded the tumor boundaries. The shell region was defined as the region that the voxels around the tumor boundaries were analyzed. Delta-radiomics feature was defined as the difference in radiomics feature before and at 4 weeks after radiation therapy begins. A total of 9394 features were extracted from T1-weighted images(T1WI) and T2-weighted images(T2WI). Using the features selected by the method of least absolute shrinkage and selection operator (LASSO) regression, two single sequence radiomics models and mixture of the two sequence were constructed using a neural network with 5-fold cross-validation. The performance of the prediction models was assessed in terms of sensitivity, specificity, accuracy and area under the receiver operator characteristic curve (AUC). **Results:** From Lasso regression, 4 radiomics features from T1WI and 8 radiomics features from T2WI and 8 radiomics features from combination of T1WI and T2WI. The accuracy, specificity, sensitivity, and AUC of the prediction model for the dataset were 70.0%, 87.5%, 41.2%, and 0.77 with T1WI, 85.6%, 91.9%, 71.4%, and 0.90 with T2WI, 82.2%, 87.8%, 75.6%, and 0.91 with the combined. **Conclusion:** The current study showed that multi-region delta-radiomics features could be an important factor to predict recurrence of cervical cancer.

TU-A-TRACK 6-04

Predicting Osteoradionecrosis from Head and Neck Radiotherapy Using a Residual convolutional Neural Network

B Reber^{*}, B Anderson, A Mohamed, L Van Dijk, B Rigaud, M McCulloch, Y He, M Woodland, C Fuller, S Lai, K Brock, UT MD Anderson Cancer Center, Houston, TX

Purpose: Osteoradionecrosis (ORN) is a detrimental radiation therapy (RT)-induced toxicity for patients after treatment of head and neck cancer. The ability to predict ORN before radiation treatment is performed could enable further optimization of the RT plan or stratification to advanced techniques (e.g. MR-LINAC, adaptive RT, dose de-escalation). A residual convolutional neural network is developed to predict ORN occurrence to aid in this endeavor. **Methods:** A residual convolutional neural network was constructed using a hyperparameter search to find the model with optimum performance, including 2D and 3D architectures. Model input consisted of 3D computed tomography (CT) images, dose distributions, and mandible contours with size (32, 128, 128). Binary outcome of ORN is used for model output. The 148 subject data was split into 111 cases (40 ORN+) training and 37 cases (11 ORN+) validation. Positive cases were oversampled to ensure a match between ORN+ and ORN- in both datasets. Accuracy, sensitivity, specificity, and area under the receiver operator characteristic curve (AUC) are used for model evaluation. Results were compared with logistic regression models using a 0.8/0.2 train/test split and 10-fold cross-validation. **Results:** The best logistic regression models had 0.68 AUC using only the dose distribution (V60) and 0.70 AUC using the dose distribution and clinical variables ($N_{\text{stage}}+V65$). The best deep learning model had 64 starting filters, 5 down-sampling operations and 1 residual block in-between down-sampling operations. The model was a 3D architecture using CT, dose distribution, and mandible contour and had 0.79 accuracy, 0.85 recall, 0.76 precision, 0.83 AUC. 3D deep learning architectures outperformed 2D architectures (0.53 AUC). **Conclusion:** The model predicts ORN with higher performance metrics compared to logistic regression models. Further evaluation on multi-institutional test data is needed. The model could be implemented during the treatment planning stages to aid in patient decision making and treatment stratifications.

TU-A-TRACK 6-05

Relationship Between Coronary Artery Radiation Doses and Risk of Late Coronary Artery Disease: A Report from the Childhood Cancer Survivor Study (CCSS)

S Shrestha^{1*}, J Bates², Q Liu³, S Smith¹, D Mulrooney⁴, A Gupta¹, C Owens¹, W Leisenring⁵, T Gibson⁶, E Chow⁵, K Oeffinger⁷, L Robison⁴, G Armstrong⁴, L Constine⁸, B Hoppe⁹, C Lee⁶, L Court¹, S Kry¹, Y Yasui⁴, R Howell¹, (1) University of Texas MD Anderson Cancer Center, Houston, TX, (2) Emory University School of Medicine, Atlanta, GA, (3) University Of Alberta, Alberta, CA, (4) St. Jude Children's Research Hospital, Memphis, TN, (5) Fred Hutchinson Cancer Research Center, Seattle, WA, (6) National Cancer Institute, Rockville, MD, (7) Duke University, Durham, NC, (8) University of Rochester Medical Center, Rochester, NY, (9) Mayo Clinic, Jacksonville, FL

Purpose: Among childhood cancer survivors, heart dose from radiotherapy (RT) is an established risk factor for coronary artery disease (CAD). Since contemporary RT can be optimized for individual substructures, coronary artery-specific dose-response relationships could refine cardiac dose constraints beyond whole heart metrics. We investigated associations between coronary artery doses and risk of CAD. **Methods:** We estimated 35-year cumulative incidence and incidence rate ratios (RR) of CTCAE grade 3-5 CAD for 25,481 five-year cancer survivors in the CCSS diagnosed at median age 6.1 years (0-20 years) between 1970-1999 at 32 institutions. For the 12,228 individuals treated with RT, fields were reconstructed on an age-scaled computational phantom with a detailed heart model with four coronary arteries. Mean doses to the left main (LMA), left anterior descending (LAD), left circumflex (LCX), and right coronary (RCA) arteries and whole heart were calculated. Associations of heart and artery doses with CAD were evaluated with piecewise exponential models adjusted for demographic, treatment-related characteristics, and cumulative anthracycline dose. **Results:** For all arteries and whole heart, mean doses ≥ 10 Gy were associated with significantly increased CAD risk. After a mean dose of 10- <20 Gy to the LMA, LAD, LCX, and RCA respectively, 35-year cumulative incidences were 4.7% (95%CI:2.7-6.7), 10.7% (95%CI:7.7-13.7), 6.8% (95%CI:4.8-8.7), and 12.6% (95%CI:10.3-15.0); RR values were 2.5-5.3 times higher than for survivors unexposed to RT. Lower doses (5- <10 Gy) to the LAD (RR 1.9, 95%CI:1.6-4.1, $p<0.001$) and RCA (RR 2.6, 95%CI:1.6-4.1, $p<0.001$) were also associated with significantly increased risk. **Conclusion:** This study expands our understanding of RT-related CAD beyond whole heart doses and establishes relationships between dose to specific coronary arteries and CAD. We uniquely identified that LAD and RCA doses as low as 5 Gy were associated with increased risk. These data can guide contemporary pediatric RT to prioritize coronary artery dose constraints.

Seed Spots Analysis to Characterize Linear-Energy-Transfer (LET) Effect in the Adverse Event Regions of Head and Neck Cancer Patients Treated by Intensity-Modulated Proton Therapy (IMPT)

Y Yang^{1*}, S Patel¹, J Bridhikitti², W Wong¹, M Halyard¹, L McGee¹, J Rwigema¹, S Schild¹, S Vora¹, T Liu³, M Bues¹, M Fatyga¹, R Foote², W Liu¹, (1) Department of Radiation Oncology, Mayo Clinic Arizona, Phoenix, Arizona, USA (2) Department of Radiation Oncology, Mayo Clinic Rochester, Rochester, Minnesota, USA (3) Department of Computer Science, the University of Georgia, Athens, GA

Purpose: High linear energy transfer (LET) radiotherapy may cause unexpected adverse events (AEs) in head and neck (H&N) cancer patients treated by intensity-modulated proton therapy (IMPT). In this exploratory study, we propose to investigate the effects of LET upon AEs in IMPT using dose-linear-energy-transfer volume histograms (DLVHs) and seed spots analysis. **Methods:** We included 14 H&N patients with unanticipated CTCAEv4.0 grade ≥ 3 AEs for analysis. The AE regions were contoured and the corresponding DLVHs of the AE regions were generated. DLVH was constructed with physical dose (Gy) and LET (keV/ μ m) as independent variables. The normalized volume of the structure was contoured as iso-volume lines in the dose-LET plane. All voxels in the structure were mapped into the dose-LET plane as dots to see how the dots with similar dose and LET were clustered. For seed spot analysis, we selected voxels at the top edge of the DLVH plots as critical voxels. Individually clustered critical voxels that are geometrically apart were considered as independent seed spots. Median dose/LET from seed spots were extracted. Bivariate-linear-regression models were established for all AEs. The dose and LET product (xBD) volume constraint of osteoradionecrosis was obtained using the receiver operating characteristic curve of 4 osteoradionecrosis patients and 15 additional independent control patients. **Results:** Dose played a dominant role for in-field AEs such as hemorrhage and ulceration, while LET played an important role in out-of-field AEs such as osteoradionecrosis and mucositis. Intercept-free linear models between the reciprocal of dose and LET were found for different AEs. The xBD volume constraint of osteoradionecrosis was derived, $V(xBD \geq 275.18 \text{ Gy-keV}/\mu\text{m}) < 0.061\text{cc}$, with an area under curve of 0.85. **Conclusion:** A potentially important LET-enhancing effect to induce AEs in H&N cancer treated with IMPT was observed. Voxel-based DLVH and seed spots analysis are powerful tools to study AEs in IMPT.

This research was supported by Arizona Biomedical Research Commission Investigator Award, the Lawrence W. and Marilyn W. Matteson Fund for Cancer Research, and the Kemper Marley Foundation.

TU-A-TRACK 6-07

Survival Prediction Models for Patients with Malignant Pleural Mesothelioma After Adjuvant Radiotherapy

Z Wang^{1*}, V Li², X Qi³, (1) UCLA School of Medicine, Los Angeles, CA, (2) USC Dornsife College of Letters, Arts and Sciences, Los Angeles, CA, (3) UCLA School of Medicine, Los Angeles, CA

Purpose: Complex target shape and unique location pose big challenges of plan quality and achievable dosimetric parameters and subsequent treatment outcome for Malignant pleural mesothelioma (MPM) on individual basis. Correlations between target characteristics, planning dosimetric parameters and overall survival were explored using machine learning methods. **Methods:** A retrospective cohort of 59 MPM patients, receiving 45 Gy/25 fractions on a Tomotherapy unit, were pooled and analyzed. The achieved dosimetric parameters for target and critical OARs were analyzed for 23 left-sided mesothelioma (LSM) and 36 right-sided mesothelioma patients (RSM) respectively. LASSO function $1/2 \|Ax - b\|_2^2 + \gamma \|x\|_1$ was adopted for selecting the most relevant predictors with dosimetric endpoints and/or overall patient survival. Machine learning methods including Multiple Layer Perceptron (MLP) were applied to construct predictive models for MPM response after a pleurectomy/decortication. The model performance was evaluated using the Area Under the ROC Curve (AUC) with 3-fold cross validation. **Results:** No differences were observed between planning target volume (PTV) coverage 94.2 $\pm$ 1.2% (LSM) vs 93.4 $\pm$ 2.4% (RSM). The achieved dosimetric endpoints were found significantly different ($p<0.05$) for OARs between the LSM and RSM: ipsilateral lung V20 (91.2 $\pm$ 6.7 vs. 85.3 $\pm$ 6.5%), ipsilateral mean lung doses (39.1 $\pm$ 3.8 vs 36.9 $\pm$ 2.5 Gy), heart mean doses (25.2 $\pm$ 3.6 vs 18.8 $\pm$ 3.7 Gy), liver mean doses (10.6 $\pm$ 2.7 vs. 23.4 $\pm$ 4.2 Gy), respectively. There was no significant difference in total lung V20-PTV mean dose 13.4 $\pm$ 2.0 vs. 14.4 $\pm$ 1.5 Gy nor expected lung pneumonitis for LSM and RSM. The MLP reached an AUC of 0.71 in predicting overall survival from combined characteristics and planning dosimetric parameters. The identified predictors that are most associated with overall survival were age, PTV volume, ipsilateral lung volume and V20Gy, and ipsilateral lung-PTV V20. **Conclusion:** Significantly dosimetric differences of OARs were observed for left- and right-side MPM. The predictive models can assist in achieving patient-specific optimal plan quantity and treatment outcome via personalized treatment.

L. Marks, University of North Carolina at Chapel Hill:

Physician Perspective on HyTEC - the Clinical Needs, Opportunities and Limits

HyTEC Overview: The HyTEC (High Dose per Fraction, Hypofractionated Treatment Effects in the Clinic) review is an effort to summarize the currently-available stereotactic body radiation therapy (SBRT) dose / volume / outcome data to update and refine the normal tissue tolerance guidelines provided by the classic “Emami” paper (IJROBP May 1991) and the recent QUANTEC publications (IJROBP March 2010), for radiosurgery throughout the body in 1 to 5 fractions. HyTEC was formed as the SBRT Working Group (WGSBRT) within the American Association of Physicists in Medicine (AAPM) under the Biological Effects Subcommittee (BESC) and consists of more than 100 authors who are physicians, physicists, radiobiologists, and biomathematicians. The effort has resulted in 7 articles addressing NTCP, 9 articles addressing TCP, and several vision and editorial articles, that will constitute a special issue of the Red Journal (May or June 2021) with free access for AAPM members. This session will provide an updated summary of the overall effort, with an emphasis on general principles and findings of the project. The recently completed Pancreas TCP paper is an example of the methods and results.

HyTEC_ the project and the product: The 16 HyTEC organ/tumor-specific papers are analyses of selected, peer-reviewed publications of sbrt treatments spanning the entire body: Cranial, Head and Neck, Thoracic, Abdominal, Pelvic, and Spinal. Results are presented in a format similar to that of QUANTEC. For each paper, a self-assembled group of experts (physicians, physicists, radiobiologists and biomathematicians) systematically triaged the literature to find papers that included sufficient data for a quantitative synthesis, preferably (but not always) in the form of a sigmoidal curve -a mathematical model-usually requiring a radiobiological dose correction to account for fractionation. Additionally, each paper summarizes such site-specific questions as volume definition and ambiguities in outcome determination. From the models, readers can determine dosimetric metrics and uncertainties associated with literature-based NTCP or TCP outcomes and can compare them with their own experience. As in QUANTEC, the HyTEC introductory article summarizes consensus dose and dose-volume metrics for the major SBRT treatment types, risk organs and tumors in tabular form, such that readers can evaluate and compare them with those used in their own clinics.

Pancreas TCP: Pancreatic cancer is the fourth leading cause of cancer death in the United States, though it is only 3% of all new cancers. Five-year overall survival (OS) is less than 25%. Treatments often combine chemotherapy, surgery and radiation therapy with a major radiation therapy goal of converting locally advanced and borderline resectable pancreatic cancer (LAPC and BRPC) to resectable. SBRT is a desirable form of radiation treatment because short treatment schedules interfere minimally with chemotherapy. However, treatment planning and delivery are complicated by respiratory motion and inter- and intra-fraction normal organ variability and proximity of the tumor to stomach and bowel limits safe prescription doses.

A PubMed search initiated in 6/2019 resulted in 414 articles of which only 32 met the inclusion criteria of providing the cumulative prescription, number of fractions, number of patients, Kaplan-Meier (KM) or individual patient data on OS or Local Control (LC), at least 75% of patients without prior pancreatic radiation and at least 90% without distant disease. These articles provided 48 data points; all but three studies used between 1 and 5 fractions. Study sizes ranged from 12 to 91 patients. There was considerable variability among these studies including the starting points for effect duration (e.g. time from diagnosis vs time from start of radiation), different applications of respiratory motion control and image guidance, the definition of local failure. Detailed dose distributions were rarely provided. For study comparisons, prescription doses were converted to equivalent dose in 3-fractions using the Linear-Quadratic model with $\alpha/\beta=10$ Gy (3fxED). Given the variability, modeling LC beyond a year was not attempted.

Resectability was the strongest factor affecting outcome; average 1 year LC was over 90% for patients with R0 resection. For unresected patients, 1 year LC was <70% for 3fxED<24 Gy, approximately 77% for 3fxED approximately 28.2 Gy and approximately 86% for 3fxED of 36 Gy. The dose response from studies in which at least 80% of patients were unresected throughout the study was significant; a logistic model was constructed: 1-year LC=100%/(1+(D50/D)⁴ g50) where D50=17.6 Gy (95% CI 8.8-21.5) and g50=0.64 (95% CI 0.27-1.02).

It is desirable for future studies to agree on starting time for KM analysis, to better stratify patients by extent of resectability, provide more detail about motion management and image guidance and provide dosimetric information beyond the prescription dose.

Physicist/Modeler's perspective: The HyTEC project has used published literature to investigate and synthesize normal tissue complication probabilities in 7 tissues and local control in 9 tumor types resulting from hypo-fractionated and single fraction radiotherapy/SBRT, resulting in models of treatment tolerances and outcomes. In this talk we will discuss the successes and limitations of this effort, in terms of the kinds of information that could be gleaned from the published data, and the subsequent uncertainties in the outcomes models, tolerances, and rates of local control. The reporting standards required to overcome the limitations that have hampered HyTEC will be summarized. Finally, we will highlight the opportunities for modelling treatment outcome that may result from SBRT treatments.

Physician's perspective: Caring for patients with cancer is a privilege. We are fortunate to be able to offer patients and their families the opportunity of cure from an often-lethal disease, as well as to relieve much pain and suffering. At the same time, with responsibility comes a level of burden. Strikingly an appropriate balance between attaining local control/cure vs. minimizing the risk of serious morbidity can be difficult. While we have “class solutions” for common clinical situations, there are often the patient-specific issues (e.g. anatomy, comorbid conditions) that can make treatment planning quite challenging. In our quest to best serve our patients, we try to make data driven objective decisions. However, sorting through the literature can be a daunting task- especially for busy clinicians. Thus, expert reviews that provide readily accessible, clinically-useful information can be most helpful. The dose/volume/outcome data provided by the prior QUANTEC, the current HyTEC, and similar initiatives (e.g. PENTEC; Pediatric Normal Tissue Effects in the Clinic), provide this type of helpful information, and we believe that these efforts have helped, and will continue to help, a large number of patients. At the same time, physicians/planners need to be cognizant of the limitations inherent in these systematic/ pooled reviews. For example, there are inherent inaccuracies in the pooling of data from different centers (e.g. related to differences in image

segmentation, treatment techniques, outcome definitions; reporting biases; patient heterogeneities; and mathematical models of uncertain accuracy). In addition, our estimates of local control and toxicity risk may appear overly optimistic; e.g. in some settings local recurrence may be difficult to establish with certainty by non-invasive imaging methods, and/or complications may not be accurately recognized, and/or there is a bias towards the publication of favorable results. Further, a wide-spread problem in much of our literature is the use of actuarial techniques to compute estimates of local control, with the censoring patients at the time of death. The accuracy of actuarial techniques requires that censoring events should be independent of the endpoint under consideration. Since the pace of disease beyond the treated site (that can cause the censoring event of death) and the pace of regrowth of treated site (that obviously impacts local recurrence) are likely related, actuarial estimates may not be accurate and may overstate the local control. Nevertheless, despite these limitations, we believe that the data provided by the HyTEC reviews are useful. These issues, as well as an “Idealized Future State” to yield better data (e.g. leveraging advances in electronic health records; standards for contouring, structure naming, outcome reporting; and patient empowerment) will be discussed.

Learning Objectives:

1. Understand AAPM's role in the HyTEC effort
2. Understand some ways in which a clinical physicist or dosimetrist can use the HyTEC 'organ papers'
3. Understand the efficacy of current SBRT techniques for treatment of pancreatic cancer
4. Understand causes of successes and failures of outcome modeling for SBRT
5. Understand future opportunities in building on reported clinical experience to improve SBRT

Wrap Up

The Ethics Case Study Working Group will present a case study concerning conflict of interest in a professional medical physics environment. Specifically, the case study focuses on a young physicist whose medical physics practice was recently acquired by a larger firm that also has an equipment manufacturing arm. The case study explores the ethical concerns of purchasing equipment when one potential vendor is financially linked to the purchaser. After a brief introduction to the AAPM Code of Ethics, presenters will describe the case study and participants will break into smaller discussion groups led by working group members to navigate through the ethical decision making process and discuss potential consequences of their decision. Smaller groups will rejoin the larger group for open discussion and potential guidance from the work group concerning the AAPM Code of Ethics.

Learning Objectives for this session include:

1. To become familiar with the AAPM code of Ethics, specifically the sections relating to conflict of interest
2. To identify the key issues in a case scenario as applies to the AAPM code of Ethics
3. To facilitate the discussion of theories and ideas regarding the case study scenarios and extract meaning from the scenario presented

Quantitative and Sensitive Diagnosis of Early Tumor Metastases Using X-Ray and Bioluminescence Tomography

J Chen*, N Zhao, Y Yang, University of Science and Technology of China, Hefei, Anhui, P.R. China

Purpose: To develop an imaging technique for sensitive and accurate detection of early tumor metastases in vivo by using dual-modality x-ray and bioluminescence tomography. **Methods:** Cone beam X-ray computed tomography (CBCT) and bioluminescence tomography (BLT) have been integrated on the image guided small animal arc radiation treatment platform. In this study, its capability of imaging early-phase tumor metastases was challenged with a metastatic castrated-resistant prostate cancer mouse model. Luciferase-expressing cancer cells were injected through left ventricles of immune-deficient mice (n=4). The tumor cells were allowed for seeding and forming metastasis for 4 weeks before imaging. Cone beam computed tomography was first conducted to provide anatomy information and three dimensional mesh for BLT reconstruction. After that bioluminescence projections were captured every 90° rotation, then collected data were put into the CBCT-assisted BLT reconstruction framework. BLT imaging performance including tumor location and size was assessed by postmortem histology. **Results:** All tumors observed in histology section were also found in BLT imaging results in the same location, and all tumors were at millimeter scale as measured in histology section. Two tumors as small as ~1mm were simultaneously detected in each of two mice. One tumor was detected in each of the other two mice. Histology results confirmed that the onboard CBCT/BLT system was able to detect millimeter scale tumor metastases in living animal with sub-organ level accuracy. **Conclusion:** The onboard CBCT/BLT system is able to precisely locate, contour and quantify the early tumor metastases in living animal at millimeter scale, which provides an exciting imaging tool for the investigation of tumor metastasis mechanisms.

Liquid Immunogenic Fiducial Eluter (LIFE) Gel for Image-Guided Radiotherapy

G Richards^{1,4*}, M Moreau^{1,2}, S Yasmin-Karim^{1,3}, W Ngwa^{1,2,3}, (1) Dana Farber Cancer Institute, Boston, MA, (2) University of Massachusetts Lowell, Lowell, MA, (3) Brigham and Womens Hospital, Boston, MA, (4) Northeastern University, Boston, MA

Purpose: To design Liquid Immunogenic Fiducial Eluter (LIFE) gel using natural biodegradable polymers: chitosan and sodium alginate, as a nano-Smart Radiotherapy Biomaterial (n-SRB) that gelifies within the calcium rich tumor micro-environment. This study shows that the LIFE gel loaded with nanoparticles and immunoadjuvants can provide Magnetic Resonance Imaging (MRI) / Computed Tomography (CT) contrast and cause regression of both local and distant unirradiated tumors. **Methods:** Two formulations of the LIFE gel were created to investigate prolonged release of nanoparticles, sodium alginate polymer crosslinked with calcium, and Chitosan-Alginate polymer crosslinked with calcium. In vitro release for these polymer formulations was characterized via fluorescence from FITC dye using a spectrophotometer. In-vitro release was studied in PBS PH 7.4 solution. MR and CT imaging of LIFE gel formulations were conducted to further characterize the release and establish that signal contrast can be obtained from the nanoparticles over time in vitro and also within C57BL6/Jac mice pancreatic tumor. Therapeutic benefit was also assessed in animals with two cervical tumors on each animal where only one was treated with the LIFE gel in combination with radiotherapy at 6Gy compared to control cohorts. **Results:** Results showed burst release from both gel formulations as well as approximately 15% higher release from alginate gel compared to that from chitosan-alginate polymer at day-5. Nanoparticle contrast decreased over time from MR and CT images highlighting prolonged retention of nanoparticles within the chitosan-alginate gel versus the alginate gel in-vitro and within mice tumor microenvironment. Cohorts of mice treated with the LIFE gel loaded with anti-CD40 showed regression of both treated and untreated tumors. **Conclusion:** This work demonstrates the potential of LIFE gel for image-guided radiotherapy, with major potential to provide MR or CT imaging contrast while also boosting therapeutic outcomes.

Quantification of Tumor Location and Growth for Orthotopic Pancreatic Cancer Model Using Bioluminescence Tomography-Guided System

Z Deng^{1*}, X Xu¹, H Dehghani², J Reyes³, J Wong³, P Tran³, K Wang¹, (1) University of Texas Southwestern Medical Center, Dallas, TX, (2) University of Birmingham, Birmingham, UK, (3) Johns Hopkins University, Baltimore, MD

Purpose: The developing radio-immunotherapy has cast radiation therapy(RT) into a pivotal role for pancreatic cancer. There is a need to study pancreatic cancer in pre-clinical setting to advance our understanding of RT. The challenge to study abdominal malignancy in vivo is lack of proper imaging guidance. Bioluminescence with its strong imaging contrast has been widely used to monitor tumor growth. We innovated bioluminescence tomography(BLT) to guide irradiation for orthotopic pancreatic ductal adenocarcinoma(PDAC), and monitor its growth and treatment response. **Methods:** To establish orthotopic PDAC model, we implanted a fraction of BxPc3-Red-Fluc tumor into nude mouse pancreas. For BLT, mice were subject to multi-spectral multi-projection bioluminescence imaging(BLI), followed by small animal radiation research platform(SARRP) CBCT imaging. CBCT image was acquired to generate anatomical mesh for BLT reconstruction. We inserted a titanium wire to tumor center as a marker to validate BLT localization accuracy. We will also quantify the accuracy of BLT-reconstructed volume with MRI and ex vivo method. Volumetric bioluminescent power(BP), related to tumor viability, will also be assessed in comparing with surface BLI and ex vivo method, to determine if it is a proper metric for tumor monitoring and assessment. We will further irradiate orthotopic PDAC guided by BLT and demonstrate the application of BLT to longitudinally assess the change of PDAC volume/power in response to treatment. **Results:** Our initial result shows BLT can retrieve the orthotopic PDAC location within 1.5mm accuracy at depth from 3-5mm, common depth observed in pancreatic study. The BP is observed linearly by 12-fold along with the tumor growth 4 weeks after tumor implanted. With BLT, we can reconstruct the 3D bioluminescent tumor volume using multiple-projection imaging. **Conclusion:** The quantitative BLT system offers unique opportunities for researchers to study important pancreatic tumor in orthotopic setting to quantify its location, growth and response to therapeutic intervention.

The research was supported by National Institutes of Health/National Cancer Institute (R21CA223403, R37CA230341, and R01CA240811), and Cancer Prevention and Research Institute of Texas (RR200042). J. Wong receives royalty payment from a licensing agreement between Xstrahl Ltd. and Johns Hopkins University.

TU-B-TRACK 2-04

Preliminary Investigation of a Novel 3D Dosimetry System Consisting of ClearView 3D Radiochromic Dosimeters with Telecentric Optical Computed Tomography Scanning

S Hoopingarner^{1*}, K Penev², M Oldham¹, (1) Duke University Medical Center, Durham, NC, (2) Modus Medical Devices, London, Ontario, CA

Purpose: To investigate and characterize a novel 3D dosimetry system consisting of ClearView radiochromic gel dosimeters and telecentric optical CT imaging. **Methods:** ClearView radiochromic dosimeters (Modus Medical Devices) are gellan gum based radiochromic dosimeters containing a water-soluble tetrazolium salt which reduces into an insoluble formazan dye (with associated color change) under ionizing radiation. Initial spectrophotometric studies investigated linearity of dose response on small volumes of ClearView in optical cuvettes. Simple single beam benchmark radiation therapy treatments were then delivered to 10 and 15-cm diameter ClearView dosimeters. The treatments were modeled with a commissioned Eclipse treatment planning system. Dosimeters were scanned submerged in a refractive index (RI) matching fluid (ca. 10% propylene glycol) by optical CT both pre- and post-irradiation (within 24h) and 3D reconstructions of the change in linear-optical-attenuation was determined using in-house software. Percent depth-dose, cross plane and in-plane profiles, and 3D gamma analysis were performed and compared to the commissioned Eclipse dose, which served as ground truth. **Results:** Linearity of dose response was confirmed in the cuvette study with excellent agreement ($R^2 \geq 0.9986$) at two wavelengths (520-and 632 nm) at 3 post-irradiation time points: 21 hours, 6 and 10 days. Dosimeter reconstructions were performed at 1mm³ resolution in full 3D. Relative dose profiles in both 15-and 10 cm dosimeters show good agreement in comparison to Eclipse dose calculations, with root mean square errors (RMSE) 0.00107-0.006649, and $R^2 \geq 0.9808$. Relative 3D gamma analysis performed at 3%3mm range from 82.91% - 99.99% agreement. Regions of known artifacts were excluded from analysis (jar walls and neck), but some remain unaccounted for (e.g., ring and cupping artifacts). **Conclusion:** This work presents the first use of a telecentric optical-CT scanner with ClearView. The system shows substantive promise for a new comprehensive 3D dosimetry system.

None. ClearView dosimeters provided by Modus Medical Devices.

TU-B-TRACK 2-05

Evolution and Development of Micro-CT and Optical Imaging for Breast Conserving Surgery

B Maloney^{1*}, S Streeter¹, M Gesner², J Kempner², K Paulsen¹, B Pogue¹, (1) Dartmouth College, Hanover, NH, (2) PerkinElmer

Purpose: A need exists for better intraoperative tools in breast conserving surgery, where there is a high re-excision rate due to malignancy missed using conventional surgical tools. One potential solution is combined micro-CT and optical imaging which have shown promise in clinical studies. The micro-CT rapidly scans the macroscale morphology and interior information of the specimen, while the optical imaging provides surface-weighted scatter contrast from fibrous tissues. The purpose of this study is to highlight the evolution of this technology towards utility as a surgical tool. **Methods:** A multimodal micro-CT and optical system imaged breast conserving surgery specimens at the time of surgery in a prospective clinical trial. In addition, a new multimodal system was developed for clinical translation. The system was built specifically to meet clinical time and cost constraints, as well as to enable ease of system control and image acquisition, reconstruction, and visualization by clinical staff. **Results:** In the prospective clinical trial, image acquisition and reconstruction of full volume micro-CT and surface optical imaging of two margins was completed in under ten minutes without impeding clinical workflow from n=46 patients, to date. The new multimodal system was developed with a focus on speed and ease of clinical use. CT imaging and reconstruction times were significantly reduced in the new system. Software tools were developed such that the system could be operated with minimal training. **Conclusion:** Micro-CT and optical imaging is feasible in the breast conserving surgery clinical workflow and has shown promise for use as a clinical tool to reduce the high positive margin rate in breast conserving surgery. This study represents the next steps toward clinical utility.

TU-B-TRACK 2-06

Use of Computer-Controlled Automatic Injector to Perform 1000-Fps High Speed Angiography During Neurointervention Procedures

S Setlur Nagesh*, A Shields, X Wu, D Bednarek, S Rudin, Canon Stroke and Vascular Research Center, University at Buffalo (SUNY) School of Medicine, Buffalo, NY

Purpose: It is well accepted that details of blood flow can influence the formation and progression of vessel pathologies such as aneurysms and stenoses. High Speed Angiography (HSA) at 1000 fps can provide detailed flow pattern images that were previously unavailable during neuro-interventional procedures. To derive such flow information, it is important to have the ability to control the rate and volume of contrast injection. In this work we present injection techniques performed by using a computer-controlled syringe injector and the resulting flow pattern. **Methods:** A 3D-printed neuro-vascular model was connected in a flow loop with a 40% glycerol and 60% water solution used as the circulating fluid. An Aries single photon counting detector (Direct Conversion Inc.) with a pixel size of 100 μ m and FOV of 7.5cmx5cm was used to acquire HSA or digital subtraction HSA sequences at 1000 fps. A KD Scientific Legato 110 syringe injector was used to inject 100% iodine-contrast agent in the flow loop. The flow patterns were evaluated for both pulsed injections (rate: 100 ml/min; injection duration: 80ms; time between injections: 120ms; total number of injections: 15; duration of image acquisition: 1.5s) and continuous injections (rate 100 ml/min; total injection duration : 2s; duration of image acquisition: 1.5s). **Results:** Pulsing the injections results in consistent formation of glob-like features when the contrast comes out of the catheter. These structures can be used by tracking algorithms to generate velocity profiles in the vasculature and subsequent wall-shear-stress determination. However, a continuous injection fills up the vessel and does not result in any trackable features that can be used for velocity determination. **Conclusion:** A properly controlled contrast injection technique that creates trackable contrast media discontinuities (globs) is necessary to be able to visualize details in the flow patterns when performing HSA at 1000- fps speeds.

TU-B-TRACK 2-07

Development and Testing of a Quality Assurance Phantom for Microwave Imaging

N Alsbou*, S Ahmad, I Ali, University of Oklahoma Health Sciences Center, Oklahoma City, OK

Purpose: The goal of this project is to develop a quality assurance phantom that can be used to characterize the image quality and provide quantitative measures of linearity, uniformity, spatial and contrast resolutions of different microwave imaging systems. **Methods:** Different phantom materials were used for testing the microwave response that include water, solid water phantoms, and phantoms with tissue-equivalent materials such as lung, breast, adipose, muscle, liver and bone. The microwave image quality parameters including linearity, uniformity, spatial and contrast resolutions were quantified using the previous phantom materials. The microwave projections were acquired using and an in-house developed microwave imaging system that uses a transmitter with 2.85cm wave length, frequency 10.525GHz, and a receiver with variable amplification 1X-10X (PASCO scientific 10101 Foothills Blvd. Roseville, CA). Microwave images were reconstructed using a back-projection algorithm considering corrections of interference and polarization effects of the microwave signal. **Results:** The microwave response was not linear as a function of density of the different tissue equivalent materials. The minimal microwave response was linear with the water volume in imaging view. The uniformity of the microwave response was within 3% over a uniform region that was made from a large solid water phantom. Spatial resolution was tested by changes in the position (2mm) of the minimal microwave intensity in regions that included small water objects that were shifted across the microwave field of view. The contrast resolution was tested with objects that included variable content of water where the microwave intensity decreased almost linearly with increasing water volume in the fields of view. **Conclusion:** A quality assurance phantom for microwave imaging is an essential tool to quantify the different image quality parameters, provides quality control tool for testing and maintaining the image quality of microwave imaging systems over time and enable the performance of quantitative imaging.

Imaging for Particle Therapy

TU-B-TRACK 6-01

Dose Tracking Using CBCT During Head and Neck Proton PBS Radiotherapy: A Feasibility Study

C Liu^{1,3*}, G Janssens², L Hong², X Liang¹, Y Zhang¹, (1) University of Florida Proton Therapy Institute, Jacksonville, FL, (2) Ion Beam Applications SA, Louvain-la-neuve, BE, (3) University of Science and Technology of China, Hefei, , CN

Purpose: Compared to photons, protons are more sensitive to organ motion and anatomy change. Verification CTs (VFCT) are often needed to evaluate the anatomy change and dose coverage during the proton treatment course. This study investigates the feasibility of using CycleGAN deep learning algorithm to generate synthetic CT (CycleGAN-sCT) from Proteus®ONE daily CBCT and use it to track the daily dose and trigger the verification CT for adaptive proton therapy. **Methods:** Among 29 head and neck patients, 39 same-day CBCT-VFCT pairs from Proteus®ONE imaging system and Philips Big Bore CT were retrospectively collected. VFCT to CBCT rigid registrations were first performed to align and standardize the size of the images. They were then fed into the deep learning training algorithm as ground truth and input, respectively. sCT generated from deformable image registration (DIR-sCT) was used for comparison. The dose was calculated with the in-house commissioned MCsquare calculation engine. 3D gamma analyses were performed to evaluate the dose accuracy calculated on CycleGAN-sCT and DIR-sCT. **Results:** Compared to CBCT, the preliminary results from two patients showed that both CycleGAN-sCT and DIR-sCT have noticeable improvement. The dose calculation gamma passing rate (TPS dose as reference) is increased from ~80% to ~90% for 3%/3mm, comparable to VFCT. DIR-sCT sometimes failed to deal with detailed

information, while CycleGAN-sCT showed better robustness, though the 3D dose gamma passing rates from both methods are comparable to VFCT. In terms of efficiency, generate 3D CycleGAN-sCT takes a couple of seconds, and DIR-sCT takes a couple of minutes. **Conclusion:** While more cases are still needed to consolidate this study, preliminary results show that the CycleGAN-sCT generated from daily CBCT for proton radiation therapy has comparable image quality as VFCT. CycleGAN-sCT can be used to track the dose and trigger the verification for adaptive proton therapy.

This work is partially supported by a master research grant from Ion Beam Applications.

TU-B-TRACK 6-02

Model-Based Reconstruction for Proton CT Detected with Multiple-Layer Ionization Chamber

X Chen*, B Sun, Y Hao, F Reynoso, A Darafsheh, D Yang, T Zhang, T Zhao, Washington University School of Medicine, St. Louis, MO

Purpose: Proton Computed Tomography (pCT), reconstructed from the integral depth dose (IDD) detected by a multiple-layer ionization chamber (MLIC), suffers from inferior image resolution and suboptimal accuracy in proton stopping power determination due to the large spot size. Although a previous study showed significant improvement with beamline collimation, it would require modification of beamline and also cause extra ambient neutron doses. Therefore, this study proposes a novel and universal model-based reconstruction for pencil beam scanning (PBS) machines with various spot sizes. **Methods:** The IDD of an uncollimated proton beam detected by MLIC was modeled as a weighted sum of percentage depth doses of elemental infinitesimal beamlets evenly spaced by 1mm. The weights followed the source distribution. Squared L2 norm between calculated and measured IDD were minimized at each gantry angle by correcting the water equivalent path length (WEPL) of all beamlets. Two iterations of correction with an intermediate smoothing were performed as a strategy to escape local minima. The corrected WEPLs were filtered back-projected to the final stopping power ratio (SPR) map. The reconstruction method was verified on a digital cylindrical water-based phantom with tissue-equivalent inserts and an ICRP adult phantom. SPR accuracy, spatial resolution, and imaging dose were evaluated. **Results:** The mean absolute deviation of SPR in ROIs was 0.66%, 0.33%, and 0.48% for the cylindrical phantom, head, and lung region of the adult phantom, respectively. MTF(10%) derived from radial edge spread function of a cortical insert was 5.30cm^{-1} . The mean imaging dose was 1.71cGy and 1.95cGy at the head and lung region of the adult phantom, accordingly. **Conclusion:** A novel model-based reconstruction method has been developed for pCT that can be utilized by all commercial PBS machines without complicated detector tracking individual protons. Excellent SPR accuracy, improved spatial resolution, and low imaging dose were achieved without additional collimation.

TU-B-TRACK 6-03

Neural Network Based Event Classification to Improve Compton Imaging for Proton Beam Range Verification

C Barajas¹, G Kroiz¹, J Polf^{2*}, S Peterson³, D Mackin⁴, S Beddar¹, M Gobbert¹, (1) University of Maryland, Baltimore County, (2) University of Maryland School of Medicine, Baltimore, MD, (3) University of Cape Town, Rondebosch, , ZA, (4) UT MD Anderson Cancer Center, Houston, TX

Purpose: To determine if Compton camera (CC) images of prompt gamma (PG) emission that occurs during proton radiotherapy (RT) can be improved by using a neural network (NN) to identify 1) "True" and "False" PG events, and 2) the correct interaction order for "True" PG events recorded by the CC. **Methods:** The Monte Carlo plus Detector Effects (MCDE) model was used to produce realistic PG interactions that occur in a CC during clinical proton RT beam delivery. The PG data was used to train a fully connected NN to identify True (due to a single PG) and False (due to multiple PGs) PG double scatter (DS) and triple scatter (TS) events. The NN predicted type and interaction order for the events were compared to the known values (from the MCDE model) to determine the accuracy of the NN predictions. Images were reconstructed using the raw MCDE data and a dataset with the NN identified False DS/TS events removed and using the NN predicted True DS/TS interaction order. **Results:** The fully trained NN was able to predict the PG event type (True/False) and interaction order with > 80% accuracy. The proton beam range could easily be identified on the PG images reconstructed using NN processed data, even for beams delivered at the highest clinical dose rates. **Conclusion:** NN processing of CC data can significantly improve the acquired images of PG emission occurring during the delivery of clinical proton RT beams. These results show that further studies of NNs for this purpose are warranted.

Performance Evaluation of An Optimization Method for Fluence-Modulated Proton CT with Dose and Variance Objectives

J Dickmann¹, F Kamp², M Hillbrand³, S Corradini⁴, C Belka⁵, R Schulte⁶, K Parodi⁷, G Dedes⁸, G Landry^{9*}, (1) Ludwig-Maximilians-Universitat Munchen, Garching Bei Munchen, BY, DE, (2) Cologne, NW, (3) Kantonsspital Graubunden, (4) University Hospital, Lmu Munich, (5) No institution provided, (6) Loma Linda University, Loma Linda, CA, (7) Ludwig-Maximilians-Universitat Munchen, Garching B. Munich, (8) Ludwig-Maximilians-Universitat Munchen, Munich, DE, (9) Ludwig-Maximilians-Universitat Munchen, Munich, DE

Purpose: To optimize dynamically modulated fluence fields for proton computed tomography (pCT) resulting in desired spatial distributions of imaging dose and image variance, with an application for adaptive particle therapy treatment planning based on frequent low-dose and high-quality imaging. **Methods:** We present an optimization algorithm for fluence-modulated pCT (FMpCT), which divides the image into a region-of-interest (ROI), in which high image quality is required and a non-ROI part for which imaging dose should be reduced. The algorithm makes use of concepts of treatment plan optimization to find modulated imaging fluences that minimize imaging dose outside of the ROI and achieve a target image variance inside the ROI using a joint cost function. Imaging doses to susceptible organs can be further reduced. Using Monte Carlo simulation, FMpCT plans were optimized for three pediatric patients with tumors in the head region for which robust proton treatment plans were used to define the ROI. Imaging doses were scored, and the accuracy of low-dose images was evaluated by re-calculating the ground truth proton plans on simulated FMpCT images. **Results:** Using the optimization, the imaging dose could be reduced by 74% outside of the ROI on average over all patients, bringing it down to only 0.3mGy per tomography. Imaging doses to susceptible structures were further reduced with up to 87% dose saving. The quality of FMpCT scans for treatment planning was maintained with treatment dose passing rates for a 1% criterion on the difference to a uniform fluence pCT scan above 98% and range passing rates for a 1mm criterion above 97%. **Conclusion:** A fluence modulation optimization algorithm for FMpCT was evaluated for its ability to save imaging dose while maintaining sufficient quality for treatment planning using three pediatric patients. Imaging doses of only 0.3mGy could pave the way towards daily adaptive particle therapy.

Scatter Correction of 4D Cone Beam Computed Tomography for Time-Resolved Proton Dose Calculation: Porcine Lung Phantom Validation

H Schmitz^{1*}, M Rabe¹, G Janssens², J Dinkel³, S Rit⁴, K Parodi⁵, C Belka^{1,6}, C Kurz^{1,5}, F Kamp^{1,7}, G Landry^{1,5}, (1) Department of Radiation Oncology, University Hospital, LMU Munich, Munich, Germany, (2) Ion Beam Applications SA, Louvain-la-neuve, Belgium, (3) Department of Radiology, University Hospital, LMU Munich, Munich, Germany, (4) Centre Leon Berard, Université de Lyon, Lyon, France, (5) Department of Medical Physics, Ludwig-Maximilians-Universität München (LMU Munich), Garching (Munich), Germany, (6) German Cancer Consortium (DKTK), Partner Site Munich, Munich, Germany, (7) Department of Radiation Oncology, University Hospital Cologne, Cologne, Germany

Purpose: A respiratory-phase-specific CBCT scatter correction algorithm, using a 4D virtual CT (4DvCT) as prior, was developed for time-resolved proton therapy dose calculations for lung tumors. The time-resolved dose calculation accuracy achievable with the resulting 4DCBCTcor, as well as with the 4DvCT, was evaluated using a porcine lung phantom allowing reproducible 4DCBCT and 4DCT scanning. **Methods:** 4DCBCT projections of a periodically breathing ex-vivo porcine lung phantom with 4 injected artificial lesions, as well as 4DCTs with two different breathing patterns (planning and day-of-treatment), were acquired. The average planning CT was rigidly registered onto the day-of-treatment 3DCBCT. Subsequently, CT mid-position images were computed using deformable image registration (DIR). Exploiting the deformation vector fields, obtained from the previous step, a 4DCBCT was reconstructed using MA-ROOSTER, followed by mid-position image generation. Applying DIR on the two mid-position images yielded a mid-position vCT, which was propagated to 4D with the inverted vector fields from the 4DCBCT mid-positioning. All DIRs were performed using a diffeomorphic Morphons algorithm. DRRs of each of the 4DvCT phases, assumed to be scatter-free, were individually exploited to scatter correct the corresponding CBCT projections. The corrected projection set was again reconstructed with the MA-ROOSTER yielding the 4DCBCTcor. The 4DvCT and 4DCBCTcor methods were evaluated by comparing dose calculations for lesion-specific robust proton plans vs. day-of-treatment reference 4DCT for individual phases and accumulated doses. **Results:** Accumulated dose DVH differences of the 4 plans for D(2%), D(98%), D(mean,ITV) and D(mean,lung), were 1.7%, 1.3%, 0.9% and 1.3% for 4DvCT-4DCT and 2.0%, 1.6%, 1.0% and 1.2% for 4DCBCTcor-4DCT. The 2%/2mm gamma pass-rate using a 10% dose threshold was always above 93.2% (4DvCT) and 94.2% (4DCBCTcor). **Conclusion:** The qualitative and quantitative agreement between the different modalities suggests that 4DCBCTcor provides sufficient image quality to perform accurate time-resolved proton dose calculation for the used porcine lung phantom.

Synthetic Dual-Energy CT for MRI-Based Proton Therapy Treatment Planning Using Label-GAN

R Liu^{1*}, Y Lei², T Wang³, J Zhou⁴, J Roper⁵, L Lin⁶, M McDonald⁷, J Bradley⁸, T Liu⁹, X Yang¹⁰, (1) Emory University, Atlanta, GA, (2) Emory Univ, Atlanta, GA, (3) Emory University, Atlanta, GA, (4) Emory University, Atlanta, GA, (5) Winship Cancer Institute of Emory University, Atlanta, GA, (6) Emory Proton Therapy Center, Atlanta, GA, (7) Emory University, Atlanta, GA, (8) Emory University School Of Medicine, (9) Emory Univ, Atlanta, GA, (10) Emory University, Atlanta, GA

Purpose: MRI-only treatment planning is highly desirable in current proton radiation therapy workflow due to its appealing advantages such as bypassing MR-CT co-registration, avoiding x-ray CT exposure dose and reduced medical cost. However, MRI alone cannot provide stopping power ratio (SPR) information for dose calculations. Given that dual energy CT (DECT) can estimate SPR with higher accuracy than conventional single energy CT (SECT), we propose a deep learning-based method in this study to generate synthetic DECT (sDECT) from MRI to calculate SPR. **Methods:** Since the contrast difference between high-energy and low-energy CT is important, and in order to accurately model this difference, we propose a novel label generative adversarial network (label-GAN)-based model which can not only discriminate the realism of sDECT but also differentiate high-energy CT (HECT) and low-energy CT (LECT) from DECT. A cohort of 57 head-and-neck cancer patients with DECT and MRI pairs were used to validate the performance of the proposed framework. The results of sDECT and its derived SPR maps were compared with clinical DECT and the corresponding SPR, respectively. **Results:** The mean absolute error (MAE) for synthetic LECT and HECT were 79.98±18.11 HU and 80.15±16.27 HU, respectively. The corresponding SPR maps generated from sDECT showed a normalized mean absolute error (NMAE) as 5.22%±1.23%. By comparing with the traditional Cycle GANs, our proposed method significantly improves the accuracy of sDECT. **Conclusion:** We developed a deep learning-based method to generate sDECT from MRI for proton radiotherapy. The results indicate that on our dataset, the synthetic DECT image from MRI is close to planning DECT, and thus shows promising potential for generating SPR maps for proton therapy. The image similarity and SPR agreement between sDECT and DECT warrants further study and development of an MRI-only workflow for MRI-based proton radiotherapy.

Beam Path Length from Isocenter to Skin On Cone Beam CT Images as An Adaptive Planning Indicator of Head and Neck Patients Undergoing Proton Therapy

N Biswal^{*}, B Zhang, J Molitoris, M Witek, B Yi, Department of Radiation Oncology, University of Maryland School of Medicine, Baltimore, MD

Purpose: This study tested the beam path length (BPL) of daily cone beam CT (CBCT) images as an adaptive planning indicator of head-and-neck (HN) patients treated with proton beam therapy (PBT). **Methods:** In this IRB approved study, we retrospectively analyzed 70 HN patients who were treated with PBT. Out of 70 patients, 30 of them underwent adaptive planning on their quality assurance CT scans (QACTs) due to different reasons, e.g. weight loss (10 patients), anatomical changes (11 patients), tumor shrinkage (8 patients) and loss of target coverage (1 patient). Each beam was ray traced from the isocenter to the skin surface along the central axis using the daily CBCT images. The patterns of change in BPL of CBCT images have been compared to those of the adaptive planning using weekly QACT. **Results:** In our study, we used a threshold of BPL change of 3 mm, beyond which an adaptive plan must be needed. Out of 119 beams for all 30 the adaptively planned patients, 58 (48.7 %) of them had BPL changes more than 3 mm. Similarly, out of 128 beams for the 40 non-adaptive planned patients, only 3 (2.3 %) beams had BPL changes of more than 3 mm. The maximum change in BPL for 29 out of 30 adaptive planned patients were larger than 3 mm, this led to a sensitivity of 96.7 % for BPL change as an indicator of adaptive planning. 37 out of 40 non-adaptive planned patients had BPL changes less than 3 mm, led to a specificity of 92.5 %. **Conclusion:** The beam path length (BPL) change from isocenter to skin surface along the beam central axis on CBCT images can be used as an adaptive plan indicator for proton beam therapy (PBT) head-and-neck patients with 96.7 % sensitivity and 92.5 % specificity.

TU-B-TRACK 7-04

Q&A

Liver and pancreas cancers are intrinsically radioresistant, and thus require large radiation doses for tumor control. However, several radiosensitive gastrointestinal (GI) organs at risk (OARs) are located near tumors in these locations, including the duodenum, stomach, and bowel. This complicates hypofractionated and stereotactic ablative radiation treatment (SBRT) of the liver and pancreas, because the tolerance doses for these OARs must be maintained to avoid life-threatening toxicities. Maintaining GI tolerances can greatly reduce the amount of ablative dose to the tumor, and hence may limit the SBRT effectiveness in terms of local control and overall survival. Moreover, respiratory motion and daily anatomic variations from intra- and inter-fractional motion impose additional therapeutic challenges. This is especially true for pancreatic cancer, as tumors often lie next to the duodenum, requiring sharp dosimetric gradients between the target and this OAR. Obtaining sharp dosimetric gradients is also complicated by daily anatomic variations from transient GI gas filling and peristalsis; these variations can affect daily dose distributions and warrant dynamic changes in the dosimetric gradient position to maintain GI OAR tolerances. Thus, consideration of these variations in the treatment planning and delivery workflow is essential. Image guidance using cone-beam CT may not provide adequate soft-tissue visualization of OARs adjacent to the tumor in the abdomen. Even advanced image guidance methods involving CT-on-rails or MR-guided radiotherapy (MRgRT) may not provide optimal treatments if an online adaptation approach is not used. Therefore, selecting patients for SBRT based on optimal tumor position with respect to OARs is essential to ensure safe delivery of SBRT and avoid exceeding GI tolerances, but this limits the population that can be treated with this ablative approach. Implementing a daily online adaptive workflow may allow additional pancreatic and liver patients to receive SBRT and provide the optimal therapeutic intervention. In this session, we will highlight the challenges with using SBRT for liver and pancreas cancers and present potential alternatives using online adaptation with both CT-on-rails and MRgRT approaches that may allow safe dose escalation beyond what can be achieved with current methods.

Learning Objectives:

1. Highlight the importance of daily volumetric imaging with soft-tissue contrast in the treatment of liver and pancreas tumors.
2. Highlight the effect of sharp dose gradients and daily variations in dose distributions to OARs
3. Present strategies using online adaptation to minimize the compounded dosimetric effects from high-dose gradients and daily variations in gastrointestinal anatomy.

A Quantitative Evaluation of Computational Paediatric Phantoms for Radiotherapy Applications

R Ahmad^{1*}, C Borrelli¹, J Cantwell², P Lim², D D'Souza², S Moinuddin², J Gains², C Veiga¹ (1) University College London, London, GB, (2) University College London Hospital, London, GB

Purpose: Computational phantoms have important applications in paediatric radiotherapy, in quality assurance of diagnostic/therapeutic protocols, and in reconstructing historical radiation doses. Detailed age-specific computational anatomical models are available, developed from average and/or healthy individuals, which may not be representative of cancer patients due to pathology and/or treatment effects. This study investigated the capability of existing phantoms in representing the paediatric radiotherapy population. **Methods:** Computational models evaluated were the International Commission on Radiological Protection (ICRP) paediatric reference computational phantoms (n=8, median age 8y, range: 1–15y) and the default 4D extended cardiac torso (XCAT) (n=75, median age 9y, range: 1–18y). Five key organs (kidneys, lungs, spleen, liver and brain) were automatically segmented on the virtual phantoms similar to clinical organ at risk segmentation protocols. Anatomical similarity was assessed in terms of organ length and mass. These quantities were measured on the phantoms and on a clinical radiotherapy dataset, consisting of planning CT images/contours from craniospinal irradiation patients (n=68, median age 7, range: 2–16y). We also compared clinical measures with published literature on healthy children (9 publications, median age 8y, range 1–16y). **Results:** For each dataset (phantom, published and clinical data) we performed a linear fit of the mass and length across the ages. Differences between clinical data and virtual phantoms/published data were calculated as the average relative difference between the linear fits for integer ages across the clinical data. For the phantoms, differences across all organs ranged from 1–22% for lengths and 4–35% for masses. For published data these were 5–23% and 7–39%, respectively. The smallest and largest differences were found for the liver and spleen, respectively. **Conclusion:** Quantitative anatomical differences were described between phantoms, literature, and routine radiotherapy data. Our findings will help selecting and tailoring the phantoms most representative of this population.

Anatomically Realistic Simulation of Random Human Airway Trees

J Whitehead*, L Torres, A Hahn, S Fain, M Speidel, M Wagner, University of Wisconsin, Madison, WI

Purpose: To develop a tool for generating high resolution, realistic and random human airway trees that abide by physiological and anatomical constraints. This tool is meant to facilitate training and validation of deep learning airway segmentation algorithms for surgical planning and pulmonary disease diagnosis. **Methods:** Airway tree generation begins with selecting terminal airway segments (endpoints) within the lung by randomly sampling a given oxygen demand map. The tree is progressively generated by calculating a connection cost between every existing branch within the tree and an endpoint. A new branch is then created from the endpoint to the lowest cost branch by forming a new bifurcation. The cost function is designed to optimize the physiological principle of minimum work (Murray's law and volume-minimization) under anatomical constraints (main airway branch to each lobe). The algorithm was adjusted to assure no airway intersections. Airways were simulated down to .4mm, equivalent to the average minimum human airway diameter. Realism was evaluated by comparing length to diameter ratios (LDR), homothety ratios (HR), and branching angles with literature data for human subjects. Simulation randomness was evaluated through a dissimilarity metric (1-Dice Coefficient) measured between airway trees. **Results:** For 40 synthetic airway trees, the LDR, HR, and branching angles [mean(std)] were found to be 2.9(1.3), 0.72(0.2) and 76.3(13) degrees, respectively. Corresponding literature values for human subjects were 2.9(2.0), 0.71(0.1) and 76.1(46) degrees. The airway tree randomness as characterized with the dissimilarity metric was 0.73(.01). **Conclusion:** A method for the simulation of realistic airway trees with LDR, HR, and branching angles close to human subjects has been developed. This algorithm can be paired with any existing digital phantoms for realistic background and could allow the training of airway segmentation algorithms with large datasets and known ground truth.

TU-IePD-TRACK 1-03

Development and Characterization of a Dynamic, Anatomically Realistic, Abdominal Phantom for Simulating Complex Deformable Motion in Cone-Beam CT

Y Liu^{1*}, H Huang¹, J Siewerdsen¹, W Zbijewski¹, C Weiss¹, T Ehtiati², A Sisniega¹, (1) Johns Hopkins University, Baltimore, MD, (2) Siemens Medical Solutions USA

Purpose: Cone-beam CT (CBCT) provides 3D guidance for interventional radiology and radiotherapy, but long acquisition time results in patient motion. Motion compensation methods require realistic models to replicate the complex interplay between image features and motion in CBCT. We report a phantom that presents realistic anatomical deformable motion via simple linear actuation. **Methods:** The phantom incorporates numerous elements within a plastic cylindrical container (23 x 24 cm): ultrasound gel interstitium; synthetic liver (Syndaver Inc.); kidneys (SuperFlab, Bebig); aorta (3 cm PMMA cylinder); spine (4 cm Teflon tube and Delrin insert); and fat fascia (vegetable shortening - Crisco, P&G). 11 Teflon spheres (3 - 9.5 mm) and two cylindrical vessels were inserted into the liver to simulate contrast-enhanced lesions and vasculature. Key to deformable motion are two rubber apertures – one at the diaphragm connected to a linear actuator for SUP-INF motion and another to allow AP motion. CBCT images were acquired on a C-arm (body protocol, Cios Spin 3D, Siemens) with 4 - 16 mm amplitude of the linear actuator. CBCT images were registered to the static reference using Elastix (mutual information, 14³ knots) to assess the imparted deformation. **Results:** X-ray attenuation of the simulated structures was accurate: 30 HU liver, 60 HU kidneys, 660 HU cortical (300 HU inner) bone, and -160 HU fat. Linear actuation yielded a rich variety of deformable motion of structures: ~30% AP in mid-anterior regions, while posterior regions remained nearly static. The magnitude and complexity of the motion field was controllable via the actuation amplitude – e.g., 0.1 - 3.8 mm and 0.3 - 12.5 mm, for 4 mm and 16 mm actuation. **Conclusion:** A realistic abdominal phantom for deformable motion was designed and tested. Linear motion applied to the diaphragm generated a rich deformable motion field, enabling testing of CBCT motion compensation techniques.

TU-IePD-TRACK 1-04

Smoothed Delineation Uncertainties Contouring (SDUC) Model

V Ly^{1*}, L Liu¹, C Cardenas², K Hoffman², L Court², X Luo¹, (1) University of Texas Health Science Center, Houston, Texas, (2) University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: Contouring is one of the largest sources of variability in radiotherapy. The purpose of this work is to develop an algorithm to inject known levels of error to clinically accepted contours, giving realistic contours with varying levels of variability. This is an important first step to investigating the dosimetric impact of contouring variability, and to developing approaches to automatically verify contouring quality. **Methods:** We have developed a smoothed-delineation-uncertainties-contouring (SDUC) model to automatically generate alternative, realistic contours. The SDUC model transforms contours (deformation, contraction and/or expansion) as a function of image contrast, based on the expectation that contouring variability is largest when image contrast is low (i.e. when structure edges are less clear). The magnitude of the delineation uncertainty is scaled by a voxel-specific displacement vector in 3 dimensions by applying a random base uncertainty, scaled by the local contrast. Finally, 3D smoothing is applied to ensure the final contours appear realistic. **Results:** For our evaluation, we use the algorithm for auto-contouring of 3 organs (the prostate, bladder, and rectum) on different variation parameters C and on 4 different patients. From the evaluation, we find that there is a decreasing trend in Dice Score Coefficient (DSC) as the variation rate C increases. Hence, for variability rate C of 5, 50, 100, 200, 300, the DSC are 0.917±0.04, 0.899±0.05, 0.861±0.06, 0.859±0.06, and 0.832±0.07, respectively. **Conclusion:** We have developed an algorithm that can simulate the effect of variability in contouring, generating variable but realistic contours.

TU-IePD-TRACK 1-05

Some Observations on the Basis Material Paradigm

R Jennings^{1*}, (1) Retired, Olney, MD

Purpose: To describe a computational approach to the basis material paradigm and describe some of its applications. **Methods:** The basis material paradigm asserts that the linear attenuation coefficient of an arbitrary material can be accurately represented by a linear combination of the linear attenuation coefficients of two dissimilar materials. The combined thicknesses of the basis materials do not, in general, match the thickness of the material being characterized. Adding a third material resolves that issue. Two equations in three coefficients, plus an equation for the volume constraint, complete the theoretical system. Attenuation coefficient data were generated by the program XCOM from NIST. Data for elements from 1 to 83 are tabulated at energies from 1.0 to 150.0 keV in steps of 0.5 keV. Total and partial (coherent scatter, incoherent (Compton) scatter, and photoelectric effect) coefficients are provided. Also included in the package is a library of materials that have been suggested as phantom components, as well as data on tissue composition from ICRU Report 44. **Results:** Solutions generally show good agreement in total and partial coefficient ratios (better than 1%) for total and Compton coefficients. Deviations for coherent scattering and photoelectric effect can be several percent. Pairs of solutions for some tissues have been found where photoelectric deviations are in opposite directions. Combinations of these can produce agreement of a few tenths of a percent from 20 to 150 keV. Electron densities calculated using the two-component and the three-component versions of the basis material paradigm match the values for the tissue in question to within a few hundredths of a percent. **Conclusion:** The method described produces accurate results and is

easy to use. Often the only input needed consists of the names of the material being studied and the suggested simulation components.

Task-Based Assessment of Pediatric Fluoroscopy by Use of Vesico-Ureteral Reflux Grading

D Olivera Velarde*, J Cruz Bastida, N Baughan, E Marshall, K Blunt, K Feinstein, I Reiser, The University of Chicago, Chicago, IL

Purpose: To propose a methodology for task-based evaluation of pediatric fluoroscopy systems analogous to the clinical diagnostic task of grading the severity of vesicoureteral reflux (VUR) in neonates. **Methods:** Four depictions of VUR corresponding to grades 2-5 were created based on published references and embedded into selected regions from 20 neonate radiographs. Synthetic patches were simulated to match the noise-power spectrum of the selected regions, with mean and standard deviation matched to each radiograph region. A reader study program was written in MATLAB to display a simulated background image with an embedded task and a random displacement and rotation of the task of up to 15 pixels and 20-degrees, respectively. The reader was then prompted to assign the task a grade, from 2-5. Three observers performed a total of 15 reader studies using the simulated patches and five different contrast levels, determined as number of printing passes. Accuracy of grade identification for each contrast level and sensitivity of each class were calculated, with standard errors obtained using a bootstrapping technique. **Results:** Accuracy increased as a function of contrast level with values of 0.45 ± 0.054 , 0.68 ± 0.040 , 0.70 ± 0.020 , 0.76 ± 0.035 , and 0.95 ± 0.0094 for 10, 12, 13, 15, and 17 passes, respectively. In this study guessing would yield an accuracy of 0.25. Grades four and five were more easily confounded yielding sensitivity values of 0.68 ± 0.040 and 0.66 ± 0.044 , respectively. Grades two and three were easier to identify, and yielded sensitivity values of 0.79 ± 0.040 and 0.78 ± 0.037 . **Conclusion:** The proposed methodology was used to simulate a diagnostic task and to establish the feasibility of using VUR grading as a surrogate task for quantitative, task-based assessment of the image quality of pediatric fluoroscopy. Future work will refine the reader study to improve reproducibility, and will extend this methodology to image quality assessment of real fluoroscopy systems.

Understanding Variability in Quantitative Imaging and Radiomics: The Use of Different Phantoms in CT to Explore the Effects of Acquisition and Reconstruction Parameters

N Emaminejad*, M Wahi-Anwar, M McNitt-Gray, David Geffen School of Medicine at UCLA, Los Angeles, CA

Purpose: Quantitative Imaging and Radiomic Features (QIFs) have been shown to be affected by the CT Imaging acquisition and reconstruction parameters used. The purpose of this study was to use a series of phantoms of increasing complexity to understand the effects of acquisition and reconstruction parameters on QIF variability. **Methods:** Image data was used from three different phantoms: (a) publicly available image data from the Credence Cartridge Radiomics (CCR) phantom; (b) publicly available image data from FDA anthropomorphic phantom with simulated lesions and (c) a water phantom. Each phantom was scanned and reconstructed at a variety of acquisition (e.g. different mAs) and reconstruction (slice thickness and kernel) conditions. For each phantom and each condition, a volume of interest (VOI) was created. For the anthro phantom, the VOI was the segmented boundary of the phantom lesion. For each VOI, three QIFs were computed – the mean HU, the standard deviation and the Gray Level Co-occurrence Matrix measure Entropy (GLCM-Entropy). QIFs were compared for pairs of phantoms (water vs. CCR; water vs. Anthro) across conditions. **Results:** The mean HU for the water and CCR phantom was very constant across conditions; however the mean HU of the anthro phantom lesion varied with slice thickness due to volume averaging effects. The standard deviation values varied substantially in almost all phantoms and conditions. Interestingly, the standard deviation of the CCR phantom was constant across acquisition (mAs) values. This was due to the heterogeneity of the material contributing more to the standard deviation than the acquisition parameters. The GLCM-Entropy values did not display consistent patterns. **Conclusion:** The use of these phantoms allowed us to explore sources of QIF variability due to acquisition and reconstruction parameters. They also allowed us to demonstrate the effects that volume averaging and material heterogeneity have on QIFs as well.

UCLA Radiology has a Master Research Agreement with Siemens Healthineers. M. McNitt-Gray receives grant support from Siemens Healthineers and is a Member of the Board of Scientific Advisors for Hura LLC.

Distribution of Peak Skin Doses from Fluoroscopic Procedures Exceeding 5 Gy Reference Air Kerma

G Fong*, K Wunderle, Cleveland Clinic Foundation, Cleveland, OH

Purpose: The reference point air kerma ($K_{a,r}$) is a readily-available dose quantity provided by most modern fluoroscopes that can provide guidance for patient dose management actions following fluoroscopically-guided procedures. This study investigates the patient peak skin dose (PSD) distribution for procedures exceeding the 5 Gy $K_{a,r}$ which is the recommended substantial radiation dose level (SRDL) by NCRP 168 for potential patient follow-up. **Methods:** Using DICOM radiation dose structured report data, PSD was calculated for 125 fluoroscopically-guided interventions (FGIs) exceeding a single procedure $K_{a,r}$ of 5 Gy using an internally-validated PSD calculation method. Additionally, for each procedure, the ratio of PSD to $K_{a,r}$ was calculated and the results pooled into one of three clinical categories: cardiac (N=67), body-interventional (N=24), and neuro-interventional (N=34). The $K_{a,r}$ distribution and PSD distribution were analyzed for all procedures in aggregate while the PSD to $K_{a,r}$ ratios were analyzed by the clinical procedure type. **Results:** The $K_{a,r}$ distribution resulted in a mean value of 6.7 Gy with a range of 5.1–18.6 Gy. The PSD distribution resulted in a mean value of 5.1 Gy with a range of 1.6–11.0 Gy. For the PSD to $K_{a,r}$ ratio differentiated by clinical categories, cardiac FGIs resulted in a mean ratio of 0.84 with a range of 0.31–1.72, body-interventional FGIs resulted in a mean ratio of 0.74 with a range of 0.43–1.41, and neuro-interventional FGIs resulted in a mean ratio of 0.53 with a range of 0.37–0.88. **Conclusion:** PSD to $K_{a,r}$ ratios yielded substantially different results with respect to the clinical categories which illustrates the possible need of a $K_{a,r}$ SRDL specific to the clinical service. Additionally, using a static $K_{a,r}$ SRDL for any clinical service could over or under predict the need for patient follow-up indicating it may be better to establish SRDLs based on PSD.

Enhancements of the Scattered Radiation Display System Training Module

J Troville*, S Rudin, D Bednarek, (1) University at Buffalo (SUNY) Jacob's School of Medicine and Biomedical Sciences, Buffalo, NY, (2) Canon Stroke and Vascular Research Center, Buffalo, NY

Purpose: The real-time scattered-radiation display system (SDS) has been expanded in functionality to facilitate interactive resident and staff-member training in a virtual-reality world. In this work we report on improvements to the training system, which enhance the information provided to the trainee. **Methods:** The SDS has

been previously expanded to include a virtual reality (VR) training module (TM). Unity3D was utilized for designing a virtual interventional room consisting of a C-Arm, patient, and patient table. When the software is initiated, a main menu is opened to select either the dose-management module (DM) or the TM. The TM has two options. In the first, the trainee can view the scatter distributions for previous fluoroscopically-guided-interventional (FGI) procedures using machine-parameter log files stored by the DM. In addition, we utilize a time-of-flight depth-sensing camera along with a custom-built convolutional neural network and NiTE 2 for identifying and tracking staff-members' locations during procedures which are also recorded in log files for post-procedure evaluation. The second TM mode allows the trainee to control parameters of an interactive virtual procedure and visualize the room-scatter-distribution display. **Results:** Within the TM, three distinct enhancements have been made: 1) the ability to select staff-locational log files for playback allowing trainees to observe doses for each of the individuals involved with a procedure; previously, only machine-parameter log files were available; 2) a dose probe to numerically analyze the scatter distribution; 3) fluoroscopic image display, which gives the trainee a frame of reference to the clinical procedure and the ability to correlate the scatter distributions with clinical technique and conduct of the procedure. **Conclusion:** We present enhancements to the SDS TM, which will further improve the training experience for staff and residents. A software system capable of VR training and real-time intraprocedural feedback will facilitate improved staff awareness and radiation-dose management during fluoroscopic-interventional procedures.

Fluoroscopic Guided Interventional Procedures, Patient and Related Staff Radiation Doses Monitoring in Mississippi

H Khosravi*, R Morris, D Garrido, J Storrs, A Fatemi, UMMC, Jackson, MS

Purpose: Interventional Radiology (IR) procedures using fluoroscopic guiding are widely implemented in healthcare systems for the diagnostic and/or treatment of diseases. Interventionists are from different specialists including surgeons, cardiologists, and radiologists. Based on complications, patient weight and habits, interventionist experience, and exposure parameters setting, the patient and staff dose will vary. In this study, the details of patients and staff dose were monitored, evaluated and the area of dose optimization was proposed in the largest healthcare system in Mississippi. **Methods:** Patient and staff doses in past 3 years, for different procedures and 15376 patients/procedures were monitored and evaluated in four distinct IR locations: Vascular Surgeons in the operating room (VSOR), Cardiologists in adult and pediatric Cath-labs, Neuro-surgeons, and IR radiologists in old and new IR divisions. Fluoro and acquisition (high-quality image) times, Dose Area Products (DAP), Cumulative KERMA at reference points (RP), and the number of events were evaluated for different procedures and IR physicians. Patient effective dose and Staff dose in vascular surgery OR were evaluated. **Results:** The highest and the lowest values were for VSOR and Pediatric Cath-lab, respectively. The average patient effective dose was 41.36 mSv, while the average monthly Staff deep, Lenses and shallow dose equivalents (DDE, LDE, and SDE) were 1.44, 4.84, and 4.81 mSv, respectively in VSOR. Recognizable patterns were seen for different staff dose metrics and patient doses delivered by known physicians. **Conclusion:** The in-house patient dose monitoring system is in place, the threshold dose has decreased from 8 Gy to 5 Gy in institutional radiation safety policy, moreover, the awareness of Interventionists was increased and the trend of the patient dose is decreasing which depicted in supporting figures. Setting the default protocols to low levels exposure parameters for both Fluoro and Acquisition were implemented as well as some practical actions in dose reduction.

Fluoroscopic Imaging Data Analysis: A Practical Study to Guide Protocol Optimization and Operator Training

J Paltani*, G Fong², K Wunderle², (1) Cleveland State University, Cleveland, Ohio (2) Cleveland Clinic, Cleveland, OH

Purpose: Fluoroscopy, 2D acquisition (2D-ACQ), and 3D acquisition (3D-ACQ) are fluoroscope imaging modes with substantially different radiation dose rates and image quality that may be used during fluoroscopically-guided interventions (FGIs). The purpose of this study was to analyze clinical procedure data to better understand imaging mode use frequency and its contribution to the reference point air kerma ($K_{a,r}$) to potentially guide protocol optimization and focused educational opportunities. **Methods:** 48,454 DICOM radiation structured dose reports originating from 59 interventional fluoroscopes in calendar year 2020 were analyzed in Excel. The data were parsed into four clinical groups performing FGIs, cardiac catheterization, cardiac electrophysiology, body-interventional, and neuro-interventional. The average percentage of irradiation events and average percentage of $K_{a,r}$ per study from each imaging mode were calculated for each clinical service. **Results:** Cardiac catheterization procedures resulted in fluoroscopy [85% of irradiation events, 65.8% of $K_{a,r}$], 2D-ACQ [15% of irradiation events, 34.2% of $K_{a,r}$], and 3D-ACQ [0% of irradiation events, 0% of $K_{a,r}$] from 19,439 procedures. Cardiac electrophysiology procedures resulted in fluoroscopy [97.6% of irradiation events, 85% of $K_{a,r}$], 2D-ACQ [2.49% of irradiation events, 15% of $K_{a,r}$], and 3D-ACQ [0% of irradiation events, 0% of $K_{a,r}$] from 6,125 procedures. Body-interventional procedures resulted in fluoroscopy [91.6% of irradiation events, 46.4% of $K_{a,r}$], 2D-ACQ [8.1% of irradiation events, 44.5% of $K_{a,r}$], and 3D-ACQ [0.3% of irradiation events, 9.1% of $K_{a,r}$] from 20,198 procedures. Neuro-interventional procedures resulted in fluoroscopy [83.3% of irradiation events, 48.4% of $K_{a,r}$], 2D-ACQ [16.3% of irradiation events, 48.6% of $K_{a,r}$], and 3D-ACQ [0.4% of irradiation events, 3% of $K_{a,r}$] from 2,692 procedures. **Conclusion:** Institutions that perform FGI procedures may benefit from similarly analyzing their procedure data to better understand how the various imaging modes are used by different clinical services and use that data to guide protocol optimization and/or educational opportunities.

Convenient Calculation of Radiation Workloads for Cardiac Angiography Using Dose Area Product

E Macdonald*, M Vanderhoeck, C Morrison, A Jackson, N Bevins, Henry Ford Health System, Detroit, MI

Purpose: The dose area product (DAP) may be a more reliable and convenient metric than mA-min for radiation shielding design. DAP is more readily available and better correlated with x-ray scatter than mA-min. We investigated the use of DAP as an alternative metric of radiation workload for modern cardiac angiography suites. **Methods:** Irradiation event data was collected from radiation dose structured reports (RDSRs) for 11 cardiac angiography suites across 4 hospitals for 3 weeks in 2019. Workload distributions as a function of kVp were calculated for DAP and mA-min. DAP was consistently provided in the RDSR but mA-min required calculation of the product of tube current (mA) and exposure time using DICOM fields in the RDSR that were populated inconsistently among vendors. To enable comparison of DAP workloads with mA-min workloads (from NCRP Report 147), a DAP-to-mA-min conversion factor was estimated. **Results:** The average DAP/patient workload was 490 dGy-cm²/patient. The DAP-to-mA-min conversion factor was 0.31. Of the 10 suites with data from ≥20 patients, this conversion factor predicted the total mA-min with a mean absolute error of 21% (error range: -45% to 58%). The average workload was slightly lower than that of NCRP-147 (150 mA-min/patient vs. 160 mA-min/patient, respectively) and had a higher average tube potential (93 kVp vs. 88 kVp, respectively). Notably, the workload at high kVp (115 – 120 kVp) was approximately five times greater than in NCRP-147. **Conclusion:** The radiation workload for modern cardiac angiography suites was readily calculated using DAP. DAP and mA-min workload distributions were compared to estimate a DAP-to-mA-min conversion factor. This conversion factor may help facilitate future comparisons between DAP workloads and mA-min workloads (from NCRP-147). Future work will investigate secondary air kerma rates for this DAP distribution which may be useful for shielding calculations.

Evaluating the Kerma Correction Factor of Modern Fluoroscopy Systems

M Fadhel*, R Perez Franco, D Vergara, Yale New Haven Hospital, Yale School of Medicine, New Haven, CT

Purpose: A model for the kerma correction factor (KCF), used for improving peak skin dose (PSD) calculation of fluoroscopy guided procedures, was presented by DeLorenzo and Goode (DG-KCF). We propose to validate the author's KCF model, and extend its application to other fluoroscopy systems. **Methods:** Under fluoroscopic service mode, table attenuated/scatter included air-kerma rates and free-in-air kerma rates were measured, using a 0.6cc thimble ionization chamber (IC) (10X6-0.6, Radcal®). The measurements were acquired with a Siemens Artis Zee under different tube voltages [60–120kVp], pre-patient copper filtration [0–0.9mm] and X-ray field sizes [9×9, 12×12, 14.5×14.5cm²], defined at an clinical patient skin location. The KCF is computed from the ratio of the two types of kerma rates. Other analytical nonlinear fits of the KCF are then generated and compared against DG-KCF. **Results:** Preliminary KCF values range between 0.79 and 1.26 for all parameters. For different kVp, the KCF directly correlates with the maximum energy output of the X-ray tube for most circumstances, except for high filtration. The change in the KCF with tube voltage was the highest in the absence of copper filtration and 14.5×14.5cm² field size and lowest in the presence of 0.9mm copper filtration and 9×9cm² field size. The increase in copper filtration increased the KCF by 1.13, 1.25 and 1.36 for the respective field sizes of 9×9cm², 12×12cm², 14.5×14.5cm². The fitted nonlinear model demonstrates a strong correlation to the recorded KCF with a square residual norm of 0.051 and maximum percent difference of 7%. **Conclusion:** Validation of the DG-KCF model was performed. Preliminary results suggest good agreement to measured data. Further validation of the model will be extended to other fluoroscopy systems and parameters. Use of the KCF model with the radiation dose structured report data will improve the accuracy of PSD calculation.

TU-lePD-TRACK 2-07

A Low Hanging Fruit for Children: Anti-Scatter Grid Removal for Significant Radiation Dose Reduction in Pediatric Cerebral Angiography

D Kim*, D Orbach, Boston Children's Hospital / Harvard Medical School, Boston, MA

Purpose: To achieve significant dose reduction by the removal of the anti-scatter grid during cerebral angiography, using a bi-plane interventional fluoroscopy system in a tertiary pediatric hospital. **Methods:** Cerebral angiography is a fluoroscopic X-ray examination that requires significant spatial resolution in order to see small blood vessels in the cerebral vasculature. Typical cerebral angiogram is performed using bi-plane interventional fluoroscopy to see the blood vessels of interest from two angles. Modern interventional fluoroscopy systems are equipped with removable anti-scatter grids that improve image quality at the expense of higher radiation to the patient. However, we hypothesized that the use of anti-scatter grid would not drastically improve the diagnostic quality of the imaging in pediatric cerebral angiography. The anti-scatter grid was removed from the lateral plane of a bi-plane interventional fluoroscopy used for cerebral angiograms, which were thereafter performed by an experienced interventional neuroradiologist who had previously used to use the anti-scatter grid for the same procedures. Dose-Area-Product (DAP) and Reference Point Air Kerma (K) from both fluoroscopic and acquisition procedures along with fluoroscopic time of the lateral fluoroscopic examinations were compared for 54 cerebral angiograms performed with the anti-scatter grid in place and 48 procedures without the grid. **Results:** The interventional neuroradiologist observed no noticeable changes in diagnostic image quality and in fluoroscopic time between the procedures with and without the anti-scatter grid among all 102 procedures. The median reduction of DAP was 47% and 33%, and the median reduction of K was 40% and 29% for patients younger and older than 10 years old, respectively. **Conclusion:** The removal of the anti-scatter grid from the lateral plane during cerebral angiography is feasible, and results in significant reduction of radiation exposure to pediatric patients and clinical staff without sacrificing the overall diagnostic performance of this complex procedure.

Deep Learning-Based Real-Time Volumetric Imaging Using Single CBCT Projections

Y Lei*, Z Tian, T Wang, J Roper, A Kesarwala, E Schreimbmann, K Higgins, J Bradley, T Liu, X Yang, Emory Univ, Atlanta, GA

Purpose: Due to the inter- and intra-fraction variations of respiratory motion, real-time volumetric imaging is highly desirable during lung SBRT delivery. Real-time volumetric imaging could improve active motion management and better account for motion interplay effects in the reconstruction of delivered dose. We recently developed a novel deep learning-based method to derive 3D CT images from a single 2D projection image and validated its efficacy via CT simulation studies. The purpose of this study is to investigate clinical feasibility using actual patient CBCT data and associated 2D projection images from lung SBRT treatments. **Methods:** The training and the inference steps for a new case follow a feed-forward path in our proposed TransNet network. TransNet is trained by several supervision mechanisms that optimize the learnable parameters to derive 2D-to-3D transformations. A single 2D projection image is input to generate a synthetic 3D CT. The training dataset is comprised of phase-binned 3D CT images and their corresponding 2D projection images from patient 4D CT studies. A 3D CT of the same respiratory phase as a 2D projection image is used as the ground truth to supervise TransNet. During inference, the trained TransNet extracts features from a patient's 2D CBCT projection image and derives a synthetic 3D CBCT. Our method was validated using clinical images from the treatments of 45 lung SBRT patients. **Results:** The mean absolute error (MAE), peak-signal-to-noise-ratio (PSNR) and normalized cross-correlation (NCC) indexes between the synthetic CBCT and original CBCT images were 134.8 ± 30.8 HU, 18.8 ± 1.3 dB, and 0.93 ± 0.02 , respectively. **Conclusion:** We have evaluated the effectiveness of our recently developed deep learning-based method to derive instantaneous synthetic CBCT images from single 2D projection images using real patient data. This study shows the potential to achieve real-time volumetric imaging during SBRT delivery to ensure treatment accuracy.

Regional Dose-Responses of Liver Functions Derived from Dynamic Gadoxetic Acid-Enhanced (DGAE) MRI of Patients with Hepatocellular Carcinoma (HCC) Treated with SBRT

L Wei^{1*}, M Aryal¹, J Simeth², K Cuneo¹, M Matuszak¹, J Evans¹, R Ten Haken¹, I El Naqa³, T Lawrence¹, Y Cao¹, (1) University of Michigan, Ann Arbor, MI, (2) Memorial Sloan Kettering, New York, (3) Moffitt Cancer Center, Tampa, FL

Purpose: To investigate dose-responses of regional liver functions from Gadoxetic Acid uptake rates (k1) mapped by DGAE-MRI and to relate them to baseline global and regional liver functions. **Methods:** 25 patients with HCC were enrolled in an IRB-approved adaptive SBRT trial. The patients had DGAE-MRI of liver pre-RT, and one-month after 3 or 5 fx of SBRT on a 3T scanner to quantify k1 maps. The accumulated doses up to the post scan were converted into EQD2 ($\square\square\square=2.5$) and co-registered to pre/post-RT k1 maps. Percentage changes in k1 from pre- to post-RT were analyzed in dose bins of every 5-Gy and 5 pre-RT k1 bins. Dose-response patterns of the whole group and individuals were analyzed by regression analysis. Responses patterns were further clustered into two groups using k-means and tested the group differences with ANOVA. Correlations between percentage changes in k1 and pre-, post-RT or changes in Child-Pugh scores were analyzed using correlations. **Results:** The averaged percentage change in k1 of the whole group showed a linear relationship with 0.44%/Gy with an adjusted R²=0.99 and a significant greater response at the highest pre-RT k1 value (P<0.0001). Two groups were clustered based on the dose-response patterns at low doses, with one group showing a linear dose-response to all doses and another having a non-linear but over-response to low doses and a linear response for the doses > 80 Gy. Responses of the two groups were significantly different (P<0.000002). The response patterns were not significantly correlated with pre, post-RT or changes in Child-Pugh scores. **Conclusion:** Different dose-response subgroups (over-sensitive to low doses vs not) were identified based on changes in GA uptake rates from pre- to post-SBRT in the patients with HCC. This could have an impact on how to spare liver functional regions in personalized SBRT for HCC.

Automatic Segmentation of Regions of Interest in Radiotherapy of Lower Abdominal Tumors with Lifelong Learning

K Men*, X Chen, B Yang, J Zhu, J Dai, Cancer hospital Chinese academy of medical sciences, Beijing, 11CN

Purpose: A main challenge that Convolutional neural networks (CNNs) face in segmentation is catastrophic forgetting. In this study, we used a published lifelong learning method to learn segmentation of regions of interest (ROIs) for lower abdominal tumors continuously without forgetting previous tasks. **Methods:** The cohort included three abdominal tumors, 600 patients of which had rectal cancer, 300 patients had cervical cancer, and 125 patients had prostate cancer. The tasks included segmentation of the three clinical target volume (cervical_CTV, prostate_CTV, and rectal_CTV), bladder, left femoral head, right femoral head, and rectum. A CNN with 103 convolutional layers was used as the basic segmentation network for a single task. The proposed lifelong learning network adopted dilation adapter to learn seven segmentation tasks one by one. Only the newly added dilation adapter (seven layers) was fine-tuning for incoming new task, whereas all the other learned layers were frozen. For comparison, seven single models for each task were trained separately. **Results:** The proposed lifelong learning can achieve better or comparable segmentation accuracy, with dice similarity coefficients of 0.84 ± 0.02 for cervical_CTV, 0.80 ± 0.02 vs. 0.79 ± 0.03 for prostate_CTV, 0.87 ± 0.02 vs. 0.87 ± 0.03 for rectal_CTV, 0.94 ± 0.02 vs. 0.94 ± 0.02 for bladder, 0.89 ± 0.03 vs. 0.89 ± 0.03 for femoral heads, and 0.80 ± 0.03 vs. 0.80 ± 0.05 for rectum. It can yield good performance with less training data. At the same time, it greatly improved the modeling efficiency, which reduced the number of parameters, the size of model, and training time by $\sim 75.5\%$, $\sim 71.5\%$, and $\sim 25.3\%$, respectively. **Conclusion:** The proposed method preserved the knowledge of previous tasks while learning a new one by using dilation adapter. It could yield comparable performance with much less training data, model parameters, and training time.

Using Artificial Intelligence to Automatically Track the Response of Brain Metastases to Stereotactic Radiosurgery

D Hsu*, A Ballangrud, J Deasy, H Veeraraghavan, K Beal, L Cervino, M Aristophanous, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: To automatically track control and progression of brain metastases (BrM) following stereotactic radiosurgery (SRS); and to provide a platform for studying BrM management with SRS and systemic therapies. **Methods:** 299 patients with 527 BrM of diameter 10+ mm were retrospectively identified for this study. They were imaged with T1 MR post-Gd prior to SRS treatment for BrM, then imaged again at least once within 1 year of SRS. The target SRS dose varied between 18 and 30 Gy in 1-5 fractions. Median time interval between SRS and first follow-up was 61 days, with interquartile range of [48, 75] days. A 3D convolutional neural network was developed in-house to segment BrM gross tumor volumes (GTVs) on T1 MR post-Gd images with 100% lesion sensitivity above 10 mm diameter, and average Hausdorff distances of 2 mm. Pre- and post-treatment images were rigidly registered using an automatic multi-step process that considers the whole head, brain, and lateral ventricles. Then, the deep learning model was applied to automatically contour BrM GTVs on all images. Based on changes in longest diameter post-SRS, BrM were classified on follow-up imaging as: size increased ($+20\%$ change or more), size stable, size decreased (-30% change or more), and unappreciable. **Results:** The registration method was robust, with error of approximately 1 mm. Relative size changes of 527 BrM were assessed on first available follow-up imaging after SRS, with 53 lesions increased in size, 83 stable, 193 decreased, and 84 unappreciable. Changes in 208 BrM (126 patients) were also analyzed after 180 days post-SRS, with 26 lesions increased in size, 58 stable, 59 decreased, and 65 unappreciable. **Conclusion:** This translational study demonstrates a proof-of-concept for automatic longitudinal tracking of BrM. Future work can build on this to study BrM dose response and interactions between systemic therapies and SRS.

TU-lePD-TRACK 3-05

Novel-View X-Ray Projection Synthesis Through Geometry-Integrated Deep Learning

L Shen*, L Yu, W Zhao, J Pauly, L Xing, Stanford University, Stanford, CA

Purpose: X-ray imaging is a widely used approach to view the internal structure of a subject for clinical diagnosis, image-guided interventions and decision-making. Here, we for the first time investigate the novel-view projection synthesis: obtain the X-ray projection image at a novel view angle from a given projection image at a specific view angle to alleviate the need for actual projection measurement. **Methods:** We propose a deep learning-based geometry-integrated projection synthesis model to generate novel-view X-ray projections through feature disentanglement and geometry transformation. The proposed deep learning model extracts geometry and texture features from a source-view projection, and conducts geometry transformation on the geometry features to accommodate the change of view angle. Then, X-ray projection in target view is synthesized from the transformed geometry and shared texture features via an image generator. We validate feasibility of the proposed approach by experimenting on the one-to-one and multi-to-multi X-ray projection synthesis using lung imaging cases across various patients. **Results:** We deploy the trained model on the held-out testing set for novel-view projection synthesis. The generated results are compared with ground truth qualitatively and quantitatively. For AP-to-lateral and lateral-to-AP view synthesis, the average NRMSE / SSIM / PSNR values over all testing data are $0.185 / 0.880 / 22.646$ and $0.173 / 0.911 / 23.908$, respectively. Promising results are also obtained for multi-to-multi view synthesis. By visualizing the generated projections, we observe the proposed model can generate images closely to the targets despite the various anatomic structures of different patients, indicating the potential of the proposed model for X-ray projection synthesis. **Conclusion:** We present a robust model combining the deep learning and geometry transformation. The generated X-ray projections reveal the internal anatomy distribution from new viewpoints, which potentially provides a new paradigm for volumetric imaging with substantially reduced efforts in data acquisition.

Liver 4D Blood Flow Model for Dose Calculation to Circulating Blood and Lymphocytes

S Xing^{1*}, J Pursley¹, J Shin¹, C Correa Alfonso², S Domal², J Withrow², W Bolch², C Grassberger¹, H Paganetti¹, (1) Massachusetts General Hospital, Harvard Medical School, Boston, MA, (2) University of Florida, Gainesville, FL

Purpose: To develop a novel 4D dynamic liver blood flow model, capable of accurate dose estimation to circulating blood during fractionated radiotherapy. **Methods:** Adult male and female liver phantoms with detailed vascular trees including the hepatic arterial, portal venous and hepatic venous trees were developed. A discrete time Markov Chain approach was applied to determine the spatiotemporal distribution of 10^5 blood particles (BP) in the human body, based on reference cardiac output and blood volume values. For BPs entering the liver, an explicit Monte Carlo simulation was implemented to track the propagation of individual BPs through the vascular trees and time-dependent radiation fields. The model was evaluated for photon (VMAT, IMRT) and proton (passive SOBP and active PBS) treatments and the impact of total delivery time on circulating blood was investigated and quantified using mean dose(μ dose), V0Gy, V0.5Gy. **Results:** The model tracks over 10^4 BPs in the liver simultaneously along 1996 distinct vascular pathways, accumulating dose from time-dependent radiation fields with a 0.1s time resolution. The simulations of the four modalities estimate μ dose(VMAT) (2.44Gy) $>\mu$ dose(IMRT) (2.42Gy) $>\mu$ dose(SOBP) (2.20Gy) $>\mu$ dose(PBS) (2.08Gy) after 15 fractions, related to the differences in mean liver dose. However, V0Gy and V0.5Gy are linked to the total delivery time, where V0Gy is lowest for VMAT (37%, 60s delivery), and highest for PBS (81%, 255s delivery). V0.5Gy shows the opposite trend, highest for VMAT (15%) and lowest for PBS (0.6%), demonstrating the tradeoff between low dose to large fractions of circulating blood and high dose to a small fraction depending on delivery speed. **Conclusion:** The 4D dynamic liver blood flow model enables realistic dose estimation to circulating blood during radiotherapy. The model allows us to study the impact of treatment modalities and delivery time on the dose to circulating blood, which will provide insights into radiation-induced lymphopenia and guide radiotherapy planning.

Development of a Deep Learning Model That Can Create Multiple Auto-Plans Prioritizing Different Clinical Goals to Facilitate Decision Making in Complex Pancreatic VMAT with Dose Painting

Y Wang*, J Wo, T Hong, Department of Radiation Oncology Massachusetts General Hospital, Harvard Medical School, Boston, MA

Purpose: To develop a deep learning (DL) model that can create multiple auto-plans prioritizing different clinical goals to support decision making in complex pancreatic VMAT with dose painting. **Methods:** A DL model was trained with 109 VMAT plans in RayStation 10B. The pancreatic tumor and regional nodes receive 50.4 Gy, with the involved vessels painted to 58.8 Gy. The model used three different sets of dose prediction and mimicking rules to generate auto-plans prioritizing PTV coverage, OAR dose and the balance between the two. The model was validated and tested on ten and 20 new patients, respectively. Each auto-plan was compared to the clinical plan using 12 clinical goals, with the p value calculated by a two-tailed t-test. The auto-plan most similar to the clinical plan was selected as the favorable plan. **Results:** On average, all three auto-plans offered some universal advantages over the clinical plan: slightly higher CTV coverage, significant reduction in stomach mean dose, kidney V18 and V10, and V50 for GI organs excluding PTV5040. For PTV coverage, uniformity in low-dose PTV and GI maximum dose, the OAR auto-plans were the most similar to the clinical plans, whereas the PTV auto-plans were the least. The PTV, balance and OAR auto-plans were picked 20%, 40% and 40% of the time as the favorable plan, respectively. Collectively, the favorable auto-plans offered similar performance to the clinical plans on seven goals and significant improvement on five. 30% of the favorable auto-plans were directly acceptable. 20% and 40% required minor and moderate processing, respectively. 10% exhibited large difference, but due to significant relaxation of some OAR constraints in the clinical plan. **Conclusion:** For patients with standard OAR constraints, the DL model could always produce an auto-plan very similar to the clinical plan, which was acceptable directly or after minor or moderate processing.

A Clinically Implemented Watchdog Program to Streamline Adaptive LINAC-Based Head and Neck Radiotherapy

M Aristophanous*, E Aliotta, A Caringi, B Rochford, N Allgood, P Zhang, Y Hu, P Zhang, L Cervino, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: We have developed and implemented an adaptive radiotherapy program, enabled by a watchdog system that detects and alerts the clinical team of anatomical changes that may require plan adaptation. In this study we report our initial clinical experience. **Methods:** Nineteen patients with cancer of the oropharynx and hypopharynx were studied. Patients that received definitive radiotherapy with no resection were included. The patients were selected at the time of planning and were scheduled on an in-house software program called AWARE (Automated Watchdog for Adaptive Radiotherapy Environment). The AWARE software automatically identifies weekly CBCTs for the scheduled patients, deforms tracked structures to the new anatomy, obtains volumetric information of these structures and alerts the adaptive team of significant changes via a daily morning email. The changes are then reviewed for accuracy and discussed with the treating physician who decides whether the plan needs to be adapted. For this initial study the primary and nodal GTVs, and the parotids were tracked. **Results:** The AWARE program was successfully deployed and used to monitor 19 patients with weekly CBCT. The primary GTV decreased on average by approximately 10% the first 3 weeks, while remaining largely stable weeks 4-7. The nodal GTV showed the largest average reduction (15%) after one week of treatment and continued to see reduction until the final week. We observed an average parotid volume change of -24% [-46% - +8%]. Of the 19 patients that were tracked, 5 received an adaptive plan. In the majority of adapted cases, adaptive plans resulted in significant reductions (>10%) in dose to critical OARs. **Conclusion:** We successfully developed and deployed watchdog software that automatically monitors anatomical changes on CBCT and alerts the clinical team. The developed software can enable and streamline personalized treatments by finding the optimum time point for adapting treatment.

A Federated Database Design for Pediatric Outcomes Modelling

J Becksfort*, L Wilson, F Xie, R John, F Pirlepsov, I Igrutinovic, J Lucas, A Faught, St. Jude Children's Research Hospital, Memphis, TN

Purpose: To model acute and long-term treatment outcomes, a well-labeled, organized database that pulls from multiple data sources is needed. When focused on a comparatively rare patient population in pediatrics, making use of all data available is essential. We set out to design a database and application capable of handling modern and historical data generated by our department. **Methods:** A DICOM RT PACS system was established using the big data toolbox provided ProKnow DS. Dose accumulation for multi-phase and adapted treatments was established using a treatment planning system (TPS) agnostic, deformable image registration workflow that transferred and accumulated all doses on a single CT simulation image. Renaming rules were applied to structures to bring historical data in line with TG-263 recommendations. The ProKnow API was used to link with SQL queries against the MOSAIQ database that updated and organized patients based on protocol and trial enrollment. The API was then used to link DICOM RT and dosimetry data with a custom, in-house database developed using PostgreSQL. Importing scripts were developed to pull in clinical data from active and legacy institutional research databases. **Results:** Dosimetry data for a total of 918 patients and 958 courses of treatment were aggregated from three different TPSs. Clinical research outcomes were loaded from 3 unique databases. Data were organized at an institutional level and into 10 unique subgroups corresponding to institutional protocols and clinical trial enrollment. A responsive web application was built which includes dashboards to interact with and easily export clinical data collected through trial and protocol databases. **Conclusion:** Well-formatted data and insightful visualizations are essential in the move towards big data style analytics. Our early success has seeded the results of several studies investigating clinical outcomes, dosimetric predictors, and physics-based planning studies.

TU-lePD-TRACK 4-03

Integrated Structure Name Mapping with CNN

P Bose^{1*}, W Sleeman², S Srinivasan³, J Palta⁴, R Kapoor⁵, P Ghosh⁶, (1) Virginia Commonwealth University, Richmond, VA, (2) Virginia Commonwealth University, Richmond, VA, (3) Virginia Commonwealth University, Richmond, VA, (4) Virginia Commonwealth University, Richmond, VA, (5) VCU Health System, Richmond, VA, (6) Virginia Commonwealth University, Richmond, VA

Purpose: Physicians give widely varying customized names to radiotherapy structures present in the prostate and lungs. The standardization of the physician-given names of the Organs at Risk (OAR), Target Organs (PTV), and other Organs inside the area of interest is a significant problem towards radiotherapy quality assurance. Prior work in this area either considered image or textual data but not both. We designed and evaluated an integrated model that considers both types of data compiled from the radiotherapy centers administered by VHA and the Department of Radiation Oncology at VCU. **Methods:** The combined VCU and VHA radiation oncology data has 16,290 prostate and 13,999 lung structures. Within each structure set name, all digits and English alphabets were converted into lower-case. The data was stratified and split into 70:30 training and testing sets. BioBERT was used to tokenize the text and the embedding layer was based on our corpus. Since the textual

data performed better than the feature-reduced image data, the textual features were assigned higher importance. Then two parallel CNNs were designed for the textual dataset and another CNN for the feature-reduced image data (with 1000 features) and all three outputs are concatenated together and fed into two dense layers of the CNN to standardize structure names. **Results:** Macro-averaged precision, recall, and F1-score for prostate were 0.886, 0.94, 0.911, and that for lung were 0.896, 0.878, 0.915, respectively. **Conclusion:** CNN-based integration of image and text data provides higher F1-scores than on individual datasets delivering state-of-the-art performance for structure name standardization. The majority of structures in real clinical datasets are not true OARs or planning targets adding class imbalance challenges leading to lower overall accuracy despite improved F1-scores. Addressing the large number of non-OAR and non-PTV structures is important for future research.

This work is funded by US VHA National Radiation Oncology Program (NROP).

TU-lePD-TRACK 4-04

NCI Imaging Data Commons

A Fedorov^{1*}, W Longabaugh², D Pot³, D Clunie⁴, S Pieper⁵, R Lewis⁶, H Aerts⁷, A Homeyer⁸, M Herrmann⁹, U Wagner¹⁰, T Pihl¹¹, K Farahani¹², R Kikinis¹³, (1) Brigham & Women's Hospital, Boston, MA, (2) Institute for Systems Biology, Seattle, WA, (3) General Dynamics IT, Bethesda, MD, (4) PixelMed Publishing, Bangor, PA, (5) Isomics Inc., Cambridge, MA, (6) Radical Imaging, Boston, MA, (7) Dana-Farber/Brigham Womens Cancer Center, Boston, MA, (8) Fraunhofer MEVIS, Bremen, , DE, (9) Massachusetts General Hospital, Boston, MA, (10) Frederick National Lab, Frederick, MD, (11) Frederick National Lab, Frederick, MD, (12) National Cancer Institute, Bethesda, MD, (13) Harvard Medical School, Boston, MA

Purpose: The National Cancer Institute's (NCI) Cancer Research Data Commons (CRDC) aims to establish a cloud-based data science infrastructure. The Imaging Data Commons (IDC) is a component of CRDC to enable access and exploration of imaging data, and to support integrated analyses with non-imaging data available in other components of CRDC, such as genomics and proteomics repositories. IDC builds on the strengths of established projects such as The Cancer Imaging Archive (TCIA) to collect and share FAIR (Findable Accessible Interoperable Reusable) imaging data. **Methods:** IDC uses a combination of commercially available Google Cloud Platform (GCP) and open source components. While the initial focus is to support clinical radiology and radiotherapy data, IDC aims to support brightfield microscopy, multi-channel immunofluorescence and other imaging modalities. Equally important is the ability to support image-derived data, such as annotations of regions of interest. IDC relies on the DICOM standard to harmonize both imaging and image-derived data. IDC data is public and contains no Protected Health Information (PHI). As CDRC grows, imaging datasets will be cross-linked to genomic, proteomic, and clinical data about the subjects. **Results:** The IDC pilot, released in October 2020, focused on radiology data from The Cancer Genome Atlas (TCGA) project. The IDC portal is available at <https://portal.imagingdatacommons.cancer.gov>, and integrates a customized web viewer for visualization of images and image annotations (specifically, DICOM Segmentation and Radiotherapy Structure Set, including multiplanar reformatting). **Conclusion:** The IDC pilot which is available to the cancer research community explores the promise of cloud-hosted public imaging collections co-located with the compute resources and a growing number of tools to support data analysis. Production release of IDC is planned for Fall 2021, and will include all of the public TCIA collections, in particular those shared by radiotherapy studies and clinical trials.

This project has been funded in whole or in part with Federal funds from the National Cancer Institute, National Institutes of Health, under Task Order No. HHSN26110071 under Contract No. HHSN2612015000031.

PIXNAT: An XNAT Imaging Archive for Collaborative Radiotherapy Research

E LoCastro*, A Apte, A Iyer, J Deasy, Department of Medical Physics, Memorial Sloan-Kettering Cancer Center, New York, NY

Purpose: We introduce our research imaging archive, the "Predictive Informatics XNAT" ("PIXNAT"). The platform is built on the well-known XNAT platform, which we work to enable with the CERR computational platform, enhanced with custom pipelines to assist with conversion between DICOM and analysis-friendly data formats. PIXNAT-housed data is secure and accessible to external researchers for research and processing. **Methods:** The PIXNAT server is a RedHat Enterprise Linux instance running XNAT v1.7.5. Pipeline processes securely run on institutional HPC cluster with multi-GPU for rapid deep network processing. PIXNAT is approved by institutional information security for housing and sharing research data. All imaging data is fully anonymized using CTP and according to 18-point institutional guidelines. PIXNAT is extended with OHIF-XNAT and ROI datatype plugins. CERR computational routines are implemented as PIXNAT pipelines to provide access to a variety of image analysis tools. Deep learning segmentation pipelines from CERR work directly from PIXNAT imaging data and produce RTSTRUCT-based segmentations to be imported and overlaid in the viewer. CERR texture map analysis is also implemented on the system, the resulting maps are converted to DICOM and imported into the session list for review with the integrated OHIF viewer. We have enabled a launch pipeline for JupyterLab notebooks which can be pre-loaded with images from PIXNAT to interactively run Python and CERR routines and visualize in-line results. **Results:** PIXNAT currently houses 24 projects, 2243 subjects, and 3067 imaging sessions. It has been used to collaborate with 5 different institutions. **Conclusion:** We have demonstrated a close integration between CERR and XNAT, resulting in a useful inter-institutional collaboration paradigm. We have furnished PIXNAT as a destination for medical physics research, open source image processing and data sharing.

Research was supported by the following grants: (1) P30 CA008748/CA/NCI NIH HHS/United States (2) R01 CA198121/CA/NCI NIH HHS/United States

The National Biomedical Imaging Archive

S Gustafson^{1*}, Q Pan², M Lerner³, T Tran⁴, C Klinger⁵, R Rieling⁶, U Wagner⁷, K Farahani⁸, (1) Ellumen Inc., (2) (3) (4) (5) (6) (7) Frederick National Lab, Frederick, MD, (8) National Cancer Institute, Bethesda, MD

Purpose: To develop an open-source software application that allows for the storage, search, and downloading of DICOM images to support data sharing, enabling imaging informatics applications and data mining for cancer research. **Methods:** The system utilizes a Java server that provides REST services to independent applications such as the Angular-based graphical user interfaces. The system also includes a Solr server that indexes all tags in the DICOM headers and allows rapid retrieval based on any of the information in the tags. The applications are loosely coupled, enabling independent upgrades, speeding the delivery of features to users. **Results:** The National Biomedical Imaging Archive (NBIA) provides web-based and programmatic access to DICOM images by using role-based security. NBIA consists of a search client, data administration tools, user administration tools, and the NBIA Data Retriever, which supports downloading of images to the user's local computer. NBIA enables several medical imaging archives, including The Cancer Imaging Archive (TCIA) of the National Cancer Institute (NCI), which currently hosts over 27.5 million images and empowers downloads of over 100 TB per month. NBIA incorporates the Clinical Trial Processor software from RSNA and supports customized de-identification of images. NBIA can integrate with other applications through a set of APIs that can facilitate data query and data transfer between multiple repositories, such as between the NCI image repositories, TCIA, and Imaging Data Commons, a cloud-based resource. The NBIA code is available on GitHub. Technical documentation including an API guide can be found on the NCI's NBIA wiki page. **Conclusion:** NBIA is an open-source software application that enables the creation of secure and searchable archives of medical images in DICOM format. NBIA is a constantly evolving system that takes advantage of new technologies and approaches to meet the needs of the cancer imaging community.

Radiation Therapy Ontology: Report of AAPM Working Group

M Phillips^{1*}, J Bona², A Dekker³, P Gabriel⁴, C Mayo⁵, (1) University of Washington, Seattle, WA, (2) University of Arkansas, (3) Maastricht Clinic, Maastricht, NL, (4) University of Pennsylvania, Philadelphia, PA, (5) University of Michigan, Ann Arbor, MI

Purpose: To build an ontology that represents the domain of radiation oncology in a manner that makes it useful for medical and scientific progress. **Methods:** A working group was established by the AAPM Big Data Subcommittee to organize and lead this effort. The working group has met on a biweekly basis since November 2018. The ontology's design follows the guidelines of the OBO Foundry whose mission is "to develop a family of interoperable ontologies that are both logically well-formed and scientifically accurate". To this end, a foundational ontology (Basic Formal Ontology) was chosen to provide the guiding principles and the basic classes and relations. Additional principles include: (a) to reuse whenever possible entities already described in other OBO ontologies to avoid duplication and confusion; (b) to embrace "realism" in the definition of entities and relations to encourage its use in clinical practice and research, and (c) to coordinate our efforts with other organizations working on standards-related projects. On a practical level, the github platform provides the infrastructure, development is accomplished using the Web Ontology Language (OWL), and the ontology software Protégé is used to develop and view the ontology. **Results:** A domain ontology has been constructed. In line with the goal of coordinating with related efforts, mapping to the ASTRO minimum data elements has been accomplished. The work has also spawned the development of an applied ontology with more specific goals. **Conclusion:** A robust fundamental ontology can be a key element in the development of data and concept-driven research in biomedicine. It provides a link to a number of practical taxonomies. Ontologies have proven to be useful in machine learning efforts in medicine. In the future, the ontology will as a basis for building applied ontologies and coordination with standards-forming organizations.

TU-lePD-TRACK 5-01

The First Modeling of the Spot-Scanning Proton Arc (SPArc) Delivery Sequence and Investigating Its Efficiency Improvement in the Clinical Proton Treatment Workflow

G Liu^{1,2*}, L Zhao¹, D Yan³, R Deraniyagala¹, C Stevens¹, X Li¹, X Ding¹, (1) Beaumont Health System, Royal Oak, MI, USA (2) Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Purpose: To quantitatively model a precise spot-scanning proton arc (SPArc) delivery sequence and assess its efficiency improvement in the routine proton clinical operation. **Methods:** The SPARC delivery sequence model (DSMSPARC) includes two kinds of parameters: (1) mechanical parameters (the maximum gantry velocity, acceleration, and deceleration speed), (2) irradiation parameters (tolerance window and buffer, spot scanning speed, energy layer switching time, and burst switching time). An independent gantry inclinometer was used to measure mechanical parameters. Log files were used to derive the irradiation parameters through a series of SPARC test plans. The in-house DSMSPARC was established by fitting both mechanical and irradiation parameters. Eight SPARC plans from different disease sites (brain, HN, lung, and liver cancer) were used to validate the model's accuracy. To quantitatively assess the treatment efficiency improvement compared to the clinical IMPT, a random clinical operation date of our proton center (total 21 cases on Jan 6th 2021) was selected, and SPARC plans were generated for all the cases. The DSMSPARC was used to simulate the SPARC treatment delivery sequence and compared to the clinical IMPT treatment logfiles. **Results:** The relative difference of treatment time between log files and DSMSPARC's prediction was $6.1\% \pm 3.9\%$ on average, and the gantry angle vs. delivery time showed a good agreement between the DSMSPARC and log file. Additionally, the SPARC plan could effectively save two hours out of 10 hours of clinical operation by simplifying the treatment workflow for a single room proton therapy center. The average treatment delivery time (including gantry rotation and irradiation) per patient was reduced to 226 ± 149 s using SPARC compared to 665 ± 407 s using IMPT ($p < 0.01$). **Conclusion:** This is the first modeling of the SPARC delivery sequence, which paves the roadmap for implementing the delivery speed and time into the SPARC optimization algorithm. Additionally, SPARC can offer a superior delivery efficiency to improve clinical treatment throughput, compared to IMPT.

This study was supported by the research fundings from Ion Beam Application Inc. (IBA) and Beaumont Health Herb and Betty Fisher Research Seed Grant Award. Xuanfeng Ding, Xiaoqiang Li, and Di Yan have a patent related to the Particle Arc Therapy (WO2017156419). The patent has been licensed to Ion Beam Application, Belgium.

4D Robust Optimization in Small Spot Intensity-Modulated Proton Therapy (IMPT) for Distal Esophageal Carcinoma

H Feng^{*}, J Shan, J Ashman, W Rule, R Bhargoo, N Yu, J Chiang, M Fatyga, W Wong, S Schild, T Sio, W Liu, Mayo Clinic Arizona, Phoenix, AZ

Purpose: To compare the dosimetric performances of small-spot 3D and 4D robustly optimized intensity-modulated proton (IMPT) plans in the presence of uncertainties and interplay effect simultaneously for distal esophageal carcinoma. **Methods:** Thirteen (13) patients were selected and re-planned with small-spot ($\sigma \sim 2-6$ mm) 3D and 4D robust optimization in IMPT respectively. The internal clinical target volumes (CTV_{high}, CTV_{low}) were used in 3D robust optimization. Different CTVs (CTV_{high}4d, CTV_{low}4d) were generated by subtracting an inner margin of the motion amplitudes in 3 cardinal directions from the internal CTVs and used in 4D robust optimization. All patients were prescribed the same dose to CTVs (50 Gy[RBE] for CTV_{high}/CTV_{high}4d and 45 Gy[RBE] for CTV_{low}/CTV_{low}4d). Dose-volume-histogram (DVH) indices were calculated to assess plan quality. Comprehensive plan robustness evaluations that consisted of 300 perturbed scenarios (10 different motion patterns to consider irregular motion and 30 different uncertainties scenarios combined, both were randomly sampled from the corresponding Gaussian distributions) were done to quantify robustness to uncertainties and interplay effect simultaneously. Wilcoxon signed-rank test was used for statistical analysis. **Results:** Compared to 3D robustly optimized plans, 4D robustly optimized plans had statistically improved target coverage and better sparing of lungs and heart (Dmean: $P = 0.001$; V30Gy[RBE]: $P = 0.001$). 4D robustly optimized plans had better heart protection (Dmean: $P = 0.010$; V30Gy[RBE]: $P = 0.017$; V40Gy[RBE]: $P = 0.010$) when uncertainties and interplay effect were considered. **Conclusion:** Even with small spots in IMPT, 4D robust optimization outperformed 3D robust optimization in terms of normal tissues protection and robustness to uncertainties and interplay effect simultaneously. Our findings support the use of 4D robust optimization to treat distal esophageal carcinoma with small spots in IMPT.

TU-lePD-TRACK 5-03

A Monte Carlo Study on Fetal Dose from Craniospinal Irradiation with Proton Pencil Beam Scanning Treatment

Y Yeom^{1*}, K Griffin², M Mille³, C Lee⁴, S O'Reilly⁵, L Dong⁶, J Jung⁷, C Lee⁸, (1) National Cancer Institute, Rockville, MD, (2) National Cancer Institute, Rockville, MD, (3) National Cancer Institute, Bethesda, MD, (4) University of Michigan, Ann Arbor, MI, (5) University of Pennsylvania, Philadelphia, PA, (6) University of Pennsylvania, Philadelphia, PA, (7) East Carolina Univ, Greenville, NC, (8) National Cancer Institute, Rockville, MD

Purpose: To evaluate fetal dose from proton pencil beam scanning (PBS) craniospinal irradiation (CSI) during pregnancy by conducting Monte Carlo (MC) dose calculations coupled with eight gestational-age dependent pregnant female phantoms (8, 10, 15, 20, 25, 30, 35, and 38 weeks). **Methods:** The pregnant phantoms were converted into DICOM-RT data (CT images and structures) and imported into a treatment planning system (TPS) (Eclipse v15.6) commissioned for an IBA PBS nozzle. From the TPS, a proton PBS CSI plan (prescribed dose: 36 Gy) was created on the phantoms. MC simulation of the proton PBS CSI to estimate fetal dose was conducted using the TOPAS MC code, for which MC beam properties at the nozzle exit (spot size, spot divergence, mean energy, and energy spread) as a function of the nominal energy were matched to the IBA PBS nozzle beam measurement data. We calculated organ/tissue-averaged absorbed doses for 28 fetal organs and tissues. For contextual purposes, the fetal organ/tissue doses from the treatment planning CT scan of the mother's head and abdomen were also estimated by using the National Cancer Institute dosimetry system for CT (NCICT, Version 3) considering a low-dose CT protocol (CTDIvol: 8.97 mGy). **Results:** The majority of the fetal organ/tissue doses from the proton PBS CSI onto the eight pregnant phantoms fell within a range from 3 to 6 mGy. The fetal doses from the proton PBS CSI were generally lower than those from the planning CT scan, which fell within a range from 7 to 13 mGy. **Conclusion:** The organ/tissue doses produced from this comprehensive MC study provide one of the first clinically informative predictions on the magnitude of fetal dose during proton PBS CSI during pregnancy because most proton TPSs cannot estimate out-of-field fetal dose.

TU-lePD-TRACK 5-04

A Novel Component Method to Delineate Surgical Spine Implants for Proton Monte Carlo Dose Calculation

C Chang¹, S Charyyev², J Harms³, R Slopesma⁴, J Wolf⁵, D Refai⁶, T Yoon⁷, M McDonald⁸, J Bradley⁹, S Leng¹⁰, J Zhou¹¹, X Yang¹², L Lin^{13*}, (1) Emory University, Alpharetta, GA, (2) Emory University, Atlanta, GA, (3) Emory University, Atlanta, GA, (4) Emory University, Atlanta, GA, (5) Emory University, Atlanta, GA, (6) Emory University, Atlanta, GA, (7) Emory University, Atlanta, GA, (8) Emory University, Atlanta, GA, (9) Emory University School Of Medicine, (10) Mayo Clinic, Rochester, MN, (11) Emory University, Atlanta, GA, (12) Emory University, Atlanta, GA, (13) Emory University, Atlanta, GA

Purpose: Spine implants has been shown to decrease local control for spinal sarcoma and chordoma patients because of artifact-induced dose calculation inaccuracies. Artificial intelligence (AI)-based methods have shown advantages for metal artifact reduction (MAR) by assuming that prior knowledge of implants is available. We propose a novel component method to accurately delineate implants from CT images to train AI-based models that potentially can increase image accuracy for proton Monte Carlo dose calculation. **Methods:** We propose a novel method to identify implant components (tulip, screw & rod), utilizing various levels of prior knowledge such as CT scanned implant components and implant volumes and screw lengths from medical records. The tulips from two major vendors are manufactured with different materials such as titanium and Chromalloy. With the use of extended Hounsfield units (HU), and a fine resolution reconstruction algorithm, the implant component method was developed and demonstrated for various levels of prior knowledge both in a phantom and in vivo for one patient. **Results:** Implant systems from two major vendors were analyzed. It was found that mischaracterization of 8 typical implants in a patient can cause under coverage of a clinical target volume (CTV) around 20 cm³, consistent with excessive proton range uncertainties of 10 mm reported in the literature. Using our method, tulip, the most important implant component, can be characterized with proper material and volume as well as other components. Intended CTV coverage can be maintained within tolerance. **Conclusion:** Our component method provides accurate implant characterization for proton dosimetry and can potentially enhance the accuracy of AI-based MAR models. The current study primarily focuses on the implant characterization for lumbar spine. Future work will include cervical spine and dental implants for head-and-neck patients where tighter margins are required due to proximity of organs-at-risk.

TU-lePD-TRACK 5-05

Adaptive Spot Placement Method for Pencil Beam Scanning Proton Therapy

B Lin^{1, 2}, Y Lin¹, M McDonald¹, J Bradley¹, S Fu², H Gao^{2*}, (1) Winship Cancer Institute of Emory University, Atlanta, GA, (2) Shandong University, Jinan, Shandong, China

Purpose: Although pencil beam scanning (PBS) proton radiotherapy (RT) can provide flexible proton spot placement for intensity modulated proton therapy (IMPT), currently the spot placement is mostly based on a fixed Cartesian grid (FG), without fully accounting for the geometry of tumor targets. This work will develop an adaptive Cartesian grid (AG) spot placement method, which will be highly adaptive to the geometry of tumor targets. **Methods:** Given the simplicity and universality of the Cartesian grid to place spots for tumor targets that can be arbitrarily shaped, AG is based on the Cartesian grid. However, compared with FG, AG places (1) a relatively fine grid of spots at the boundary of tumor targets to account for the geometry of tumor targets and treatment uncertainties (setup and range uncertainty) for improving dose conformality, and (2) a relatively coarse grid of spots in the interior of tumor targets to reduce the number of spots and increase the spot weights for improving delivery efficiency. **Results:** AG was validated using representative clinical cases in comparison with FG, with clinically used DVH planning objectives, beam angles, and uncertainty level. The same plan objectives, the same optimization algorithm, and the same plan normalization were used for the fair comparison of AG and FG. The preliminary results demonstrate that AG provided better plan quality than FG in both target coverage and OAR sparing, with up to 50-60% reduction in number of spots. **Conclusion:** We have developed an AG spot placement method with adaptive Cartesian grid that is fully compatible with existing treatment planning convention and systems. Compared with the conventional FG on a fixed Cartesian grid, AG can improve both lateral dose falloff (for better plan quality) and spot utility (for better delivery efficiency).

This research is supported in part by Varian Medical Systems and NIH grant R01CA250921.

TU-lePD-TRACK 5-06

Robustness in Biological Dose-Guided IMPT Planning for Rectal Cancer Using a Monte Carlo-Based Optimizer

J Rivera^{*}, J Ma, K Gergelis, R Mutter, H Wan Chan Tseung, C Hallemeier, N Remmes, M Herman, Mayo Clinic, Rochester, MN

Purpose: Intensity modulated proton beam therapy (IMPT) affords exquisite geometric control of dose deposition in targets and enables improved sparing of normal tissues; however, critical, dose-limiting structures may prevent the delivery of curative radiation doses. We previously demonstrated the feasibility of using an in-house Monte Carlo-based inverse planning optimizer to capitalize on a convergence of Bragg peaks to enhance the linear energy transfer (LET) in a given volume. The resulting increase in biological dose (BD) achievable may provide superior anti-tumor effects for treating otherwise highly radio-resistant tumors. This planning study systematically evaluates various parameters in the optimizer in an effort to escalate high-LET within targets while limiting deposition of high-LET within organs-at-risk (OAR). We hypothesize modest LET escalation in rectal plan GTVs may be leveraged to enhance BD while meeting OAR constraints. **Methods:** Standard and LET-enhanced IMPT plans are created for 10 resectable (T2-T3) rectal cancer patients. Patients are planned with Eclipse and Monte Carlo-based optimization to the same prescription dose, including two target volumes (CTV 2500cGy, GTV 2800cGy) and two equally-weighted posterior-oblique fields. Multivariate generalized linear models are used to assess the influence of planning and optimization parameters on LET-enhancement, physical, and biological dose. Relevant metrics include CTV/GTV coverage reproducibility with changes in internal organ motion, rectal gas filling, patient positioning, and tissue density

inhomogeneities. **Results:** Dose-volume histogram (DVH)-analyses reveal LET-guided plans achieved comparable CTV physical dose homogeneity and OAR sparing compared to standard IMPT plans. LET-guided plans also achieved significant LET and BD enhancement in GTVs. However, robustness analyses of plans cast onto verification CTs indicate LET-enhancement in GTV may inversely correlate with plan Robustness for select optimization parameters. **Conclusion:** LET-guided IMPT planning for rectal cancer GTV biological dose escalation is feasible. Although tradeoffs exist between optimization parameters, LET-enhanced rectal treatments may allow for enhanced therapeutic windows.

TU-lePD-TRACK 5-07

Toward Online Adaptive Proton Therapy of Sinonasal Cancer: The Dosimetric Accuracy of Utilizing Deep- Learning Synthetic CT from CBCT for Daily Treatment Dose Verification

A Qin*, L Zhao, S Chen, X Li, W Zheng, D Yan, R Deraniyagala, X Ding, Proton therapy Center, Beaumont Health System, Royal Oak, MI

Purpose: Proton beam is sensitive to anatomy variation, especially for sinonasal cancer patients due to daily nasal cavity fillings variation and tumor shrinkage. With online CBCT increasingly available and daily acquired in the proton treatment room, we hypothesized that daily proton dose can be accurately reconstructed from CBCT using a deep-learning model for sinonasal cancer patients. **Methods:** 35 pairs of pre-treatment CT and first-fraction CBCT were selected from patients treated with proton therapy in our institution for training. Deformable-registration(DIR) was performed to eliminate potential anatomy variation between the simulation and first treatment. A Generative-Adversarial-Networks(GAN) model, including one generator with Residual-Unet architecture, and one discriminator using a multi-layer convolutional neural net(CNN), were trained from scratch to predict CT from CBCT, with random 3D B-spline deformation as augmentation. Five additional sinonasal patients with same-day re-plan CT and CBCT were selected for dosimetric evaluation. The re-plan CTs were deformed to the same-day CBCT to eliminate any neck flexion variation and served as the ground-truth(GT-CT). The synthetic CTs(Syn-CT) were compared to the GT-CTs by Mean-Absolute-Error(MAE). The clinical plans(3-5beams) were re-calculated on both Syn-CT and GT-CT using a commercial Monte-Carlo algorithm with 0.5% uncertainty. Clinically relevant DVH parameters and γ -passing rates were utilized to quantify the dosimetric discrepancy. **Results:** The prediction takes less than 10s per patient. The MAE of Syn-CT was 53.58 ± 5.3 HU. Compared to the reference doses on GT-CT, the average 1%/1mm, 2%/2mm, 3%/3mm γ -passing rates of the doses on Syn-CT were 82.6%, 97.5%, and 99.0%. The mean D₉₉ of CTV, D₁ of (brain-stem, cord, optical nerves, chiasm), and D_{mean} of parotids on Syn-CT are 99.9%, 101.7%, 102.5%, 104.5%, 98.9%, and 100.2% of those on GT-CT, respectively. **Conclusion:** The Synthetic CTs predicted by the GAN-model achieved clinically acceptable dosimetric accuracy as evaluated by the same-day re-plan CT. The method could be utilized to monitor daily treatment dose online and trigger plan adaptation for patients with undesired dosimetric variations.

TU-lePD-TRACK 6-01

Development of a Multi-Layer Quality Assurance System for Adaptive Radiotherapy

H Zhong*, K Kainz, X Li, Medical College of Wisconsin, Milwaukee, WI

Purpose: Dose accumulation is a key component in adaptive radiotherapy (ART). The purpose of this study is to develop a multi-layer quality assurance system to verify dose accumulation performed in an ART program. **Methods:** The development involves the following steps: converting HU and dose in daily and planning CTs to mass and energy, generating a pseudo-inverse map ϕ -1 for each displacement vector field ϕ generated by the ART program, and using the map ϕ -1 and a mass-and-energy congruent mapping (EMCM) method to reconstruct dose on the planning CT. To generate ϕ -1, the source voxels of ϕ were divided into three categories: empty, unique and clustered voxels, and the center-of-mass and tetrahedron-based continuous mapping methods were used to generate the inverse displacements for the clustered and empty source voxels, respectively. The HU-mass density tables used in clinic were adopted for the dose-to-energy conversions. An inverse consistency error (ICE) metric, energy conservation and Gamma index were taken as criteria to evaluate the displacements, energy and dose reconstructed by the ART program. Five registration cases were evaluated: three performed from daily MVCTs to planning CTs using PreciseART and two performed between the end-inhale and end-exhale of 4DCTs using MIM software. **Results:** The results showed that the empty, unique, and clustered voxels are 45.6%, 10.2% and 44.2% on average for the three daily image registrations, and 20.7%, 65.9% and 13.4% for the 4DCT registrations. Their average ICEs are 1.05 ± 0.92 mm and 1.26 ± 1.22 mm, respectively. After dose reconstruction, the average energy in PTV changed by 0.4 ± 0.13 % for EMCM and 3.22 ± 0.58 % for PreciseART. Compared with the results of EMCM, the dose and energy reconstructed by PreciseART show the 5%/5 mm gamma passing rates of 96.9 ± 2.1 % and 90.6 ± 3.3 %, respectively. **Conclusion:** A multi-layer quality assurance system has been developed to verify deformable dose accumulations performed in ART.

Development of a Quantitative Method to Evaluate Organ Segmentation for Enhanced Error Detection

E Pryser*, F Reynoso, M Schmidt, G Hugo, N Knutson, Washington University School of Medicine, St. Louis, MO

Purpose: Accurate segmentation of organs at risk (OARs) for treatment planning is crucial for the delivery of high-quality care and the prevention of adverse events in radiation therapy. A method to rapidly and quantitatively evaluate the geometric characteristics of an organ against the expected geometry is proposed as a technique for detecting segmentation errors. **Methods:** Relationships between organ volume, patient gender, and geometric characteristics including length, width, depth, mean area, and complexity were modeled as a least-squares linear fit for 30 common organs based on metrics gathered from 1,331 patients. Complexity is defined in this context as the ratio of the organ's volume (V_{org}) to that of the bounding-box. For each individual organ, the perpendicular distance from the linear fit with slope M and intercept B was multiplied by a weighting-factor (ω) to generate a sub-score (μ) for each characteristic: $\mu_{\text{area}} = \omega_{\text{area}} * |M_{\text{area}} * V_{\text{org}} - \text{AREA}_{\text{org}} - B_{\text{area}}| * (M_{\text{area}}^2 + 1)^{-2}$. The final score (S_{org}) was calculated as the sum of individual sub-scores and a sub-score based on the organ's volume and the mean organ volume (V_{av}) and standard deviation (σ_v) determined from an independent dataset: $S_{\text{org}} = \mu_{\text{area}} + \mu_{\text{depth}} + \mu_{\text{width}} + \mu_{\text{length}} + \omega_v * |V_{\text{org}} - V_{\text{av}}| * \sigma_v^{-1}$. Individual weighting-factors were iteratively adjusted using a subset of the data to optimally assign higher scores to those organs with contouring errors, with a value of $S_{\text{org}} > 1$ indicating a suspected error. **Results:** Of the 10,846 organs in the dataset not used in algorithm training, 746 erroneous contours were correctly identified, 7 erroneous contours were not identified, 2,071 contours were incorrectly identified as erroneous, and the remaining 8,022 were correctly identified as error-free, giving an overall sensitivity of 99.1% and specificity of 79.5%. **Conclusion:** A method of quantitatively evaluating OAR contours against demographic data has been developed with the goal of identifying contouring errors. As a classifier, the proposed structure score demonstrates excellent sensitivity, and reasonable specificity in detecting errors in OAR delineation.

A Convolutional Neural Network-Based Retrospective Search for Previously Unreported Treatment Errors in a Planar X-Ray Setup Image Database
R Petragallo*, D Low, J Lamb, University of California, Los Angeles, Los Angeles, CA

Purpose: The radiation oncology clinical workflow involves numerous patient safety checks; however, rare but serious treatment errors do still occur and may go unreported. Here we present a semi-automated process, based on a convolutional neural network (CNN) misalignment detection algorithm, to retrospectively search a setup imaging database for near miss events and treatment errors not previously reported. **Methods:** A CNN-based error detection model was developed using 57,036 digitally reconstructed radiograph (DRR)/ x-ray image pairs obtained from the records of patients treated at our institution from 2014-2017 using a stereoscopic onboard imaging guidance system. The model was trained to detect alignment errors between the x-ray and the DRR using simulated 1 cm translational errors. The model was applied to previously unseen data from 2018 in order to flag potential errors. Flagged events were cross-referenced with record-and-verify systems, incident learning systems, and external image-guidance systems to determine whether they represented treatment errors, near misses, or false positives. **Results:** When the CNN was used to classify DRR/x-ray image pairs from 2018, a total of 1,233 image pairs (out of 27,278 total) were identified as misaligned. 136 image pairs were manually reviewed. Cross-referencing led to the following categorizations: treatment error, near miss, alignment mismatch corrected with repeat imaging, alignment mismatch corrected by imaging with a different system, fiducial marker match with bony anatomy mismatch, image acquisition failure, and algorithmic false positives. **Conclusion:** Manual retrospective audits of image guided radiotherapy databases could lead to detection of previously unreported treatment errors, but are infeasible due to the sheer size of such databases. Previously unreported errors and near misses can provide key insights to improve the safety of the radiotherapy workflow. To our knowledge this report is the first use of an automated misalignment detection algorithm to pre-select potential errors, thus making systematic comprehensive retrospective review feasible.

Retrospective Evaluation of Incident Learning Data in the Six Months Prior to and During COVID-19
J Crosby*, D Jacqmin, University of Wisconsin, Madison, WI

Purpose: The COVID-19 pandemic caused many changes in our clinic, including variable patient volume, a shift towards hypofractionation, and changes in on-site staff availability. This work sought to retrospectively evaluate incident learning data before and after our state declared a public health emergency due to COVID-19. **Methods:** Our clinic has been operating an electronic incident reporting system since January 2017. All staff members can voluntarily report patient safety incidents and other clinical issues. The reports submitted during the six months pre- and post-March 13th, 2020, were reviewed and analyzed for trends that could be associated with clinical changes due to COVID-19. The reports (n=475) were categorized with respect to event classification (incident, near miss, etc.), whether a dosimetric change was required, anatomical site, the process step where incidents occurred and were discovered, the role of the reporter, and the type of intervention. Within each category, the number and distribution of reports before and during COVID-19 were compared to identify changes over time. **Results:** The overall number of reports decreased by 19% (262 to 213) in the 6 months following March 13th. The event classifications that had the greatest decrease were “near miss” (-36%) and “operational/process improvement” (-19%). Of all team members, incident reporting by physicists remained the closest to baseline (-7%). While the overall number of reports submitted decreased, the number that involved a plan revision increased by 18%. The proportion of reports addressed with a quality improvement intervention increased during COVID-19 from 45% to 63%. In direct response to the pandemic, a change in the operational model for physician coverage was implemented. **Conclusion:** Patterns of incident reporting changed during COVID-19, with fewer reports being submitted for low-severity issues. This change may be attributable to staff effort being redirected to respond to COVID-19-associated clinical changes.

Always-On Cherenkov Imaging for Incident Learning in Radiation Therapy

D Alexander^{1,*}, M Jermyn^{1,2}, P Bruza^{1,2}, R Zhang^{1,3,4}, B Pogue^{1,2,3,4}, L Jarvis^{3,4}, D Gladstone^{1,3,4}, (1) Thayer School of Engineering, Dartmouth College, Hanover, NH, (2) DoseOptics LLC, Lebanon, NH, (3) Geisel School of Medicine, Dartmouth College, Hanover, NH, (4) Norris Cotton Cancer Center, Dartmouth-Hitchcock Medical Center, Lebanon, NH

Purpose: Cherenkov imaging has been shown to be capable of displaying certain treatment irregularities that might otherwise go unnoticed with standard QA processes. In this study we report on a clinical QA/QI study investigating the use of always-on treatment delivery monitoring with Cherenkov imaging in a radiotherapy clinic. **Methods:** Cherenkov imaging systems (BeamSite, DoseOptics LLC, Lebanon NH) were installed in two linac bunkers in our clinic, which provided continuous imaging of Cherenkov and background images of all treatments. For this project, a custom data transfer and central storage infrastructure was employed to efficiently handle the collection and review of the current 3500-fraction dataset. Images were reviewed post-treatment by a team clinical staff consisting of therapists, physicists, and physicians, and any irregularities were interpreted and analyzed using standard clinical tools and procedures. **Results:** Offline review of 200 patient treatments uncovered 3 independent delivery events, all related to patient positioning. One case consisted of unfavorable chin positioning during an AP-PA thoracic spine treatment which was corrected mid-fraction. The remaining two cases involved arm/hand placement which resulted in unintended exposure; one was found to have persisted for 7/10 fractions resulting in an estimated 3 Gy of exit dose to the arm and no negative impact on the treatment area. Independently, during this same period, 12 events were reported in the hospital-based incident reporting system, all deemed to have no detectable harm to the patient. **Conclusion:** Clinical review of Cherenkov images identified non-ideal patient positioning events during treatment which were not identified in the existing QA program. This system has the potential to improve radiation oncology incident learning through the increased visibility of clinical events during patient treatment. Future work will focus on data-driven automatic incident detection with improved sensitivity and development of appropriate action procedures to improve efficacy and efficiency.

Hardware and software support for this project was provided by DoseOptics LLC, a company manufacturing Cherenkov imaging cameras. B. Pogue is the President and M. Jermyn and P. Bruza are employees of DoseOptics LLC. D. Alexander reports receiving consulting fees from DoseOptics LLC.

Risk Assessment for Custom Software in the Clinic

E Covington*, R Cardan, R Popple, UAB University of Alabama, Birmingham, Birmingham, AL

Purpose: To present a method for assessing risk of custom clinical software using an approach based on failure modes and effects analysis (FMEA). **Methods:** We created a novel model for assessing risk for custom clinical software analogous to FMEA. Using this risk model, we integrated a literature review and institutional experience to form a practical guide for risk mitigation. This model was refined by application in a clinic with a high volume of clinical software development. **Results:** We identified three parameters, population (P), intent (I), and complexity (C), analogous to the FMEA parameters of occurrence, severity, and detectability, respectively. Population classifies the scale of the software tool and is a direct measure of the percentage of the clinic's population that the tool will impact. Intent refers to the classification of the software and how it's used in clinical decision making. Complexity is a measure of how difficult it is to find an error by an independent reviewer. Analogous to FMEA risk priority number, multiplying these parameters gives the software risk number (SRN). **Conclusion:** Software risk number serves as a quantitative metric for the posed risk if the code does not perform as anticipated or if the design is flawed. After SRN is evaluated, clinics can rank tools by

highest SRN and intent to determine the most hazardous tools. Tools with the highest SRN and those used for direct clinical decision making can be allotted the appropriate resources during development, commissioning, and routine quality assurance. This model has been integrated into our clinical software development practice.

How Do More Relaxed Treatment Couch Tolerance Tables Lead to More Consistent Patient Positions? A Statistical Approach to Help Reduce Alert Fatigue
C Hui*, M Egan, Arizona Oncology Associates, Phoenix, AZ

Purpose: To show the benefits of deriving meaningful tolerance tables from data, and how the proper number of warnings could improve setup consistency. **Methods:** One year of historical patient positions were collected from the record and verify database. A set of new tolerance tables for different anatomical sites was created based on twice the standard deviation of the corresponding patient positions. In most scenarios, the new tolerance tables were more relaxed than the historical ones, and they were subsequently implemented for clinical use. To investigate the impacts of the new tolerance tables, three months of patient positions controlled by either the historical or new tolerance tables were studied and compared. **Results:** For photon beam therapy, the couch override frequencies for patient positions were 6.7% lateral, 11.9% longitudinal, and 2.8% vertical using the historical tolerance tables. This was compared to 2.1% lateral, 1.8% longitudinal, and 0.4% vertical for the new tables. The standard deviations in patient positions were 1.13 cm lateral, 2.43 cm longitudinal, and 0.29 cm vertical for the former, versus 1.07 cm lateral, 2.04 cm longitudinal, and 0.29 cm vertical for the latter. In general, using the new tolerance tables resulted in smaller lateral and longitudinal standard deviations ($p < 0.01$). As for electron therapy, the override frequencies were 4.4% lateral, 8.5% longitudinal, and 6.1% vertical using the historical tolerance tables, and 5.9% lateral, 3.0% longitudinal, and 2.6% vertical using the new tables. The standard deviations in patient positions were 1.75 cm lateral, 4.00 cm longitudinal, and 0.74 cm vertical for the former, versus 1.17 cm lateral, 2.23 cm longitudinal, and 0.51 cm vertical for the latter. The differences in all three dimensions were significant ($p < 0.01$). **Conclusion:** Applying statistically derived tolerance tables, even with more relaxed tolerances, can significantly reduce the variation in patient positions.

MedPhys Slam is a research communication competition for student, resident, and junior members of the AAPM in which participants prepare a three-minute presentation aimed at sharing the significance of their science to the general public in a compelling and coherent manner. Researchers spend their days investigating every minutia of their topics, but to engage investors, employers, and the general public, the importance of their research must be understood by more than just the scientific community. It's all in the art of communication, and this is what MedPhys Slam aims to foster in the medical physics community.

The preliminary competitions took place at the local chapter meetings throughout the year, and those winners will participate in the final competition at the AAPM 2019 Annual Meeting. The rules are simple: participants have three minutes to present their research using a maximum of three PowerPoint slides. Participants will be judged on two equally weighted categories, comprehension/content and communication/engagement. Not only will this be of interest to those within medical physics, it can be expanded as an AAPM media initiative aimed at communicating what we do to the public.

Learning Objectives:

1. Develop the ability to communicate research objectives and results to a general audience.
2. Develop confidence and conciseness in presentation skills.
3. Learn to incorporate creativity into science.

Audience Q & A

In Nuclear Medicine imaging and therapy applications, molecularly targeted radionuclides may be used to either provide medical images or to deliver a therapeutic dose of radiation. Across this wide range of applications, there are different methods of estimating the organ and tumor doses received by the patient. In this session, dose calculations for nuclear medicine imaging applications will be discussed along with the need for accurate dose calculations in the therapeutic setting. The session will conclude with a discussion of the current methodologies for dose calculations for therapeutic applications including 131I-MIBG, 177Lu-DOTATATE and 177Lu-PSMA.

Learning Objectives:

1. Understanding the MIRD schema for assessment of radiation dose at multiple anatomic levels.
2. Understanding fixed activity versus dosimetry driven treatment planning
3. To become familiar with the current methodology for I131-MIBG dosimetry based treatment planning.
4. To become familiar with the requirements for patient specific dosimetry for 177-Lu based therapies.

A Deep Learning Technique for Projection Interpolation in CBCT Reconstruction

K Lu^{1*}, Z Zhang¹, L Ren², F Yin², (1) Duke University, Durham, NC, (2) Duke University Medical Center, Durham, NC

Purpose: Some previous studies used DL techniques for sinogram interpolation prior to CT reconstruction to reduce the imaging dose. However, few studies have applied DL techniques on CBCT projection interpolation for cone-beam CT (CBCT) reconstruction. This study develops a novel DL technique that performs CBCT projection interpolation before the reconstruction step to improve CBCT image quality, reduce artifacts caused by sparse sampling, as well as reduce the imaging dose. **Methods:** Due to the limitation of GPU memory, the proposed technique re-slice the stack of projection data along the axial direction. The processed data are fed into the custom-designed network slice by slice. As the network iterates through each slice in the input stack of sparsely sampled projections, the outputs of the network are stacked together to form the stack of fully sampled projections. These projections are then used to reconstruct CBCT with the Feldkamp, Davis, and Kress (FDK) algorithm. The proposed technique is tested for CBCT reconstruction using sparsely sampled data. We compared the CBCT images reconstructed from projections interpolated with the conventional bilinear interpolation method and the proposed technique to demonstrate its feasibility and advantages. The quantitative evaluation metrics used are peak-signal-to-noise ratio (PSNR), structural similarity (SSIM) index, and root-mean-square error (RMSE). **Results:** Average PSNR, SSIM, and RMSE values are 41.552, 0.988, and 0.008 for CBCT images reconstructed from projections interpolated with the proposed DL technique; 37.774, 0.975, and 0.013 for bilinear interpolation method; 39.692, 0.978, and 0.010 for images reconstructed without projection interpolation. The proposed technique shows an overall improvement in PSNR, SSIM, and RMSE. **Conclusion:** The proposed DL interpolation technique can perform accurate CBCT projection interpolation that reduces artifacts for CBCT reconstructed from sparsely sampled projections as well as the imaging dose.

BEST IN PHYSICS (IMAGING): A GAN-Based Technique for Synthesizing Realistic Respiratory Motion in the 4D-XCAT Phantoms

Y Chang*, Z Jiang, P Segars, Z Zhang, F Yin, L Ren, Duke University Medical Center, Cary, NC

Purpose: Synthesize realistic and controllable respiratory motions in the 4D-XCAT phantoms by developing a GAN-based deep learning technique. **Methods:** A motion generation model was developed using bicycle-GAN with a novel 4D generator. The model input includes the end-of-inhale (EOI) phase of 4D-CTs and a Gaussian perturbation, and it generates inter-phase deformable-vector-fields (DVF), which are compounded and applied to the EOI image to generate 4D images. A separate machine-learning respiratory motion amplitude control model was built to predict the perturbation needed to generate a specific motion amplitude. The models were trained and validated using 71 patient 4D-CT data and tested using 6 XCAT to generate 4D-XCAT phantoms with realistic respiration. The simulated 4D images were evaluated by Dice coefficients calculated for the lungs. The generated DVFs were evaluated by deformation energy, the correlations of DVFs and derived ventilation maps with those from the reference images. Results were compared to those from the original 4D-XCAT to demonstrate the improvement of motion realism. **Results:** For the simulated 4D-CTs, the lung volume deviation was within 5.8%, and the Dice coefficients of the lungs reached at least 0.95. The cross-correlation of DVFs achieved $0.89 \pm 0.10 / 0.86 \pm 0.12 / 0.95 \pm 0.04$ along the x/y/z directions in the testing group. The cross-correlation of ventilation maps derived achieved $0.80 \pm 0.05 / 0.67 \pm 0.09 / 0.68 \pm 0.13$, and the Spearman's correlation was $0.70 \pm 0.05 / 0.60 \pm 0.09 / 0.53 \pm 0.01$, respectively, in the training/validation/testing groups. The generated 4D-XCAT phantoms presented similar deformation energy (0.36 ± 0.07) as patient data (training: 0.33 ± 0.17 ; validation: 0.22 ± 0.14 ; testing: 0.36 ± 0.14), compared with 0.07 ± 0.01 in the original 4D-XCAT. The Dice coefficient between the original and generated 4D-XCAT phantoms of similar breathing amplitudes was 0.95. The motion amplitude control error was less than 0.5 mm. **Conclusion:** The results demonstrate the efficacy of synthesizing realistic controllable respiratory motion in the 4D-XCAT phantom using the proposed method. This crucial development enhances the value of XCAT phantoms for various 4D imaging and therapy studies.

A Method for 4D Cone-Beam CT in Under 20 Seconds with New Generation Linacs

S Blake*, O Dillon, R O'Brien, ACRF Image-X Institute, University of Sydney, Sydney, NSW, AU

Purpose: The Halcyon linear accelerator (Varian Medical Systems, Palo Alto, CA) has an integrated x-ray imaging system capable of performing cone-beam CT (CBCT) acquisitions four times faster than conventional systems, including a free-breathing fast acquisition protocol for 3DCBCT in which 491 projections are acquired in 16.6 seconds. A conventional 4DCBCT acquires 1320 projections over 240 seconds to provide enough information for conventional reconstructions to produce images of sufficient quality across the respiratory cycle. This study presents a method by which the fast <20 second acquisition can produce 4DCBCT images and quantify image quality relative to conventional 4DCBCT. **Methods:** We used two 4DCT scans of the same patient from the Cancer Imaging Archive 4D-Lung dataset, defining the first as a "planning" 4DCT and the second as a "ground-truth" for 4DCBCT simulation and image quality quantification. The open-source Reconstruction Tool Kit (RTK) was used to simulate conventional and rapid CBCT acquisitions over a 200-degree arc by generating 1320 and 491 forward projections respectively, assuming 13-15 breaths per minute. Both acquisitions were reconstructed using the 4D Feldkamp-Davis-Kress (4DFDK) algorithm. The rapid

acquisition was also reconstructed using the Motion Compensated FDK (MCFDK) algorithm, in which data is backprojected along curved paths to account for motion estimated from the planning 4DCT. Image quality was quantified in terms of contrast-to-noise ratio (CNR), root-mean-square error to ground-truth (RMSE-GT) and structural similarity index to ground-truth (SSIM-GT). **Results:** The phase averaged CNR, RMSE-GT and SSIM-GT for the conventional 4DFDK were 2.695, 78.93 and 0.415 respectively. The phase averaged CNR, RMSE-GT and SSIM-GT for the rapid 4DFDK and MCFDK reconstructions were 2.006, 292.8, 0.072 and 2.864, 134.7, 0.205. **Conclusion:** The data acquired in the <20 second protocols offered on new generation linacs can deliver 4DCBCT images of quality comparable to 4-minute protocols but only when motion compensated reconstruction is implemented.

This work was funded by an NHMRC project grant 1138899 and partially by the Cancer Australia PdCCRS project grant number 1123068. RO was funded by a Cancer Institute NSW career development fellowship.

TU-C-TRACK 3-04

Dual-Encoder Convolutional Neural Network (DeCNN) for Average Image-Constrained 4D-CBCT Reconstruction

Z Jiang^{1*}, Z Zhang², Y Chang³, F Yin⁴, L Ren⁵, (1) Duke University, Durham, NC, (2) Duke University, Durham, NC, (3) Duke University, Durham, NC, (4) Duke University, Durham, NC, (5) Duke University, Durham, NC

Purpose: 4D-CBCT is valuable for 4D-target verification in radiotherapy. However, due to the scanning time and imaging dose constraints, projections acquired for each respiratory phase are intrinsically under-sampled, leading to streak artifacts in FDK reconstruction or blurriness in iterative reconstruction using compressed sensing (CS). Introducing the average 4D-image constraint to the CS-based reconstruction, such as prior-image-constrained CS (PICCS), can improve the edge sharpness of the static structures. However, PICCS can lead to motion artifacts in the moving regions. In this study, we proposed a dual-encoder convolutional neural network (DeCNN) for fast and high-quality average image-constrained 4D-CBCT reconstruction. **Methods:** The proposed DeCNN has two parallel encoders to extract features from the average images and the under-sampled target phase images, respectively. The two encoders have the same architecture but do not share weights. Average image features and under-sampled image features are extracted at multi-scale levels and are then concatenated and fed into the decoder to reconstruct the high-quality images of the target phase. DeCNN was trained on 28 lung 4D-CBCT and tested on 12 lung 4D-CBCT data. Its results were both qualitatively and quantitatively evaluated using RMSE, PSNR, and SSIM, and compared against other state-of-the-art methods. **Results:** 4D-CBCT reconstructed by DeCNN showed: (1) qualitatively, clear and accurate edges for both stable and moving structures; (2) quantitatively, low RMSE, high PSNR, and high SSIM compared to the ground-truth images; and (3) superior quality to those reconstructed by other methods, including back-projection, CS total-variation, PICCS, and the single-encoder CNN. DeCNN took only about 1.8 seconds to reconstruct images of one respiratory phase. **Conclusion:** The proposed dual-encoder architecture demonstrated effectiveness in improving the 4D-CBCT image quality with average image constraint, thus improving 4D-CBCT's clinical utility for the moving target localization.

This work was supported by the National Institutes of Health under Grant No. R01-CA184173 and R01-EB028324.

Faster Safer Clearer 4DCBCT: Results of the ADAPT Clinical Trial

O Dillon^{1*}, B Lau¹, T Reynolds¹, P Keall¹, S Vinod², A Wallis³, S Smith⁴, J Sonke⁵, R O'Brien¹, (1) University of Sydney, Sydney, NSW, AU, (2) University Of New South Wales, Sydney, NSW, AU, (3) Liverpool Hospital Sydney, Sydney, NSW, AU, (4) South Western Sydney Lhd, Sydney, NSW, AU, (5) Netherlands Cancer Institute, Amsterdam, NH, NL

Purpose: Conventional pre-treatment thoracic 4DCBCT scans take 1320 projections over 240 seconds. The ADAPT clinical trial (NCT04070586) uses first-in-world implementations of motion compensated acquisition and reconstruction to reduce scans to just 200 projections over 20 breaths (40 to 160 seconds). We present results of the first 20 of 30 trial patients and investigate our motion compensated acquisition and reconstruction relative to conventional 4DCBCT. **Methods:** The ADAPT trial enrolled 30 lung cancer radiation therapy patients for additional imaging in their first 2 treatment fractions. For each fraction, they receive a conventional 4DCBCT, followed by a 200 projection motion compensated 4DCBCT. In motion compensated acquisition, the imaging hardware is adapted to patient respiration in real time to ensure even data spread across the respiratory cycle. In motion compensated reconstruction, the Motion Compensated McKinnon Bates (MCMKB) algorithm estimates patient anatomy and motion so that data acquired at every phase contributes to reconstruction of each phase. Acquisition performance was quantified by scan dose and time, as well as Root-Mean-Square-Deviation (RMSD) between our real time adaptive gantry control against perfectly even breathing and data spread. Reconstruction performance was quantified with Contrast-to-Noise-Ratio (CNR), Structural SIMilarity Index (SSIM) to conventional and Tissue Interface Sharpness (TIS) at the diaphragm and tumour boundaries. **Results:** Relative to conventional 4DCBCT, motion compensated 4DCBCT delivered 85% less dose, was on average 64% faster, had RMSD of 1.8° from ideal, images had 35% better CNR, 99% structural similarity, 47% better diaphragm TIS and 56% better tumour TIS. **Conclusion:** The ADAPT clinical trial provides real world evidence that motion compensated acquisition and reconstruction can be implemented on standard linacs to perform thoracic 4DCBCT with 85% less dose, 64% faster and with improved image quality.

This research was supported by NHMRC project grant #1138899 and grant #1123068 which was awarded through the Priority-driven Collaborative Cancer Research Scheme and funded by Cancer Australia. TU-C-TRACK 3-06

Rapid Low Dose 4DCBCT

B Lau^{1*}, O Dillon¹, T Reynolds¹, P Keall¹, J Sonke², S Vinod³, R O'Brien¹, (1) ACRF Image X Institute, University of Sydney, Sydney, NSW, AU, (2) Netherlands Cancer Institute, Amsterdam, (3) University Of New South Wales, Sydney, NSW, AU, (4) Liverpool Hospital Sydney, Sydney, NSW, AU

Purpose: Prior to thoracic radiotherapy treatments, patients are commonly aligned using conventional 4DCBCT scans (1320 projections over 4 minutes). We determine the viability of rapid low dose 4DCBCT scans by simulating scans as low as 60 projections over 25 seconds, using data from 20 patients of the ADAPT clinical trial (NCT04070586). **Methods:** The ADAPT clinical trial performs adaptive 4DCBCT scans by adapting gantry rotational speed and projection acquisition in accordance to real-time patient breathing rate changes, this produces 600 and 200 projection scans in a quarter of conventional scan time. In this study, these adaptive 4DCBCT scans were down sampled and simulated into even faster and lower imaging dose 310, 160, 110 and 60 projection. Reconstructed image quality was quantified using Structural Similarity Index (SSIM), Signal-to-Noise-Ratio (SNR), Contrast-to-Noise-Ratio (CNR), Tissue Interface Sharpness-Diaphragm (TIS-D) and Tissue Interface Sharpness-Tumour (TIS-T). Conventional 4DCBCT scans were used as a comparator. **Results:** The simulated 310, 160, 110 and 60 projection adaptive acquisitions deliver approximately (76%, 87%, 91%, 95%) reduction in imaging dose via reduction in total number of projections acquired and (48%, 73%, 82%, 90%) shorter scan time on average compared to conventional 4DCBCT scans, respectively. The 310, 160 and 110 projection adaptive acquisitions from all patients matched or improved compared to the conventional acquisition across all image quality metrics. The minimum number of projections to maintain the image quality metrics of conventional scans (SSIM=1±0, SNR=11.9±11.7, CNR=9.5±3.1, TIS-D=0.59±0.3 and TIS-T=0.41±0.1) was the 110 projection adaptive scan (SSIM=0.98±0.01, SNR=18.5±8.9, CNR=10.2±3.5, TIS-D=0.72±0.4, TIS-T=0.57±0.7). **Conclusion:** 110 projection adaptive acquisition results show image quality can be maintained comparable to conventional acquisition whilst reducing scan time by 95% and dose by 90%.

This study is funded by NHMRC grant 1138899 and partly by a Cancer Australia grant number 1123068. RO is supported by a Cancer Institute NSW career

development fellowship, and PK is supported by an Australian NHMRC Senior Principal Research Fellowship.

Reference-Free, Learning-Based Rigid Motion Compensation in Cone-Beam CT for Interventional Neuroradiology

H Huang^{1*}, J Siewersden^{1,2}, W Zbijewski¹, C Weiss², T Ehtiaty³, A Sisniega¹, (1) The Johns Hopkins University, Baltimore, MD (2) Russell H. Morgan Department of Radiology, Johns Hopkins University, Baltimore, MD (3) Siemens Healthineers, Forchheim, Germany

Purpose: Cone-beam CT (CBCT) provides guidance in interventional neuroradiology, but limited acquisition speed (4 – 30 s) results in motion artifacts. Autofocus motion compensation (MoCo) was successfully applied in head CBCT but autofocus metrics do not guarantee preservation of anatomical structures. Similarity metrics (e.g., visual information fidelity, VIF) provide quantification of image quality and structural similarity to a reference. However, motion-free, matched, references are seldom available. We propose DL-VIF, a learned reference-free autofocus metric that preserves anatomy. **Methods:** DL-VIF was estimated with a deep CNN implementing a cascade of 3D residual blocks acting on downsampled head CBCTs (128³ voxels). The network was trained on simulated motion-free and motion-contaminated CBCT pairs. Random rigid motion trajectories (0-8mm amplitude) were applied to 38 head MDCT volumes (12100 instances). DL-VIF was integrated into an autofocus framework and assessed on 20 CBCTs generated analogously to the training data. Further validation was obtained on 5 CBCTs of a cadaver head acquired on a robotic C-arm (Artis Zeego, Siemens Healthineers) with motion induced by shifting and rotating the specimen. The performance of DL-VIF was compared to a conventional autofocus metric (gradient entropy). **Results:** DL-VIF showed good agreement with the reference (slope = 0.980, R² = 0.996). DL-VIF MoCo showed reduction of motion artifacts in simulated data, with 0.099 improvement in SSIM, compared to 0.094 for conventional autofocus. In the cadaver study, DL-VIF outperformed conventional autofocus, providing robust compensation in cases of moderate and severe motion, where conventional autofocus failed. An overall 6x larger increase in SSIM and 7x reduction in SSIM standard deviation was observed, restoring visualization of cranial anatomy. **Conclusion:** The learned DL-VIF provided reliable estimation of structural similarity without a reference image and yielded consistent reduction of motion artifacts with anatomically realistic solutions. DL-VIF offers an important step in robust autofocus MoCo methods for CBCT.

Biologically- and Functionally-Guided Radiation Therapy

TU-C-TRACK 4-01

Evaluation of CT-Derived Lung Perfusion with Deep Learning in Radiotherapy Patients

G Ren^{1*}, B Li^{2,1}, Y Lu², R Mao², H Ge², F Kong³, W Ho⁴, J Cai¹ (1) Department of Health Technology and Informatics, The Hong Kong Polytechnic University, Hong Kong, CN (2) Radiation Oncology Department Of Henan Cancer Hospital, CN (3) Case Western Reserve University- School of Medicine, Cleveland, OH (4) Department of Nuclear Medicine, Queen Mary Hospital, Hong Kong, CN

Purpose: Deep learning-based CT perfusion mapping (DL-CTPM) has been proposed to provide regional function information for functional lung avoidance radiotherapy (FLART). This study aims to evaluate the DL-CTPM synthesized perfusion images in radiotherapy patients for FLART. **Methods:** SPECT/CT perfusion scans of 19 lung cancer patients were retrospectively collected from Henan Anti-cancer Hospital. All patients underwent radiation therapy afterward. The left/right lungs were separated to augment the dataset to 38 (20 for transfer training; 18 for testing). These images were processed by a deep learning-based framework to extract features from 3D-CT images and synthesize CT-derived perfusion (CTDP). Transfer learning strategies of fine-tuning and fixed-encoder were used to reuse information learned from a previously built dataset of different types of lung diseases. The Spearman's correlation coefficient (R) and structural similarity index measure (SSIM) between the CTDP and the corresponding SPECT were computed to assess the statistical and perceptual image similarities, respectively. To assess the function-wise concordance, the Dice similarity coefficient (DSC) was computed to determine the similarity of the low/high functional lung volumes. The dosimetry evaluation is undergoing. **Results:** The fine-tune transfer learning model has the best performance in terms of the voxel-wise agreement. The evaluation shows a high voxel value correlation (0.8111±0.1090) and high structural similarity (0.8094±0.0517) between the CTDP images and SPECT images. The evaluation of the function-wise concordance obtains an average DSC value of 0.7869±0.0634 for high-functional lungs, ranging from 0.6460 to 0.8984, and 0.7806±0.0727 for low-functional lungs, ranging from 0.6743 to 0.8902. Of the testing cases, 94% have high functional lung larger than DSC > 0.7, and 83% for low functional lung. **Conclusion:** The CT-derived lung perfusion using the DL-CTPM method showed a high agreement with the SPECT perfusion for lung cancer patients. This method holds great promise to provide lung function images for image-guided FLART.

Functional Dose Sparing of the Parotid Glands: How Sparing the Parotid Ducts Yields Improvements in Patient Reported Xerostomia

D Fried^{*}, M Ahmidouch, K Pant, S Das, C Shen, K Pearlstein, L Marks, B Chera, University of North Carolina, Chapel Hill, NC

Purpose: To assess efficacy of prospectively sparing parotid ducts during treatment planning. **Methods:** 38 patients prospectively underwent MRI sialography-guided parotid ductal sparing (PDS) and had their patient reported xerostomia (PRX) evaluated at 6 and 12 months. 28/38 patients received de-escalated chemoradiotherapy. A parotid duct atlas was created, evaluated and used to generate parotid duct contours on a baseline cohort who did not receive PDS but were on the same de-escalation trials. PRX, defined as moderate to very severe symptoms, in the de-escalated PDS patients was compared to the aforementioned baseline cohort. Nested multivariate models including mean dose to the contralateral submandibular and parotid glands with and without mean parotid ductal doses were generated to determine if ductal dose improved model fit for PRX. **Results:** The atlas-generated parotid duct contours had a mean distance-to-agreement of 3.6mm compared to the MRI sialography imaged contours and an average absolute dose difference of 3.5Gy. Atlas based contours found the mean dose to the contralateral and ipsilateral ducts was lower in patients receiving PDS by an average of 11.4Gy and 17.2Gy, respectively. PRX was lower in patients receiving PDS at 6 months post-CRT (46% vs 67%, p=0.03), and trended lower at 12 months post-CRT (32% vs 49%, p=0.11). The nested models were compared and the addition of mean parotid ductal dose significantly improved model fit at 6 and 12 months post CRT (p=0.030 and 0.047, respectively). **Conclusion:** Atlas-based contours of parotid ducts demonstrated a substantial reduction of parotid ductal dose is possible with prospective sparing. This dose reduction yielded an approximately 20% absolute reduction in rates of PRX at 6 and 12 months. The significant improvement of model fit upon including mean parotid ductal dose suggests that the dose received by the parotid ducts relates to PRX even when considering traditional dosimetric predictors.

BEST IN PHYSICS (MULTI-DISCIPLINARY): Lung Treatment Planning with Parametric Response Mapping Function Guidance

C K Matrosic^{*}, D R Owen, D Polan, Y Sun, S Jolly, C Schonewolf, M Schipper, R Ten Haken, C Galban, M Matuszak, University of Michigan, Ann Arbor, MI

Purpose: Advancements in functional lung imaging have improved the pretreatment understanding of a patient's pulmonary function and have enabled the development of function-guided radiotherapy (RT) planning. Parametric response mapping (PRM) is a voxel-wise image analysis technique used for CT-based functional imaging that classifies lung abnormality phenotypes and has previously shown utility in the assessment of pulmonary complication risk in a diagnostic setting. The purpose of this work was to implement PRM guidance in a clinical RT planning workflow and examine the potential clinical impact. **Methods:** PRM analysis was performed for 18 lung cancer patients using paired pretreatment inspiration/expiration CT scans to classify each voxel as normal, emphysema, small airway disease (SAD), or parenchymal disease (PD). The non-normal PRM data were converted to topological maps and high-density regions of each classification were contoured as avoidance structures for VMAT treatment planning. Treatment plans were optimized to maintain clinical organ-at-risk dose limits to the Lungs-GTV, spinal cord, heart, esophagus, and brachial plexus contours. Dosimetric comparisons were performed between non-function-guided plans and PRM-guided plans which included additional low priority goals reducing the V20Gy of PRM avoidance contours. **Results:** The PRM-guided workflow was successfully implemented and the inclusion of PRM guidance resulted in statistically significant ($p < 0.05$) improvements to the V20Gy of the PRM avoidance contours. The average reduction of the V20Gy(%) of all PRM avoidance contours was 5.4%. The inclusion of PRM guidance did not significantly ($p > 0.05$) increase relevant dose metrics for OARs or decrease PTV coverage but did result in increased plan complexity. **Conclusion:** PRM guidance in RT treatment planning was found to be effective at redistributing dose away from avoidance structures in the lung while maintaining OAR dose limits and PTV coverage constraints. The presented workflow provides a framework for the potential clinical implementation of PRM-guided treatment planning.

TU-C-TRACK 4-04

Predicting Lung Ventilation Loss Caused by Local and Distant Radiation-Induced Damage

E Vicente^{1*}, A Modir¹, J Kipritidis², K Yu³, Y Yan⁴, D R Owen⁵, M M Matuszak⁵, P Mohindra¹, R Timmerman⁴, A Sawant¹, (1) University of Maryland School of Medicine, Baltimore, MD, (2) Northern Sydney Local Health District, Sydney, Australia, (3) Broncus Medical, Inc., San Jose, CA, (4) UT Southwestern Medical Center, Dallas, TX, (5) University of Michigan, Ann Arbor, MI

Purpose: This work challenges the conventional assumption of “locoregional radiation damage” to lung parenchyma, implicit in current functional lung avoidance (FLA) radiotherapy (RT). Here, we investigate the impact of including “distant damage” by accounting for the radiation-induced injury to airways, branching serial structures distant from the point where the damage is observed. Consequently, we propose a method to predict post-RT ventilation loss that considers not only the locoregional parenchymal damage but also the airflow disruption caused by injury to airways. **Methods:** Breath-hold CTs (BHCTs) and simulation 4DCTs were acquired from seven lung RT patients. Airways were auto-segmented (12 generations, ~235 airways/patient) on the BHCTs using a virtual bronchoscopy software. 4DCT-based ventilation maps were used to estimate pre-RT ventilation. Conventional IMRT plans were recreated to obtain dose distribution. Post-RT ventilation loss was estimated studying three contributions: (i) Using the pre-RT ventilation and a normal tissue complication probability model we estimated loss due to parenchymal damage ($\Delta V_{\text{loss(P)}}$). (ii) Connecting each terminal airway with a lung sub-lobe volume (SLV), we estimated loss due to airway damage ($\Delta V_{\text{loss(A)}}$) by calculating the contribution of pre-RT ventilation in not-ventilated SLVs. A SLV was considered not ventilated if only one of the upstream airways was collapsed post-RT, using our probability of airway collapse model. (iii) Finally, the loss due to both effects ($\Delta V_{\text{loss(P+A)}}$) was calculated by subtracting from the total pre-RT ventilation the contribution of the post-RT ventilation (due to parenchymal damage) in the post-RT ventilated SLVs. **Results:** Preliminary results showed that average $\Delta V_{\text{loss(P)}}$ was 13%, $\Delta V_{\text{loss(A)}}$ was 22%, and the combined effect, $\Delta V_{\text{loss(P+A)}}$, was 25%. **Conclusion:** These results reveal that airway damage is not only important but may be a more critical factor than locoregional parenchymal damage. Ignoring this distant effect and focusing primarily on parenchymal damage can lead to spurious choices in current FLA strategies.

Simultaneous Whole-Lung Ventilation-Perfusion Imaging with Volumetric CT in Non-Small Cell Lung Cancer: A Feasibility Study

H Young^{1,2,3*}, F Su³, T Lee^{2,3,4}, S Gaede^{1,2}, (1) London Regional Cancer Program, London, ON, CA, (2) Western University, London, ON, CA, (3) Robarts Research Institute, London, ON, CA, (4) Lawson Health Research Institute, London, ON, CA

Purpose: To generate a comprehensive map of regional lung function including both ventilation and perfusion in a single dynamic contrast-enhanced CT scan using a volumetric CT scanner. **Methods:** Two patients with non-small cell lung cancer were imaged on a GE Revolution volumetric CT scanner before and 6 weeks after radiotherapy with standard fractionation. Images were acquired at a single couch position using the following parameters: cine mode, 0.28s/revolution, 100kV, 100mA, and 160mm axial field-of-view for 45-50s. Iodine-based contrast was injected 6s after the start of the acquisition. All images in the series were non-rigidly registered in Elastix using a b-splines transformation and a normalized mutual information metric. The lung volume was segmented on the registered images using a semi-automated density-based method. Blood flow maps were generated using GE's prototype CT Perfusion software. End-inhale and end-exhale images were identified from the pre-contrast images and were used to calculate specific ventilation maps using an existing density-based method. Ventilation (V) and perfusion (Q) maps were normalized to the 99th percentile of the distribution to facilitate direct comparison, and V/Q maps were calculated as a ratio of the normalized maps. **Results:** After radiotherapy, ventilation in the treated lung decreased for both patients and blood flow decreased in one patient but increased in the second. Tumour blood flow was heterogeneous in one patient, and uniformly low in the second. In both patients, regions of the lung that appear to have normal function based on ventilation or perfusion imaging alone are shown to have V/Q mismatch. **Conclusion:** These results demonstrate the feasibility of generating both ventilation and perfusion imaging using volumetric CT in a single imaging protocol performed in under 1 minute. This method may facilitate the clinical translation of functional lung imaging in radiation treatment planning.

Ventilation Derived from Clinical 4D-CBCT Using a Deep Learning-Based Model: First Comparison with Technegas SPECT Ventilation

Z Liu^{*}, Y Tian, J Dai, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College Beijing CN

Purpose: Ventilation derived from 4D cone-beam computed tomography (CBCT) may predict specific radiation sensitivity, but the current algorithms for measuring ventilation highly depend on deformable image registration (DIR). With single-photon emission-computed tomography ventilation (SPECT-V) acting as a gold standard, this study proposes new deep learning (DL) model-independent of DIR for deriving ventilation from 4D-CBCT and investigates whether the accuracy could be improved in comparison with DIR dependent methods. **Methods:** The study consists of 4D-CBCT and 99mTc-Technegas SPECT/CT scans of 28 esophagus or lung cancer patients. For each patient, the scans were acquired before the first radiotherapy treatment and rigidly registered. Using these data, ventilation images from 4D-CBCT (CBCTVI) were derived by using a deep-learning-based model with two forms of the dataset [(a) ten phases and (b) two phases of peak-exhalation and peak-inhalation] as input. A Sevenfold cross-validation procedure was used to evaluate the performance. For comparative evaluation, density-change- and Jacobian-based (HU and JAC) methodologies are also used to calculate CBCTVIs for each patient. The SPECT-V and derived CBCTVIs were segmented into high, medium, and low functional lung (HFL, MFL, and LFL) regions. The spatial overlap of corresponding HFL, MFL, and LFL for SPECT-V against CBCTVIs was evaluated by using the dice similarity coefficient (DSC) and analyzed with a one-factor ANOVA model among different methods. **Results:** The averaged DSC values were

0.34, 0.34, and 0.59/0.58 for the CTVI(HU), CTVI(JAC), and CTVI(DL(a)/DL(b)), respectively. These results showed the DL method yielded the highest similarity with SPECT-V with the prominently significant difference. **Conclusion:** This study proposed a DL model for deriving CBCTVI and performed a validation against SPECT-V. The results demonstrated that DL method increased the accuracy in comparison to HU and JAC methods, and can be a stepping stone to extract dynamic changes in the respiration patterns of patients during radiotherapy.

The authors sincerely thank Dr. Li Mei and her team in nuclear medicine department of Peking TongRen Hospital for their great help in acquiring SPECT image for patients. TU-C-TRACK 4-07

Protons Combined with PARP Inhibition Sensitize Cancer Cells and Activate Immune Signaling More Than Photons

M Ben Kacem*, S Bright, B Turner, D Flint, M Manandhar, D Martinus, C McFadden, S Shaitelman, G Sawakuchi, University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: Due to their higher ionization density compared to photons, protons induce more clustered DNA lesions including clustered double strand breaks (DSBs), clustered single strand breaks (SSBs) and clustered base damages (BDs). Clustered SSBs and BDs can be converted into DSBs during attempted repair, increasing the number of DSBs. If not properly repaired, DSBs can generate micronuclei (MN), which are displaced chromosomes or chromosome fragments enclosed by the nuclear membrane and are known precursors of immune activation. Here we show that protons+PARP inhibitor (PARPi) sensitize cancer cells more than photons+PARPi, and that this combination might also induce antitumor immune signaling. **Methods:** We obtained clonogenic cell survival for H460, H1299, PANC-1 and Panc 10.05 cell lines to quantify the effect of a PARPi on radiosensitization. We used immunohistochemistry in H1299, PANC-1, HCC1937 (BRCA mut) and HCC1937 (BRCA complemented) cell lines to measure MN and cGAS-positive MN (MN-cGAS+) numbers to quantify antitumor immune signaling at 24 and 72 h post-radiation. Cells were treated with 6 MV x-rays at 10 cm water equivalent depth or 100 MeV unmodulated protons at 4.3 water equivalent depth (9.9 keV/ μ m dose-weighted LET in water) alone or with a PARPi (0.1 or 1 μ M, Olaparib). **Results:** PARPi radiosensitizes multiple cell lines to both photons and protons. Relative to photons alone, protons+PARPi provided sensitizations of 1.70 ± 0.04 (H460), 1.94 ± 0.06 (H1299), 1.93 ± 0.05 (PANC-1) and 1.70 ± 0.09 (Panc 10.05). PARPi resulted in a modest increase (5%) or a significant decrease (-10%) in RBE. MN and MN-cGAS+ were increase by both photons and protons. However, protons+PARPi further amplified MN-cGAS+ compared to all other treatment combinations. **Conclusion:** Protons+PARPi increase cell death to levels that are only achievable with carbon ions. Protons+PARPi also amplify precursors associated with antitumor immune signaling. Additional investigation is warranted to evaluate if these effects are seen in vivo.

State-Of-The-Art Multi-Omics

Rapid development in machine learning (ML) and radiomics in the last decade has stimulated substantial interest in precision medicine as well as research activities in applying radiomics and artificial intelligence (AI) for radiation therapy treatment assessment and outcome prediction. At the same time, the radiation oncology community is eager to understand its efficacy and limitation in order to narrow down the gap between scientific research and clinical application and prepare for emerging field evolution. This symposium aims to provide fundamental knowledge of radiomics and artificial-intelligence (AI) development in precision medicine, including open-source informatics. The impact of imaging parameters and image processing techniques on radiomics/ML as well as some general and specific guidelines recently recommended by a number of medical professional societies will be discussed to improve the robustness of using medical images for the outcome research. As an extension of radiomic application in multimodality cancer treatment, multiple omics applications in cancer treatment assessment and outcome prediction will also be introduced.

Learning Objectives:

1. To learn the role of radiologic AI with other -omics data for precision medicine and open-source informatics developments
2. To learn the current recommendations for incorporating radiomics in oncology clinical studies and the impact of imaging and image processing on radiomics applications
3. To learn the methodology of incorporating biological data into radiomics for the assessment of tumor heterogeneity

A DNA Repair Inhibitor Targeting ATR Modulates Immune Responses to Radiotherapy

S Bright^{1*}, B Turner², M Manandhar³, C McFadden⁴, D Flint⁵, D Martinus⁶, M Ben Kacem⁷, S Shaitelman⁸, G Sawakuchi⁹, (1) UT MD Anderson Cancer Center, Houston, TX, (2) UT MD Anderson Cancer Center, Houston, TX, (3) UT MD Anderson Cancer Center, Houston, TX, (4) UT Southwestern, Dallas, TX, (5) UT MD Anderson Cancer Center, Houston, TX, (6) UT MD Anderson Cancer Center, Houston, TX, (7) MD Anderson Cancer Center, Houston, TX, (8) MD Anderson Cancer Center, Houston, TX, (9) UT MD Anderson Cancer Center, Houston, TX

Purpose: Radiotherapy (RT) has been shown to induce antitumor immune responses whereby the host immune system is stimulated to recognize tumor and activate mechanisms to clear it. RT-induced antitumor immunity is rare but once achieved it offers robust and long-lasting antitumor immunity. Because RT-induced antitumor immunity is thought to be mediated through DNA damage we set out to establish if inhibitors of DNA damage repair proteins, particularly targeting ataxia telangiectasia and Rad3-related protein (ATR), can induce greater immune responses than RT alone. **Methods:** We used a triple negative breast cancer murine model, 4T1, on the hind leg of BALB/c mice. Animals were treated with vehicle or an ATR inhibitor (ATRi) (75 mg/kg, AZD6738) 2 h prior to each radiation fraction (3x6 Gy using 6 MV x-rays) or sham exposure. Tumors were harvested 7 days after the last fraction to isolate sub-populations of immune cells (CD8⁺ T-cells, CD4⁺ T-cells, T-regs, CD8⁺ PD-1⁺ T-cells, type 1 and 2 macrophages and classical dendritic cells type 1 and 2) within the tumor. Tumor growth delay and survival data were also acquired. **Results:** RT delayed tumor growth and modestly increased survival. RT+ATRi enhanced these effects significantly. RT alone was able to increase the percentage of macrophages present in the tumor (12.9%) compared to vehicle alone (4.6%). RT+ATRi also increased macrophage numbers (24.8%) but also significantly increased CD4⁺ (9.3% vs vehicle 3.2%) and CD8⁺ (5.6% vs vehicle 2.6%) T-cells. Dendritic cells were also increased after RT+ATRi. **Conclusion:** RT alone can alter the tumor microenvironment by increasing macrophage recruitment. This effect can be increased with RT+ATRi. Furthermore, RT+ATRi significantly increased the number T-cells (CD4⁺ and CD8⁺) and non-significantly, dendritic cells. This suggests differential signaling at 7 days between RT and RT+ATRi. Further analysis is required to identify pro- and anti-tumor subpopulations within these sub-types.

DNA Repair Inhibitors Combined with Protons Increase Cell Radiosensitivity in Vitro

D Flint^{1*}, S Bright, B Turner, M Manandhar, M Ben Kacem, S Shaitelman, G Sawakuchi, UT MD Anderson Cancer Center, Houston, TX

Purpose: To compare the competing radiosensitizing effects of DNA-repair inhibitors and proton LET in vitro. **Methods:** We treated H460 and H1299 non-small cell lung cancer and PANC-1 and Panc 10.05 pancreatic adenocarcinoma cells with varying concentrations (0.1-10 μ M) of DNA repair inhibitors (DRIs) targeting the DNA repair proteins Rad51 (BO2), DNA-PKcs (NU7441), ATM (KU5593), ATR (ADZ6738) and PARP (AZD2281), or with DMSO vehicle as a control. We irradiated the cells with 6 MV x-rays or 9.9 keV/ μ m protons (dose-weighted LET in water) and performed clonogenic assays to characterize their survival. To parameterize cell radiosensitivity, we estimated the dose required to achieve 10% survival, D10%. To quantify drug sensitization at a given radiation quality, Q, we calculated the sensitization enhancement ratio, SER(Q)=D10%(DMSO,Q)/D10%(drug,Q). To quantify the proton LET effect, we calculated the RBE for each drug combination as: RBE=D10%(drug,x-rays)/D10%(drug,protons). To quantify the combined sensitizing effect of protons and drugs, we calculated the total radiosensitivity enhancement, TRE=D10%(DMSO,x-rays)/D10%(drug,protons). **Results:** The SERs varied greatly across drug combinations and cell lines, ranging from 1.00 $\pm$ 0.02 (H460, 5 μ M BO2, x-rays) to 3.23 $\pm$ 0.13 (H1299, 1 μ M ADZ6738, x-rays). Between radiation qualities, the SERs were positively correlated ($r=0.8807$), suggesting that DRIs that are effective for x-rays are similarly effective for protons. However, the RBE values were negatively correlated with SER(x-ray) ($r=-0.6160$), suggesting that the greater the DRI-induced sensitization, the less benefit there will be from the proton LET effect. Nevertheless, the TREs from combining DRIs with protons were generally larger than SER(x-ray) values (30 $\pm$ 3% on average), and were positively correlated with SER(x-ray) ($r=0.8911$), suggesting that even when DRIs reduce proton RBE, there is still a net radiosensitivity gain when combining them with protons. **Conclusion:** Although protons+DRI may reduce proton RBE, the DRI-induced sensitization outweighs the RBE loss, resulting in a substantial net sensitization beyond that achieved with DRI+photons.

Features Of TOPAS-nBio – Release 1.0

J Schuemann^{1*}, A McNamara¹, J Ramos-Mendez², N Dominguez-Kondo³, J Perl⁴, D Yoo¹, N Henthron⁵, J Warmenhoven⁵, S Ingram⁵, M Merchant⁵, K Kirkby⁵, K Held¹, J Laverne⁵, H Paganetti¹, B Faddegon², (1) Physics Division, Department of Radiation Oncology, Massachusetts General Hospital and Harvard Medical School, Boston, Massachusetts, USA, Boston, MA, (2) University of California San Francisco, San Francisco, CA, (3) Benemerita Universidad Autonoma de Puebla, Puebla, Mexico, (4) Stanford Linear Accelerator Center, Menlo Park, CA, (5) Division of Cancer Sciences, Faculty of Biology, Medicine and Health, The University of Manchester and The Christie NHS Foundation Trust, Manchester, United Kingdom, GB, (6) The University of Notre Dame, Notre Dame, IN

Purpose: The goal of the TOPAS-nBio project is to provide intuitive nanometer scale Monte Carlo (MC) simulations for radiobiology experiments that do not require programming expertise. Here we present new functionalities of the TOPAS-nBio system available in the first full release (v1.0). **Methods:** Since the open-source beta-release of TOPAS-nBio in 2019, the framework offers to connect energy deposition within irradiated cells (physics) via molecular reactions (chemistry) to cell kill/repair (biology) at the level of sub-cellular targets such as DNA. To facilitate the setup of simulations we further developed a Graphical User (GUI) Interface. TOPAS-nBio is an extension to TOPAS and layered on top of the Geant4/Geant4-DNA MC toolkit. The new release was built for TOPAS release 3.6 (based on Geant4.10.6.p3) and will be compatible with all future releases of TOPAS. **Results:** New geometries that were developed include two new methods to fill the cell nucleus: a whole nucleus DNA model using chromatin fibers and a fractal walk filling pattern, as well as a filling of the nucleus using spheres to represent topologically associated domains (TADs) of DNA based on the Hi-C technique. New scoring options offer direct scoring of single and double strand breaks (SSB and DSB) as well as output the DNA damage in the SDD (Standard for DNA Damage) scoring format. Chemistry was improved to provide better agreement with experimental data of G-values, both for step-by-step chemistry and a newly included independent reaction time method, which offers faster chemistry simulations. Biological outcome can now be simulated directly within TOPAS-nBio using the DaMaRiS biological effect model, or via the SDD which offers a convenient interface to other models such as MEDRAS. **Conclusion:** The new features of TOPAS-nBio v1.0, offer improved modeling from initial DNA damage to cell outcome, or from energy depositions to G-value propagation over time is possible.

Investigating the Impact of Sustainable Delivery of Immunoadjuvant From Smart Radiotherapy Biomaterial in Pancreatic Cancer

M Moreau^{1,3*}, S Yasmin-Karim^{1,2}, N Bih¹, W Ngwa^{1,2,3}, (1) Dana Farber Cancer Institute, Boston, MA, (2) Brigham and Womens Hospital, Boston, MA, (3) University of Massachusetts Lowell, Lowell, MA

Purpose: To investigate the impact of sustained delivery of an immunoadjuvant drug, anti-CD40 monoclonal antibody (Ab_CD40), compared to its single direct in-situ administration in preclinical studies for determining optimal delivery of treatment for metastatic pancreatic tumors. **Methods:** Smart radiotherapy biomaterials (SRBs) were designed similar to currently used gold fiducials, but with smart polymers that can provide imaging contrast and containing similar amount of anti-CD40 that lead tumor regression in animals. C57BL6/Tac mice were subcutaneously injected with KPC cells on one flank to study: a) the release of a fluorescent monoclonal antibody (anti-CD40-AF750) for up to 12-days and b) abscopal effect and mice survival post treatment. A small animal radiation research platform (SARRP) was used to deliver 5Gy at the tumor site followed by either a) free intratumoral injection of Ab_CD40 and b) SRB_Ab_CD40 treatment. Tumor volume size, survival and Immune cell infiltrations in tumors were assessed and results compared for the free direct injection of Ab_CD40 versus the SRB_Ab_CD40 that affords sustained delivery. **Results:** Results showed sustained presence of the anti-CD40 in the tumors treated with SRB_Ab_CD40. The results further showed significant increase in abscopal response rates for animals treated with SRB_Ab_CD40 ($p < 0.001$) compared to animals treated with direct injection. Moreover, significant increase in survival was also observed for the SRB_Ab_CD40 cohort ($p < 0.01$) compared to direct free injection. Significantly more CD8+ T-cells ($p < 0.001$) and CD4+ T-cells ($p < 0.01$) were observed to infiltrate the SRB_CD40_5Gy tumor compared to the cohort that received free injection of Ab_CD40_5Gy. **Conclusion:** Sustained delivery of anti-CD40 with smart radiotherapy biomaterials was more effective in boosting abscopal response rates compared to direct intratumoral injection. This establishes additional potential advantage of using smart sustained delivery of immunotherapy to boost the immune-mediated abscopal effect to engender robust local and metastatic tumor kill.

Nanoparticle-Mediated Assessment of ROS and Radiosensitization of Brain Cancer Cells for Improved Radiotherapy Outcomes

C Thiegs*, K Djam, H Kramer, Y Walter, A Hubbard, A Benoit, E Yank, O Salas, M Schwengler, J Lewison, S Mckinley, A Ekenyong, Creighton University, Omaha, NE

Purpose: Although glioblastoma is the most common primary brain tumor in adults, it remains one of the least treatable. The median survival is only 15 months following current standard of care which includes combinations of surgery, radiotherapy, and chemotherapy. This dismal outcome is partly due to the high radio-resistance of glioblastoma. The purpose of this work is to develop strategies that will ultimately enhance radiotherapy outcomes for glioblastoma through radiosensitization. **Methods:** Having recently developed and published a novel assay using fluorescence intensity modulation of PEGylated (biocompatible) CdSe/ZnS quantum dots (QDs) to assess reactive oxygen species (ROS) generation during chemotherapy and radiotherapy for cancer cells, we have added other nanoparticles to this assay and are applying it for concurrent measurement of ROS and radiosensitization. Using a Faxitron Cell Irradiator, we irradiate (5 Gy, 10 Gy, 20 Gy, 50 Gy) glioblastoma cancer cell lines (T98G and U87 cells) treated with QDs and carbon quantum dots (CQD) and measure both their QD/CQD fluorescence intensity and their migration. We measure and quantify the migration using a commercially available Electric Cell Impedance Sensor (ECIS). **Results:** U87 and T98G cells attach and migrate significantly ($p < 0.0001$) more than non-irradiated cells in the first 20 hours post-irradiation with 20 Gy. Our results show QD intensity reduction due to ROS production as expected, but intensity enhancement for CQD. Furthermore, relative peak fluorescence intensity ratio calculations and average intensity comparisons show highly significant ($p < 0.001$) enhancement of ROS for 5 Gy and 20 Gy irradiation. **Conclusion:** We have developed a nanoparticle-based assay for in vitro concurrent measurement of ROS and radiosensitization of cancer cells. This suggests using PEGylated QDs, CQDs and similar conjugates to improve radiotherapeutic outcomes for glioblastoma and other highly radio-resistant tumors.

TU-C-TRACK 6-06

Potential Anti-Kras Activity OffFlavonoid Derivative of Cannabis Is Enhanced by a Single Fraction of Low Dose of Radiation Therapy

S Yasmin-Karim^{1*}, M Moreau², N Bih³, N Toyang⁴, W Ngwa⁵, (1) Harvard Medical School, Boston, MA, (2) Dana Farber Cancer Institute, Everett, MA, (3) Dana Farber Cancer Institute, Boston, MA, (4) Flavocure Biotech LLC, Baltimore, MD, (5) Brigham and Womens Hospital, Boston, MA

Purpose: Usually, 2 out of 3 patients of pancreatic cancer have Kras mutation causing fast progression of the disease. Prior research shows that, flavonoid derived from Cannabis sativa (FBL-03G) demonstrates significant therapy potential in the treatment of murine pancreatic adenocarcinoma, including potential for radiosensitization and treatment of metastatic tumors through immunomodulation. Here we demonstrate the potential for FBL-03 in targeting the Kras-gene expression in a murine pancreatic cancer model. **Methods:** FBL-03G (Mw = 368.38 g/mol) was delivered intratumorally loaded in smart radiotherapy biomaterial (SRB) for sustained action. In house SRBs were developed with Poly (lactic-co-glycolic) acid (PLGA) polymer. KPC cells were derived from a LSL-Kras;p53+/floxex,Pdx-cre mouse used for generating orthotopic pancreatic tumors in C57BL/6 background mice. Tumors were treated with SRB-FL-03 or 6 Gy of radiation or in combination. Post-vivo tumors were collected on day 10 post treatment and tumor weight and intratumor immune cell population were analyzed. To further evaluate the role of these treatment models in Kras-gene expression, western blot analysis was performed on same treated tumor tissue using Kras antibody. **Results:** We observed significant reduction of tumor weight with the treatment of SRB-FBL-03G and in combination treatment with RT+SRB-FBL-03G. Radiation was shown to further enhance the antitumor activity of SRB-FBL-03G. Further investigation with flowcytometry also demonstrates increase infiltration of T helper cells (CD45+CD3+CD4+) in both SRB-FL-03 ($p < 0.01$) and RT+SRB-FL-03 ($p < 0.001$) treated groups. Similarly, most important cytotoxic T cells (CD45+CD3+CD8+) was also increased in SRB-FBL-03G ($p < 0.01$), and RT+SRB-FBL-03G (0.001) treated groups, confirming the antitumor immune response with these treatments. Western Blot analysis of the treated tumor tissue also confirmed the suppression of Kras-gene expression in both SRB-FBL-03G ($p < 0.05$) and RT+SRB-FBL-03G ($p < 0.01$) treated groups. **Conclusion:** Significant suppression of Kras expression was observed along with immune-modulation and reduction of tumor growth in the FBL-03G treatment, which was further enhanced by radiation.

There is no conflict of interest.

BEST IN PHYSICS (THERAPY): Radio-Immunotherapydose-Painting with Survival Boost Using Checkpoint Inhibitors

S Yasmin-Karim^{1*}, M Moreau², N Bih³, J Wirtz⁴, W Ngwa⁵, (1) Harvard Medical School, Boston, MA, (2) Dana Farber Cancer Institute, Everett, MA, (3) Dana Farber Cancer Institute, Boston, MA, (4) University of Ulm, Ulm, Germany, (5) Brigham and Women's Hospital, Boston, MA

Purpose: Abscopal responses during radiotherapy are rare, especially for immunologically cold tumors like Castration resistant prostate cancer. Here we investigate a new approach called radio-immunotherapy dose-painting (RAID), which specifically targets tumor sub-volumes with radiotherapy and in-situ delivered immunoadjuvant to boost abscopal responses. The study is conducted in metastatic castration-resistant prostate cancer animal model with and without check-point inhibitors. **Methods:** Syngeneic murine model of castration resistant prostate adenocarcinoma (CRPA) was generated in both flanks of wild C57/BL6 background mice using androgen deprived TRAMP-C1 cell lines. The palpable sized tumor of one of the flanks was treated as four different randomized cohorts: control with no treatment, direct treatment with 5 Gy of radiation, intra-tumor treatment with Immunogenic Biomaterial (IBM) loaded with AntiCD40, and in combination. Tumor growth was measured on both sides. The highest responded treatment method (RT+IBM) was rechallenged by adding checkpoint inhibitors, AntiPD1 and CTLA4,

for survival study. Checkpoint inhibitors were given in systemic doses for 3 consequent administrations. Image Guided Radiotherapy (IGRT) targeting tumor and tumor sub-volumes was administered with the small animal radiation research platform. **Results:** We demonstrate that the RAID approach substantially boosts abscopal responses for prostate cancer. Adding checkpoint inhibitors with 5 Gy of IGRT+IBM, further increases the survival duration, where the combination treatment with (RT+IBM) demonstrates enhancement of abscopal effect ($p<0.001$) compares with only RT, and only IBM. Adding AntiPD-1 ($p<0.001$) and CTLA4 ($p<0.01$) with the combination of RT+IBM, show significant increase in the survival duration. whereas, AntiPD-1 shows the longest duration of survival (>250 days), compared to others (<50 days) for at least one third of the treated mice. **Conclusion:** RAID with IBM represents a promising new approach to significantly boost abscopal response rates for immunologically cold tumors like prostate cancer. Moreover, Checkpoint inhibitors like AntiPD-1 can further boost treatment outcomes.

Motion Tracking with MLC and Jaw During Tomotherapy Delivery

Motion management solutions for external beam radiation therapy can potentially enable a smaller volume of normal tissue irradiated and target dose escalation. In recent years, many optical, infrared, kV and MV radiographic imaging techniques have emerged clinically, and continued to be developed, to manage the effect of intra-fraction motion. Imaging and positional data are also often coupled with tracking systems using MLC and jaw to manage respiratory and non-respiratory motion during radiation therapy. The applications and procedural considerations for select imaging technology for respiratory motion management will be presented. Using implanted fiducials, prostate motion can be monitored with planar radiographic during radiation treatment delivery. Moreover, MLC and jaw tracking approaches are now available different linear accelerator systems. An educational overview of these systems, their clinical implementation and associated quality assurance considerations will be presented.

Learning Objectives:

1. Review methods to account for respiratory motion using optical and infrared imaging systems.
2. Present treatment planning and delivery requirements for implementing (and performing QA on) MLC tracking systems.
3. Present methods of intra-fraction monitoring for prostate motion with planar radiographic imaging of implanted fiducial markers.
4. Understand implementation and clinical experience of motion tracking using jaws and MLC during helical tomotherapy delivery.

Q&A

In the last few years, artificial intelligence (AI) has emerged as powerful tool in the field of diagnostic medical imaging with applications in areas such as image processing, image reconstruction, and image interpretation. AI is a multidisciplinary field that takes ideas from computer science and neuroscience to try to replicate human intelligence in machines with the idea of solving complex problems typically requiring human intelligence. Machine learning (ML) is a subset of AI where the algorithm is designed to learn from data without explicit programming. A popular ML algorithm is the artificial neural network (ANN) which was designed to mimic the neural networking in the human brain. Deep learning (DL) is a further subset of ML involving very deep neural network models with many layers. When applied to medical images, a popular variant of the ANN is the convolutional neural network (CNN) which can learn image patterns and features from training images. These learned features can then be used to solve a wide array of problems such as classification or segmentation.

Current and potential AI applications in diagnostic radiology may include improving image quality, reducing radiation dose, decreasing MRI imaging time, enhancing technical protocols, standardizing the detection and characterization of image findings, and improving workflow. With an ever-increasing amount of data, the potential for AI in the field of diagnostic medical imaging is greater than ever.

Learning Objectives:

1. Understand the basics concepts of Artificial Intelligence (AI) and it's relation with Machine Learning (ML) and Deep Learning (DL)
2. Understand primary components of DL architectures and neural network.
3. Understand selected AI applications in diagnostic radiology.

Convolutional Neural Network Based Metal Artifact Correction for Sparse View Dental CT Imaging

S Kim*, J Ahn, B Kim, J Baek, Yonsei University, Incheon, 28KR

Purpose: We aim to reduce complex artifacts due to both metal implants and sparse view sampling in dental CT images by utilizing prior images via convolutional neural network (CNN). **Methods:** To generate sparse view dental CT images in the presence of metal implants, we inserted two circular-shaped gold implants within a region of the teeth and acquired projection data by simulating polychromatic X-ray CT scans with one-fourth of full view data set. CT images were then reconstructed with the filtered backprojection algorithm. Since the image quality is severely degraded by metal implants, we initially reduced the metal artifacts using linear metal artifact reduction (LMAR) algorithm. To reduce the streak artifacts, we trained CNN in the image domain, which is denoted by LMARCNN. Then, by using a thresholding, the prior image was acquired from the results of LMARCNN. By utilizing prior images, normalized metal artifacts reduction (NMAR) method is applied for the sparse view sampled sinogram data. Then, the residual streak artifacts are reduced again by CNN in the image domain, which is denoted by NMARCNN. For both CNNs, we employed a U-net architecture to ensure a large receptive field to capture the globally distributed streak artifacts. **Results:** It is observed that NMARCNN can reduce the residual errors of NMAR and shows the best qualitative and quantitative quality of images through ROIs. The quantitative evaluation of mean squared error (MSE) and structural similarity (SSIM) also confirm our observations. Since the remaining streak artifacts in LMAR were reduced in LMARCNN, clear prior images can be acquired. **Conclusion:** In this work, we proposed CNN-based NMAR approach for sparse view dental CT image reconstruction. Our results show that the combination of metal artifacts and streak artifacts due to sparse view sampling can be reduced effectively by the proposed method.

Low-Dose CT Image Enhancement Through a Texture Transformer

S Zhou^{1*}, L Yu², M Jin¹, (1) University of Texas at Arlington, Arlington, TX, (2) Mayo Clinic, Rochester, MN

Purpose: To improve the spatial resolution and to suppress the noise of the low-dose computed tomography (CT) images, we adapted a Texture Transformer network for image Super-Resolution (TTSR) method. **Methods:** The TTSR is a reference-based image super-resolution method. We adapted it to translate the low-dose (low-resolution and noisy) CT images to the full-dose (high-resolution and clean) CT images. The low-dose CT images and full-dose images are severed as queries and keys in a transformer, respectively. The image translation is optimized through deep neural network (DNN) texture extraction, relevance embedding, and attention-based texture transfer and synthesis to enable joint feature learning between low-dose and full-dose images. 4D XCAT phantom program based on 18 patients' data was used to generate both benchmark full-dose CT images (512x512 in-plane resolution) and low-dose images (20% dose and 128x128 in-plane resolution). The data from 17 patients were used as training data and the rest one was used as test data. The reference images in TTSR were randomly selected from the training set, which were not the same as the test images. The peak signal-to-noise ratio (PSNR) and structural similarity index (SSIM) were used as the quantitative metrics. For comparison, we used cubic spline interpolation and generative adversarial network (GAN) with cycle consistency (GAN-CIRCLE). **Results:** The performance of different methods (mean $\pm$ std) are PSNR = 31.57 $\pm$ 0.89dB, and SSIM = 0.74 $\pm$ 0.02 for cubic spline interpolation, PSNR = 34.85 $\pm$ 0.32dB and SSIM = 0.88 $\pm$ 0.02 for GAN-CIRCLE, and PSNR = 37.23 $\pm$ 0.42dB and SSIM=0.84 $\pm$ 0.02 for TTSR. TTSR also recovers more details in enhanced low-dose CT images than the other two methods, although some artifacts are noticeable. **Conclusion:** TTSR based on texture transformer and attention mechanism is effective to improve the spatial resolution and to suppress the noise of low-dose CT images in general. Further work is needed to minimize the artifacts.

Multi-Resolution Residual Deep Neural Network for Generating Synthetic CT Images with High HU Accuracy and Structural Fidelity

W WU^{1*}, J Qu², J Cai³, R Yang¹, (1) Peking University Third Hospital, Beijing, China (2) Capital Medical University, Beijing, China (3) The Hong Kong Polytechnic University, Hong Kong, China

Purpose: Cone-beam computed tomography (CBCT) is frequently used for accurate image guided radiation therapy (IGRT). However, the poor CBCT image quality prevents its further clinical use. Thus, it is important to improve the HU accuracy and structure preservation of CBCT images. **Methods:** In this study, we proposed a novel method to generate synthetic CT (sCT) images from CBCT images. A multi-resolution residual deep neural network (RDNN) was adopted for image

regression from CBCT images to planning CT (pCT) images. At the coarse level, RDNN was first trained with a large amount of lower resolution images, which can make the network focus on coarse information and prevent overfitting problems. More fine information was obtained gradually by fine-tuning the coarse model using fewer number of higher resolution images. Our model was optimized by using aligned pCT and CBCT image pairs of a particular body region of 153 prostate cancer patients treated in our hospital (120 for training, 33 for testing). **Results:** The averaged accuracy of mean absolute error (MAE) between CBCT and pCT on testing data was 121.61 HU, while the MAE between the sCT and pCT images was only 27.62 HU. And the averaged structural similarity index measure between sCT and CBCT was 48.89% higher than that of CBCT and pCT. Our proposed multi-resolution RDNN also provides an overall better image quality in terms of HU accuracy and structural fidelity than U-Net and RDNN trained only using high-resolution CBCT and pCT image pairs. **Conclusion:** The sCT images generated by our proposed multi-resolution RDNN have higher HU accuracy and structural fidelity, which may promote the further applications of CBCT images in the clinic for structure segmentation, dose calculation and adaptive radiotherapy planning.

Renal Stone Quantification in Contrast Enhanced CT Using Convolutional Neural Network Assisted Dual-Energy Virtual Non-Contrast Imaging

H Gong*, A Ferrero, J Marsh, N Huber, J Fletcher, C McCollough, S Leng, Mayo Clinic, Rochester, MN

Purpose: Virtual non-contrast (VNC) technique has been proposed to detect renal stones in contrast-enhanced dual-energy CT (DECT) but has demonstrated limitations of reduced stone volume and removal of small stones. We aim to improve stone detection and quantification accuracy by developing a novel convolutional neural network (CNN) assisted VNC technique. **Methods:** A dual-task CNN with customized loss functions was developed to synergistically integrate material-classification and -decomposition. The classification provided a probability weighting scheme to material decomposition, to minimize the ambiguity between calcium and iodinated soft-tissue. Multi-energy CT phantoms were scanned on a dual source DECT (80/Sn150 kV) and image patches (50x50 pixels) of insert materials (e.g. hydroxyapatite, iodine, and iodinated-blood mixture) were used to train the CNN. Random-shaped numerical inserts with additional densities were simulated to augment training dataset. Iodine component was subtracted from original CT images to generate VNC images. Human stone specimens (n=35; 20 calcium-based/15 non-calcium-based) embedded in an abdomen-sized water phantom were scanned with and without iodine contrast (20mg/cc). CT number and volume per stone was measured using in-house stone quantification software and compared to commercial VNC (Syngo.VIA, Siemens). Mean-absolute-percent-error (MAPE) was calculated using true non-contrast (TNC) images as ground truth and Wilcoxon signed rank test (5% significance level) was used to gauge stone volume discrepancy between VNC and TNC images. **Results:** CT number of stones from commercial VNC were significantly reduced (MAPE: 32.9%), resulting in significantly-underestimated stone volume (bias: -26.4%, MAPE 26.5%, p<0.01). Stones were much brighter in CNN-assisted VNC than those in commercial VNC, and density plot showed CT numbers recovered to those of the original CT images. The stone volume was also more accurate in CNN-assisted VNC, with not significant difference from that of TNC (bias: -2.1%, MAPE 10.6%, p=0.568). **Conclusion:** The CNN-assisted VNC improves the quantification of renal stones in contrast-enhanced DECT.

Synthesize 3D Realistic CT Textures and Anatomy in the XCAT Phantom Using Generative Adversarial Network (GAN)

Y Yuan*, L Ren, Y Chang, Duke University Medical Center, Durham, NC

Purpose: Generate 3D realistic textures and anatomy in the thorax region of extended cardiac torso (XCAT) phantom. **Methods:** We proposed to generate realistic anatomical textures and structures in the XCAT phantom using a conditional generative adversarial network (CGAN) and 3D U-net. 300 and 100 3D CT images were used for training and validation, respectively. Organ maps were generated from patient CT images with uniform intensities in each organ to mimic XCAT images. The model was trained to simulated realistic CT textures and structures in organ maps to match with real CT images. To capture the fine details and guarantee the continuity of lung vessels, we used multiple generators to generate lung vessels and other body parts separately before integrating them together. The results from the training and validation group were evaluated by measuring the SSIM, L1, and L2 metric between the real CT images and simulation images generated from organ maps. After training, XCAT phantoms were input into the model to generate textured XCAT phantoms. The result was compared to our prior work using the 2D GAN model. **Results:** Compared to the 2D GAN model, the 3D model achieved higher SSIM and PSNR and lower L1 and L2 losses in the validation group. In the generated XCAT phantoms, the model generated similar contrast and anatomical textures as real CT images. The generated phantom also showed 3D continuity by visual examination from different views, especially for lung vessels. Additionally, we found the strategy of using separate generators for lung vessels and other parts greatly enhanced the realism of the generated images. **Conclusion:** The study demonstrated the feasibility of generating realistic 3D anatomical textures and structures in XCAT phantoms using the proposed method. This development dramatically enhances the phantom's value for various clinical applications, such as testing and optimizing novel imaging techniques.

Task-Based Loss Function for Convolutional Neural Network-Based CT Denoising

B Nelson^{1*}, D Gomez Cardona², N Huber¹, A Missert¹, L Yu¹, C McCollough¹, (1) Mayo Clinic, Rochester, MN, (2) Gundersen Health System, La Crosse, WI

Purpose: To develop a task-based loss function in a deep convolutional neural network (CNN) to reduce noise and maintain spatial details simultaneously. **Methods:** A U-Net CNN was trained with simulated-quarter-dose head CT images reconstructed with smooth and sharp kernels and using routine-dose images of each kernel as targets. A baseline model was trained using mean-squared-error (MSE) loss and image patches from 100 scans; 5 additional scans were used for validation and 5 more for testing. To better retain sharpness in the bone and reduce noise in the brain, a loss function with two task-based loss terms was introduced. The first term enforced similarity with the sharp kernel target images in the HU range outside of the brain (<0 or >80) while penalizing sharp kernel noise within the brain HU range using total variation loss. The second term enforced similarity with the smooth kernel target images within the brain HU range. Results from the task-based model were compared against those of the baseline model using region of interest (ROI) measurements of standard deviation to assess noise reduction and line profile measurements to assess spatial resolution preservation. **Results:** The CNN model trained using the task-based loss function achieved a 51.6% and 70.5% greater noise reduction when applied to routine and low-dose CT images compared to the MSE loss model while simultaneously maintaining image sharpness in the bone comparable to the sharp kernel input. **Conclusion:** A task-based loss function that specified where each input kernel should be emphasized, outperformed the same model trained under equal conditions but using MSE loss alone. Superior performance was noted in terms of noise reduction and sharpness preservation.

Evaluation of Image-Domain Training Frameworks for Deep Learning Based Denoising and Deconvolution

P VanMeter^{1*}, S Hsieh¹, J Marsh¹, N Huber¹, A Ferrero¹, C McCollough¹, (1) Department of Radiology, Mayo Clinic, Rochester, MN

Purpose: Spatially matched full-dose/low-dose (FD/LD) pairs are often used as training input and target for supervised learning. Training data is commonly simulated

using projection noise insertion; however, inability of many institutions to access CT projection data motivates development of widely accessible image domain methods. In this work, we evaluated two image domain training frameworks for CNN-based dual-energy denoising and deconvolution applied to ex-vivo kidney stone specimens. **Methods:** We compared two image domain training frameworks, a Generalizable Noise and Artifact Reduction Network (GARNET) and an isotropic colored noise insertion technique (Iso-NI), with an existing reference technique using projection-domain noise insertion (PD-NI). GARNET training data was synthesized using the following procedure: noise-only images were extracted from phantom scans, re-scaled to the desired dose, and added back to FD images to mimic LD images for training. Iso-NI training data was synthesized by backprojecting filtered Gaussian random noise into an image, which was then blurred to match the noise power spectrum of the LD images. Patches derived from FD/LD pairs were used to train a separate CNN for each technique, and denoised/deconvolved kidney stone images were inferred. Inferred images were input into a dual-energy stone composition algorithm to evaluate the performance in a clinical task. **Results:** GARNET and the PD-NI reference technique were found to have similar noise power spectra, whereas Iso-NI inferred images were slightly noisier. All methods resulted in comparable, excellent performance for kidney stone composition quantification (9 out of 11 mixed stones properly identified by all methods vs 0/11 in the original data). **Conclusion:** Inferred images using both GARNET and Iso-NI trained CNNs were shown to significantly reduce noise and improve stone quantification relative to the original images. These methods provide a suitable substitute to projection domain noise insertion when access to proprietary projection data is unavailable.

Q&A

Importance of Quantitative Imaging Biomarkers' Technical Performance Characteristics in Designing and Analyzing Clinical Trials

Quantitative imaging biomarkers (QIBs) are being used increasingly to diagnose disease, predict patients' outcomes, and monitor and adapt treatment. In clinical trials, QIBs are used to identify patients eligible for trials and often serve as non-invasive endpoints, providing results earlier than traditional patient outcomes. Yet biomarker measurements are inherently biased and imprecise. When their bias and imprecision are overlooked, measurements can be mis-interpreted, studies can be underpowered, and treatment effects can be over- or under-estimated.

In this presentation I first review the key technical performance characteristics of a QIB, namely precision, bias, linearity, and the regression slope against true values. I then examine four scenarios using QIBs in clinical practice and in trials. I illustrate how the technical performance characteristics of a QIB affect the interpretation of pulmonary nodule volume doubling time in ruling out malignancy, the sample size of a trial investigating ultrasound elastography to diagnose stage F4 liver cirrhosis, the eligibility of Parkinson's disease subjects for a trial of a new intervention, and the treatment effect of the rate of brain atrophy in a randomized clinical trial of progressive multiple sclerosis. Methods for correcting for the QIB measurement error are presented for each scenario.

Dr. Obuchowski is the statistician for the Quantitative Imaging Biomarker Alliance, through a contract between RSNA and the Cleveland Clinic

ATR Inhibition Suppresses DNA Damage Signaling and Sensitizes Cancer Cells to Photons and Protons

D Martinus*, S Bright, D Flint, B Turner, M Manandhar, M Ben Kacem, S Shaitelman, G Sawakuchi, UT MD Anderson Cancer Center, Houston, TX

Purpose: ATR is a DNA damage response protein essential to double strand break (DSB) repair and cell cycle checkpoint regulation. Here we investigate the influence an ATR inhibitor (ATRi) has on DSB repair and radiosensitization in response to photons and protons. **Methods:** We exposed H1299 cancer cells to 6 MeV x-rays and 9.9 keV/μm protons (dose-weighted LET) with and without an ATRi (0.1-5 μM, AZD6738). We then performed immunofluorescent staining of 53BP1, a DNA repair protein involved in double strand break repair and fixed cells at 2, 4, and 24 h timepoints post-irradiation. Clonogenic cell survival assay was also performed. **Results:** ATRi radiosensitized to both photons and protons and increased the RBE of protons. At 4 h post-irradiation, increasing ATRi concentration suppressed the number of 53BP1 foci. Cells exposed to 5 Gy of photons alone had an average of 28.55±0.17 foci/nucleus while the photons + ATRi (1 μM) had a significantly lower average of 21.7±0.2 foci/nucleus at 4 h post-irradiation. However, at 24 h post-irradiation, increasing ATRi concentration resulted in a significant increase in 53BP1 foci (p<0.0001). Photons alone had an average of 10.61±0.11 foci/nucleus while the photons + ATRi (1 μM) had a significant increase at 16.43±0.15 foci/nucleus. Additionally, we observed a threshold on the ATRi concentration in the 24 h timepoint. Below a concentration of 0.5 μM, ATRi had very little effect on 53BP1 foci number for all timepoints. This suggests that ATR inhibition has an effective time window relating to the stage of DNA repair. **Conclusion:** ATR inhibition sensitizes cancer cells to both photons and protons. The sensitization is due in part to the role of ATR in DSB repair as the number of persistent 53BP1 foci at 24 h post-irradiation was much higher relative to radiation alone.

Modeling DNA Structure with Different Chromatin Compaction in TOPAS-nBio Using Hi-C Representations

D Yoo^{1*}, N Henthron², S Ingram², M Merchant², K Kirkby², J Warmenhoven², A McNamara¹, K Held¹, H Paganetti¹, J Schuemann¹, (1) Department of Radiation Oncology, Massachusetts General Hospital and Harvard Medical School, Boston, Massachusetts, USA (2) Division of Cancer Sciences, Faculty Of Biology, Medicine and Health, The University of Manchester and The Christie NHS Foundation Trust, Manchester, United Kingdom

Purpose: TOPAS-nBio is an open source MC application for nanodosimetry developed to advance our understanding of radiobiology effects at the (sub-)cellular scale. Several approaches were introduced to calculate DNA damages induced by ionizing radiation using TOPAS-nBio. In the TOPAS-nBio, a human fibroblast nucleus model was provided that includes chromatin territories with the same DNA density across the nucleus (6.08 Gbp DNA and DNA density of 14.4 Mbp/um³). However, the DNA density varies for each cell, chromatin territory and cell cycle, consisting of higher and lower DNA density (heterochromatin and euchromatin, respectively). The aim of this study is to design a realistic DNA geometry containing both heterochromatin and euchromatin. **Methods:** In order to design a realistic DNA geometry containing both heterochromatin and euchromatin, we use a previously developed method of filling a nucleus with spheres representing topologically associated domains (TADs) using the Hi-C technique. Hi-C data consist of several thousand TADs that classify the chromosome territories (separated by color). Each TAD (sphere) was filled with voxels using three different voxel sizes (12, 24, and 48 nm) depending on the TAD radius to efficiently model DNA packing inside the TADs. **Results:** Various geometries of DNA packing were placed inside the TADs to construct heterochromatin and euchromatin regions. Depending on the voxel size, the number of nucleosomes inside the voxel was adjusted differently. A maximum of one nucleosome was packed inside the 12 nm voxel, 8 nucleosomes were packed inside the 24 nm and 16 nucleosomes were packed inside the 48 nm voxel. The nucleosome packed inside the TADs was organically linked to each other to construct the heterochromatin and euchromatin regions. **Conclusion:** The modeling of DNA structure with different chromatin compaction organized in TADs based on Hi-C data will allow studies of DNA damage considering the heterochromatin and euchromatin regions.

Mechanistic Modelling of Oxygen Enhancement Ratio with DNA Damage by gMicroMC

Y Lai^{1, 2*}, Y Chi², X Jia¹, (1) innovative Technology of Radiotherapy Computation and Hardware (iTORCH) laboratory, Department of Radiation Oncology, University of Texas Southwestern Medical Center, Dallas, TX, (2) Department of Physics, University of Texas at Arlington, Arlington, TX

Purpose: Oxygen plays an important role determining the radiobiological effects of ionizing radiation. It is understood that oxygen can fix damages to DNA, hence enhancing strand breaks. In this work, we used a GPU-based Monte Carlo (MC) simulation package to mechanistically model the oxygen fixation hypothesis and compute oxygen enhancement ratio (OER). **Methods:** We implemented two kernel functions in gMicroMC to model the OER. The first one simulated the water radiolysis process in the presence of DNA and recorded the initial DNA damage. Chemical reactions involving oxygen was included in the simulation. The second one was a probabilistic model to capture the oxygen fixation effect on DNA damage sites. As cell survival fraction is mainly dominated by the number of DNA double strand break (DSB), we assume that the same number of DSB results in the same biological effect, OER was computed as the ratio of doses reaching the same level of DSB with and without having oxygen. We searched in the parameter space of reaction rate between damage site and oxygen, probability of repairing a damage site with/without oxygen fixation to match OER with published experimental results of photon irradiation. We applied the developed model to proton irradiation cases. **Results:** Parameters was found to reaction rate 4.75×10^7 L/(mol·s), probability of repairing with and without oxygen 0.72 and 0.92, respectively. The computed OER as a function of oxygen concentration matched with published experimental results of photon irradiation with a mean relative error 3.18%. The model gave OER of 3.04 for photon case and 2.93 for proton case at oxygen partial pressure of 15.2 mmHg. **Conclusion:** We modelled OER in a mechanistic approach using microscopic MC simulations. The mechanistic modeling approach is expected to be important for understanding oxygen impacts in different scenarios, such as FLASH with multi pulses.

Radiodynamic Therapy for Treatment of Lung Cancer: An In-Vivo Study

D Yang*, D Cvetkovic, L Chen, C Ma, Fox Chase Cancer Center, Philadelphia, PA

Purpose: Radiodynamic therapy (RDT) uses Cerenkov light induced by photon beams to treat deep-seated tumors that photodynamic therapy cannot perform due to the low penetration depth of laser beams. The purpose of this study was to investigate the therapeutic effect of RDT with 15MV photon beams combined with 5-aminolevulinic acid (5-ALA) using a mouse model. **Methods:** A subcutaneous murine KP1 small-cell lung cancer model using male C57 black mice was used. The tumors (n=18) were randomly assigned into four groups, including control (untreated, n=4), radiation treatment (RT) only (n=4), 5-ALA only (n=4), and RDT (n=6), to observe individual and synergistic effects of 5-ALA and radiation treatment. For mice treated with radiation, 4 Gy in a single fraction was delivered to the tumors using 15MV photons on a Varian Clinac iX accelerator. For the RDT group, 5-ALA was injected at a dosage of 100mg/kg by tail-vein 4 hours prior to RT. Tumor volumes were measured using a 1.5T MR scanner on the treatment day and weekly post-treatment. Tumor growth for each tumor was quantified as the ratio of tumor volume one and two weeks after treatment to the tumor volume on the treatment day. **Results:** RDT achieved a decrease in tumor volume by $27.5 \pm 11.4\%$ and $26.9 \pm 11.4\%$ at one- and two-week post-treatment, respectively, compared to the tumor volume on the treatment day. The tumor growth in the RDT group was delayed by $73.1 \pm 25.4\%$, $82.6 \pm 28.9\%$, and $81.2 \pm 19.4\%$ two weeks after treatment compared to 5-ALA only ($P < 0.05$), RT only ($P < 0.01$), and control group ($P < 0.01$), respectively. There were no significant differences in tumor growth between 5-ALA only, RT only, and the control group. **Conclusion:** Radiation treatment with 5-ALA resulted in a significant tumor growth control compared to the other groups. The preliminary (hypothesis-generating) results advocate a further investigation into larger sample sizes.

Second Generation Silica-Based Bismuth Gadolinium Nanoparticles for Tumor Dose Enhancement and Real-Time MR-Tracking

N Virani^{1*}, P Rocchi^{2,3}, F Lux^{2,3}, T Doussineau^{2,3}, C Williams⁴, E Huynh⁴, E Kaza¹, O Tillement^{2,3}, R Berbeco¹, (1) Brigham and Women's Hospital, Dana-Farber Cancer Institute, and Harvard Medical School, Boston, MA, (2) NH Theragix, Lyon, France, (3) Institut Lumiere Matiere, CNRS, Universite de Lyon, Villeurbanne, France, (4) Brigham and Women's Hospital, Boston, MA

Purpose: The purpose of this study is to develop a new generation of theranostic silica-based bismuth-gadolinium nanoparticles for local tumor dose enhancement and adaptive treatment planning using a clinical Viewray MRIdian MRI-Linac System. **Methods:** First generation silica-based gadolinium nanoparticles (AGuIX) were modified at different ratios to exchange gadolinium-DOTA complexes with bismuth-DOTA complexes. A new generation of AGuIX-Bi nanoparticles were developed with three ratios of Gd/Bi (70/30, 50/50, and 30/70). Nanoparticles were characterized via ICP-MS, HPLC-UV, DLS, and T1 relaxometry. In vitro toxicity analysis and clonogenic assays were conducted to confirm radiosensitization of nanoparticles in a human non-small cell lung carcinoma (NSCLC) cell line. In vivo studies in agar phantoms and NSCLC mouse models were conducted to evaluate changes in MR contrast of AGuIX-Bi nanoparticles compared to AGuIX in a clinical 3T Siemens MR scanner and a 0.35T MRIdian MRI-Linac. **Results:** Each AGuIX-Bi nanoparticle formulation was characterized with final ratios of 70/30, 50/50, and 30/70 of Gd/Bi with an approximate size of 4.5-5.1 nm and 93-96% purity. As the ratio of Gd relative to Bi increased, T1 shortening was observed, confirming an enhancement of MR contrast. Even nanoparticles with the lowest ratio of Gd (30/70 Gd/Bi) showed strong T1 shortening, thus retaining improved contrast. In vitro MTT studies confirmed relatively low toxicity of all nanoparticles up to 3 g/L in a human NSCLC A549 cell line. Clonogenic assays identified a sensitizer enhancement ratio (SER = 50%) of 1.28 for 30/70 AGuIX-Bi nanoparticles compared to 1.125 for AGuIX (gadolinium only). In vivo MR imaging of subcutaneous

NSCLCs further confirmed retention of strong signal enhancement of 30/70 AGuIX-Bi nanoparticles compared to AGuIX in a TrueFISP and T1-weighted MR-Linac scan and a T1-weighted 3T MR scan. **Conclusion:** This study develops a new generation of theranostic nanoparticles for real-time MR-guidance and localized tumor dose amplification.

Development of a Novel System for Preclinical Small Animal MR-Guided Radiation Experiments

J Grandinetti*, Y Zhong, Y Peng, C Shen, X Jia, The University of Texas Southwestern Medical Ctr, Dallas, TX

Purpose: Small Animal Radiation Research (SARR) serves as a critical counterpart to human radiation therapy (RT). Current SARR platforms use cone-beam CT for image-guidance, which results in poor soft-tissue contrast, additional radiation dose, and lack of real-time imaging. Whereas magnetic resonance-guided RT (MRgRT) has become available for human RT, SARR platforms currently lack on-board MRI capabilities. This study proposes a novel MR-guided SARR platform and reports our on-going progress. **Methods:** We propose the use of an inhomogeneous unilateral low-field MR design to ease the integration of MR to a SmART irradiator (Precision X-Ray Inc.). Targeting a 4cm-diameter field of view (FOV), we designed a magnet by optimizing the arrangement of neodymium magnets in a Halbach cylinder using a genetic algorithm. The decaying magnetic field along the axial direction is naturally used for spatial encoding. We constructed the magnet using 3D-printed holders to mount the magnets accurately. We designed and constructed gradient coils with a 4cm gap to allow the beam to pass unobstructed. We designed a 4cm gapped radiofrequency (RF) coil with three resonant circuits to span a wide bandwidth needed to cover the FOV. The inhomogeneous magnetic field allows acquisition of images in a set of curved surfaces, which are resampled to form a volumetric image in Cartesian coordinates. We simulated the MR imaging formation process. **Results:** Optimizing magnet orientations was able to increase field strength by 47%, resulting in a 78mT field strength at a distance of 2cm from the surface of the magnet assembly. The measured field strength agreed with our calculations within 3%. The gradient coils achieved linearity through a gapped distance of 4cm. RF coil is under construction. **Conclusion:** We proposed a novel approach for MR-guided SARR and are in the process of constructing the system.

Improving the Efficiency of Small Animal IMRT with Submillimeter Dose Deposition Kernels and Total Variation Regularization

X Liu*, A Van Slyke, K Shoniyozyov, R Wiersma, University of Pennsylvania, Philadelphia, PA

Purpose: There is growing interest in the use of modern 3D printing technology to implement intensity-modulated radiation therapy (IMRT) on the preclinical scale which is analogous to clinical IMRT. However, current 3D-printed IMRT methods suffer from long delivery times, excess filament usage, and complex modulation patterns. In this work, a comprehensive practical implementation of IMRT using 3D-printed beam compensators on the Xstrahl Small Animal Radiation Research Platform (SARRP) is presented, with an emphasis on accurate submillimeter dose calculation and the use of total variation regularization (TVR) to facilitate 3D printing. **Methods:** Custom micrometer-scale dose deposition kernels were developed based on actual beam commissioning data. TVR-IMRT, a technique designed to minimize the intensity difference between neighboring beamlets, was used to optimize the beamlet intensity map, which was then converted to corresponding compensator thicknesses in copper-doped PLA filament. IMRT and TVR-IMRT plans using five beams were generated to treat a mouse heart while sparing lung tissue. The individual field doses and composite dose were delivered to film and compared to the corresponding planned doses using gamma analysis. **Results:** The use of micrometer-scale dose kernels led to better agreement between the planned and measured doses, especially in low-dose regions. TVR-IMRT reduced the total variation of both the beamlet intensities and compensator thicknesses by 45-55%. The total mass of compensator material consumed and radiation beam-on time were both reduced by 15-25%, while DVH curves remained comparable. Gamma analysis passing rate with 3%/0.5mm criterion was 93.6% for IMRT and 97.3% for TVR-IMRT. **Conclusion:** TVR can be applied to small animal IMRT in order to produce fluence maps and subsequent 3D-printed compensator patterns with less total variation, facilitating 3D printing and reducing the amount of filament required. The TVR-IMRT plan required less beam-on time while maintaining the dose conformity when compared to a traditional IMRT plan.

Imaging: CT Artifacts, Reconstruction, and Imaging Performance Assessment

TU-IePD-TRACK 1-01

Development of An Automated Analysis Software for Daily CT QA

A Hart^{1*}, A Watkins², M Bazalova-Carter¹, C Uribe^{3,4}, (1) University of Victoria, Victoria, BC, CA, (2) Simon Fraser University, Burnaby, BC, CA, (3) University of British Columbia, Vancouver, BC, CA, (4) BC Cancer, Vancouver, BC, CA

Purpose: Positron emission tomography/computed tomography (PET/CT) imaging is used for a wide range of applications from diagnosis, to staging and radiotherapy treatment planning. Daily quality assurance (QA) testing is an essential duty of both physicists and technologists in order to verify that the x-ray CT images produced by PET/CT scanners meet performance standards. As part of an effort to bring scanners into compliance with standards in an efficient manner, a software package was developed to automate the analysis of x-ray CT images of the GE VCT QA phantom. This work aimed at developing an automatic solution that would analyze the results of the daily CT QA scans. Our tool reduces the burden on technologists and contributes to a more robust QA procedure. **Methods:** The software was developed using Python (v3.8.2) to aid in the daily CT QA procedure for GE DMI and D690 PET/CT scanners. The developed software automates each analysis step by automatically placing ROIs and performing calculations for the following tests: laser alignment, contrast scale, spatial resolution, noise and uniformity, slice thickness, and low contrast detectability. **Results:** The software has been implemented clinically in three centres. The software can automatically log data through an API connection. All analysis tests conducted using the automatic software agreed with the manual analysis and results have been within manufacturer specification. For example, the differences in measured image noise ($\Delta SD = 0.16\text{HU}$) and slice thickness ($\Delta x = 0.01\text{mm}$) were not statistically significant ($p > 0.05$). **Conclusion:** The automated analysis software developed in this work requires fewer manual hours from the technologists and allows the physicists overseeing the QA program to easily audit the performance of scanners located in several centres from a centralized location. This software is also compatible with standalone CT systems that use the GE VCT QA phantom for daily tests.

CARE-CT: CARDiac and RESpiratory Adaptive Computed Tomography

N Morton*, T Reynolds, P Keall, R O'Brien, University of Sydney, Eveleigh, NSW AU

Purpose: To safely plan high dose radiotherapy treatments for thoracic cancers and novel treatments such as non-invasive cardiac radioablation, 4DCT requires the capacity to account for multiple motion sources. We have developed a novel acquisition method, CARE-CT (CARDiac and RESpiratory adaptive Computed Tomography), to gate for dual motion and quantified the reduction in image artifacts. **Methods:** CARE-CT and conventional cine 4DCT imaging were simulated on

a deformable digital phantom (XCAT) for nineteen patient-measured ECG and respiratory traces. Our software monitored motion in real-time, triggering a simulated CT acquisition during combined cardiac and respiratory phases with 0.36s gantry rotation and 2cm/1s couch translation. Six and ten respiratory phases during cardiac diastole (60-80% through cardiac cycle) were acquired for each scan. Image artifacts were quantified and compared for 13 thoracic substructures using the normalized cross correlation between axial slices (Δ NCC). The 13 substructure volumes were compared to an average XCAT ground truth and compared between protocols. Total scan and beam-on times were recorded. **Results:** Compared to conventional 4DCT, the pooled mean reduction in the Δ NCC was 19% and 20% for the 6 and 10 bin CARE-CT scans respectively, with the largest reduction of 37% for the left ventricular wall. The mean variation in total structure volumes compared to the ground truth was reduced from 3% (-19% to 59%) for conventional 4DCT to 0% (-1% to 2%) for CARE-CT. The mean total scan times were increased from 1.8 $\pm$ 0.4min for conventional 4DCT to 3.5 $\pm$ 0.9min and 7.5 $\pm$ 2.2min for 6 and 10 bin scans, respectively. The total beam on time was reduced from 98 $\pm$ 28s for conventional 4DCT to 27 $\pm$ 0.2s and 45 $\pm$ 0.6s for 6 and 10 bin scans, respectively. **Conclusion:** CARE-CT reduced image artifacts in thoracic substructures while reducing beam-on time as compared. This study provides a crucial first step towards dual-motion management for central tumours.

A Spatiotemporal Denoising Method for Low-Dose Cardiac CT Images

J Yang¹, S Zhou^{1*}, J Huang¹, L Yu², M Jin¹, (1) University of Texas at Arlington, Arlington, TX, (2) Mayo Clinic, Rochester, MN

Purpose: To develop a spatiotemporal denoising method using an unpaired video-to-video translation model, which can improve the image quality of low-dose cardiac CT images by exploiting both spatial and temporal correlations of dynamic image frames. **Methods:** The new spatiotemporal denoising model is built upon the generative adversarial network with cycle consistency (CycleGAN), which is an unpaired image-to-image translation model. In order to utilize the temporal dynamics of image frames, a recurrent loss of image frames in both domain (low-dose and full-dose CT images) is added to enforce the temporal correlation between image time frames. This is particularly useful for denoising of low-dose dynamic CT images, such as multi-phase cardiac CT angiography, where consecutive cardiac gates exhibit strong temporal dependencies. The 4D XCAT phantom program based on 18 patients' data is used to generate both benchmark full-dose and low-dose (80% reduction) cardiac CT images (8 gates for each patient). 17 of 18 patients are used as training data and the rest one is used as test data. To qualitatively evaluate the model performance, peak signal noise ratio (PSNR) and structural similarity index (SSIM) are used. **Results:** The spatiotemporal denoising method achieves better quantitative performance (PSNR: 38.35 $\pm$ 1.46 dB and SSIM: 0.9300 $\pm$ 0.0112) than the low-dose images (PSNR: 31.56 $\pm$ 1.74 dB and SSIM: 0.8436 $\pm$ 0.0284) and CycleGAN (PSNR: 36.85 $\pm$ 1.29 dB and SSIM: 0.9240 $\pm$ 0.0122). It also significantly improves the low-dose CT image quality compared to CycleGAN. **Conclusion:** We proposed a new unpaired deep-learning based denoising method using spatial cycle consistent and temporal recurrent consistency for low-dose CT image sequences. The simulation study demonstrated the superior performance of the proposed method. The future study will investigate its effectiveness on real patient data.

Automated Assessment of Image Sharpness Degradation in Iterative CT Reconstruction Techniques: Vessel-Sharpness in Contrast-Enhanced Liver

M Chun^{1*}, H Jin¹, S Kim², WK Jeong³, C Heo², J Kim^{1,2}, (1) Seoul National University Hospital, Seoul, KR, (2) Seoul National University, Seoul, KR (3) Samsung Medical Center, Seoul, KR

Purpose: Iterative CT reconstruction techniques were often accompanied with the degradation of lesion sharpness. In this study, we developed a quantitative vessel sharpness measurement techniques and compared them with the previous slope estimation method in contrast-enhance liver CT. **Methods:** After IRB approval, a total of 120 CT images were acquired. The CT images were scanned with four scanners of GE Discovery CT750 HD (GE), Ingenuity CT (Philips), Definition Flash (Siemens), and Aquilion One (Canon). For a given image, the structure coherence feature was firstly calculated which is consisted of an edginess feature to represent the likelihood of a pixel being located on an anatomical structure and the randomness of the pixel orientation to signify the absence of an anatomical structure. The outline of enhanced vessel was drawn, and then was dilated with structural element of 7 pixels. An average of structure coherence feature for this region was defined as edge sharpness. To demonstrate the efficacy of suggested algorithm, the median slope value of the least squares regression line fit was obtained in the same edge profile. The correlation between two sharpness was analyzed. Fully automated sharpness measurement contains segmentation of candidate liver mask, adopting regions with structure coherence feature greater than the 70th percentile, and defining the representative sharpness as an average of structure coherence features on the segmented edges. The mean sharpness in FBP and iterative reconstruction image was compared. **Results:** For 120 FBP images, the Pearson correlation coefficient between manual and automated sharpness was 0.844. Compared to the FBP images, the mean sharpness was degraded in each vendor's iterative reconstruction algorithm by 17.8%, 16.3%, 9.8%, and 26.0% for GE, Philips, Siemens, and Canon, respectively. **Conclusion:** Degradation of image sharpness in iterative CT reconstruction techniques could be quantified automatically by using our proposed vessel sharpness measurement technique.

Quantitative Evaluation of Noise Texture of Deep-Learning-Based CT Reconstruction with An Anthropomorphic Phantom

K Yang^{*}, J Cao, N Pisuchpen, T Marshall, X Li, R Gupta, A Kambadakone, B Liu, Massachusetts General Hospital, Boston, MA

Purpose: Using an anthropomorphic phantom, quantitatively study noise texture of CT images reconstructed with deep-learning image reconstruction (DLIR, True Fidelity, GE) and compare them with filtered back-projection (FBP) and iterative reconstruction (ASiR-V). **Methods:** Axial CT scans of abdomen region of an anthropomorphic phantom (Kyoto Kagaku CTU-41) were acquired from a GE Revolution scanner with four CT DIvol levels ranging from 2.5 mGy (25% of TCM determined mAs) to 46.94 mGy (scanner max mAs). CT slices were reconstructed using all three algorithms, 1.25 mm and 5 mm slice thicknesses, five strength levels of ASiR-V (0% for FBP, 10%, 40%, 80%, and 100%) and three levels of DLIR (low, medium, and high). The 2D noise power spectrum (NPS) was estimated through Fourier analysis of difference images by subtracting two matching images from identical scans. Visual comparison of noise texture was performed between recon algorithms and dose levels via 1D NPS plots. Noise variance (0D NPS) as a quantitative metric was used to study the dependence of noise on algorithm, dose level, and slice thickness. **Results:** Image variance had a strong ($R^2 > 0.99$) power relationship with dose level for all algorithms, with the power around -0.65. Image variance was reduced by 66% from 1.25 mm to 5 mm slice thickness, by 8% for each 10% of ASiR-V strength increment and by 24% for each DLIR level increment from FBP. The shape of NPS from ASiR-V gradually biased towards lower spatial frequency and deviated away from that of FBP. Our results show a deterioration in spatial resolution with increasing ASiR-V strength. NPS from DLIR had very close shapes to that of FBP, for all three strength levels. **Conclusion:** Noise texture with DLIR reconstruction is closer to FBP than ASiR-V. DLIR, as compared to ASiR-V, preserves spatial resolution while reducing imaging noise.

Assessing the Severity of Metal Artifacts and Detectability of Lesions in CT Metal Artifact Reduction Images

C Topbas*, F Dong, The Cleveland Clinic, Solon, OH

Purpose: Metal Artifact Reduction (MAR) algorithms are becoming increasingly utilized to improve image quality and lesion detectability around prostheses. Performance assessment of these algorithms in clinical studies is complex due to ethical issues and lack of reference standards to confirm the presence of lesions. The goal of this study was to develop a quantitative method to assess the severity of streak artifacts and detectability of lesions in CT phantom images with and without MAR via change in image noise and HUs around metal inserts. **Methods:** A semi-anthropomorphic phantom (40 HU) manufactured with spherical lesions of various attenuations (20, 25 and 30 HU) embedded around arthroplasty inserts, cobalt-chromium sphere attached to a titanium rod, was scanned at 140 kVp, 300 mAs and 0.6-mm collimation. A control material (120 HU), simulating bone, was used instead of metal inserts. Images were reconstructed using FBP and MAR with identical parameters. Axial images were retrospectively analyzed with a post-processing software where multiple circular ROIs, near and away from the inserts were drawn and applied consistently to each series. **Results:** The degree of streak artifact (noise ratio to the control within corresponding ROIs) in MAR images were graded as significantly less ($p < 0.001$, Wilcoxon signed rank test) than for the FBP images at both near and away from the inserts. There was less CT number change (exceeding 20 HU compared to control) in MAR images than FBP (30% and 94% of the ROIs respectively) around the cobalt-chromium insert while this change was lower around the Titanium rod (25% for FBP and none for MAR images). These changes made two of the lesions undetectable in FBP images while all were distinguishable in MAR. **Conclusion:** MAR achieved more accurate attenuation values and less streak artifact than FBP, providing better detection of lesions near metal inserts in a phantom model.

"Focused" CT: A Reconstruction Algorithm Permitting Radiation Dose Reduction for Region-Of-Interest Viewing

T Olson¹, S Leon^{2*}, (1) Dept. of Mathematics, University of Florida, Gainesville, FL (2) Dept. of Radiology, University of Florida, Gainesville, FL

Purpose: CT scans often image an anatomical region of interest (ROI), such as the spine. Traditional reconstruction algorithms require roughly-equal signal levels throughout the axial plane of the body, a limitation which has stymied any attempt to reduce radiation dose to off-ROI tissues not of clinical interest. We propose a modified filtered back-projection (FBP) algorithm, Focused CT (FCT), that permits accurate reconstruction of a limited scan-FOV with a 90% or greater reduction of radiation exposure outside the clinical ROI. **Methods:** FCT splits the Fourier transform into low-frequency and high-frequency components. The high-frequency component uses low-noise data from within the ROI (acquired at a typical clinical dose). The low-frequency component uses high-noise data from the entire axial plane, with the off-ROI data acquired at 10% of the typical dose. To simulate a single CT exam acquired at different doses, a cadaver was scanned twice, with CTDIvol values of 17 mGy and 1.7 mGy. Matlab was used to create several hybrid slices combining ROI data from the 17-mGy acquisition with off-ROI data from the 1.7-mGy acquisition. Projection data for these combined images were simulated, then re-reconstructed using the FCT algorithm. The resulting HU values were compared to those from the 17-mGy image alone: quantitatively by use of the mean-square error, and visually by creation of a difference image. **Results:** ROI images generated with the 1.7-mGy off-ROI dose appeared identical to those using the 17-mGy dose throughout the axial plane. The mean-square error was negligible (0.0041). The difference image showed no perceptible structures within the ROI. **Conclusion:** The FCT algorithm permits accurate reconstruction of an ROI, with off-ROI dose reduction of at least 90%. The development of a mathematical basis for "focused" reconstruction may lead to the engineering of a physical mechanism to reduce radiation dose to off-ROI tissues.

Multi-Disciplinary: Adaptive Radiation Therapy

TU-IePD-TRACK 3-01

A Method to Select Optimal Candidates for Adaptive Radiation Therapy (ART) in Anal Cancer

O Dona^{1*}, D Horowitz^{1,2}, M Savacool¹, K Rayn¹, F Li¹, M Price³, C Wu¹, L Kachnic^{1,2}, (1) Columbia University, New York, NY, (2) Herbert Irving Comprehensive Cancer Center, New York, NY, (3) Vanderbilt University Medical Center, Nashville, TN

Purpose: Adaptive Radiation Therapy (ART) is a treatment technique that may allow for reducing radiation dose to normal structures, such as bowel. However, accessibility to this treatment modality is limited because it is resource intensive. Here, we propose a method to select anal cancer patients that will benefit most from ART in terms of bowel sparing, allowing more efficient allocation of resources. **Methods:** Retrospective treatment data from 4 patients (5400cGy/30 fractions) were evaluated. Daily adapted CTs were created in Velocity v4.1 based on daily CBCTs. The structure sets from the planning CTs were deformed onto each adapted CT and ultimately corrected and revised by two qualified radiation oncologists. The original treatment plan was recalculated on each fraction's adapted CT to establish the true dose received during treatment. Dose statistics (Mean, Max, Min) and DVHs were extracted and analyzed. **Results:** The ratio (V4500cGyRatio) of the initial plan bowel V4500cGy to the plan-specific constraint was used to stratify patients into three groups (V4500cGyRatio < 0.65, 0.65 < V4500cGyRatio < 0.85, V4500cGyRatio > 0.85). Every fraction was classified as pass/fail based on the true daily bowel V4500cGy meeting constraint. Daily bowel V4500cGy significantly ($p < 0.05$) correlates with daily bladder volume. A scatter plot of the daily/planned bladder volume ratio vs. the V4500cGyRatio of the initial plan for every fraction shows which combinations of these lead to passing or failing the plan-specific constraint. For inter-fraction bladder volume variability at our clinic, V4500cGyRatio < 0.65 needs little adaptation (2/30 fractions), 0.65 < V4500cGyRatio < 0.85 needs daily adaptation depending on daily bladder volume (10/30 fractions), and V4500cGyRatio > 0.85 requires daily adaptation (29/30). **Conclusion:** Patient plan V4500cGyRatio can help determine which anal cancer patients will benefit most from ART in terms of bowel sparing. Decreasing inter-fraction variability of bladder volume may reduce the number of patients requiring ART.

A Prediction Model for Dosimetric-Based Lung Adaptive Radiotherapy

C Ma*, R Wang, H Wu, F Jiang, Z Feng, Q Hu, A Shi, F Yang, Peking University Cancer Hospital & Institute, Beijing, China

Purpose: To quantify anatomical changes of lung cancer patients and evaluate the resulting dosimetric effect according to on-treatment cone-beam computed tomography (CBCT) scans. To develop a dosimetric-based lung adaptive radiotherapy (ART) decision tool based on features of patients' anatomy and anatomical changes. **Methods:** Eleven non-small cell lung cancer patients were enrolled in this study. A planning CT (pCT) and weekly CBCTs of each patient were collected. A virtual CT (vCT) was generated by deforming the pCT to each CBCT and the dose distribution was recalculated on the vCT (DvCT). The replanning status of a CBCT was labeled as positive if the DvCT was clinically unacceptable or could be potentially improved according to two sets of dosimetric criteria, otherwise labeled as negative. The region of anatomical changes (region of interest, ROI) between each CBCT and the pCT was extracted. Twenty-four features from the ROI and the pCT anatomy were extracted for each pCT-CBCT pair. A model based on nonlinear supporting vector machine was built for replanning status prediction. A nested cross-validation (CV) scheme was used for model evaluation, where the recursive feature elimination method was applied for feature selection. **Results:** Thirty-Five CBCT-pCT pairs were identified of having a ROI, among which only 7 CBCTs had positive replanning status. Six features were selected for model fitting and the top 6 most frequently selected features were from both feature categories. A high prediction accuracy of 0.84 was achieved and the area under the mean curve was

0.82. A balanced sensitivity and specificity of 0.70 could be obtained by lowering the probability threshold. **Conclusion:** Our preliminary results demonstrated that the proposed model has the potential to identify the replanning need for lung cancer patients from CBCTs. Further study will be done to alleviate the imbalanced class problem and refine the model performance.

Analysis of the Benefits of Daily Online Adaptive Radiotherapy Via Ethos for Prostate Cancer

M Moazzezi*, K Moore, B Rose, X Ray, UC San Diego, La Jolla, CA

Purpose: to evaluate the Varian Ethos online-adaptive platform for prostate cancer including 1.auto-segmentation accuracy for CTV and OARs, 2.achievable dosimetric improvements, and 3.minimal margin necessary with daily adaptation. **Methods:** 25 retrospective prostate patients were re-planned using an Ethos emulator, 12-field IMRT, and 2Gy fractions. CTVs included intact prostate and 1cm proximal seminal vesicles. Our clinical asymmetric margin was used: 3mm posterior, 5mm left/right/anterior, and 7mm superior/inferior. Adapted and non-adapted dose distributions for 10 fractions per patient were calculated using their on-treatment CBCTs. No corrections to the auto-segmentation were performed prior to adaptive plan optimization, however all contours were reviewed/corrected for dosimetric evaluation. The auto-segmentation was evaluated by comparing DVH metrics from auto-segmented versus corrected contours. Dosimetric improvements were measured by comparing DVH metrics from adapted and non-adapted doses to corrected contours. Minimum safe CTV-to-PTV margins were determined by replanning each fraction with a clinically-validated RapidPlan™ knowledge-based planning routine and symmetric 2-5mm margins. Then CTV-Dmin with reduced margins and daily adaptation was compared to standard margin without adaptation. **Results:** 70% of CTV edits (88% Bladder, 90% Rectum), were less than 10% of the total volumes and resulted in small average changes of: 0.13%±2.9% CTV-D95%, 0.43%±3.3% Bladder-V90%, and 0.12%±5.1% Rectum-V90%. Without adaptation, CTV-Dmin was greater than 95% of prescribed dose for only 45% of fractions; adaptation with clinical margin increased this to 83%. For non-adapted fractions where the OAR-V90% exceeded its clinical threshold, adaptation reduced it on average by 0.6%±4.0%(Bladder) and 2.0%±5.5%(Rectum). For these cases, using 2mm margin preserved an improvement in tumor coverage(65% fractions CTV-Dmin>100%), and further improved the OAR-V90 metrics by 3.5%±6.0%(bladder) and 11.5%±4.7%(rectum). **Conclusion:** we established Ethos's online adaptive workflow without pre-treatment segmentation edits can substantially improve prostate CTV coverage and reduce OAR dose. This approach minimizes the impact on the clinical workflow and dosimetrically benefits patients.

Elimination of the Set-Up Margin Using Daily Adaptive Radiotherapy for Head and Neck Radiotherapy: A Feasibility Study

M Lin*, J Park, X Zhong, L Chen, H Morgan, Z Trivedi, A Godley, A Pompos, S Jiang, D Sher, UT Southwestern Medical Center, Dallas, TX

Purpose: Involved Nodal Radiotherapy using AI-based Radiomics (INRT-AIR) for head-and-neck cancer eliminates the elective neck treatment altogether and focus treatment on the nodes themselves. This pilot dosimetric study leverages adaptive therapy to further reduce PTV margins and assess resulting dosimetric gain. **Methods:** A total of 10 patients treated with INRT-AIR were recruited and replanned with Ethos treatment-planning-system. Ethos plans were created with planning-target-volume (PTV) margin 5mm and 1mm (for intrafractional-motion), respectively. The plans were virtually delivered in the Ethos emulator using the CBCT acquired in the patient's prior treatments. The 5mm plans were delivered with image-guidance-radiation-therapy (IGRT) to mimic the current delivery while the 1mm plans were delivered with daily adaptive therapy. The initial plan quality was compared to quantify the dosimetric improvements. The adaptive plan quality was compared with the initial plan to evaluate the robustness of the 1mm INRT-AIR plan against patient's daily anatomy change. Independent fractions of delivered dose of the two cohorts were compared to evaluate the efficacy of 1mm adaptive therapy over the conventional 5mm IGRT. The gross-tumor-target (GTV) and clinical-target-volume (CTV) coverages along with the organs-at-risk (OAR) dose were the denominators. A dose difference of 300cGy was considered clinically significant. **Results:** Among the high impact OARs, the 1mmINRT-AIR plans exhibited clinically significant improvements in contralateral-submandibular-gland (Avg.1775cGy), constrictor muscle (Avg.457cGy), contralateral-parotid-gland (Avg.363cGy), and mandible(Avg.335cGy). Despite the adaptive workflow is fully automatic and user has very minimum control of adaptive plan optimization, over 83% frequency that 1mm adaptive plan recovers the initial plan quality. While 5mmIGRT delivery degraded both the target coverage and OAR sparing, 1mm adaptive delivery holds the promise of dosimetric benefit from margin reduction. **Conclusion:** We demonstrated the significant dosimetric benefit of dramatic PTV margin reduction made viable using daily-adaptive-radiotherapy, even in the context of INRT-AIR planning that has improved OAR dosimetry.

Initial Experience of CBCT-Based Adaptive Radiotherapy with Ethos for Postoperative Prostate SBRT

H Morgan*, D Nguyen, A Garant, N Desai, M Folkert, R Hannan, B Cai, M Lin, S Jiang, J Park, Department of Radiation Oncology, UT Southwestern Medical Center, Dallas, TX

Purpose: To investigate whether Cone-Beam Computed Tomography (CBCT)-based adaptive planning improved dosimetry for patients receiving postoperative prostate stereotactic body radiotherapy (SBRT) over 5 fractions. **Methods:** A retrospective cohort of 5 patients with prostate cancer receiving adjuvant or salvage radiotherapy to the prostatic fossa were included. With the Ethos emulator environment, initial treatment plans were created using baseline CT simulation images and prescribed to 32.50Gy in 5 fractions with a 3mm planned target volume (PTV) expansion (initial plan). Subsequently, 25 fractions were delivered by two separate **Methods:** (1) adaptation to the CBCT of the day (adapted plan) and (2) dose recalculation using the initial plan on the same CBCT (scheduled plan). Dosimetry for targets and organs at risk were recorded. Independent fractions were compared between the initial, adapted, and scheduled plans with paired-samples t-tests. **Results:** Rectal dosimetry improved with CBCT-based adaptation (V25Gy 10.7 + 3.4 cc), when compared to both the initial (16.4 + 7.2 cc, p=0.001) and scheduled (16.4 + 8.3 cc, p<0.001) fractions, which appeared primarily secondary to changes in rectal distension from gas or stool. Bladder wall dosimetry slightly improved with adaptation (V25Gy 32.7 + 6.4 cc) when compared to the initial (35.5 + 33.6 cc, p=0.002) and scheduled (33.6 + 6.4 cc, p=0.024) fractions. PTV coverage was acceptable for all fractions: adapted (D95% = 100%), initial (100%), and scheduled (98.5% + 1%). Further, this adaptive planning process on Ethos is largely automated, taking an average of 12.9 + 1.7 minutes to generate a new adaptive plan from the patient's daily CBCT, of which only 5 to 6.5 minutes were spent manually editing contours. **Conclusion:** Overall, CBCT-based adaptation with Ethos provided superior plans with better rectal sparing whilst maintaining excellent target coverage. Ethos offers a fast and effective method to generate adaptive plans for postoperative prostate SBRT.

Use of Deep Learning Segmentation and Biomechanical Models to Improve Dose Accumulation Accuracy in GI Structures

M McCulloch¹*, G Cazoulat¹, B Rigaud¹, B Anderson¹, E Kirimli¹, S Gryshkevych², S Svensson², A Ohrt¹, J Ohrt¹, N Chopra¹, R Mathew¹, M Zaid¹, D Elganainy^{1,3}, P Balter¹, E Koay¹, K Brock¹, (1) UT M.D. Anderson Cancer Center, Houston, TX, (2) RaySearch Laboratories AB, Stockholm, SE, (3) Dana-Farber Cancer Institute, Boston, MA

Purpose: Dose accumulation in luminal gastrointestinal (GI) structures during radiotherapy (RT) for abdominal cancers can potentially improve toxicity prediction

models. The purpose of this study is to assess the benefit of deep learning (AI) and biomechanical model-based deformable image registration (DIR) to improve DIR-based dose accumulation accuracy. **Methods:** Dose accumulation was conducted on 75 patients with primary and metastatic liver cancer treated with external beam RT guided by daily CT-on-rails (CTOR), using a “Merged” DIR approach with biomechanical model-based DIR (FEM) inside the liver and intensity-based DIR outside. On a sub-cohort, FEM with boundary conditions on the liver and combined stomach and duodenum (GI_ROI) was applied (FEM+GI). The GI_ROI was auto-contoured on CTOR using a 3D UNet model trained on another 102-patient cohort. Contours were compared to physician-drawn contours on 8 CTOR, using Dice similarity coefficient (DSC), mean distance to agreement (DTA), Hausdorff distance (HD), and planned dose metrics. Intra-observer variability was evaluated. DSC was evaluated on the stomach and duodenum propagated after application of the Merged DIR approach. Accumulated doses based on Merged and FEM+GI were converted to EQD2 ($\alpha/\beta=3.5$) and compared. **Results:** Average(SD) DSC, DTA, and HD between AI and physician-drawn GI_ROI were 0.9(0.1), 0.2(0.1)cm, and 2.4(2.2)cm; intra-observer: 0.9(0.0), 0.1(0.0)cm, and 2.3(0.8)cm, $p>0.1$. Average D50(SD) and D1(SD) differences between AI and physician-drawn contours were 0.6(1.1)Gy and 0.5(0.2)Gy; intra-observer: 0.2(0.3)Gy and 0.3(0.3)Gy, $p>0.1$. Average(SD) DSC of the stomach and duodenum mapped via Merged were 0.8(0.1) and 0.55(0.2), respectively, compared to manual contours. Average(SD) accumulated D1 (EQD2) using Merged and FEM+GI were 26.2(13.8) and 25.6(13.7)Gy for stomach, and 20.3(18.0) and 19.6(18.1) for duodenum, respectively. These distributions were significantly different ($p<0.05$), with differences ranging 0.7-3.9Gy. **Conclusion:** The use of AI-generated segmentation to drive biomechanical model-based DIR led to significant differences in the accumulated dose estimations which may improve toxicity prediction models.

CBCT-Based, Physicist-Driven Daily Adaptive Protocol for Locally Advanced Cervical Cancer: Improved Target Coverage and Reduced Margins in a 20-Minute Treatment Slot

D Branco*, J Mayadev, K Moore, X Ray, UC San Diego, La Jolla, CA

Purpose: To evaluate a physicist-driven, CBCT-based daily adaptive protocol in locally advanced cervical cancer for multiple endpoints: on-couch time, physicist contouring accuracy of daily CTVs, and target coverage with reduced PTV margins versus non-adapted standard-of-care. **Methods:** CT scans of 13 retrospective cervical cancer patients with original CTV_SIM were re-planned on the Varian Ethos platform using 12-field IMRT and 3mm symmetric CTV-to-PTV margins. Each plan was adapted on five CBCT scans to simulate Ethos’ auto-segmentation and auto-planning workflow. Required contouring edits were made by one of three physicists, mimicking daily adaptation without real-time physician review. Time spent editing OARs and CTVs was recorded, as was total treatment time (CBCT acquisition to treatment start, inclusive of auto-segmentation, contour review/edits, replanning, and evaluation). All physicist-adapted targets, CTV_PHYS, were reviewed by an experienced gynecologic radiation oncologist for accuracy and, when necessary, corrected to establish ground truth, CTV_GT. The adaptive coverage frequency was compared to non-adaptive standard-of-care treatment by assessing whether daily CTV_GT was contained inside PTV_PHYS=CTV_PHYS+3mm and/or PTV_SOC=CTV_SIM+(5mm-nodal, 10mm-vagina/parametrium, 15mm-uterus/cervix). **Results:** The average time spent editing OAR/CTV contours was 3.8(range:1.0-15) and 7.1(range:2.5-12.5) minutes, respectively. The average total time was 16.7(range:7.0-29.0) minutes. 54/65 sessions were completed <20 min; only 1/65 required >23 min. Physician reviews of CTV_PHYS resulted in: 47/65 requiring no further editing (CTV_GT=CTV_PHYS), 14/65 requiring target size reduction (CTV_GT<CTV_PHYS), and 4/65 requiring target size expansion (CTV_GT>CTV_PHYS). CTV_GT extended outside the non-adapted PTV_SOC in 53/65(81.5%) fractions, while the daily CTV_GT extended outside of PTV_PHYS in only 4/65(6.2%) fractions. **Conclusion:** Our results demonstrate that CBCT-driven, daily adaptation of cervical cancer without real-time physician review is feasible in a typical time slot (<20 minutes). With daily adaptation, even substantially reduced PTV margins resulted in markedly increased CTV coverage frequency. These margin reductions would also improve normal tissue sparing, providing further motivation for daily adaptation.

A Deep Reinforcement Learning Based Pipeline for Prostate Segmentation on MRI with Low Variance Performance

L Xu^{1*}, W Shi¹, N Wen², (1) Wayne State University, Detroit, MI, (2) Henry Ford Health System, Detroit, MI

Purpose: To effectively address the scarce annotation problem, we proposed a Deep Reinforcement Learning (DRL) based pipeline approach for image segmentation. Unlike supervised machine learning, DRL is a self-learning algorithm to learn through the interactions with the given environment, and adjust the action based on observed state and received reward. We aim to develop a DRL-based approach for prostate gland segmentation on MRI by self-learning, and introduce a novel post processing approach based on the Kalman filter to enhance the segmentation accuracy in 3D volumes. **Methods:** We considered the segmentation as a painting task and trained a DRL agent to draw the structure’s boundary in a sequential decision-making approach. The pipeline has two phases: (a) a backbone encoder capturing the global information and providing the start point for the agent; (b) a DRL based agent to delineate boundary on 2D MRI by interacting with the environment. The segmented slices for each patient were then aggregated and post-processed using a Kalman filter to rectify the contour results in the 3D space. The proposed model was trained with SPIE-AAPM-NCI PROSTATEx-2 Challenge (SPIE) dataset, and evaluated on both SPIE and an in-house dataset. Dice similarity coefficient (DSC) and 95% Hausdorff distance (HD) were used as the evaluation metrics. **Results:** The proposed method achieved a DSC of 87.88%±3.0%, 87.89%±1.7% on the validation and test based on the 2D slices, and 85.20%±10.3% and 85.27%±10.4% on the 3D volumes using the SPIE data. The results were 84.18%±4.3% and 81.72%±11.7 on the 3D and 2D respectively using the in house data. The 3D 95% HD was 4.08±0.94 mm and 5.28±2.21 mm on the validation and test, 6.49±2.48 mm on the in-house dataset. **Conclusion:** The DRL agent provides promising prediction results on organ segmentation and the Kalman filter-based post segmentation shows its effectiveness in alleviating the segmentation variance.

Automatic Segmentation of Low-Contrast Head and Neck Tumors for Palliative Radiotherapy

S Gay^{1*}, C Cardenas¹, C Nguyen¹, T Netherton¹, A Aggarwal², K Naidoo³, H Simonds³, B Beadle⁴, L Court¹, (1) The University of Texas MD Anderson Cancer Center, Houston, TX, (2) Guys Cancer Centre, London, UK, (3) Stellenbosch University, Stellenbosch, ZA, (4) Stanford University, Stanford, CA

Purpose: To automatically contour gross tumor volumes (GTVs) for palliative head-and-neck (HN) radiotherapy at multiple treatment sites from single-modality, low-contrast scans. **Methods:** 110 palliative and 234 curative treatment plans (CT scans and physician-approved GTV contours) for nine HN treatment sites were retrospectively obtained. Mean target volume was 88.9 (σ 123.3) cc, and both palliative and curative cases were evenly split 80%/20% into training-validation and test sets, respectively. First, state-of-the-art CNNs (e.g. U-Net) were evaluated. Then, a novel, coarse-to-fine cascading 3D Attention U-Net was developed to segment the GTVs. Model performance was evaluated by comparing Dice similarity coefficient (DSC) and mean surface distance (MSD) to measure target coverage and structure similarity of predicted and clinical GTVs. **Results:** Over the entire test dataset (curative & palliative cases), the best scores achieved with the conventional U-Net architecture were median DSC and median MSD of 0.65 (σ 0.22) and 2.08 (σ 7.65) mm, respectively. For the cascading 3D Attention U-Net, these scores changed to 0.67 (σ 0.23) and 2.26 (σ 4.27) mm; thus, this approach improved both median DSC and the extent of MSD outliers. Segmentation of large, high-visibility tumors performed better than smaller or low-visibility tumors. Across treatment sites, base of tongue, mandible, and thyroid median DSC scores were 0.70 or greater, with mandible achieving the highest median DSC (0.74). Additionally, median DSC scores for glossopharyngeal sulcus, head and neck, thyroid, tonsil, and other were 0.60 or greater. **Conclusion:** We developed a novel 3D segmentation network to find GTV delineations for palliative HN treatments. To our knowledge, this is the first work developed for multiple HN treatment sites.

This work was partially supported by a grant from the Wellcome Trust.

Evaluation of Deep Learning-Based Automatic Segmentation of the Pancreas

B Rigaud^{1*}, E Kirimli², S Yedururi³, G Cazoulat⁴, B Anderson⁵, M McCulloch⁶, M Zaid⁷, D Elganainy⁸, E Koay⁹, K Brock¹⁰, (1) The University of Texas MD Anderson Cancer Center, Houston, TX, (2) Md Anderson, , , (3) The University Of Texas Md Anderson Cancer Center, (4) The University of Texas MD Anderson Cancer Center, Houston, TX, (5) University of Texas MD Anderson Cancer Center, Houston, TX, (6) Houston, TX, (7) The University Of Texas Md Anderson Cancer Center, (8) The University Of Texas Md Anderson Cancer Center, (9) MD Anderson, Houston, TX, (10) UT MD Anderson Cancer Center, Houston, TX

Purpose: Investigate the performance of multiple deep learning (DL) models for the automatic segmentation of pancreas on contrast enhanced CTs. **Methods:** A total of 595 CTs of pancreas with various characteristics were gathered from our institution and publicly available datasets. The population was separated into 425, 60, and 110 CTs for the training, validation and withheld test datasets. Both the training and validation datasets were composed of cyst, pancreatic and extra pancreatic tumor, pancreas from our institution (n=204) and the MICCAI Medical Segmentation Decathlon (MSD) (n=281). The withheld test dataset was composed of healthy pancreas from the NIH-82 (n=80) and SYNAPSE MICCAI (n=30) challenges. Four DL models were investigated: attention Unet (attUnet), 2D DeepLabV3+, 3D patch-based BasicUnet from MONAI, and 2-step Unet from RaySearch Laboratories (RSLab). The segmentation resulting from the majority vote (MV) of all DL models was also evaluated. The DL models' performance compared to manual segmentation was reported using the Dice similarity coefficient (DSC), distance to agreement (DTA), Hausdorff distances (100thHD and 95thHD). The intra- and inter-observer variability was reported for 20 pancreas segmentations. **Results:** The median (min-max) DSC between manual and automatic pancreas segmentations on the test dataset were 0.78 (0.16-0.88), 0.80 (0.44-0.89), 0.80 (0.00-0.88), 0.82 (0.34-0.88), 0.82 (0.59-0.89), for the attUnet, DeepLabV3+, RSLab, MONAI, and MV models. Majority vote was able to reduce the number of segmentations with a DSC <0.7 to 5.0% and 7.3% for the validation and test datasets. Using the MONAI as reference, the disagreement between the MONAI and DLV3 models was able to detect 72% of the failing cases (DSC<0.7). The median (min-max) intra- and inter-observer delineation DSC were 0.83 (0.62-0.92) and 0.87 (0.78-0.91). **Conclusion:** Multiple DL model's majority vote improved the performance similarly to observer variability. DL model agreement could be used to automatically detect cases where DL fails.

TU-lePD-TRACK 4-04

Improving Deep Learning Auto-Segmentation Using an Adaptive Spatial Resolution Approach

A Amjad^{1*}, J Xu², D Thill², M Awan¹, M Shukla¹, W Hall¹, B Erickson¹, X Li¹, (1) Medical College of Wisconsin, Milwaukee, WI, (2) Elekta Inc., MO

Purpose: Deep learning-based auto-segmentation (DLAS), although has been shown to substantially improve organ delineation efficiency, performs generally poor for organs with small/narrow size (e.g., inner ears) or complex shape (e.g., bowels). To overcome this problem, we introduce an adaptive spatial resolution approach (ASRA) for DLAS. **Methods:** The framework of ASRA uses a fine spatial resolution in a subregion that contains small/narrow and/or complex anatomy while using default or coarse resolutions in other regions to balance the accuracy and efficiency of DLAS. We implemented ASRA in 3DResUnet and trained the DLAS models for selected organs in head and neck (HN) based on CT by using a fine spatial resolution of $1 \times 1 \times 2 \text{ mm}^3$ inside the subregions, and $2 \times 2 \times 2 \text{ mm}^3$ outside it. To overcome a common issue that a portion of a large organ (e.g., small bowel) far away from the target may not delineated or may be missing in the training dataset, we extended existing contours via 8-fold repetition of last contoured slice using 3D elastic transformation, thus stimulating a larger field-of-view. DLAS models were trained with 47 datasets for HN and 58 for abdomen. Performance of the obtained models with and without ASRA was compared. **Results:** DLAS accuracy was substantially improved with the use of ASRA compared to that without ASRA, with maximum improvement observed for small/narrow organs, e.g., eye lens and optic nerves with dice similarity coefficient (DSC) of 0.74 – 0.8 vs. 0.25 – 0.45. For complex structures, e.g., small and large bowels, DSC/mean distance to agreement (MDA) of 0.84/3.8 mm and 0.87/2.37 mm vs 0.71/7.9 mm and 0.7/14 mm, were observed with 3D extended volume respectively. **Conclusion:** The proposed adaptive spatial resolution approach can substantially improve accuracy of deep learning-based auto-segmentation, particularly for organs with small/narrow sizes or complex shapes.

TU-lePD-TRACK 4-05

On the Application of a Variational Autoencoder (VAE) and Transfer Learning to Account for Inter-Observer Uncertainties in Automatic Prostate Gland Segmentation

X Li^{1*}, H Bagher-Ebadian^{2,3}, E Mohamed^{2,3}, B Movsas^{2,3}, D Zhu¹, IJ Chetty^{2,3}, (1) Wayne State University, (2) Henry Ford Health System, Detroit, MI, (3) Henry Ford Cancer Institute, Detroit, MI

Purpose: Inter-observer variation is an important issue for automated segmentation in the clinic. To account for inter-observer variability in delineating the prostate gland, we employed a deep neural network architecture, comprised of a U-net and a variational autoencoder (VAE). VAE encodes inter-observer variability and produces multiple segmentations for each image CT slice robust to the inter-user uncertainty. To our knowledge, this is the first such application of a VAE. **Methods:** The source dataset contained 300 patient CT images in which the prostate was delineated by a single physician. The target dataset used for incorporating inter-observer variation was comprised of 10 patient CT datasets, where the prostate for each patient was segmented by 5 independent physicians. Data augmentation utilizing random rotation (<5degrees), cropping and horizontal flipping was applied to each dataset to increase the sample size by factor of 100. Probabilistic hierarchical U-net with VAE (PHiSeg) was pre-trained using the source dataset for 30 epochs. Model weights were then transferred to fine tune PHiSeg using the target dataset for 100 epochs via transfer learning. Ten iterations using random permutation sampling (with training/validation/test ratio of 6:1:3) of the augmented

target dataset were performed. **Results:** Average results of models trained with the target dataset only versus source followed by target datasets (transfer learning) were as follows: Dice score=0.76+0.03 vs. 0.80+0.02 ($p=0.001$); Hausdorff distance (mm)=11.48+2.28 vs. 10.18+1.35 ($p=0.019$); normalized-cross-correlation=0.52+0.10 vs. 0.62+0.06 ($p=0.006$); generalized energy distance=0.33+0.09 vs. 0.26+0.06 ($p=0.002$). All metrics were shown to improve significantly using the proposed VAE and transfer learning approach. **Conclusion:** A VAE combined with a hierarchical U-net demonstrated promise toward accounting for inter-observer variability in automatic prostate segmentation. Multiple segmentations for each CT slice enable users to determine clinical tradeoffs in selecting the “best fitting” contour, which offers advantages over a standard U-net, where output is limited to just one contour.

Deploying Deep Learning-Based Image Segmentation Models Via CERR

A Iyer*, E LoCastro, J Deasy, A Apte, Memorial Sloan-Kettering Cancer Center, New York, NY

Purpose: Despite the availability of several general-purpose platforms for deep learning-based segmentation (DLS), we lack similarly comprehensive platforms with functionality specific to medical images. We present an open-source extension to the Computational Environment for Radiological Research (CERR) for deploying DLS models that leverages CERR's existing functionality for radiological data import, transformation, management, and visualization. **Methods:** CERR's deep learning pipeline utilizes Java Script Object Notation (JSON) format configuration files to specify input and output data formats; methods and parameters for transforming images, populating channels, and post-processing segmentations. Several pre-processing operations specific to the medical imaging domain are supported, including automated cropping around patient outline, 2D/3D resampling, 2D/2.5D/3D and multimodal channels, and orientation transformations (transverse, sagittal, coronal). CPU and GPU implementations of pre-trained DLS models are packaged using Singularity containers (Linux) and Conda environment archives (Windows, macOS) for distribution. The returned segmentation labels are imported to CERR for further processing and export to DICOM format. Various post-processing operations are supported to minimize manual editing, including filtering to retain connected component(s) by size or within a user-defined region of interest. Custom pre/post-processing functions and dynamic label-to-structure mapping (where the number output labels is variable) are supported through the use of flexible JSON-format configuration files. This pipeline has additionally been made compatible with GNU Octave for license-free use. **Results:** CERR's DLS pipeline, along with a JupyterLab notebook demonstrating its usage, are distributed as open-source GPL-copyrighted software at <https://www.github.com/cerr/CERR>. It has been successfully used in conjunction with MIM workflows to deploy DLS models developed in-house for segmenting organs-at-risk on head & neck CT images and T2-weighted MR prostate images in the clinic. **Conclusion:** We developed a comprehensive, open-source pipeline for deploying deep learning-based medical image segmentation models. In addition to its clinical applications, this pipeline facilitates reproducible and consistent segmentation across institutions for research purposes.

Saliency-Guided Deep Learning Network for Automatic Gross Target Volume Delineation in Partial Breast Irradiation

M Kazemimoghdam*, W Chi, A Rahimi, N Kim, P Alluri, C Nwachukwu, X Gu, W Lu, UT Southwestern Medical Center, Dallas, TX

Purpose: To accommodate an efficient scan-plan-treat clinical workflow in partial breast irradiation (PBI) such as GammaPod, fast, accurate and automated target delineation is desired. In this study, we develop a saliency-based deep learning segmentation (SDL-Seg) algorithm for automatic gross tumor volume (GTV) delineation in post-op breast irradiation. **Methods:** Our approach incorporates saliency information into a U-Net model for target delineation. The visual saliency maps were generated using surgical clips as markers identified on CT images, and a distance-transformation coupled with a Gaussian filter were adopted to convert markers' locations to probability maps. The CT images and the corresponding probability maps form a two-channel input for the segmentation network. The dataset used for model training, validation and testing (19:5:5) is comprised of 145 prone CT images from 29 post-operative breast cancer patients, who had surgical clips and received 5-fraction PBI regimen on GammaPod. We used the Dice similarity coefficient (DSC), 95 percentile Hausdorff distance (HD95) and average symmetric surface distance (ASD) to assess segmentation results using SDL-Seg and compared it with those generated with basic U-Net. **Results:** Our model achieves mean (standard deviation) of 76.4(2.7) %, 6.76(1.83)mm, and 1.9(0.66)mm for DSC, HD95, and ASD respectively outperforming basic U-Net by 13.8%, 1.63mm, and 0.9mm. For all 5 testing cases, the saliency-guided U-Net showed increased DSC compared to basic U-Net. The average DSC for each case using SDL-Seg are 74.3%±4.8%, 79.35±3.7%, 75.6±1.7%, 73.6%±4.4% and 79.3%±1.5%, while using basic U-Net the outcomes are: 70.8.6±2.1%, 57.8%±21.1%, 63.2%±4.3%, 51.9%±9.5% and 69.2±3.7%. **Conclusion:** We developed a deep learning model integrating visual saliency information into the network for GTV delineation. Results demonstrate that SDL-Seg outperforms basic U-Net and is a promising approach for improving the efficiency and accuracy of the on-line treatment planning procedure of PBI, such as GammaPod.

A Feasibility Study of Proton Beam Dosimetry Using Cerenkov Radiation

S Thompson*, University of Florida, Gainesville, FL

Purpose: To study the relationship between Cerenkov photon emission and absorbed dose in water, soft tissue, and cortical bone for a primary proton beam. A proportionality constant between the number of Cerenkov photons and the absorbed dose is produced, which will aid in future dosimetry work. **Methods:** A proportionality constant is introduced to quantify the amount of Cerenkov radiation emission per Gray of absorbed dose. MCNP 6.2 is then used to obtain said proportionality constant for a typical proton therapy spread-out Bragg peak. A correlation between proton energy and Cerenkov emission is also obtained for a water, soft tissue, and cortical bone phantom for proton energies of 10 – 150 MeV. The central axis depth dose curve for a solid water phantom was also produced and compared to the central axis Cerenkov emission profile to ascertain the feasibility of using Cerenkov output as an estimator of the Bragg peak location. **Results:** The cortical bone emitted the most Cerenkov photons, followed by water and then soft tissue. The cortical bone produced the most Cerenkov photons due to its larger Sellmeier coefficients, and therefore larger refractive index. The differences between the water and soft tissue output is likely due to the larger electron density for water. The proportionality constant between Cerenkov photon emission and absorbed dose is 6.99×10^8 photons/Gray. The Cerenkov output was found to be a poor predictor of the Bragg peak location. **Conclusion:** Body parenchyma emits Cerenkov photons in proportion with increasing proton energy. A proportionality constant, which relates the quantity of Cerenkov photon emission to absorbed dose, was determined for a primary proton beam. A polyenergetic proton beam was used to incorporate some energy dependence into the parameter. The Cerenkov light output was found to be an inadequate predictor of the Bragg peak location.

Characteristics Evaluation of Contact Lens in Vivo Ocular Dosimeter for Proton Therapy

J Son^{1*}, J Han², J Jeong³, S Jung³, C Choi¹, J Park¹, J Kim¹, (1) Department of Radiation Oncology, Seoul National University Hospital, Seoul, KR, (2) Biomedical Research Institute, Seoul National University Hospital, Seoul, KR, (3) Proton therapy center, National Cancer Center, Goyang-si Gyeonggi-do, KR

Purpose: The aims of this study were to investigate the characteristics of contact lens in vivo ocular dosimeter (CLOD) which directly measured the in vivo dose delivered by treatment beam in ocular tumor for proton therapy. **Methods:** The proton beam irradiation was carried out using IBA cyclotron PROTEUS 235 at National Cancer Center in Korea. CLOD was composed of biocompatible materials such as LiPCDA, Tartrazine and Sorta clear 40. It was analyzed using an EPSON Expression 10000XL scanner in reflective mode. The analysis of CLODs was used to RIT software (Radiological Imaging Technology, Inc., Colorado Springs, CO, USA). For characteristics evaluation, we had investigated the dose response for RGB channels, linearity, energy & dose-rate dependence, angular dependence and sensitivity. **Results:** For RGB channels, the red channel is the most sensitive one among the RGB channels. The results of linearity showed that the CLOD is linearly related to the irradiated dose in the range from 0 to 15 Gy. The energy response obtained for the 122.9, 159.9, 206.9 MeV/u were 0.2%, 1.6% and 1.6% compared to the 147.3 MeV/u. In the range from 1 to 5 Gy/min, the dose rate responses differ by up to 1.8% compared to the 3 Gy/min. The angular dependence normalized to the response at 0 obtained for different angle was also observed to be <2.0% for all angle. **Conclusion:** The CLOD has been proven to be an in vivo dosimeter which verify the delivered dose compared to the planned dose for proton therapy. The evaluation of dose characteristics in open field condition shows that the CLOD can be applied to an in vivo dosimeter for ocular tumor in proton therapy.

Validation of a Commercial Treatment Planning System for Small-Field Patient-Specific Apertures in Pencil Beam Scanning Proton Therapy

J Holmes^{1*}, J Shen¹, J Shan¹, W Wong¹, R Foote², S Patel¹, M Bues¹, W Liu¹, (1) Mayo Clinic, Phoenix, AZ, (2) Mayo Clinic, Rochester, MN

Purpose: Patient-specific apertures are increasingly being studied and developed for pencil beam scanning proton therapy. RayStationTM, a commercial treatment planning system, is capable of simulating apertures and has previously been validated for general use, however validation is needed for small fields with apertures. This work aims to validate the modelling of apertures with small openings in RayStationTM by comparison to in-water point-dose and film measurements and by cross-validation in patient geometries with MCsquare, an open source Monte Carlo dose calculation engine. **Methods:** The original MCsquare does not support apertures. We enhanced MCsquare to support apertures for cross-validating RayStationTM. Apertures with openings of 1,2,3,4, and 5 cm have been manufactured and used in the irradiation of proton beams in a water phantom. Two setups were used in the irradiation, one with a range shifter and the other without. The doses were measured in the phantom using point-dose detectors and films and were cross-validated by the enhanced MCsquare. We further cross-validated MCsquare and RayStationTM for 10 small-field treatment plans in patient geometries. **Results:** Comparing to the absolute point-dose in-water measurements, MCsquare differed by $1.8\% \pm 3.6\%$ while RayStationTM differed by $1.2\% \pm 1.0\%$. Compared to the in-water film measurements, MCsquare and RayStationTM both performed well with an average 2D Gamma passing-rate of 99.7% and 99.4% (3%/3mm) respectively. A t-test by comparing the film measurements' agreement to the calculation results between MCsquare and RayStationTM suggests that the dose distributions calculated by MCsquare and RayStationTM are statistically indistinguishable. Directly comparing the dose calculations between MCsquare and RayStationTM over 10 patients resulted in 3D Gamma passing-rates of 98.5% (3%/3mm) and 94.1% (2%/2mm) respectively, where the average target volume size was 8.3 cc. **Conclusion:** RayStationTM and the enhanced MCsquare were validated for small field dose calculation with patient-specific apertures in pencil beam scanning proton therapy.

Proton Modulation Technique But Not Acceleration Method Is Associated with Variations in Dose-Averaged Linear Energy Transfer

L Wilson*, V Moskvina, F Pirlapessov, A Faught, St. Jude Children's Research Hospital, Memphis, TN

Purpose: Although the association between proton linear energy transfer (LET) and biologic effectiveness is well established in vitro, this association is unclear in patients. Analyzing this association in clinical data is further complicated by confounding factors such as treatment delivery variations. We previously assessed the effect of proton modulation techniques on dose-weighted LET (LET(D)), but the contribution of different acceleration methods to LET(D) variability remained unknown. Therefore, the purpose of this study was to determine the extent to which proton acceleration methods affect LET(D). **Methods:** We used TOPAS Monte Carlo transport code to model the protons exiting medical cyclotrons and synchrotrons. We calculated the dose and LET(D) from a single proton beam incident on a virtual water phantom with three treatment delivery conditions: passively scattered (PS) protons from a cyclotron, pencil-beam-scanned (PBS) protons from a cyclotron, and PBS protons from a synchrotron. Treatment plans for all conditions matched the absorbed dose distributions. **Results:** Comparing the spatial LET(D) distributions revealed no significant difference between cyclotron- and synchrotron-based treatments with the same modulation technique in (IQR: [2.70, 4.20] keV/μm and [2.65, 4.12] keV/μm, respectively) or near (IQR: [11.89, 14.91] keV/μm and [11.55, 13.94] keV/μm, respectively) the treatment volume. LET(D) significantly differed between the modulation techniques but was unaffected by the acceleration method (average LET(D) ratio (PBS/PS): cyclotron 2.29 +/- 0.44; synchrotron 2.18 +/- 0.39). Furthermore, the spectral fluence incident on the water phantom was characterized by the modulation technique, with minimal variation with acceleration method. **Conclusion:** LET(D) is unaffected by different proton acceleration methods but is affected by modulation technique. These results suggest that multicenter studies aiming to elucidate the biologic effectiveness of proton therapy in patients can safely integrate data from synchrotron- and cyclotron-based systems but should exercise caution when considering data from different modulation techniques.

Investigate the Delivery Efficiency and Accuracy of Spot-Scanning Proton Arc (SPArc) in Comparison with Conventional IMPT, Automatic Step-And-Shoot Multifield IMPT

L Zhao*, G Liu, D Yan, X Li, X Ding, Beaumont Health System, Royal Oak, MI

Purpose: To quantitatively investigate the treatment delivery efficiency improvement using Spot-Scanning Proton Arc (SPArc) in comparison with automated step and shoot multi-field IMPT (IMPTauto) treatment and clinical IMPT treatment. **Methods:** Total 12 cases from the three disease sites such as head neck, lung and brain cancer were retrospectively selected. SPARC and IMPTauto plans were generated with the same plan objectives and robustness parameters like clinical IMPT. SPARC utilized a partial arc with 2.5 degree of sampling frequency and IMPTauto used beam angles 40 degree apart covering the partial arc trajectory. A dynamic arc controller is designed to connect the velocity between control points during SPARC and IMPTauto treatment delivery with the following machine configurations (maximal gantry rotation speed 5 degree/s; The maximal acceleration and deceleration are 0.6 degree/s² and 0.48 degree/s²; ±1 degree delivery tolerance window). Total treatment delivery time of each case was compared among SPARC, IMPTauto simulation and clinical treatment log files. 3D gamma index was used to evaluate the treatment delivery accuracy between SPARC and IMPTauto from the simulated dose reconstruction. **Results:** The SPARC and IMPTauto delivery accuracy is clinical acceptable with ±1 degree delivery tolerance window. The average 3D gamma index comparison showed 97.85± 2.77% passing rate for SPARC and 99.07±

0.73% for IMPTauto. Excluding the time spent on the initial patient setup and IGRT workflow, the SPARC could reduce the average treatment time to 175 ± 74 s compared to the clinical IMPT (641 ± 428 s) and IMPTauto (595 ± 254 s). In comparison with clinical IMPT, SPARC simplified the clinical treatment workflow by eliminating the time for each beam request, preparation, transfer time from OIS to delivery system and manually gantry rotation between each treatment field. In comparison with IMPTauto, SPARC effectively reduced the energy layers and spot number. **Conclusion:** SPARC technique could significantly simplify and improve the proton treatment workflow.

Hausdorff Distance Between Plan and Delivery Logs for Daily Treatment Quality Assurance

Y Hao*, B Sun, A Darafsheh, T Mazur, W Smith, T Zhang, T Zhao, Washington University School of Medicine, St. Louis, MO

Purpose: Intensity-modulated proton therapy (IMPT) provides better treatment quality than conventional radiotherapy at the cost of increased complexity. Parameters that could cause catastrophic consequences include energy, spot location, spot weight (MU), and leaf positions for some proton units. This work proposes a novel method for quality assurance (QA) of daily IMPT treatment records. **Methods:** This method was tested on a synchrotron unit equipped with adaptive apertures for shaper penumbra with layer-by-layer and spot-by-spot collimation. Four types of parameters were extracted from daily delivery logs and arranged into a 35-D Hausdorff space (HS), including 18 range shifter plates for energy layer, 14 leaves (7 pairs) for the adaptive aperture, 2 coordinates for spot position, and weight. A unitless weighted Hausdorff Distance (HD) was calculated between the planned and delivered HS for all pulses in a field. The weight of each dimension in the HS is based on the severity of any deviation. An automated report tool was developed to verify treatment records for all patients daily. **Results:** The tool reported deviations in delivery with HD larger than 5. Among the 42 fractions tagged by the tool in the last two months, 36 were not reported by our R&V system. Those errors have been analyzed, and none caused significant dosimetric concern. The analysis provides valuable information identifying the spot index, energy layer, and range shift plates involved in any fault to support repair and preventative maintenance. **Conclusion:** Our machine log file analysis can catch errors originating from data transfer problems, machine delivery issues, and other human mistakes. The dosimetric impact of these errors can be recomputed based on machine delivery conditions. The historic failure trends can assist in maintaining system operation at high efficiency.

TU-lePD-TRACK 5-07

A 3D Printed Phantom for Range Verification of Low-Energy Proton Fields

G Roe^{1*}, J Scholey², S St. James², (1) University of California-Davis, Davis, CA (2) University of California San Francisco, San Francisco, CA

Purpose: Range uncertainties have been identified as a major source of error in the delivery of proton radiation therapy. In recent years, tolerances for ranges in clinical proton beams have been proposed and are typically measured using either a scanning chamber in water or a dedicated multi-layer ion chamber. For small fields with range on the order of 3 cm, such as the ones used to treat ocular melanoma, these methods are not practical. To address this unmet need we designed and tested a phantom that can be used to quickly measure the range in these challenging conditions. **Methods:** 3D printed plastics were first evaluated to determine their water equivalent thickness (WET) in a 67.5 MeV proton beam. Once the WET was known, two phantoms were designed. The main component of the phantoms is water with the secondary component being the printed plastic. Both phantoms had a base of 2.5 cm, with either a cone of height 0.7 cm and base diameter of 2.3 cm, or a reverse cone of the same height and diameter. The phantoms were irradiated with a pristine 67.5 MeV proton beam with gafchromic film placed behind the phantom. The resulting 2 irradiations resulted in either a cold circle in the film center (cone) or a cold annulus (reverse cone). The diameter of the circles was related to the range of the measured proton beam. **Results:** The range measurements were less than 1 mm different from the measured range performed using a water column. **Conclusion:** The method presented here is robust and accurate and will be used in an updated Quality Assurance program for small fields with range less than 3 cm. Additional measurements will be performed to determine the sensitivity of this phantom to detect differences of ± 1 mm in range.

Imputation of Truncated Tumor Growth Data Via Bayesian Mixed Modelling

ML Bleile^{1,2*}, Yixun Xing^{2,3}, Casey Timmerman⁴, Dan Nguyen^{2,5}, Benjamin Chen⁵, Michael Story⁵, Robert Timmerman⁵, Debabrata Saha⁵, Steve Jiang^{2,5}, Daniel Heitjan^{1,6} (1) Southern Methodist University Statistical Science Department, Dallas, TX, (2) UT Southwestern MAIA lab, Dallas, TX, (3) Texas Wesleyan University Applied Statistics and Chemistry, Fort Worth, TX, (4) UT Southwestern Pathology, Dallas, TX, (5) UT Southwestern Radiation Oncology, Dallas, TX, (6) UT Southwestern Population and Data Sciences, Dallas, TX

Purpose: Dropout occurs when an experimental unit, on which one is taking serial measurements, becomes unavailable for further evaluation prior to the planned end of follow-up. A common instance of dropout is the removal of mice from tumor xenograft experiments, which occurs when the animals either naturally die or undergo sacrifice for morbidity. The unobserved tumor volumes from the lost animals are not, strictly speaking, missing, because the animals are no longer alive. Nevertheless, one approach to analyzing such studies is to treat these truncated data values as missing observations and apply techniques from the statistical modeling of dropout in longitudinal studies. We introduce a novel method for imputing the lost tumor volume values, as well as an R package that implements the method. **Methods:** Based on data of measured tumor volumes of mice at multiple prescribed times, we modeled the series of log tumor volumes for each mouse as a set of observations from a multivariate Gaussian distribution. We estimated this model using a Bayesian approach, and sampling values from the posterior distribution of the mean and variance. Using these, for each mouse with dropout we impute the counterfactual tumor volumes (i.e., sample from its predictive distribution), conditional on its observed sequence. We have implemented the method in an R package. **Results:** Plots of the imputed values reveal consistency with the trend of the observed data. Simulation revealed that the method captures true values reliably. Our R package, *tgmix*, is available on Github. **Conclusion:** We have created a computational tool which allows users to impute counterfactual values in longitudinal datasets with dropout. Further directions may include computational optimization of efficiency in implementation, more extensive tests of the method via simulation, and modification of the method to account for different types of dropout, potentially including nonignorable (biased) dropout.

Amplification of Reactive Oxygen Species Generation Under Gamma-Ray Irradiation for Gold Nanoparticle Mediated Radiation Therapy

N Charchi*, K Xie, A Ray, E Parsai, D Shvydka, University of Toledo Medical center, Toledo, OH P Nath, University of Toledo

Purpose: An approach of selective enhancement of the tumoricidal radiation effect with gold nanoparticles (AuNPs) have been successfully explored experimentally, both in-vivo and in-vitro. Significant amplification of reactive oxygen species (ROS) generation under irradiation in the presence of AuNPs is proposed as the main mechanism responsible for the biological effect. We have a two-fold purpose in this study: 1) finding a sensor suitable for quantitative characterization of ROS

species in both aqueous media and cell cultures; 2) establishing a reliable protocol for fluorescence measurements with the sensor. **Methods:** Radiolytic products such as hydroxyl radicals and hydrogen peroxide, generated under high-energy photon irradiation can be quantitatively characterized by fluorescence spectroscopy, providing a reliable sensor is identified. 2',7'-dichlorodihydrofluorescein diacetate (H2DCFDA) dissolved in DMSO (dimethyl sulfoxide) was used as a ROS sensor in experiments comparing radiolysis in pure water and 0.005mg/ml concentration AuNP solution (particle diameter 30nm, citrate coating). Samples in glass capillaries were irradiated under Ir-192 HDR treatment source (average energy ~380keV) to dose levels up to 100Gy. Fluorescence signal measurements were performed on irradiated samples within 1 hour after HDR treatment. **Results:** The fluorescence intensity signals were normalized to those of the 0Gy, used as control in each experiment. The signal intensity increased with the dose for both aqueous and AuNP solutions, demonstrating AuNP-mediated ROS enhancement above 30% for higher doses. The sensor was found suitable for aqueous media only after cleavage in cell culture. The concentration of AuNPs used in the study leads to negligible physical dose enhancement. The same sensor was used with cells, demonstrating strong fluorescence signal after irradiation. **Conclusion:** An experiment procedure for quantitative characterization of ROS species in both aqueous media and cell cultures using H2DCFDA was established and validated. Fluorescence signal enhancement is attributed to amplification in ROS production in presence of AuNPs.

TU-IePD-TRACK 6-03

Monte Carlo Simulation of Enhanced Free Radical Generation Due to Presence of Gold Nanoparticle Under High Energy Photon Irradiation

K Xie*, A Ray, D Shvydka, University of Toledo Health Science Campus, Toledo, OH

Purpose: Quantitative experimental characterization of free radical generation under high-energy photon irradiation, demonstrate enhancements in presence of gold nanoparticle (GNP). A concomitant free radical quenching effect leads to decreasing enhancement if nanoparticles are not precipitated immediately after irradiation. The two opposing effects are extremely difficult to decouple in experiment. In this study, Monte Carlo method is used to simulate those reaction processes in order to estimate the true amounts of free radicals generated in water radiolysis. **Methods:** An in-house developed Monte Carlo model is based on a series of interaction probabilities, of which some are fixed based on established reaction parameters, some are set to adjustable parameters varied until a modeled outcome approaches that acquired through experiments. Statistics of different pathways of free radicals are tallied and analyzed as the results. **Results:** Simulations for both pure water and GNP solutions were conducted to fit the measured data. Analysis of simulated data shows total amount of free radical generated with 30 nm diameter GNP in presence at 0.0005 mg/ml concentration is 265%±2% of that of pure water at all dose levels. About 37% of the free radicals are quenched by GNP. Excluding quenched, the ratio of released free radical is 159%±2%. The ratio of detected free radical amounts of two groups are dose dependent, similar to experimental result. **Conclusion:** With Monte Carlo simulations we can successfully estimate the actual total amount of free radicals generated with the presence of GNP, including the fraction quenched, which is not easily measurable through experiments. The total free radical generation enhancement due to GNP compared to pure water is much higher than can be detected. The decreasing enhancements vs dose is due to faster decline of sensor molecule concentration in the presence of GNPs.

TU-IePD-TRACK 6-04

Development of a Treatment Planning System for Preclinical Small Animal Irradiation with Intensity-Modulated Radiation Delivery Capability

D Kuksenok*, Y Lai², H Liu³, Y Zhong¹, C Shen¹, Y Gonzalez¹, X Jia¹, (1) UT Southwestern Medical Center, Dallas, TX, (2) University of Texas at Arlington, Arlington, TX, (3) Fox Chase Cancer Center, Philadelphia, PA

Purpose: Preclinical research on small animals pivots the discovery of novel radiotherapy techniques. Intensity-modulated radiation delivery (IMRD) – a gold-standard in clinical settings – still finds its way into small animal research. To circumvent this issue, we are developing a new generation irradiator that entangles IMRD via an automated rectangular collimator. This work elaborates on the ongoing development of the custom small animal irradiator with emphasis on the treatment planning system development. **Methods:** The developed in-house treatment planning system enables to accomplish the following tasks: load CT images, segment CT geometry into structures, define irradiation setup (isocenter, beam angles, etc.), simulate distribution dose for the forward or inverse radiation delivery using Monte Carlo (MC) simulations. Of note, the modulation of intensities is achieved via apertures of rectangular shapes by a motorized collimator. The x-ray focal-spot intensity map impacts the dose distribution; hence, we measured the x-ray projections of a tungsten ball bearing with the imaging detector available on our irradiator and determined the focal-spot intensity map via an optimization approach. The x-ray focal spot was modeled in our in-house GPU-based MC dose-calculation engine. For IMRD optimization, the problem was solved using the Direct Aperture Optimization algorithm. **Results:** The measured x-ray focal spot size was 1.62 × 1.50 mm² with an inhomogeneous intensity map. IMRD performance was assessed in comparison with the conformal radiation delivery that utilizes a fixed-size rectangular collimator. The evaluation was performed on two phantoms with the bony structure inside the PTV and a nearby C-shape organ. IMRD enabled reduction of the maximum dose in PTV from ~340% to ~230% when normalizing to PTV D95%, and organ D50% from ~117% to ~63%. **Conclusion:** We developed a treatment planning system for IMRD to support preclinical small animal radiation research. Integration with hardware is currently in progress.

This work is supported through the NCI grant # R37CA214639.

TU-IePD-TRACK 6-05

Hesperetin Enhances Radiotherapy of Human Lung Cancer Cells

A Fam¹*, W Ngwa², G Makrigiorgos³, S Yasmin-Karim⁴, (1) Northeastern University, Boston, MA, (2) Brigham and Womens Hospital, Boston, MA, (3) Dana Farber Cancer Institute, Boston, MA, (4) Harvard Medical School, Boston, MA

Purpose: Lung cancer is the leading cause of cancer death in the United States and new/improved treatment options are needed. Recent studies show that flavonoids like Hesperetin can bind strongly to the ACE2 receptors abundant on lung cancer cells. We hypothesize that hesperetin, a naturally occurring major flavonoid, inhibits the progression of lung tumor cells and amplifies damage to tumors during radiotherapy. **Methods:** In-vitro survival studies were performed in A549 human lung cancer cell line (adenocarcinoma human alveolar basal epithelial cells) to compare cells treated with hesperetin, with and without radiotherapy vs. controls. Cells were treated with 5 to 100 ug/ml of hesperetin, with and without radiation treatment. Radiation doses of 2, 4, 6, and 8 Gy were delivered via a Small Animal Radiation Research Platform (SARRP). The cells were treated with 0, 25, 50, 75, and 100 ug/ml of Hesperetin concentrations. The survival, toxicity, and cell viability were analyzed using clonogenic death assays. **Results:** Our data show that radiation enhances the effects of hesperetin treatment on human lung cancer cells A549 by reducing the colony-forming ability when cells are seeded in 6-well plates with 400 cells in each well. Irradiation with 2Gy photons demonstrated complete inhibition of colony growth when combined with at least 25 ug/ml of hesperetin treatment. Substantial colony-forming ability was observed via treatment of up to 50 ug/ml concentration hesperetin solution. However, a single treatment of Hesperetin of 75 ug/ml concentration or higher was enough to kill all plated cancer cells in 7 days. **Conclusion:** Radiation demonstrates enhancement of the anti-tumor effect of Hesperetin. The results justify additional studies in-vivo, including delivery with Hesperetin-loaded nanoparticles ('drones') to target lung cancer during radiotherapy.

TU-IePD-TRACK 6-06

Monte Carlo Dose Calculations for Radiobiology Studies

C Mahuvava¹*, N Espen², S Kry³, M Bazalova-Carter⁴, (1) University of Victoria, Victoria, British Columbia, CA, (2) University of Victoria, Victoria, BC, CA, (3) University of Texas MD Anderson Cancer Center, Houston, TX, (4) University of Victoria, Victoria, BC, CA

Purpose: To provide small-animal percentage depth-dose (PDD) data as a function of source-to-skin distance (SSD), field size (FS) and animal size (AS) in order to

translate experimentally-measured TG-319 skin dose to the dose at target depth. **Methods:** The x-ray tube designs for two biological irradiators, the RT250 and the PXi XRAD-320, were simulated using the BEAMnrc Monte Carlo (MC) code to generate 200 and 320kVp photon beams, respectively. The 320 kV beam was simulated with two filtrations: a soft F1 aluminium filter and a hard F2 filter made of aluminium, tin and copper. Beams were collimated into circular fields of 0.5–10cm in diameter at SSDs of 10–60cm. MC dose calculations in 1–5cm diameter homogeneous small-animal phantoms as well as in heterogeneous phantoms with 3-mm diameter cylindrical bone inserts were performed using DOSXYZnrc. The depth doses in three simulated test-cases were estimated by applying SSD, FS and AS correction factors to a reference case (40cm SSD, 1cm FS and 5cm AS) and comparing the results with the simulated doses to assess the accuracy of dose estimation. **Results:** The depth doses for three test-cases calculated at 200, 320 F1 and 320 F2 kVp agreed well with simulated doses, yielding dose differences of 1.4, 0.1 and 1.0%, respectively. Dose enhancement on the bone-tissue proximal interface ranged from 1.2 to 2.5 times the dose in the absence of bone for rib and 1.3 to 3.7 times for cortical bone, whilst the dose drop-off at 1cm depth behind the bone ranged from 1% to 6% for rib and 3% to 12% for cortical bone. **Conclusion:** The developed dose estimation method can be used to translate TG-319 measured skin dose to dose at any depth.

This research was funded by the Natural Sciences and Engineering Research Council (NSERC) and the Canada Research Chair program.

TU-IePD-TRACK 6-07

Radiotherapy Enhanced by Cherenkov Photo-Activation in a Novel Rat Brain Slice Model

R Holden*, A Lynnette Price, J Park, D Dunn, S Floyd, M Oldham, Duke University Medical Center, Durham, NC

Purpose: RECA (Radiotherapy Enhanced by Cherenkov photo-Activation) is a novel treatment with potential to add an anti-cancer immunogenic component through Cherenkov activation of a photo-chemotherapeutic (psoralen). Here we investigate RECA in a novel tissue representative in-vitro model consisting of 4T1 murine cancer cells grown on thin slices of viable rat-brain tissue. **Methods:** Six, 12-well-plates, each containing 1cm of agarose supporting a 400 μ m thick coronal slice of viable rat brain tissue were created. Each plate corresponded to an arm of an experiment incorporating the psoralen derivative 4'-aminomethyl trioxsalen (AMT): MV control, MV+AMT, no-irradiation control, and AMT-alone control. 20,000 4T1 cells expressing both mCherry-flourescent and firefly luciferase-luminescent reporter proteins were plated on each rat brain slice hemisphere. The MV arms received ~4 Gy from a 15 MV Varian linear accelerator beam. Images were taken of the plates each day for 5 days, including filtered for mCherry signal. An optimized CellProfiler pipeline quantified cell colony survival and growth. A luciferase assay was done on day 5 as another measure of relative viability. **Results:** The brain slice model was assessed daily, and found viable for supporting 4T1 cell colony growth for up to 5 days. The optimized CellProfiler colony counting pipeline was validated in simulations, and found to have excellent performance, also enabling uncertainty estimation. Integrated intensity analysis of mCherry signal revealed a significant decrease in tumor proliferation by day 5 between the MV control (5.65 ± 0.78 -fold growth) and MV+AMT (3.49 ± 0.52 -fold growth) arms. This result is consistent with psoralen activation in the MV+AMT arm. The growth observed in the Dark control arm was consistent with the 13.6 ± 1.5 hour doubling time for 4T1 cells. **Conclusion:** The early results from ongoing experiments are consistent with psoralen activation and cell kill in RECA treated cells (MV+AMT arm). Further work will be presented to fully quantify the effect.

Audience Q&A and Feedback

Medical Physics is a Physics specialty with documented inequities with regards to gender and race. Currently, data is being collected to better understand the proportion of underrepresented scientists in the field and their experiences in the workplace and within the AAPM. To that end, the AAPM has created the Ad Hoc Committee on Equity, Diversity and Inclusion (AHCDI) to address equity, diversity and inclusion (EDI) goals and to make recommendations to improve the experience of diverse members in the AAPM. This session will explain what EDI is, will discuss the EDI goals of AAPM, and will highlight the achievements and data collection and metrics organized by AHCDI, the AAPM Diversity and Inclusion subcommittee (WMRSC) and the Women's Professional Subcommittee (WPSC). It is important for AAPM members to understand the purpose of the data collected in the 2021 AAPM EDI Climate Survey and through other means as baseline data, and the benefit of tracking EDI metrics for our membership. This workshop will establish a sense of transparency regarding AAPM EDI goals and provide opportunity for feedback from membership to leadership, AHCDI, WMRSC and WPSC, in order to further improve AAPM EDI efforts.

Learning Objectives:

1. Define EDI terms
2. List current and upcoming EDI efforts
3. Describe recently collected EDI data
4. Provide feedback to leadership and involved committees related to EDI efforts

Audience Q & A

Novel breast imaging technologies are increasingly becoming part of routine clinical practice, including contrast-enhanced mammography, molecular breast imaging, and emerging breast ultrasound applications. The goal of this education symposium is to prepare and familiarize the medical physicist with these new modalities. For each modality, clinician and physicist presenters team up to discuss clinical applications and utility, as well as basic physics principles and quality-control procedures. This will allow the medical physicist to gain a thorough understanding of the clinical use, potential pitfalls, and will help them establish and implement a quality control program.

Learning Objectives:

1. To understand clinical utility of novel breast imaging technologies
2. To become familiar with the physics principles of each modality
3. To be able to implement quality control procedures for each modality

Q&A & Panel Discussion

Quantitative SPECT is an emerging technology that incorporates standardized uptake values (SUV) and/or activity concentration information to conventional SPECT/CT imaging. In this session we will report on the technical developments that have enabled quantitative SPECT and provide context for understanding its capabilities and limitations. The current role of SPECT/CT for radionuclide treatment planning and external beam treatment planning will be presented through clinical examples with a focus on value and limitations.

Learning Objectives:

1. To learn about the technical developments in terms of acquisition and processing that enabled the evolution of SPECT from qualitative to quantitative imaging
2. To learn about the application of SPECT in radionuclide and external-beam treatment planning

An Imaging Based Biological Framework for Personalizing Radiation Therapy of Lung Cancer Using Interpretable Bayesian Networks and NTCP-Based Treatment Planning

A Ajdari^{1*}, T Bortfeld², (1) Harvard Medical School & Massachusetts General Hospital, Boston, MA, (2) Massachusetts General Hospital, Boston, MA

Purpose: To develop a biological framework for adapting radiation therapy (RT) treatment plans of lung cancer patients by integrating functional imaging, machine learning, and convex optimization. **Methods:** Seventy-four non-small cell lung cancer (NSCLC) patients treated with passive scattered proton (PSP, n=28) and intensity modulated RT (IMRT, n=46) were retrospectively analyzed. Baseline and mid-treatment [18F]-fluorodeoxyglucose (FDG) positron emission tomography (PET) imaging information was integrated with clinicopathological/dosimetric information to estimate the patient-specific response. A novel Bayesian Network (BN)

was trained and validated for predicting grade2+ radiation pneumonitis (RP) at three months post-RT. BN predictions were used to estimate an individualized normal tissue toxicity probability (NTCP) function for each patient. The updated NTCP functions were then integrated in the RT inverse optimization and a convex optimization algorithm was developed to solve the resulting problem. The framework was tested on 20 patients (PSP, n=10; IMRT, n=10) to optimally adapt the dose distribution according to mid-treatment biological information. **Results:** BN model was able to predict the RP risk with an AUC of 0.82 (95% CI=[0.72-0.91]). The treatment plans for 17 patients (85%) were adapted to keep the updated RP risk below 20% (9 in PST and 8 in IMRT groups). Treatment plans for patients whose predicted RP risk exceed the predefined threshold were de-escalated (n=14, average target dose reduction = 5.4Gy). Patients with predicted NTCP lower than 20% saw an increase in average tumor dose after RT adaptation (n=6, average target dose increase = 4.1Gy). Overall, 17% decrease in predicted RP risk was achieved using the proposed methodology (SD=7.4%). No difference between PSP and IMRT groups were observed in terms of RP risk prediction or plan adaptation. **Conclusion:** Mid-treatment adaptation could significantly lower the risk of RP without compromising tumor control. The proposed methodology could help the design of personalized clinical trials for NSCLC patients.

BEST IN PHYSICS (MULTI-DISCIPLINARY): Focused KV X-Rays for Radiotherapy and Imaging of Small Targets

W Liu^{1*}, N R Bennett¹, Y Li¹, L Shi¹, Z Zhang¹, H Yan², W Sun³, E Graves¹, L Xing¹, C MacDonald³, A Wang¹, (1) Stanford University, Stanford, CA, (2) Capital Medical University, Beijing, China, (3) University of Albany, SUNY, Albany, NY

Purpose: Radiotherapy machines deliver intrinsically divergent x-ray radiation, requiring collimation to a diseased region. The penumbra and power efficiency limit the minimal size of the field to ~5 millimeters for conventional photon and charged particle beams. Therefore, many medical conditions that may be responsive to local radiation cannot be effectively treated because of their small size and susceptibility to intolerable collateral damages to surrounding critical organs. To overcome the fundamental issues of collimated radiation, we are developing a focused kV technique based on novel usage of polycapillary x-ray lenses, which can focus x-ray beams to <0.2 mm in diameter with a dose peak well below the skin region. **Methods:** Unlike diffraction lenses, polycapillary optics are broadband, based on total external reflection. We simulated the optics using Monte Carlo (MC)-based ray tracing. Multi-arc scanning was simulated to deliver highly conformal radiation treatment to 3 types of small targets of a few millimeters size. Because the lens output focal spot is smaller than the x-ray tube focal spot, we also used the lens output focus as a virtual x-ray source to acquire phantom and rat head x-ray and CBCT images (60 kVp) to demonstrate improved resolution. **Results:** The simulated beam dosimetric characteristics were verified by EBT3 film measurements within 10%. MC simulated treatments of choroidal melanoma and age-related macular degeneration demonstrated more conformal target coverage and substantially reduced critical structure doses compared to standard treatments. Simulations also demonstrated irradiating 1-2 mm neurofunctional regions in rat heads with sharp penumbras. CBCT of a thin wire showed 33% reduction of the FWHM of a reconstructed wire with vs without lens. CBCT of a rat head could distinguish ~0.3mm fine bony structure with lens, but not without. **Conclusion:** Focused kV x-ray technique offers the capability of treating mm size targets and improved x-ray imaging resolution.

TU-EF-TRACK 4-03

Biologically Guided Deep Learning for Post-Radiation PET Image Outcome Prediction: A Feasibility Study of Oropharyngeal Cancer Application

C Wang^{1*}, H Ji², A Bertozzi², D Brizel¹, Y Mowery¹, F Yin¹, K Lafata¹, (1) Duke University Medical Center, Durham, NC, (2) University of California, Los Angeles, Los Angeles, CA

Purpose: To develop a method of biologically guided deep learning for post-radiation ¹⁸FDG-PET image outcome prediction based on pre-radiation images and radiotherapy dose information. **Methods:** Based on the classic reaction-diffusion mechanism, a novel biological model was proposed using a partial differential equation that incorporates spatial radiation dose distribution as a patient-specific treatment information variable. A 7-layer encoder-decoder based convolutional neural network (CNN) was designed and trained to learn the proposed biological model. As such, the model could generate post-radiation ¹⁸FDG-PET image outcome predictions with possible time-series transition from pre-radiotherapy image states to post-radiotherapy states. The proposed method was developed using 64 oropharyngeal patients with paired ¹⁸FDG-PET studies before and after 20Gy delivery (2Gy/fx) by IMRT. In a two-branch deep learning execution, the proposed CNN learns specific terms in the biological model from paired ¹⁸FDG-PET images and spatial dose distribution as in one branch, and the biological model generates post-20Gy ¹⁸FDG-PET image prediction in the other branch. As in 2D execution, 718/233/230 axial slices from 38/13/13 patients were used for training/validation/independent test. The prediction image results in test cases were compared with the ground-truth results quantitatively. **Results:** The proposed method successfully generated post-20Gy ¹⁸FDG-PET image outcome predictions and the associated time-series evolutions with breakdown illustrations of biological model components. SUV mean values in ¹⁸FDG high-uptake regions of predicted images (2.45±0.25) were similar to ground-truth results (2.51±0.33). In 2D-based Gamma analysis, the median/mean Gamma Index (<1) passing rate of test images was 96.5%/92.8% using 5%/5mm criterion; such result was improved to 99.9%/99.6% when 10%/10mm was adopted. **Conclusion:** The developed biologically guided deep learning method achieved post-20Gy ¹⁸FDG-PET image outcome predictions in good agreement with ground-truth results. With break-down biological modelling components, the outcome image predictions could be used in adaptive radiotherapy decision-making to optimize personalized plans for the best outcome in future.

TU-EF-TRACK 4-04

Computing Dose to Circulating Blood Cells Using Whole-Body Blood Flow Simulations

J Shin^{1*}, S Xing¹, A Hammi¹, J Pursley¹, C Correa Alfonso², J Withrow², S Domal², W Bolch², H Paganetti¹, C Grassberger¹, (1) Mass General Hospital and Harvard Medical School, Boston, MA (2) University of Florida, Gainesville, FL

Purpose: To develop a time-dependent computational method to estimate dose to circulating blood from radiation fields for any treatment site. **Methods:** Two independent dynamic models were implemented: one describing the spatiotemporal distribution of blood particles (BPs) in organs and a second describing the time-dependent radiation field delivery. A whole-body blood flow network based on blood volumes and flow rates from ICRP Publication 89 was simulated to produce the spatiotemporal distribution of BPs in organs across the entire body using a discrete-time Markov process. Constant or time-varying transition probabilities were applied to the Markov process and their impact on transition time was investigated. The impact of treatment time and different anatomical sites was investigated using a liver and brain cancer patient. The impact on the blood dose-volume histograms (bDVHs) was assessed using bDVH metrics (V0Gy, V0.05Gy, D2%). **Results:** Simulations revealed different dose levels to the circulating blood for brain compared to liver even for similar field sizes due to the different blood flow properties of the two organs. For the constant probability model, the volume of blood receiving any dose (V0Gy) after a single radiation fraction increases from 1.2% for 1s delivery time to 25.8% for 120s for brain and from 10% (1s) to 55.8% (120s) for liver, respectively. With time-dependent probability, V0Gy increases from 1.2% to 20.9% for brain and from 10% to 48.7% for liver, respectively. Changes in V0.05Gy show a similar pattern, while D2% decreases with longer delivery time. Unexpectedly, delivering the dose using a realistic time structure for every field only changes the bDVH negligibly compared to delivering the entire dose distribution over the treatment time. **Conclusion:** This publicly available framework estimates patient-specific dose to circulating blood cells based on organ DVHs and enables studying the impact of different treatment plans, dose rates, and fractionation schemes.

Deep Learning-Based Framework for the Assessment of Radiation Dermatitis in Nasopharyngeal Carcinoma (NPC) Patients

R Ni^{1*}, G Ren¹, V Tam¹, Z Dai², X Wang³, S Lee¹, J Cai¹, (1) The Hong Kong Polytechnic University, Hong Kong, China, (2) Guangdong Provincial Hospital of Chinese Medicine, Guangzhou, 44, CN, (3) The Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, 44, CN

Purpose: Radiation dermatitis (RD) is a common, unpleasant side-effect of patients receiving radiotherapy. Its severity is graded manually through visual inspection in clinical practice, which is resource-demanding and leads to inter-rater variation. To overcome this difficulty, this study aims to develop an end-to-end automatic RD grading framework based on deep learning (DL) techniques. **Methods:** A dataset of 1120 photographs of the head and neck region was built for NPC patients undergoing radiotherapy. These photographs were graded by qualified assessors based on Radiation Therapy Oncology Group (RTOG) guidance. We further classified RD Grade 0&1 as mild cases and RD Grade 2 and above as severe cases. An end-to-end RD grading framework was developed by combining DL-based segmentation and RD severity classification models. Models were trained separately for the front and side view. First, the neck region was segmented from the camera-captured photographs via U-Net. Secondly, a convolutional neural network (CNN) classifier (VGG16-BN with pretrained) was applied to the segmented region for RD severity classification. The performance of the proposed DL methods was qualitatively and quantitatively evaluated for both segmentation and classification parts. **Results:** Preliminary results of segmentation showed that the averaged Dice Similarity Coefficients (DSCs) were 91.2% and 90.8% for front and side view, respectively. For RD severity classification, the overall accuracy of 111 test photographs was 93%. Our method accurately classified 94% (82/87) of the mild cases and 92% (22/24) of the severe cases. Mild cases were predicted with precision of 0.98, recall of 0.94 and F1-score of 0.96; severe cases with precision of 0.81, recall of 0.92 and F1-score of 0.86. **Conclusion:** We demonstrated a DL-based end-to-end framework for automatic grading of RD severity in NPC patients. This method holds great potential to facilitate the monitoring and management of RD in NPC patients and improve patients' quality of life.

TU-EF-TRACK 4-06

Patient-Specific Deep Learning-Based Self-High-Resolution for MR Imaging

Y Lei^{*}, J Roper, E Schreiebmman, H Mao, J Bradley, T Liu, X Yang, Emory Univ, Atlanta, GA

Purpose: High-resolution (HR) magnetic resonance imaging (MRI) is desirable in many clinical applications, but there is a trade-off between image resolution and acquisition time. HR generation methods may yield fine details from fast acquisitions; however, most current methods attempt to solve this ill-posed problem using external atlases to derive the transformation from low-resolution (LR) to HR images. In this study, we propose a deep-learning-based self-HR method, which instead generates HR images directly from a patient's thick-cut MRI. **Methods:** We propose a new deep-learning-based, patient-specific method using a self-HR framework. Two LR-to-HR deep-learning models are pre-trained on HR in-plane images from a training dataset and then are fine-tuned on each test patient's in-plane images. To generate HR through-plane MR images for a test patient, the LR sagittal and coronal images are input into the trained model, and the resulting HR MRIs are fused together to obtain a HR 3D MRI. This technique was validated across 50 clinical datasets of multimodal MRIs: Flair, T1-weighted contrast and T2-weighted images. The native HR images were used as the ground truth for evaluating resolution recovery from down-sampled images. **Results:** The normalized mean absolute error (NMAE) and peak-signal-to-noise-ratio (PSNR) were calculated between the generated and original HR images. The LR data was obtained via down-sampling the MRI in z-axis. The down-sampling factor was set to 3. Overall, the mean NMAE and PSNR were 0.019±0.005 and 32.1±1.6 dB for Flair, 0.018±0.005 and 32.4±1.5 dB for T1c, and 0.015±0.003 and 33.7±1.1 dB for T2, which demonstrated the accuracy of the proposed method. **Conclusion:** We have proposed a patient-specific deep learning-based self-HR method to derive high through-plane resolution MR images and validated its feasibility. This proof-of-concept study shows potential to improve image resolution without any high through-plane resolution MR data and its self-HR capability could have broad clinical applications.

TU-EF-TRACK 4-07

Spatiotemporal Dose Characterization of An Electron FLASH Beam from a LINAC Using Radioluminescence and Cherenkov Imaging

M Rahman<sup>^{1*}, M Ashraf¹, R Zhang^{1,2,3}, D Gladstone^{1,2,3}, X Cao¹, B Williams^{1,2,3}, J Hoopes^{1,2,3,4}, B Pogue^{1,3,4}, P Bruza¹, (1) Thayer School of Engineering, Dartmouth College, Hanover, NH, (2) Department of Medicine, Radiation Oncology, Geisel School of Medicine, Dartmouth College, Hanover, NH, (3) Norris Cotton Cancer Center, Dartmouth-Hitchcock Medical Center, Lebanon, NH, (4) Department of Surgery, Geisel School of Medicine, Dartmouth College, Hanover, NH

Purpose: Spatiotemporal pulse to pulse beam profile for an ultra-high dose rate (UHDR, >40Gy/s) electron FLASH (eFLASH) irradiator was characterized via Cherenkov emission and radioluminescence imaging using iCMOS cameras. **Methods:** Cameras time-gated to the delivered clinical LINAC pulses, imaged radioluminescence and Cherenkov emission signals incited by single pulses of 10MeV eFLASH irradiation at the treatment room isocenter. The two cameras imaged the entrance Cherenkov emission from a solid water phantom surface or scintillation from a screen on top of the phantom and the projected depth profile from a tank filled with water or quinine sulfate solution. A 450nm peak bandpass filter was considered for improving imaged depth profiles. The optical results were compared to lateral profiles measured by Gafchromic film at varying depths including the surface. **Results:** The per pulse beam output, from Cherenkov imaging, agreed with the photomultiplier tube (PMT) Cherenkov output to within 3%, after the first ~5-7 ramp-up pulses. In comparison to film measurements, Cherenkov emission and scintillation images were dose rate independent to >300Gy/s and linear with dose ($R^2=0.987, 0.995$, respectively). The surface dose profiles from film agreed more with scintillation than Cherenkov emission imaging (3%/3mm gamma pass rate of 98.9% and 88.8% respectively). A 450nm bandpass filter improved the quinine sulfate-based water images of the projected depth optical profiles to match projected film dose within 5%. **Conclusion:** The cameras resolved dose profiles of the UHDR beam with a single pulse (60Hz) temporal and 1mm spatial resolution. The agreement of scintillation screen imaging with film measured dose suggests it can accurately confirm the consistency of the beam's parameters for quality assurance. The cross validation of Cherenkov images with PMT temporal profile of each pulse suggest it can monitor beam output but required its optical filtering to acquire accurate dose via quinine sulfate-based water imaging.

TU-EF-TRACK 4-08

Thermoacoustic Range Verification During Pencil Beam Delivery of a Clinical Plan to An Abdominal Imaging Phantom

S Patch<sup>^{1*}, C Nguyen², M Cohilis³, K Souris⁴, J Lambert⁵, S Ono⁶, T Lynch⁷, G Janssens⁸, R Labarbe⁹, (1) UW-Milwaukee, Milwaukee, WI, (2) Uw-milwaukee, (3) University catholique de Louvain, Bruxelles, , BE, (4) UCL, Brussels, , BE, (5) The Rutherford Cancer Centres, , (6) Computerized Imaging Reference Systems, Inc, , (7) CIRIS, Norfolk, VA, (8) Ion Beam Applications SA, Louvain-la-neuve, BE, (9) Ion Beam Applications (IBA), Louvain-la-neuve, BE

Purpose: The purpose of this phantom study is to demonstrate that thermoacoustic range verification could be performed clinically. Thermoacoustic emissions generated in an anatomical multimodality imaging phantom during delivery of a clinical plan are compared to simulated emissions to estimate range shifts compared to the treatment plan. **Methods:** A single-field 12-layer proton pencil beam scanning (PBS) treatment plan created in Pinnacle prescribing 6 Gy/fraction was delivered by a superconducting synchrocyclotron to a triple modality (CT, MRI, and US) abdominal imaging phantom. Data was acquired by four acoustic receivers rigidly affixed to a linear ultrasound array. Acoustic receivers (transducer + amplifier) were tuned to this application provided 15-25 dB amplification relative to 1 mV/Pa over 10-100 kHz. Receivers 1-2 were located distal to the treatment volume, whereas 3-4 were lateral. Receivers' room coordinates were computed relative to the ultrasound image plane after co-registration to the planning CT volume. For each prescribed beamlet, a Monte Carlo simulation of the energy density provided initial pressure from which simulated emissions were computed. To overcome the diffraction limit, range estimates were computed by comparing measured to simulated emissions. **Results:** Shifts were small for high-dose beamlets that stopped in soft tissue. Signals acquired by channels 1-2 yielded shifts of -0.2 ± 0.7 mm relative to Monte Carlo simulations for high dose spots (~40 cGy) in the second layer. Additionally, for beam energy ≥ 125 MeV, thermoacoustic emissions qualitatively tracked lateral motion of pristine beams in a layered gelatin phantom, and time shifts induced by changing phantom layers were self-consistent within

nanoseconds. **Conclusion:** Acoustic receivers tuned to spectra of thermoacoustic emissions may enable range verification during proton therapy. Improving receive sensitivity by another 20 dB could enable range verification during delivery of a standard 2 Gy fraction.

TU-EF-TRACK 4-09

Thoracic 4D Cone-Beam CT Registration Incorporating a Fan-Beam CT-Derived Feasible Motion Descriptor

Y Sang*, D Ruan, Department of Radiation Oncology and Department of Bioengineering, University of California, Los Angeles, CA

Purpose: Cone-beam CTs (CBCTs) are readily available for on-table acquisition in companion with treatment and have lower imaging dose compared to fan-beam CTs (FBCTs). Deformable registration between phases in a 4D-CBCT can potentially provide on-table 4D volumetric information of target location and motion. However, CBCT registration is very challenging due to strong artifacts and the lack of structural details. In this study, we aim to develop an enabling approach for thoracic 4D CBCT registration. **Methods:** We propose a novel approach to incorporate a learned implicit regularizer as a feasibility prior of respiratory motion, into the training of an unsupervised image registration network to improve registration accuracy and robustness to noise and artifacts. Specifically, a feasibility descriptor from a set of deformation vector fields (DVs) is first generated from FBCTs. Subsequently, this FBCT-derived feasibility descriptor was used as a spatially variant regularizer on DVF Jacobian during the unsupervised training for 4D-CBCT registration. In doing so, the higher-quality, higher-confidence information from FBCT is transferred into the much challenging problem of CBCT registration, without explicit FB-CB synthesis. The method was evaluated using manually identified landmarks on five real CBCTs and automatically detected landmarks on nine simulated CBCTs. **Results:** The method presented good robustness to noise and artifacts and generated physically more feasible DVFs. The target registration errors on the real and simulated data were (1.63 ± 0.98) and (2.16 ± 1.91) mm, respectively, significantly better than the classic bending energy regularization in both the conventional method in SimpleElastix and the unsupervised network. The average registration time was 0.04 s. **Conclusion:** The proposed method imposes a strong and robust motion feasibility prior and enhances registration networks' resistance against undesired image qualities. It demonstrates the strength of a learned and implicit feasibility prior, in comparison to the pre-defined regularization energies.

TU-EF-TRACK 4-10

Toward Magnetic Resonance Fingerprinting for Low-Field MR-Guided Radiation Therapy

N Mickevicius*, Z Morris, C Glide-Hurst, University of Wisconsin-Madison, Madison, WI

Purpose: Magnetic resonance fingerprinting (MRF) unlocks incredible potential for efficient multi-parametric quantitative MRI. When coupled with MR-guided radiation therapy, MRF will push new boundaries for online functional plan adaptation. This work establishes the feasibility of MRF on a 0.35T MR-linac and introduces a novel deep learning-based method to improve quantitative parameter precision from clinically feasible MRF scan times. **Methods:** MRF was benchmarked on a 0.35T MR-linac in the NIST/ISMRM System quantitative phantom. Gold standard multi-inversion recovery and multi-echo spin echo scans were acquired to derive reference quantitative T_1 and T_2 maps. A fully sampled MRF was designed and acquired in ~20 minutes. MRF-derived T_1 and T_2 times were compared to gold standard via linear regression and mean percent error. To assess the impact of accelerating MRF, the fully sampled dataset was undersampled to three radial k-space spokes/frame (28 seconds). Two acceleration approaches were tested: (1) uniformly spaced spoke angles with a linear reconstruction, and (2) spoke angles determined by a neural network with a deep learning regularized reconstruction. T_1 and T_2 times from both acceleration approaches were compared to fully sampled MRF using paired t-tests. **Results:** Fully encoded MRF at 0.35T yielded precise T_1 and T_2 estimates relative to gold standard (mean percent errors of 4.65% and 8.24%, respectively) and correlation coefficients >0.996 . Acceleration approach (1) produced T_1 and T_2 times different from those measured with the full 21-minute MRF scan ($p=0.009$ and $p=0.013$, respectively). The deep learning acceleration approach produced similar estimates for T_1 and T_2 ($p=0.121$ and $p=0.363$, respectively). **Conclusion:** These encouraging results suggest that MR fingerprinting is feasible at 0.35T and, when coupled with deep learning-assisted acceleration, accurate MRF can be performed efficiently. Future work will optimize MRF for in vivo quantitative imaging, thereby opening the door for subvolume tumor targeting and treatment response assessment.

Abdominal Flash Proton Irradiation Does Not Benefit the Intestine

Q Zhang*, E Cascio, Q Yang, I Gerweck, P Huang, A McNamara, W Sung, J Schuemann, Department of Radiation Oncology, Massachusetts General Hospital and Harvard Medical School, Boston, Massachusetts, USA, Boston, MA

Purpose: Abdominal Flash irradiation has been reported to spare the intestinal tissue, while some other reports suggested no gastrointestinal benefit was gained. In the present study, we plan to investigate the potential effect of Flash proton irradiation on the intestine. **Methods:** A homogenous elliptical field of 1.2×1.6 cm² was obtained through the established Flash proton platform to cover 60~80% of the whole abdomen. The MRI scanning was conducted before irradiation and the mice were fixed on a designed holder to receive a single dose of 13.8 Gy, 16 Gy, 16.2 Gy, or 17.5 Gy. The dose rate of Flash irradiation was ~120 Gy/s and the one for the conventional dose rate (CDR) group was ~0.36 Gy/s. The Ki67 immunofluorescent staining of the intestine tissue was performed at 7 days and 14 days after irradiation. For the late effect, the mice were kept for as long as 210 days for the weight detection. **Results:** Higher survival fraction of the mice was observed after 16 Gy conventional dose rate proton irradiation. There was no significant survival difference between the Flash and CDR groups after 17.5 Gy exposure. The Ki67 staining showed that the ratio of the proliferating cells in the crypts recovered at 7 days in both 13.8 Gy Flash and CDR groups. Compared with the 16.2 Gy CDR group, the long-term weight monitoring indicated more severe weight loss in the Flash group with the corresponding dose. **Conclusion:** No benefit of Flash proton irradiation was gained after partial abdominal exposure. There should be some undiscovered physical and biological factors that impact the Flash effect on the intestine if it does exist.

Analysis of Proton Inter-Track Interactions at Ultra-High Dose Rates

S Thompson*, K Prise, S McMahon, Queen's University Belfast, Belfast, GB

Purpose: Laser-accelerated ultra-high dose rate proton therapy offers dose rates on the order of 10^9 Gy/sec. Such dose rates reduce delivery to nanosecond timescales, equivalent to the lifetime of chemical species within a biological medium. This means reactive chemical species from individual tracks could interact and recombine, and tracks can no longer be considered independently. This work investigated the temporal evolution of chemical species for a range of proton LETs to quantify inter-track interactions. **Methods:** The TOPAS-nBio Monte Carlo toolkit was used to find the radial dimensions of proton tracks from 1 MeV to 100 MeV between 1 ps to 1 μ s timepoints, defined as the radius which contained 80% of the physical and chemical interactions. From this, the likelihood of interaction was calculated using the geometric probability of incident track areas overlapping as a function of dose, time and LET. **Results:** Track radius ranged from 50 to 254 nm, increasing with diffusion time after irradiation, and falling with LETs above 2 keV/ μ m. Physical inter-track effects were rare at clinical doses, with a probability of 32% for 2 Gy of 100 MeV protons, falling to 0.4% for 1 MeV protons due to reduced fluence and track area. Radiochemical overlap probabilities at 1 μ s were larger due to diffusion, with over 90% overlap probability predicted for 80 and 100 MeV protons. However, when considering the reduced lifetime of chemical species in cells due to biological scavenging, the likelihood of inter-track effects remains small, with a maximum probability of 29% for a shorter 1 ns diffusion time. **Conclusion:** The likelihood of track overlaps has been evaluated in a pure water and scavenging setup, considering both the physical and chemical stages of irradiation. These observations suggest that inter-track interactions play a negligible role at clinically relevant doses, even at ultra-high dose rates.

BEST IN PHYSICS (THERAPY): FLASH Sparing of Normal Tissue in a Proton Spread Out Bragg Peak

M Kim*, I Verginadis, A Haertter, D Goia, K Shoniyozov, J Zou, C Koumenis, J Metz, K Cengel, L Dong, E Diffenderfer, University of Pennsylvania, Philadelphia, PA

Purpose: To determine the biological effects of FLASH proton radiotherapy (F-PRT) using the spread out Bragg peak (SOBP) compared to standard dose rate proton radiotherapy (S-PRT) in a whole abdomen mouse model. **Methods:** An IBA Proteus Plus C230 Cyclotron was used to deliver 230 MeV proton beams (range 32 g/cm²) to a fixed beam line in a dedicated research room. An SOBP was generated with a custom made ridge filter placed between the first and second scatterer in the beam. Range shifting material was placed prior to the final collimator to irradiate mouse whole abdomen with the SOBP. To investigate the acute radiation damage, 8-10 week old C57BL/6J mice were randomly assigned to 15 Gy whole abdomen irradiation into one of four groups: (1) SOBP F-PRT, (2) SOBP S-PRT, (3) entrance F-PRT, (4) entrance S-PRT. Mice were injected with EdU at 3.5 days after irradiation and jejunum segments were harvested and preserved for further staining. Upon staining, EdU-positive proliferating cells and regenerated intestinal crypts were quantified. **Results:** The generated SOBP had a modulation (width) of 2.5 cm from the proximal to distal 90%. Mice were irradiated with FLASH dose rates of 101.3 ± 2.8 Gy/s and standard dose rates of 0.94 ± 0.02 Gy/s with a SOBP. Using the entrance region of the proton beam, dose rates were 115.4 ± 7.4 Gy/s and 1.1 ± 0.01 Gy/s for F-PRT and S-PRT, respectively. Film irradiation showed uniform dose delivery across the whole abdomen throughout the mouse body width. FLASH preserved a significantly higher percentage of regenerated crypts compared to standard dose rate radiation using both the entrance and SOBP. **Conclusion:** SOBP F-PRT beams were delivered to healthy mouse whole abdomen. FLASH-irradiated mice exhibited normal tissue sparing when compared to S-PRT. SOBP for proton FLASH can lead to better dose conformity around targets and increased normal tissue sparing.

Measuring Oxygen Concentration at Ultra-Fast Rates During Proton FLASH Delivery Using Phosphorescence Quenching of Soluble Oxyphor Probes

A L Van Slyke*, M El Khatib, K Shoniyozov, E Diffenderfer, M Kim, C J Koch, S A Vinogradov, R D Wiersma, University of Pennsylvania, Philadelphia, PA

Purpose: The mechanism underlying the tissue sparing effect of FLASH radiation therapy is currently unknown, but the depletion of tissue oxygen at FLASH dose rates has been proposed as a potential candidate. This hypothesis has only been supported by modeling studies, primarily due to the difficulty of measuring oxygen concentration on millisecond timescales during irradiation. Here we use the phosphorescence quenching method to monitor oxygen concentration during proton delivery at conventional and FLASH dose rates. **Methods:** Oxygen concentration was measured at rates of up to 3kHz using a soluble phosphorescent oxygen probe and a phosphorometer. Sealed glass vials, containing the experimental solution and probe, were placed in a proton beam and irradiated at conventional (conv) (~1Gy/s) and FLASH (~100Gy/s) dose rates. The g-value of oxygen depletion was measured at multiple dose rates and oxygen concentrations. Experiments were performed using three solutions containing 1, 2, and 5% albumin and a fourth designed to emulate the intracellular environment, containing glucose, glycerol, and glutathione (Buffer 3G). Oxygen concentration was continuously monitored before, during, and after irradiation. **Results:** We found that FLASH dose rates resulted in lower g-values for oxygen depletion when compared to conventional dose rates by ~15% (range: 7.2-22.5%) for all solutions tested. E.g., for a 30Gy dose to Buffer 3G, the g-value was 16% lower for FLASH than for conventional ($g_{conv} = 0.72 \pm 0.02 \mu\text{M}/\text{Gy}$, $g_{FLASH} = 0.63 \pm 0.02 \mu\text{M}/\text{Gy}$) (all values listed are mean $\pm$ S.E.M.). The g-value was higher for Buffer 3G than for the albumin solutions ($g_{conv} = 0.72 \pm 0.02$ and $0.58 \pm 0.03 \mu\text{M}/\text{Gy}$ respectively, $g_{FLASH} = 0.63 \pm 0.02$ and $0.54 \pm 0.01 \mu\text{M}/\text{Gy}$ respectively). **Conclusion:** We have demonstrated that ultra-fast measurements of oxygen concentration can be performed during actual proton irradiation. Furthermore, we found that the g-value of oxygen depletion at FLASH dose rates is lower than that of conventional dose rates by ~15%.

Modeling of Cellular Response After FLASH Irradiation: A Quantitative Analysis Based On the Radiolytic Oxygen Depletion Hypothesis

H Zhu¹*, J Li², X Deng¹, R Qiu², Z Wu², H Zhang², (1) Department of Radiation Oncology, Sun Yat-sen University Cancer Center, Gangzhou, Guangdong, CN, (2) Department of Engineering Physics, Tsinghua University, Beijing, CN

Purpose: Recent studies have suggested that ultra-high dose rate (FLASH) irradiation can spare normal tissues from radiotoxicity, while efficiently controlling the tumor, and this is known as the "FLASH effect". This study performed theoretical analyses to quantitatively investigate the impact of radiolytic oxygen depletion (ROD) on the cellular responses after FLASH irradiation. **Methods:** Monte Carlo simulation was used to model the ROD process, determine the DNA damage, and calculate the amount of oxygen depleted (LROD) during FLASH exposure. A mathematical model was applied for the analysis of oxygen tension (pO₂) distribution in human tissues and the recovery of pO₂ after FLASH irradiation. DNA damage and cell survival fractions after FLASH irradiation were calculated, and the impact of initial cellular pO₂, FLASH pulse fractionation, pulse interval, and radiation quality of the source particles on ROD and the subsequent cellular responses were systematically evaluated. **Results:** The simulated LROD range was 0.220–0.248 mmHg/Gy when pO₂ ranged from 7.5–160 mmHg. The calculated DNA damage and cell survival fractions show that the radioprotective effect is more evident in cells with a lower pO₂. Different irradiation setups alter the cellular responses by modifying the pO₂. Single pulse delivery or multi-pulse delivery with pulse intervals lower than 10–50 ms resulted in fewer DNA damages and higher cell survival fractions. Source particles with a low radiation quality have a higher capacity to deplete oxygen, and thus, lead to a more conspicuous radioprotective effect. **Conclusion:** Here, a systematic analysis of the cellular response following FLASH irradiation was performed to provided suggestions for future FLASH sparing effect study. Single pulse delivery or multi-pulse delivery with short pulse intervals are suggested for FLASH irradiation to avoid oxygen tension recovery during pulse intervals. Source particles with low radiation quality are preferred for their conspicuous radioprotective effects.

TOPAS-NBio Simulation of Radiation Chemistry Following FLASH Irradiation Including Reactions of Biological Importance

M Grochowska^{1*}, A Rucinski², R Schulte³, J Ramos-Mendez⁴, (1) University of Warsaw, Warsaw, , PL, (2) Institute of Nuclear Physics PAN, Krakow, PL, (3) Loma Linda University, Loma Linda, CA, (4) University of California San Francisco, San Francisco, CA

Purpose: Ultra-high dose rate irradiation has demonstrated to improve sparing of normal tissues while maintaining an equivalent tumor response (the FLASH effect). Although the biological mechanism of the FLASH effect is still not understood, oxygen depletion seems to be one of the plausible hypotheses. However, current mechanistic studies rely on pure liquid water calculations. We implemented two models of water radiolysis with chemical reactions of oxygen and molecules of biological importance, which might help evaluate the FLASH effect in tissue in a more reliable way. **Methods:** We extended TOPAS-nBio to allow delivering pulses of radiation and reactions with oxygen in two different scenarios: including reactions between free radicals and DNA (Model 1); and additional reactions with RNA, proteins, amino acids and free nucleotides (Model 2). Those molecules were implemented as scavengers with reaction rates and concentrations obtained from the literature. Our simulations were carried out using microsecond-width pulses of 1 MeV electrons uniformly irradiating a water phantom cube of 1 μm side. The oxygen depletion without replenishing was compared for a conventional dose rate (0.29Gy/s) and FLASH irradiation conditions (... Gy/s) for 21% oxygen concentration. **Results:** At the end of the electron pulse, and for all irradiation settings, both models predict that FLASH irradiation depletes 2.7 times more oxygen than conventional irradiation for the same absolute dose. This is caused by the intertrack and interpulse reactions between reactive species. The oxygen consumption varied by 16.7% between the two Models, which results from introducing competing scavengers that react with free radicals. **Conclusion:** The proposed models under pulsed irradiation allowed us to quantify the time course of oxygen depletion under more realistic biological conditions than pure liquid water. Further work is performed under even more realistic conditions mimicking the cell environment and will be validated by experimental studies.

Modeling Radiation-Induced Oxygen Depletion and Its Effects on Normal Tissue Complications in FLASH-RT

S Cui^{1*}, G Prax², Stanford University, Palo Alto, CA

Purpose: Ultra-high dose rate irradiation (FLASH) has emerged as a promising technique that may increase the therapeutic ratio of radiation therapy. A leading hypothesis is that the reduction of normal tissue toxicity is mediated by transient radioprotective hypoxia. A computational model is developed to simulate heterogeneous oxygen levels in the mouse brain during FLASH and investigate the effect of transient oxygen depletion on normal tissue complication probability. **Methods:** A 3D model of mouse brain vasculature was constructed using a publicly available two-photon fluorescence microscopy dataset. A dynamic oxygen distribution was modeled by considering oxygen diffusion, metabolism and radiolytic depletion. During FLASH, the oxygen enhancement ratio (OER) was incorporated into the linear-quadratic (LQ) model to obtain cell killing rate and compute an effective dose distribution considering oxygen depletion and heterogeneous distribution. **Results:** The effective dose is calculated for a FLASH pulse of 2-50Gy and mean oxygen levels 0.1-35mmHg in extra-vascular space. For a fixed physical dose, dose modifying factors (DMFs) first decrease and then increase with increasing oxygen tension. The oxygen tension at which DMF is minimized (maximal FLASH effects) shifts toward higher oxygen levels with increasing dose. For a fixed initial oxygen level, FLASH effects increase and then saturate with increasing physical dose. In the range 12-22Gy, V12 (a predictor of brain necrosis) yields a higher value for extreme cases of 0.1 and 35mmHg and a lower value for 6, 9, and 15mmHg. **Conclusion:** The proposed computation model is a useful tool to analyze various factors, i.e., alpha, beta (in LQ), metabolism, oxygen tension, OER, physical dose affecting the FLASH effects. The tissue oxygen heterogeneity may play an important role in mediating the FLASH effect. The same concept can be easily applied to the tumor and eventually help provide insight into determining the optimal treatment parameters for the FLASH RT.

Automatic Segmentation of High-Risk CTV for Tandem and Ovoid Brachytherapy Patients Using a Dual-Path Convolutional Neural Network

Y Cao*, A Vasantachart, O Ragab, J Cui, A Zhuang, Z Shen, S Balik, M Gribble, E Chang, W Yang, University of Southern California, Los Angeles, CA

Purpose: Pre-implant MRI is the gold standard on image-guided brachytherapy for cervical cancer. However, HDR planning is typically done on post-implant CT-based high-risk CTV (HR-CTV) because transferring of pre-implant MR-based GTV to post-implant planning CT is difficult due to large anatomical changes. The goal of this study is to train a dual-path convolutional neural network (CNN) for automatic segmentation of HR-CTV on post-implant planning CT. **Methods:** Pre-implant T2-weighted MR images and post-implant CT for 55 (48 for training and 7 for testing) patients were retrospectively solicited. MR was aligned to the corresponding CT using rigid registration. HR-CTV and GTV were manually contoured on CT and MR by an experienced radiation oncologist. All images were then resampled to a spatial resolution of 0.5x0.5x1.25 mm. A 3D CNN architecture was constructed with two encoding paths based on CT (no mask) and MR (masked by GTV). Each path used the same 3x3x3 kernel to capture the features from CT and MR. As a comparison, single path CNN with only CT input was trained. Voxel-based dice similarity coefficient (DSC), sensitivity, precision, and Hausdorff distance (HD) were used to evaluate model performance. Cross-validation was performed to assess model stability. **Results:** The dual-path CNN model achieved average DSC of 0.76 (0.70-0.81), Sensitivity of 0.82 (0.79-0.86), and Precision of 0.85 (0.83-0.90). The single-path CNN with only CT input achieved DSC of 0.65 (0.55-0.76), Sensitivity of 0.76 (0.68-0.80), and Precision of 0.78 (0.75-0.83). The area under the curve (AUC) values were 0.83 (0.82-0.84) and 0.76 (0.75-0.77) for dual-path and single-path models, respectively. The HD for the two models were 7.6 mm (4.2-10.5 mm) and 8.3 mm (5.1-12.5 mm). **Conclusion:** A CNN model with two encoding paths from pre-implant MR and post-implant CT was successfully developed for automatic segmentation of HR-CTVs for tandem-and-ovoid brachytherapy patients.

Cardiac Substructure Segmentation Using a Mask-Scoring Attention Convolutional Neural Network

J Harms*, Y Lei, S Tian, N McCall, K Higgins, J Bradley, T Liu, X Yang, Winship Cancer Institute of Emory University, Atlanta, GA

Purpose: Radiation-induced heart disease is a post-treatment toxicity which directly impacts overall survival for many thoracic cancer patients. Dose to specific cardiac substructures can better predict post-treatment toxicity than whole heart dose. However, delineation of substructures during treatment planning is not feasible in most clinics. This study proposes a deep-learning-based framework for simultaneous, automatic generation of substructure contours which can be used to better understand the relationship between radiation dose and post-treatment toxicity. **Methods:** The proposed mask-scoring regional convolutional neural network (MS-R-CNN) with attention gate consists of five subnetworks: backbone, regional proposal network (RPN), R-CNN, mask network with an attention gate, and mask-scoring network. Relying on CT alone, the backbone extracts multi-scale feature maps. The RPN utilizes these maps to detect the volume-of-interest (VOI) around all substructures, and the final three subnetworks extract structural information from these VOIs. An attention gate enforces a deep attention strategy which highlights informative features for accurate substructure segmentation. A retrospective study with 55 patients undergoing radiotherapy for lung cancer has been conducted to evaluate the proposed segmentation method. The whole heart and 15 cardiac substructures have quantitatively been accessed based on Dice score coefficients (DSC) and mean surface distances (MSD). **Results:** The proposed method achieved average DSC for the whole heart, chambers, great vessels, coronary arteries, the valves

of the heart of 0.96, 0.94, 0.93, 0.66, and 0.77 respectively. MSD between substructures segmented by the proposed method and the physicians' manual contours were 1-5 mm for all substructures. After network training, all substructures and the whole heart can be segmented on new datasets in less than five seconds. **Conclusion:** A deep-learning network was developed for automatic delineation of cardiac substructures based on CT alone. The tool has high potential for investigating cardiac substructure dose and treatment toxicities for improved cardiac sparing treatment planning.

GAN-Driven Anomaly Detection for Active Learning in Medical Imaging Segmentation

M Woodland^{*1,2}, A Patel^{2,3}, B Anderson¹, E Lin¹, E Koay¹, B Odisio¹, K Brock¹, (1) The University of Texas MD Anderson Cancer Center, Houston, TX, (2) Rice University, Houston, TX, (3) Baylor College of Medicine, Houston, TX

Purpose: One barrier to the clinical deployment of deep learning-based image segmentation models is the existence of “anomalous” cases where the segmentation model may fail, despite external validation. We developed methods that enable the detection of images on which the segmentation models are likely to fail, thereby aiding in clinical deployment of these models. **Methods:** We designed an anomaly detector that approximates the performance of a liver segmentation model on CT images by determining whether the images have a high likelihood of falling within the model's training distribution. We consider an image to be within the training distribution if our anomaly detection model can reconstruct the image. We use backpropagation to map input images to a latent space and a GAN to reconstruct the images. We used a StyleGAN2 network, due to its cutting-edge performance on high-resolution images. We will score reconstructed images using a residual loss. If this score is over a specified threshold, the image will be classified as anomalous. We trained the detection model on 96 CT scans and have 50 unseen CT scans available for anomaly detection. We use standard image similarity metrics for evaluation. **Results:** We successfully trained the StyleGAN2 network on slices extracted from non-contrast enhanced abdominal CT images. The network achieved a Fréchet-Inception score of 31.102. It also attained a Wasserstein distance of 1.388, a KL-divergence of 0.004, and a mutual information score of 0.241 between the pixel distributions of 120 real and 120 generated images. After successful reconstruction of images, a radiologist classified real and generated images as such with equivalent accuracy (60%). **Conclusion:** We defined an anomaly detection paradigm that determines when a segmentation model is likely to fail on an image. This paradigm can aid the clinical deployment of segmentation models, diversify medical imaging datasets, and prioritize images for labeling.

Research reported was supported in part by the National Cancer Institute of the National Institutes of Health under awards 1R01CA221971 and R01CA235564 and the Tumor Measurement Initiative at MD Anderson Cancer Center.

TU-E-TRACK 6-04

Multi-Organ Auto-Segmentation of Abdominal Structures from Contrast-Enhanced and Non-Contrast-Enhanced CT Images

C Yu^{>sup>1}, 2*, C Anakwenze², Y Zhao^{1,2}, R Martin², J Niedzielski², E Ludmir², J Yang^{1,2}, L Court^{1,2}, C Cardenas^{1,2}, (1) University of Texas MD Anderson UTHealth Graduate School of Biomedical Sciences, (2) University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: To develop a deep-learning-based tool for accurate and robust upper abdominal organs-at-risk(OAR) autosegmentation suitable for treatment planning and adaptive replanning. **Methods:** Forty pancreas SBRT patients with contrast-enhanced breath-hold planning CT images were selected. All OARs (duodenum, small bowel, large bowel, stomach, liver, spleen, left kidney, right kidney and spinal cord) were edited or recontoured under physician supervision to ensure accuracy and consistency. We used the self-adapting nnUNet framework to customize a 3D U-Net for our data to predict all organs concurrently. We tested our model using five-fold-cross-validation and calculated Dice-similarity-coefficients(DSC) and 95th-percentile Hausdorff(HD95) distances. A radiation oncologist assessed the performance of the tool on 8 randomly selected patients. This assessment was then repeated on non-contrast-enhanced daily CT images of the same patients. **Results:** The mean dice-similarity-coefficient/95th-percentile Hausdorff distance between the automatic segmentation and the ground truth on contrast-enhanced CT images were 0.88±0.07/8.94±10.29mm for small bowel, 0.89±0.08/12.46±15.09mm for large bowel, 0.80±0.08/12.29±8.10mm for duodenum, 0.91±0.04/5.98±4.59mm for stomach, 0.96±0.02/5.43±9.93mm for liver, 0.97±0.01/2.28±2.09mm for spleen, 0.95±0.05/2.78±2.02mm for left kidney and 0.96±0.02/2.46±1.42mm for right kidney. For clinical performance evaluation, all contours on contrast-enhanced planning CT images and non-contrast-enhanced daily CT images were clinically acceptable. The radiation oncologist suggested minor edits for the following OARs: large bowel (1 patient), small bowel (1 patient), liver (1 patient), and duodenum (7 patients). All other OARs were rated as “use-as-is”. For non-contrast-enhanced daily CT images, large bowel (2 patients), small bowel (2 patients), liver (1 patient), stomach (1 patient), and duodenum (7 patients) required minor edits. All other OARs were rated as “use-as-is”. **Conclusion:** We developed an auto-contouring tool for upper abdominal OAR segmentation for both contrast-enhanced and non-contrast-enhanced CT images. Our tool achieved a high-level of clinical acceptability on both types of images, which can provide accurate and consistent contours for treatment planning and adaptive replanning.

TU-E-TRACK 6-05

Rapid Organ-At-Risk Delineation in Pancreatic CBCT for CBCT-Guided Adaptive Radiotherapy

X Dai^{*}, Y Lei, J Janopaul-naylor, J Wynne, T Wang, J Zhou, J Roper, J Bradley, P Patel, T Liu, X Yang, Emory University, Atlanta, GA

Purpose: Rapid re-planning is a fundamental requirement in on-line adaptive radiotherapy. The delineation of organs-at-risk (OARs) is rather time-consuming and labor-intensive in the plan adaptation process. This study aims to develop a deep learning-based multi-organ segmentation to facilitate efficient and accurate re-planning for CBCT-guided adaptive pancreatic radiotherapy. **Methods:** Considering the relatively low quality of daily CBCT acquired in the treatment machine, two-stage-in-one model was designed. In the first stage, taking CBCT as input, a cycle-consistent generative adversarial network is used to generate synthetic CT images with improved image quality. Then, in the second stage, the synthetic CT is fed into a mask-scoring regional convolutional neural network (MS-R-CNN) which is constructed by five subnetworks including a backbone, a regional proposal network (RPN), a R-CNN, a mask network, and a mask scoring network for the detection of the positions and shapes of multiple organs simultaneously. The model was trained and tested on a cohort of 40 patients. Metrics including the Dice similarity coefficient (DSC), 95th percentile Hausdorff distance (HD95), mean surface distance (MSD), and residual mean square distance (RMS) were computed to quantitatively assess the proposed method. **Results:** A mean DSC of 0.92 (0.89 - 0.97), mean HD95 of 2.90 mm (1.63 mm - 4.19 mm), mean MSD of 0.89 mm (0.61 mm - 1.36 mm), and mean RMS of 1.43 mm (0.90 mm - 2.10 mm) were achieved by our proposed method across eight abdominal OARs including duodenum, large bowel, small bowel, left and right kidneys, liver, spinal cord and stomach. The contours of eight OARs can be obtained on the order of seconds once the model was trained. **Conclusion:** We have proposed a novel deep learning-based multi-organ segmentation algorithm for CBCT-guided adaptive pancreatic radiotherapy. It could be implemented in the setting of pancreatic adaptive radiotherapy to rapidly contour OARs.

TU-E-TRACK 6-06

Simultaneous Segmentation of Target and Organ at Risk in Thoracic Kilovoltage Images

M Mueller^{1,2*}, A Mylonas^{1,2}, P Keall¹, J Booth², D Nguyen^{1,2,3}, (1) ACRF Image X Institute, Sydney, NSW, AU, (2) University of Technology Sydney, Ultimo, NSW, AU (3) Royal North Shore Hospital, Sydney, NSW, AU

Purpose: The ability to simultaneously localize the treatment target and local organs-at-risks (OARs) can improve SABR treatment efficacy and reduce side effects by ensuring the target dose and avoiding irradiating the OARs. We present a fiducial-less Multi-Target-Segmentation (MTS) approach that utilizes the standard-equipped kV-imager of a conventional linac. **Methods:** MTS used a conditional generative adversarial network to simultaneously segment the tumor and the heart in kV-images. MTS was trained on the DRRs of the planning CT for each patient, such that it can be deployed for intra-fractional target tracking. A patient-specific training dataset consisted of 36000 DRRs, created by forward-projecting each of ten planning 4D-CT phases and segmented target volumes equidistantly over a full imaging rotation. The labels of multiple targets were stacked as separate image channels. Data was augmented during training by randomly cropping the field-of-view within ± 3 mm. MTS was trained individually for three lung SABR patients and tested on kV-images of three treatment fractions per patient. The ground truth target positions were determined through manual alignment of the forward-projected target volumes onto the kV-projections. The geometric accuracy was determined by comparing the centroid of the segmented targets on each image to the ground truths. Additionally, the dice-similarity-coefficient (DSC) was calculated to evaluate MTS. **Results:** MTS had a mean tumor localization accuracy of -0.4 ± 2.6 mm and 0.7 ± 1.7 mm in the lateral/ anterior-posterior and superior-inferior directions of the images, respectively. The mean heart localization accuracy was 1.9 ± 1.6 mm and 1.4 ± 1.1 mm in the lateral/anterior-posterior and superior-inferior directions of the images, respectively. The mean DSC was 0.72 ± 0.12 for the tumor and 0.88 ± 0.04 for the heart, respectively. **Conclusion:** Simultaneous target and OAR localization without fiducials is feasible and can achieve clinically relevant accuracy for clinical deployment. MTS may widen the therapeutic index of SBRT by minimizing thoracic toxicity for targets in close proximity of critical OARs.

Towards Artificial Intelligence and Clinician Integrated Systems (AICIS): Interactive Contour Revision with Deep Boundary Net

T Bai*, A Balagopal, M Dohopolski, H Morgan, R McBeth, J Tan, D Nguyen, S Jiang, UT Southwestern Medical Center, Dallas, TX

Purpose: Accurate organ contours are required to ensure the quality of a radiotherapy treatment plan. However, contours generated by current auto-segmentation tools are not perfect, will never be, and may require significant revisions which can be tedious and time consuming. This work proposes an artificial intelligence and clinician integrated systems (AICIS) that can interact and assist clinicians to quickly revise the contours. **Methods:** The pipeline starts with a convolutional neural network (CNN)-based auto-segmentation model, which generates an initial contour. After review by the clinician, if it is not acceptable, the clinician will click on the boundary that exhibits large errors. This boundary click will be converted into a Gaussian point and then fed into the network to guide an interactive model revising the contour. This interaction process can be iterated multiple times. The input of our interactive model consists of three channels: the CT image, the current segmentation result, and the Gaussian point. The training dataset is built upon the existing dataset for auto-segmentation model training by simulating clinician's click. In this work, we reasonably assume the clinician prefers to click on the boundary point that exhibit large errors which can be quantified by Hausdorff distance (HD). We used three different head-and-neck (HN) datasets to train and test our model. For quantification, we measure the percentage of acceptable contours that meet the criterion $HD95 < 2.5$ mm and the number of clicks required to reach this criterion. **Results:** On average, 42.6% of the auto-generated contours were acceptable. With the aid of our AICIS system, the percentage of acceptable contours were improved to 92.3%. The mean number of clicks required to reach our criterion was 1.57. **Conclusion:** We developed an artificial intelligence and clinician integrated systems that can substantially improve the clinician's contour revision efficiency.

Presentation Title: "PULSAR: The adaptation of SabR toward personalized medicine."

Radiotherapy dogma, based on conventional daily dosing, insists that treatments be completed without interruption. In fact, randomized trials conducted in the 70's and 80's with a "split" inserted into a course of conventional daily dose treatment resulted in improved toxicity (as predicted), but poorer tumor control (tumor control penalty) leading to abandonment. The implementation of Stereotactic Ablative Radiotherapy (SABR) successfully challenged another radiotherapy dogma condemning hypo-fractionation by showing higher rates of tumor control WITHOUT increasing late toxicity. Building on this reality, we and others have hypothesized that potential benefits of a "split course" might be re-examined with SABR where more potent dosing could avoid the tumor control penalty while providing other opportunities to exploit for improving therapy. New radiotherapy platforms with sophisticated on-board imaging and software are capable of rapid re-planning enabling an "adaptive" approach where change triggers a modified treatment. The benefit of adaptive radiotherapy using conventional small dose daily fractionation is marginal because little changes. So here we introduce a new treatment paradigm called Personalized Ultra-fractionated Stereotactic Adaptive Radiotherapy (PULSAR). PULSAR uses independently planned, potent SABR treatments called "pulses" to trigger change in the tumor, in its microenvironment and in the patient as a whole. Pulses are separated by ample time (weeks to months) hoping for ample changes to occur. Multiple interrogations proceed between pulses to guide the next pulse which is independently planned (adapted). Interrogations might include imaging (anatomical and functional), blood/urine tests, assays, history and physical exam, toxicity assessments and even repeat biopsy. With time, these tests are likely to uniquely change for each patient facilitating adaptations personalizing the therapy. Much work needs to be done to guide the adaptations as this is much more than just adapting to position and shape. Treatments may be altogether changed combining different drugs with different pulses depending on the evolution of change, perhaps even abandoning the original treatment altogether. PULSAR defines

both opportunities and complicated assessments. Artificial intelligence tools will likely be helpful in making PULSAR a revolutionary new treatment paradigm

Learning Objectives:

1. Learn about the concept and the advantages of Personalized Ultra-fractionated Stereotactic Adaptive Radiotherapy (PULSAR) for adaptive radiotherapy
2. Learn about potential changes in the tumor and its microenvironment triggered by PULSAR and how to use them to optimize the treatments.

Speaker 2: Dr. Yolanda Prezado, Institut Curie (France), EFOMP's representative

Presentation Title: "Overview of Spatially Fractionated Radiation Therapy: from photons to charged particles."

Despite remarkable advancements, the dose tolerances of normal tissues continue to be the main limitation in radiation therapy (RT). One possible solution could be to employ distinct dose delivery methods, activating different biological processes from those ones in standard RT. Along this line, the strong spatial modulation used in techniques such as GRID, Lattice therapy or minibeam radiation therapy (MBRT), has already demonstrated a significant reduction of normal tissue toxicity and an important increase of the therapeutic index for some (radio-resistant) tumors. While spatially fractionated radiation therapy (SFRT) has mainly used photon beams, the alliance of SFRT and the benefits of charged particles for therapy has recently started. This presentation will provide a general overview on SFRT and how it is evolving from the use of photons to charged particles.

Learning Objectives:

1. Learn about spatial fractionation of the dose in radiation therapy and its advantages
2. Learn about radiobiology in SFRT

Speaker 3: Prof. Sha Chang, University of North Carolina

Presentation Title: "Understanding the correlation between dosimetric parameters and treatment responses for spatially fractionated radiation therapy"

A solid understanding of correlation between dosimetry and treatment response is crucial for radiation therapy for cancer. We have gained such an understanding for conventional seamless radiation therapy but it may not apply for spatially-fractionated radiation therapy (SFRT).

SFRT is a nonconventional radiation therapy where dose distribution is highly fractionated in space. Decades of clinical and preclinical data have shown that SFRT has promising potentials as a very high therapeutic ratio radiation therapy, especially when used as a neoadjuvant therapy and for cancers that cannot be adequately managed by conventional therapies. These cancers include large late stages cancers, in- or near-field reoccurrences, refractory cancers, and cancer within or near highly radiosensitive critical organs.

Two major obstacles for broad SFRT clinical application are lack of understanding of working mechanism and of the correlation between complex SFRT dosimetric parameters and treatment responses. The key questions to be answered include what is the most proper dosimetric parameter to be used for SFRT treatment prescription and what is an "apple to apple" comparison between a SFRT treatment and the "gold standard" conventional radiation therapy for a given endpoint. In this presentation we intend to shed lights on these and other important questions by reviewing and analyzing available data and discuss directions for future research.

Learning Objectives:

1. Recognize that understanding the correlation between dosimetric parameters and treatment response is crucial to advance SFRT.
2. Understand that preclinical SFRT studies indicate that peak dose may not be closely correlated with treatment response.
3. Learn methods to conduct research on SFRT dosimetry vs. treatment response.

Speaker 4: Prof. Ke Sheng, University of California,

Presentation Title: "Radiotherapy beyond 4pi"

Despite the potential for significantly improve the dose conformity, OAR sparing, and target dose escalation, gaps exist to prevent 4 π radiotherapy from being widely used in the clinic. The gaps include the complexity of the optimization, the cumbersomeness of the C-arm gantry system to achieve the non-coplanar angles, and the long time needed for treatment delivery. The presentation will discuss the technical roadmaps to overcome these challenges. Artificial intelligence can be used to streamline treatment planning in two aspects. First, the plan dose can be individually predicted based on previously treated patients. Second, Artificial intelligence methods can be used to simplify dose calculation and optimization or circumvent certain steps of the optimization to speed up the calculation. A new robotic hardware platform is expected to effectively and efficiently access the non-coplanar angles without rotating the patient couch. The reduction in the form factor afforded by cutting-edge linear accelerator affords additional beam angles that were unavailable previously. The new many-isocenter optimization methods blur the traditional definitions of field of view and intensity modulation resolution. Ultimately, the combination of hardware and software innovations will move 4 π closer to clinical reality.

Learning Objectives:

1. Learn the challenges that exist in 4 π radiotherapy and the hardware development to overcome the challenges.
2. Learn the optimization methods that allow the same system to treat both small targets with high intensity modulation resolution in SRS and large tumors with conventional fractionation.

Q&A

A treatment plan captures a single moment in time and does not account for changes in anatomy over the course of treatment. Changes in weight or variations in internal anatomy, for example, can result in displacement of the target volume and OARs relative to the planned dose. The process of adapting a plan can be labor-intensive and time-consuming for both physicians and staff. Artificial intelligence (AI) has the potential to improve the accuracy, precision, efficiency, and overall quality of radiation therapy for patients by automating adaptive radiotherapy workflows such as target segmentation, treatment planning, quality assurance and, in some cases, radiotherapy delivery. Vendors will present their AI adaptive solutions and describe how their products can improve the workflow and empower the clinician and staff to make informed decisions related to patient cancer treatments.

Keywords: Artificial intelligence, automated contouring, adaptive, treatment planning, treatment delivery

Learning Objectives:

1. Review the rationale behind adaptive planning.
2. Explore the different means of adapting a plan including off-line, on-line, and real-time adaptive planning.
3. Explain how AI can help streamline the adaptive treatment process.

Moderated Panel Discussion / Drawing for Attendees

The New Professionals Subcommittee (NPSC) offers a New Member Symposium (NMS) at each Summer Meeting in order to provide information about how to become involved with AAPM and how to deal with issues that students, trainees, and anyone new to the AAPM organization are faced with. This summer we invite you to come with your questions about how to search for a job, become a team member, and how to become a volunteer for AAPM.

AAPM President James Dobbins will discuss leadership of the AAPM, and a panel of experts will discuss topics relevant to AAPM's volunteer organization: Frederic Fahey, Chair of Administrative Council, Joann Prisciandaro, Chair of Education Council, Jatinder Palta, Chair of International Council, Brent Parker, Chair Professional Council Chair, Jan Seuntjens, Chair of Science Council. A question and answer will follow to discuss your interests, concerns, and ideas.

Learning Objectives:

1. Gain familiarity of the leadership structure of the AAPM
2. Explore how to become involved in committees in AAPM and in AAPM leadership
3. Gain understanding of new initiatives and future directions in each AAPM council

Estimating Ischemic Core Volume with Four Dynamic Images in CT Perfusion

K Chung*, D Lee, S Pandey, J Mandzia, A Khaw, T Lee, University of Western Ontario, London, ON, CA

Purpose: Simplifying CT perfusion (CTP) protocols may encourage its use at less-experienced centers to guide patient selection for thrombectomy in acute ischemic stroke. In this simulation study, we demonstrate that the cerebral blood flow (CBF) map can be calculated with four images equivalent to standard of care non-contrast CT (NCCT) and multiphase CT angiography (mCTA) to measure the ischemic core volume required for patient selection. **Methods:** Twenty-eight consecutive patients with acute ischemic stroke and CTP at admission were included in this study. The standard CTP protocol consisted of 22 dynamic images acquired over 60 s. NCCT and mCTA were simulated by manually selecting the four dynamic CTP images that corresponded to the pre-contrast baseline (NCCT), peak arterial enhancement, and two delayed images at 8 and 16 s after the peak (mCTA). Early or late timing of the peak and of the delayed images was also simulated by shifting the selection of contrast-enhanced images up to three time points (<9 s) before or after the true peak. CBF maps were generated by a model-based deconvolution algorithm from which ischemic core was identified by $\text{CBF} < 30\%$ of the contralateral hemisphere. Bland-Altman analysis and the intraclass correlation coefficient (ICC) assessed agreement and reliability, respectively, of measured core volumes compared to those from a standard CTP study. **Results:** With correct timing of the arterial peak, the mean difference (MD; limits of agreement) and ICC were 3.7 (−4.9 to 12.4) ml and 0.94 (0.72 to 0.98), respectively. MD and ICC were similarly good when the peak was timed early by up to 6 s or late by 3 s ($\text{MD} < 5.9$ ml; $\text{ICC} > 0.86$) but poor with earlier (≈ 9 s) or later timings (> 3 s). **Conclusion:** Core volumes measured with only four images equivalent to NCCT and mCTA were consistent to those from a standard CTP study.

JACK FOWLER EARLY-CAREER INVESTIGATOR COMPETITION WINNER: Imaging from the Cervical to the Lumbar Spine with a Continuous Multi-Turn Reverse Helical 3D Cone-Beam CT Scan

T Reynolds^{1*}, Y Ma², G Gang², O Dillon¹, T Russ³, W Wang², T Ehtiat⁴, C Weiss², N Theodore², J Siewerdsen², R O'Brien¹, J Stayman², (1) ACRF Image X Institute, University of Sydney, Sydney, NSW, AU (2) Johns Hopkins University, Baltimore, MD, (3) Heidelberg University, Mannheim, GER, (4) Siemens Healthineers, Forchheim, GER

Purpose: The current axial coverage of intraoperative 3D cone-beam CT imaging is limited by detector length. For neurosurgical interventions, for example, this prevents the alignment of the entire spine to be assessed from a single 3D scan. Here, we investigate the feasibility of realising whole spine 3D cone-beam CT imaging for the first time within the interventional suite. **Methods:** A Siemens ARTIS pheno robotic angiography imaging system in conjunction with a Siemens Test Automation Control System (TACS) was used to image a 3D printed spine phantom (Sawbones) containing cervical, thoracic, and lumbar vertebra with a multi-turn reverse helical scan. The TACS was used to control both the C-arm rotation and table movement. The C-arm was rotated continuously through a total of 1350° (400° clockwise, 400° anticlockwise, 400° clockwise and 150° anticlockwise) around the table at $20^\circ/\text{s}$, acquiring projections at a fixed frame rate of 10 f/s, while the table was translated backward from the C-arm at a rate of 10 mm/s. The 3D images were reconstructed using penalized-likelihood reconstructions. To compare the axial coverage with current 3D imaging capacity, a conventional circular scan (4 second, 248 projections) was acquired of the thoracic spine. Image quality was examined visually and via the Structural Similarity Index Metric (SSIM). **Results:** The multi-turn reverse helical scan enabled a total axial coverage of 76 cm, capturing all 24 vertebrae. Comparatively, the conventional scan enabled 17 cm of axial coverage, encapsulating 6 thoracic vertebrae. The multi-turn reverse helical scan took 80 seconds to complete, acquiring 790 projections. Structural similarity of the multi-turn to the conventional scan from T-4 to T-9 was 97.83%. **Conclusion:** This is the first time a continuous multi-turn reverse helical scan has been implemented on a clinical robotic angiography system, allowing the entire spine to be imaged in a single scan.

TU-F-TRACK 3-03

Intraoperative Cone-Beam CT Image Quality and Dose with a Slot Collimator On the O-Arm

X Zhang^{1*}, P Wu¹, Y Huang¹, A Uneri¹, C Jones^{1,2}, P Helm³, S Lo⁴, W Zbijewski¹, J Siewerdsen^{1,4}, (1) Johns Hopkins University, Department of Biomedical Engineering, Baltimore, MD, (2) Johns Hopkins University, Department of Computer Science, Baltimore, MD, (3) Medtronic Inc., Littleton, MA, (4) Johns Hopkins University, Department of Neurosurgery, Baltimore, MD

Purpose: An actuated slot-beam collimator was implemented on an intraoperative cone-beam CT system (Medtronic O-armTM), hypothesizing benefits to dose and soft-tissue contrast resolution for the slot-beam geometry. This study investigates the dose, scatter-to-primary, and contrast-to-noise characteristics for slot- and cone-beam configurations for scenarios that may benefit from improved soft-tissue image quality. **Methods:** The collimator features three narrow slots that can be automatically moved into position during scanning, each exposing a detector area of 40 cm width x 2.5 cm longitudinal. Slot- and cone-beam configurations were evaluated with and without a focused linear anti-scatter grid (12:1 GR). Dose, scatter, and soft-tissue contrast resolution were evaluated in phantom studies for head and body protocols (~ 745 projections over 360° , $0.388 \times 0.776 \text{ mm}^2$ pixels, 80-120 kV, 75-940 mAs) with reconstruction performed via 3D filtered backprojection. Quantitative evaluation included scatter-to-primary ratio (SPR), contrast-to-noise ratio (CNR), modulation transfer function (MTF), and absorbed dose. **Results:** The slot-beam configuration reduced SPR by $\sim 6\times$ compared to a cone-beam, and the grid reduced SPR by $\sim 3\times$ compared to no-grid. As anticipated, the slot-beam with a grid yielded the lowest SPR (< 0.1 and < 0.3 for the head and body, respectively) and increased soft-tissue CNR by 2-2.5x compared to cone-beam at equivalent dose. MTF was unaffected among all configurations. The dose for the slot-beam configuration was $\sim 1/5$ that for the cone-beam due to reduction of scatter dose, ranging 0.013-0.037 mGy/mAs for the head and 0.006-0.017 mGy/mAs for the body. **Conclusion:** Implementation of an actuated slot-beam collimator demonstrated strong improvements in image quality and dose that may benefit certain interventional imaging scenarios – e.g., high-quality soft-tissue visualization within a region of interest to assess the quality of surgical product or as a check against hemorrhage. It also provides a potential step toward intraoperative helical scanning on such systems.

The research was supported by academic-industry partnership with Medtronic Inc.

Ordered Subsets PWLS Reconstruction of Multi-Layer Detector MV-CBCT Data Using TIGRE

M Jacobson^{1*}, M Lehmann², P Huber², M Myronakis¹, T Harris¹, I Valencia Lozano¹, R Fueglistaller², C Williams¹, D Morf², R Berbeco¹, (1) Brigham and Women's Hospital, Dana-Farber Cancer Institute, and Harvard Medical School, Boston, MA (2) Varian Medical Systems, Baden-Dattwil, Switzerland

Purpose: Recently, clinical use of MV cone beam CT (CBCT) for radiotherapy guidance has increased. However, even in systems capable of lower MV energies, image quality suffers from detection efficiency limitations in traditional x-ray detectors. By combining a high DQE multi-layer detector prototype with dose-efficient, iterative Penalized Weighted Least Squares (PWLS) reconstruction, improved MV-CBCT image quality is pursued. **Methods:** The proposed imager consists of 4 detector layers, each with a 0.506 mm GOS scintillator and a 0.7 mm photodiode sub-layer. Copper blocking layers are omitted to improve DQE at lower (2.5 MV) energies. The iterations of PWLS are accelerated by using the Ordered Subsets Momentum-Based (OSMOM) technique to enhance convergence rate, and the public-domain Tomographic Iterative GPU-based Reconstruction (TIGRE) library to alleviate forward/back projection time. Refinements to TIGRE were made that allowed it to communicate input/output as MATLAB gpuArray objects. This enabled all iterative computations to be executed within MATLAB on the GPU, eliminating overhead from CPU-to-GPU transfers. The overall technique is evaluated in terms of noise and contrast-to-noise (CNR) in scans of the Catphan 604, and qualitatively in a pelvis phantom. **Results:** The proposed technique demonstrated 3 times lower noise as a function of spatial resolution compared to a conventional MV detector architecture and reconstruction algorithm (FDK). Reconstructed noise levels closely approached that of the Varian Edge LINAC's clinical kV-CBCT Spotlight protocol at matched dose (CTDI=12.5 mGy). This resulted in CNR about half that of kV-CBCT in a soft tissue (LDPE) region of interest. On the GTX 1080 Ti graphics card, reconstruction time for the pelvis was about 30 sec. using a 400x400x170 voxel grid and 200x320x400 projections. **Conclusion:** Combining a multi-layer imager with PWLS reconstruction greatly diminishes the image quality gap between MV-CBCT and standard kV-CBCT. Moreover, short reconstruction times are implementable with MATLAB and non-proprietary GPU software.

Reconstructing Dual KV Data Using the COSSCIR "One-Step" Direct Inversion Algorithm

B Rizzo^{1*}, E Sidky², T Schmidt¹, (1) Marquette University, Milwaukee, WI, (2) University of Chicago, Chicago, IL

Purpose: This study applies the one-step inversion material decomposition algorithm, cOSSCIR, to Dual kV spectral CT and validates our approach on digital and experimental phantom data. **Methods:** The cOSSCIR algorithm is a one-step inversion approach in which the basis images are directly optimized from the spectral projection measurements. cOSSCIR demonstrated reduced artifacts caused by beam hardening and photon starvation for photon-counting CT. The cOSSCIR approach does not require spectral measurements to be registered and thus may provide additional benefits for clinical Dual kV CT systems. By modifying the spectral response and accounting for the detector gain, an integrating detector model was developed and tested on a simple digital phantom. A subsequent inverse crime study was used to validate the approach. A preliminary experimental study was also performed using a physical phantom composed of cylindrical rods of PMMA, Polystyrene, and Teflon. Projection data was acquired at 80 and 130 kV over 500 equally spaced view angles. The system consists of a micro-focal x-ray source (Hamamatsu 9181-02) and a high resolution flat panel detector (Varian PaxScan 2520 DX). The Aluminum and PMMA basis images were then reconstructed using cOSSCIR. For each basis image, the mean value in each material ROI was compared with their predicted values. **Results:** Convergence to the digital phantom suggests that our integrating detector model is consistent with the mathematical framework developed for cOSSCIR. Furthermore, the experimental results demonstrate good recovery of the materials present within the physical phantom. The percent error in the PMMA basis image was 1.9% 3.3%, 4.3% in the polystyrene, PMMA, and Teflon ROIs. Similarly, in the Aluminum basis image the percent error was 7.5%, and 38.4% in the Polystyrene and Teflon ROIs. **Conclusion:** By incorporating an integrating detector model into the cOSSCIR framework we demonstrate direct inversion material decomposition for Dual kV data.

Weight-Bearing C-Arm Cone-Beam CT Using a Dynamic Range Reducer (DyRaR): Initial Prototype and Phantom Studies

N Bennett^{1*}, H Zhang², K Mueller³, R Fahrig⁴, A Maier⁵, M Levenston¹, G Gold¹, A Wang¹, (1) Stanford University, Stanford, CA, (2) Memorial Sloan Kettering Cancer Center, New York, NY, (3) Siemens Medical Solutions, San Francisco, CA, (4) Siemens Healthcare GmbH, Forchheim, Germany, (5) FAU University, Erlangen, Germany

Purpose: Cone-beam CT (CBCT) with automatic exposure control saturates the flat-panel detector in peripheral regions, leading to inferior image quality and excess skin dose. For example, in weight-bearing CBCT of knees, a traditional fixed bowtie filter cannot fully address this challenge. Thus, we constructed a prototype dynamic range reducer (DyRaR) which comprises four independently controlled brass wedges on each lateral side. The DyRaR is pre-programmed to conform to the patient-specific knee shape and continuously attenuate the beam beyond the knee outline as the gantry rotates. In this work, we demonstrate the DyRaR for weight-bearing CBCT using a knee phantom. **Methods:** A knee phantom was first scanned using the weight-bearing CBCT trajectory to establish baseline image quality and to design phantom-specific DyRaR wedge positions. A second scan of the knee phantom was then acquired with the DyRaR mounted to the collimator of the C-arm. Finally, an air scan with just the DyRaR was acquired to correct the previous scan. Note that direct subtraction of the two scans is not ideal due to differences in beam hardening and scattering. Thus, we segmented the projections of knee+DyRaR scan into knee only, DyRaR only, and overlap regions, and used a 2nd-order polynomial to correct different regions. **Results:** The DyRaR substantially attenuated the beam and prevented overexposure in air or near the knee outline by precisely following the designed trajectory. With proper projection correction, we could reconstruct CBCT images of the knee phantom with minor artifacts around the knee boundaries, although further image processing is needed to fully correct beam hardening and residual artifacts. **Conclusion:** We have designed a prototype DyRaR and evaluated its application on a C-arm system for weight-bearing CBCT of knees. This study demonstrates the potential to design patient-specific DyRaR trajectories toward achieving optimal CBCT image quality.

Simultaneous Analytical Image Reconstruction and Material Decomposition Denoising in Single-Scan Dual-Energy Cone-Beam CT Using Dual Energy Vectorization and Joint Bilateral Filtering

X Jiang^{*}, C Fang, H Cui, L Zhu, Y Yang, University of Science and Technology of China, Hefei, Anhui, P.R.China

Purpose: Dual-energy cone-beam CT (DE-CBCT) with a flat-panel detector (FPD) has promising applications in various clinical tasks. Rotating-filter based DE-CBCT (RF-DECT) technique could acquire dual-energy projections within single circular rotation, enabling shorter scan time and reduced patient dose compared with two-scan method. Here we propose a new method for RF-DECT imaging which achieves analytical image reconstruction and material decomposition denoising

simultaneously. **Methods:** RF-CBCT employs a rotatable filter to produce low and high energy projections alternately. CT images were first separately reconstructed using filtered back-projection (FBP) method on the down-sampled projection set of each energy, then we compactly represented the reconstructed low and high energy images in a vectorized form, which was further characterized as an amplitude image and an argument image. Based on the analysis of noise dependence and image complementarity, a joint bilateral filter using amplitude image as a guide was then designed for edge-preserved smoothing of argument image. Finally, reconstructed images with reduced streaks were recovered from the amplitude image and the smoothed argument image, decomposed noise could be effectively suppressed simultaneously. **Results:** On Catphan®600 phantom, the proposed method reduced streaking artifacts while preserving spatial resolution in the reconstructed images. Compared with typical two-scan results, proposed method reduced noise by a factor of 21.2, 38.0, 2.5 for soft tissue, bone tissue and electron density image, respectively, and achieved electron density accuracy within 1.5% for each material. On anthropomorphic head phantom, the proposed method successfully recovered the intricate brain structures in both high energy and electron density images. **Conclusion:** Using down-sampled projections in single-scan DE-CBCT, proposed method achieves simultaneous analytical image reconstruction and material decomposition denoising. This method demonstrated superior performance on spatial resolution enhancement, decomposition noise reduction and electron density accuracy, allowing better material differentiation and dose calculation, while using only half radiation dose.

Simulating Spatial-Temporal Dose Rate Deposition on Tissue Sparing for Scanned Pencil-Beam Vs Double-Scattered Protons

R Yang^{1*}, (1) BC Cancer - Centre for Southern Interior, Kelowna, BC, CA; E Diffenderfer², (2) University of Pennsylvania, Philadelphia, PA

Purpose: To develop a proton dose calculation framework simulating both spatial distribution and time structure of ultra-high dose rate deliveries, enabling comparison of scanned pencil-beam (PBS) vs double-scattered (DS) sequences on local tissue sparing. **Methods:** Physical proton dose was implemented based on the validated superposition model in Eclipse, with a novel grid interpolation framework enabling rapid computation of each time-step. Oxygen depletion and tissue sparing was modeled across the calculation grid as exponential depletion and recovery proportional to concentration gradient, each time-step coupled to the Oxygen-Enhancement-Ratio k-curve, yielding effective dose. Dose equivalent PBS and DS plans were created with various time structures to explore their effective dose which depends on oxygen concentration at each moment of energy deposition. Beam currents were extrapolated to FLASH dose rates. **Results:** DS deliveries consistently yielded greater tissue sparing proximal to the spread out Bragg peak (SOBP). Slow time between spots and layers inherent to PBS deliveries allowed oxygen to recover to nearly physiologic levels, whereas DS modulation irradiates the entire field near simultaneously, for widespread oxygen depletion even at a fraction of the PBS instantaneous dose rate. DS offered nearly twice the differential sparing of regions proximal to the SOBP, where dose to organs-at-risk are of concern. PBS can be improved by minimizing slow time and number or dose repainting. **Conclusion:** The spatial-temporal structure of high dose rate deliveries yields insight into differential tissue sparing, as groundwork for proton treatment planning while considering FLASH effects. PBS scanning trajectories can be explored which maximize differential sparing in regions of interest. Radiochemistry and tissue sparing models can be refined with further experimental evidence towards a planning paradigm considering dose rate modulated tissue sparing.

TU-F-TRACK 5-02

Feasibility of 3D Printed Ridge Filter to Enable SBRT FLASH Therapy Using Scanning Proton Beam

R Liu^{1*}, S Charyyev², J Zhou³, X Yang⁴, T Liu⁵, M McDonald⁶, K Higgins⁷, J Bradley⁸, L Lin⁹, (1) Emory University, Atlanta, GA (2) Emory University, Atlanta, GA, (3) Emory University, Atlanta, GA, (4) Emory University, Atlanta, GA, (5) Emory University, Atlanta, GA, (6) Emory University, Atlanta, GA, (7) Emory University, Atlanta, GA, (8) Emory University School of Medicine, (9) Emory Proton Therapy Center, Atlanta, GA

Purpose: Due to long proton energy switching time, most FLASH therapy is limited to single energy and to spare normal tissue without conformity of treatment target along the depth direction. We investigate if a 3D ridge filter can enable dose conformity of stereotactic radiation therapy (SBRT) target in FLASH treatment using scanning proton beams. **Methods:** Varian ProBEAM's FLASH energy of 250 MeV was degraded to 120 MeV to treat simulated SBRT spherical targets of 30 mm and 50 mm diameters at depths of ~80 mm of a water phantom. We develop a method to optimize the height and location of the PMMA pins of the ridge filter so that the spread-out Bragg peaks at each location can correspond to that of the sphere targets. The ridge filter pins must meet the 0.1-mm lateral and height resolutions of a 3D printer. Geant4 was used to simulate radiation transport. The spot weights were also optimized to achieve lateral target conformity. **Results:** The simulation results showed that it is feasible to use 3D printed ridge filters to achieve location-dependent spread-out Bragg peaks for SBRT spherical targets for one fixed energy. Delivering 10 Gy dose in such spot maps is estimated to be below 250 ms, achieving a Flash dose rate of 40 Gy/s. The validation of timing and simulated dosimetric distributions will be performed since Flash mode has been recently delivered at Emory. **Conclusion:** According to Geant4 simulation, it is feasible to use a 3D ridge filter to enable proton SBRT FLASH therapy up to 50 mm diameter sphere target.

TU-F-TRACK 5-03

Need for Beam Collimation Design for Dose-Rate Fall-Off in Proton Flash Treatment Using Pencil Beam Scanning

E Bentefour^{*}, A Sawant, S Mossahebi, University of Maryland School of Medicine, Baltimore, MD

Purpose: Flash irradiation requires delivering a spatial high dose-rate that is consistently above the Flash dose-rate threshold (>40Gy/sec). This requirement is not fully met for Gaussian beam distributions such as proton pencil beam scanning as the lateral fall-off of dose (or dose-rate) profile can be below the Flash threshold. In this study, we evaluate the use of proton beam collimation to reduce the non-Flash dose-rate of proton pencil beam. **Methods:** The profile of a proton pencil beam captured using a plastic scintillator with and without 8 mm pinhole collimation using a lead aperture. The measurements were performed using 245 MeV proton beam at 5, 15 and 37 cm depth in water, similarly, for 150 MeV beam at of 5 and 15 cm depths. The data analysis focused on (i) Comparison of the spatial Intensity distribution of the collimated and non-collimated beams, (ii) Determining the adequate collimation ratio, defined as the ratio of beam spot-size to diameter of the pinhole aperture, and (iii) Determining the proportion of non-flash dose delivered by the collimated beam. **Results:** The collimation of 245 MeV (with the spot size of $\sigma=3.62$ mm) reduces the non-Flash dose by to 6%, 9% and 15% of the delivered dose at the respective depths of 5, 15 and 37 cm in comparison to 26% from non-collimated beam. The collimation of 150 MeV beam ($\sigma=4.47$ mm) is satisfactory as it limits the non-Flash dose to less than 4.3% for all depths comparing to 25% for non-collimated beam. **Conclusion:** The collimation of Gaussian proton beam can reduce the Flash beam dose-rate fall-off as long as the collimation factor is higher than 0.5.

TU-F-TRACK 5-04

Prompt Gamma Timing as a Real-Time Relative Dose Rate Monitor of FLASH Proton Delivery

A Haertter^{*}, M Kim, J Zou, K Shoniyozov, S Avery, B Teo, J Metz, K Cengel, L Dong, E Diffenderfer, Hospital of the University of Pennsylvania; Department of Radiation Oncology, Philadelphia, PA

Purpose: To investigate the feasibility of real-time proton FLASH relative dose rate monitoring via prompt gamma ray (PG) timing. PG event measurements are used for secondary relative verification of absolute dose rate delivery and for visualization into the temporal dose rate characteristics of proton FLASH deliveries up to 138 Gy/s. PG counts are processed to provide insight into an optimized PG detection system performance. **Methods:** A PG detection and measurement system consisting of a NaI(Tl) scintillator and nuclear electronic pulse processing system are used along with transmission ionization chamber absolute dose measurements. Varying dose rates were delivered to measure PG counts and count rates to investigate PG count and proton FLASH dose rate linearity, time structures, and delivery stability. **Results:** PG counts and count rates are found to increase linearly with delivered dose and dose rate. Upon beam termination, PG counts exhibit an exponential decay due to scintillation crystal afterglow with a half-life of 2.495 ± 1.35 ms, which corresponds to the theoretical minimum response time in which a real-time dose rate monitoring system would be able to terminate beam delivery upon recognition of $\geq 7.0\%$ dose rate variation per single delivery. With no detector collimation, FLASH dose rates cause detection system paralyzation, leading to PG count saturation; after detector dead time and paralyzation correction calculations, true unsaturated PG count rates for dose rates up to 138 Gy/s were determined. Variations in absolute dose rate measurements provide a $>6.59\%$ threshold variation for which PG counts could provide substantial dose rate variation detectability. **Conclusion:** PG counting systems can be designed to perform real-time relative proton dose rate monitoring for <36 Gy/s deliveries, and with corrections accounting for PG count saturation, real-time relative monitoring may be feasible for FLASH dose rates; allowing for verification of critical research and clinical setting delivery parameters.

Pulse Resolved Beam Characterization and Feedback for FLASH-RT Using Radioluminescent Dosimeters

M Ashraf^{1*}, M Rahman¹, R Zhang², B Williams², J Hoopes¹, D Gladstone², B Pogue¹, P Bruza¹ (1) Dartmouth College, Thayer Engineering, Hanover, NH, (2) Dartmouth-Hitchcock Med. Ctr., Lebanon, NH

Purpose: Beam monitoring for FLASH-RT is challenging due to ultra-high dose rate conditions. In this study, dose-rate independent radioluminescent based techniques are presented for pulse-resolved beam characterization and real-time feedback to a FLASH enabled Linac. **Methods:** A modified clinical linac delivered a radially symmetric 10 MeV electron FLASH beam (~ 300 Gy/s, 1 Gy/Pulse) to isocenter. Lateral projected 2D dose distributions for each linac pulse were imaged in a fluorophore-doped water tank using a time-gated camera. An inverse Abel transform reconstruction provided 3D images for on-axis depth dose values. The central axis depth dose values were compared against film data. For pulse-by-pulse feedback, a scintillating point dosimeter was coupled to a gated integrator and a field programmable gate array (FPGA)-based control system. **Results:** The camera images were reconstructed at a spatial resolution of 0.5 mm. The D_{max} , R_{50} , and R_p measured with film and camera based method agreed to within 1 mm for a 1.5 cm circular beam and the beam with jaws wide open (40×40 cm²). Central axis cross beam profiles for both beams agreed with film data with $>95\%$ passing rate (2%/2mm gamma criteria). Beam energy measurements based on the R_{50} criteria using optical measurements revealed a stable beam energy between adjacent pulses. However, a ramp-up period was observed where the dose per pulse increased for the first few pulses and then stabilized. The dose-read out scheme for individual pulses using the gated integrator and the FPGA based system was characterized. **Conclusion:** Radioluminescence based techniques were presented as a high spatio-temporal resolution technique for online monitoring of FLASH beams. The presence of a ramp-up requires that feedback to the Linac should be based on dose accumulation. Therefore, the gated integrator and the FPGA based control system can enable accurate feedback for FLASH.

Absolute Dosimetry of Ultra-High Dose Rate Pulsed Electron Beams Using a Graphite Probe Calorimeter

F Keszi^{1*}, A Bourgouin², A Schueller², W Simon³, A Schoenfeld³, J Seuntjens¹, J Renaud⁴, (1) McGill University, Montreal, QC, CA, (2) Physikalisch-Technische Bundesanstalt (PTB), Braunschweig, Lower Saxony, DE, (3) Sun Nuclear Corporation, Melbourne, FL, (4) National Research Council Canada, Ottawa, ON, CA

Purpose: To evaluate and verify the dosimetric response of a clinically-deployable probe-format graphite calorimeter when operated in ultra-high dose rate (or 'FLASH') pulsed electron beams. **Methods:** The ion chamber-sized graphite calorimeter, termed Aerrow, was operated in quasi-adiabatic mode. In this mode, the absorbed dose deposited in the graphite core can be obtained by calculating the product of the specific heat capacity and the radiation-induced temperature rise. The measurements were carried out at the Metrological Electron Accelerator Facility of the German National Metrology Institute (PTB). Ultra-high dose rate pulses were delivered with a 20 MeV electron beam. The dose-per-pulse was varied in the range of 0.5 – 5.5 Gy. The detector response measurement was repeated 5 times for each pulse, with pulse deliveries separated by 90 seconds. The pulse charge was monitored non-destructively with a previously validated beam current transformer (ICT). Dose conversion factors from graphite to water were calculated using the EGSnrc Monte Carlo code system. The heat transfer correction factor was assessed through finite element analysis using COMSOL Multiphysics. **Results:** The response of the calorimeter was found to be independent of dose-per-pulse in the investigated range of pulse charges. The absorbed dose values measured by Aerrow had an average absolute deviation of 0.11 % and a maximum absolute deviation of 0.42 % from the fit on the ICT signals (which have uncertainties of 0.05 %). The response uncertainty corresponding to a coverage factor of $k = 2$ was 0.2 % (on average) for the higher dose rates (≥ 4.5 Gy/pulse) and reached a maximum of 1 % at the lowest dose rate. **Conclusion:** This feasibility study demonstrates that Aerrow can produce accurate and reproducible dose measurements in the ultra-high dose rate regime of pulsed electron beams, making it a suitable candidate for absolute dosimetry of clinical FLASH radiotherapy beams.

This work was supported financially by the CREATE Medical Physics Research Training Network grant of the Natural Sciences and Engineering Research Council (NSERC) (#432290) and NSERC operating grant (#RGPIN 2019-06746). Absorbed dose calorimetry research at McGill University is in part supported by Sun Nuclear Corporation.

A Pyroelectric Calorimeter with Electrometer Readout for the Absolute Dosimetry of FLASH Radiation: Proof of Principle

J Renaud^{*}, B Muir, National Research Council, Ottawa, ON

Purpose: Given the extremely short delivery times of FLASH beams, real-time dosimetry is essential. The poor performance of ion chambers in high dose-per-pulse beams is well known and the alternative proposed to date is absorbed dose calorimetry. However, to-date, such devices are complex to operate and require instrumentation for readout not normally possessed by clinics. This work describes the development and initial characterization of a pyroelectric calorimeter capable of FLASH dosimetry measurements that can be read out with only an electrometer. **Methods:** A square pyroelectric crystal (lead-zirconate-titanate; PZT) with a side length of 2.8 mm was mounted in a cylindrical Delrin holder. The holder reproducibly compresses the crystal between two electrodes. The pyroelectric crystal is a current source with a signal magnitude that is directly proportional to a change in temperature, hence a calorimeter. As an initial test, a calibrated thermistor was affixed to the crystal and the assembly was embedded in a copper block. The temperature of the copper was then modulated by exposing it to the heat of a halogen lamp, simulating the effect of a FLASH beam. Pyroelectric readout was performed with an electrometer (Keithley 6517A) in current mode, while thermistor resistance was measured with an 8.5-digit multimeter (HP 3458A). **Results:** A set of 6000 data points were acquired spanning rates of temperature change from ± 8 mK/s, or 3.5 Gy/s in terms of equivalent dose rate. Pyroelectric current varied linearly with the time derivative of the thermistor temperature. The proportionality constant, which is the detector's calibration coefficient, was measured to be $2.300(3)$ nC/K, a value consistent with the literature on PZT. **Conclusion:** This proof of principle demonstrates the feasibility of operating a pyroelectric calorimeter with an electrometer for the purpose of absolute determination of absorbed dose rates greater than a few Gy/s, relevant for FLASH dosimetry.

3D Dense U-Net for Fully Automated Multi-Organ Segmentation in Female Pelvic Magnetic Resonance Imaging

F Zabihollahy*, E Schmidt, A Viswanathan, J Lee, Department of Radiation Oncology and Molecular Radiation Sciences, Johns Hopkins University, Baltimore, MD

Purpose: Brachytherapy (BT) combined with external beam radiotherapy (RT) is the current standard of care for cervical cancer patients. Accurate segmentation of organs at risk (OAR) is a prerequisite step for RT planning. In this study, we propose a two-step automatic multi-organ segmentation method using convolutional neural network (CNN) in female pelvic magnetic resonance (MR) images. **Methods:** Our segmentation model consists of two cascaded steps; 1) organ localization and 2) fine segmentation of individual organs. The first step employs a 3D U-Net to localize each organ from which organ-specific regions of interest (ROIs) are produced. The original MR volume is then cropped, based on the ROIs, yielding organ-specific volumes for the next step. For fine segmentation, modified 3D Dense Block (BD) is embedded into a 3D U-Net-like architecture to simultaneously capture intra- and inter-slice information while facilitating information flow in the network. A total of 221 3D T2-weighted MR volumes from 135 patients, were used for this study. Training images were augmented using shift and rotation operations and the networks were trained for 200 epochs using a total of 804 MR volumes. **Results:** The proposed method was applied to segment the bladder, rectum, and sigmoid. Compared to the expert radiation oncologists' manual segmentations, average dice similarity coefficients (DSC, mean $\pm$ standard deviation) for 20 test cases are 0.93 ± 0.04 (bladder), 0.87 ± 0.03 (rectum), and 0.78 ± 0.09 (sigmoid). Our methods was also compared to the standard 3D U-Net and 3D Dense U-Net and showed superior performance ($p < 0.05$). Using this newly created model, the segmentation takes 7-8 seconds per each organ. **Conclusion:** We proposed a novel fully automated multi-organ segmentation algorithm for female pelvic MR images. Our experimental results demonstrate that the developed method is accurate, fast, and reproducible, potentially reducing the burden of tedious manual image contouring and thus improving efficiency in RT planning.

Automatic Segmentation and Physician Review of Intact and Post-Operative Prostate Radiotherapy Contours

M El Basha^{1,2*}, D Fuentes^{1,2}, J Pollard-Larkin^{1,2}, F Poenisch², Z Yu^{1,2}, S Frank², C Tang², A Aggarwal³, L Court^{1,2}, C Cardenas^{1,2}, (1) UT MD Anderson UT Health Graduate School of Biomedical Sciences, Houston, TX, (2) University of Texas MD Anderson Cancer Center, Houston, TX, (3) Guy's and St. Thomas' NHS Foundation Trust, London, UK

Purpose: To develop and clinically review a deep learning segmentation algorithm that segments intact and post-operative targets (prostate, prostate bed, seminal vesicles (SV), and SV fossa) and five normal structures for prostate cancer treatment planning. **Methods:** A modified two-stage 3D UNet model was developed using retrospective clinical CT data from 670 patients (8:1:1 train, validation, test split). Stage one inputs a downsampled CT volume and outputs a localized coarse region of interest (ROI) containing multiclass segmentations. The ROI segmentations from stage one are then processed using k-means clustering to identify centroids for 3D patches that are cropped from the full-resolution CT image to generate final segmentation predictions. The 3D patches are then combined by averaging pixel-wise prediction probabilities when there is overlap between 3D patches to generate individual ROI segmentations. The resulting tissue contours were then evaluated quantitatively (Dice, mean surface distance) and qualitatively (radiation oncologist review). **Results:** Segmentations of 9 planning structures were generated with the following average Dice/mean surface distances: prostate $0.79 \pm 0.11/2.9 \pm 2.0$ mm, prostate bed $0.75 \pm 0.05/3.1 \pm 0.6$ mm, SV $0.6 \pm 0.17/3.7 \pm 4.3$ mm, SV-Fossa $0.49 \pm 0.18/4.2 \pm 3.1$ mm, rectum $0.87 \pm 0.05/2.1 \pm 1.0$ mm, bladder $0.96 \pm 0.01/0.8 \pm 0.1$ mm, penile bulb $0.74 \pm 0.11/1.6 \pm 0.8$ mm, femoral heads $0.92 \pm 0.03/1.6 \pm 1.0$ mm, sigmoid $0.40 \pm 0.25/12.6 \pm 13.5$ mm. Two radiation oncologists each reviewed at least two intact and two post-operative patient datasets. The preliminary qualitative review of contours showed the majority of bladder, penile bulb, and femoral head contours were acceptable without edits; the rectum, prostate bed, and SV contours required minor edits; and the sigmoid, SV fossa, and prostate contours required either minor or major edits. **Conclusion:** We developed and evaluated an auto-segmentation algorithm for intact and post-operative prostate radiotherapy. Additional qualitative review is necessary to determine clinical acceptability of the automated contours.

Autosegmentation Anomaly Detection by Clustering of Shapes

D Sawkey*, Varian Medical Systems, Toronto, CA

Purpose: As machine learning (ML) systems become more and more widely used, it is critical to build mechanisms for them to report the confidence level of predictions. For organ-at-risk (OAR) autosegmentation, one measure of confidence is whether the shape determined at prediction time is similar to shapes used to train the model. Here, we develop an ML method to characterise the distribution of OAR shapes and use it to find erroneous training data and anomalous shapes in simulated prediction data. **Methods:** We built a 3D Resnet-style classifier with 13 layers using TensorFlow(TM) 2.3.1 and Keras, and trained it to classify 11 head and neck OAR from a publicly-available dataset [1]. 20 of each OAR were used. The trained model was used in inference mode to classify 878 OAR from the same dataset. The shape distribution was determined by reducing dimensionality of weights in intermediate layers of the classifier to 2, using principal component analysis and t-SNE. Outliers were detected by visual inspection or calculating distances of data points from cluster center-of-mass. t-SNE variables (perplexity) and classifier layer were varied. [1] Wee, L., & Dekker, A. (2019). Data from Head-Neck-Radiomics-HN1 [Data set]. The Cancer Imaging Archive. <https://doi.org/10.7937/tcia.2019.8kap372n> **Results:** Examples of anomalous shapes were detected include mislabelling (both cochlea labelled 'left cochlea' in training data); unusual anatomy (oral cavity of patient without teeth); patient positioning differences (brain of a patient with reduced neck extension); contouring styles (volume of cochlea, inferior limit of spine contour). One OAR (oral cavity) showed two distinct clusters indicating variation in contouring styles. **Conclusion:** Clustering of OAR shapes is useful for cleaning ML training data and flagging potentially incorrect predictions. This may be used to help autosegmentation programs determine prediction confidence levels.

Auto-Segmentation of Organs-At-Risk in Head and Neck CT Images with Dual Shape Guided Network

S Wang*, T Yanagihara, B Chera, C Shen, P Yap, J Lian, UNC at Chapel Hill, Chapel Hill, NC

Purpose: The accurate segmentation of organs-at-risk (OARs) in CT images is a critical step for radiation therapy of head and neck cancer patients. However, manual delineation for numerous OARs in this region is time-consuming and challenging due to low soft-tissue contrast. We propose a novel dual shape guided network (DSGnet) to delineate nine important OARs in CT images automatically. **Methods:** To deal with the large shape variation and unclear boundary of OARs in head and neck CT images, we represent the organ shape using an organ-specific unilateral inverse-distance map (UIDM) and guide the segmentation task from two different

perspectives: direct shape guidance by following the segmentation prediction and across shape guidance by sharing the segmentation feature. In direct shape guidance, the segmentation prediction is supervised by the true label mask and the true UIDM, implemented through an encoder-decoder mapping from the label space to the distance space. In the across shape guidance, UIDM is used to facilitate the segmentation by optimizing the shared feature maps. Our method was applied to 699 images. The Dice Similarity Coefficient (DSC) and Average Surface Distance (ASD) of the segmentation result were compared with another seven published start-of-art deep learning methods. The time spent in revising automatically generated contours by our algorithm was compared with the time for the complete manual contouring. **Results:** Our model showed the overall DSC value of 0.842 and ASD value of 1.204 mm across nine OARs. Compared with competing methods, our method achieved the best DSC for all nine OARs and the best ASD for eight OARs. Manual delineation time is saved 64% when aided by the contours created from our algorithm. **Conclusion:** We have developed a novel dual shape guided fully convolutional network for the accurate segmentation of organs-at-risk in head and neck CT images.

SW and JL are in part supported by NIH 1R01CA206100.

Improving Cone-Beam CT Based Organ Segmentation with Attention and Knowledge Transfer

H Zhou^{1*}, Y Min², A Kishan², S Yoon², M Cao², D Ruan^{1²}, (1) Department of Bioengineering, UCLA, Los Angeles, CA, (2) Department of Radiation Oncology, UCLA, Los Angeles, CA

Purpose: It is desirable to utilize Cone-beam CT (CBCT) for on-table patient anatomy monitoring to perform daily dose accumulation and even plan adaptation. However, CBCT suffers from low image quality, resulting in difficulty to perform segmentation, either manually or automatically; and are usually associated with a high level of uncertainty and inconsistency. In this study, we aim to improve CBCT based segmentation by proposing a deep learning approach with common domain embedding to transfer planning quality image inference and contour confidence to CBCT-based segmentation. **Methods:** A YOLO detector trained from multiple views was first applied to localize the region of segmentation interests. Using 2.5D UNet as the basic segmentation structure, two approaches injected FBCT into the segmentation module were explored: (1) a brute-force approach where training data contained images and the corresponding contours from both modalities, entering the network randomly; (2) a two-stream model with partially coupled encoder and early inference, where CBCT went through one stream, and a randomized subset of CBCT and FBCT went through another stream. The proposed approach was applied to the prostate region, where rectum and bladder were segmented from the background. **Results:** The two-stream model enhanced the segmentation accuracy of the rectum/bladder to DSC $0.68\pm0.09/0.92\pm0.02$ for testing subject1, and $0.79\pm0.04/0.87\pm0.01$ for testing subject2; and MSD $3.67\pm1.23/1.77\pm0.51$ mm and $3.24\pm1.62/3.75\pm0.64$ mm; compared to the baseline UNet trained with CBCT which had DSC $0.66\pm0.07/0.90\pm0.03$ and $0.76\pm0.04/0.77\pm0.03$; $3.47\pm0.58/2.20\pm0.88$ mm and MSD $2.80\pm0.54/5.43\pm0.81$ mm; and with CBCT+FBCT of DSC $0.67\pm0.08/0.91\pm0.02$ and $0.78\pm0.04/0.86\pm0.01$; MSD $3.51\pm0.85/1.96\pm0.64$ mm and $3.59\pm0.97/4.55\pm0.64$ mm, respectively. **Conclusion:** The proposed YOLO + two-stream model effectively enhanced the segmentation performance in CBCT by regulating its features extraction and early inference with FBCT. We will adjust the coupling to allow for modality-specific feature variation and also regulate the output contour. Moreover, we are actively investigating approaches to minimize uncertainty associated with the CBCT label themselves.

TU-F-TRACK 6-06

Measuring the Clinical Impact of the Introduction of a Novel Auto-Contouring Workflow for 0.35T MRI-Guided Pelvic Radiotherapy

Y Abdulkadir*, D Luximon, E Morris, P Chow, J Lamb, University of California, Los Angeles, Los Angeles, CA

Purpose: Deep neural nets have revolutionized the science of auto-segmentation and present great promise for treatment planning automation. However, little data exists regarding clinical implementation. We evaluated the performance and clinical implementation of a novel deep learning-based auto-contouring workflow for 0.35T magnetic resonance imaging (MRI)-guided pelvic radiotherapy. **Methods:** An auto-contouring model was developed using a UNet-derived architecture for the femoral heads, bladder, and rectum. Training data was taken from 75 patients treated on an 0.35T MRI-guided radiotherapy machine. Post-processing steps were developed in order to optimize usability of the resulting contours. The model was tested against 20 retrospective cases outside the training set, and subsequently was clinically implemented by interfacing it to the software used for clinical contouring in our department. Usability was evaluated on the first 10 consecutive clinical cases by computing 2D slice-by-slice Dice similarity coefficient (2D-DSC) and the fraction of slices that were used un-modified by planners. Final contours were retrospectively reviewed by an experienced treatment planner and clinical significance of deviations was graded as negligible, low, moderate and high probability of leading to actionable dosimetric variations. **Results:** Average 2D-DSC for the retrospective test data were 92.8 ± 4.9 , 91.8 ± 8.2 , 91.6 ± 13.3 , and 87.2 ± 11.8 for the right and left femoral heads, bladder, and rectum respectively. Post-implementation, average 2D-DSC were 100.0 ± 0.4 , 99.3 ± 4.3 , 94.9 ± 10.5 , 94.5 ± 14.4 , respectively. For each organ, 99.1, 96.3, 53.7, and 64.7 percent of slices were used unmodified by the planner. In retrospective review of contours used for planning, a total of 6 deviating slices in 2 patients were graded as low potential clinical significance. No deviations were graded as moderate or high clinical significance. **Conclusion:** We have presented an analysis of the clinical implantation of a novel auto-contouring workflow. Research-oriented performance metrics correlate imperfectly with clinical utility. Substantial workflow savings were obtained, and little automation bias was observed.

TU-F-TRACK 6-07

Weaving Attention U-Net for Head and Neck Multi-Organ CT Segmentation

Z Zhang*, T Zhao, H Gay, W Zhang, B Sun, Washington University in St. Louis, St. Louis, MO

Purpose: Manual contouring used in the current treatment planning process is tedious, time-consuming, and can produce inconsistent results. We develop a novel and efficient CNN-based deep learning method for automated multi-organ segmentation on head and neck (HN) CT images. **Methods:** The new method uses a densely weaving attention U-net (WAU-net) structure as the backbone and implements a novel boosting-style training strategy. WAU-net follows the basic U-net structure and uses attention fusion blocks for the decoder path. It evolves from shallow structures to more complex ones while forcing itself to exploit deeper features by down-weighting the regions correctly contoured by simpler networks. Under the boosting-style training strategy, the network evolves gradually, stressing previously wrongly labeled pixels to achieve finer segmentation outcomes. We trained our new method to contour 10 OARs within a single forward propagation. We performed 10-fold cross-validation with 90 cases and tested the performance on the rest 25 cases. The accuracy of modeled contours was evaluated with the Dice similarity coefficient (DSC), average Hausdorff distance (AHD), and average surface Hausdorff distance (ASHD) using clinical contours as a reference to the ground truth. The accuracy of the model was compared to other popular deep learning methods. **Results:** Our method achieved superior or comparable results to several existing deep learning approaches. In addition, our new model used substantially fewer model parameters and less computation cost. The model also achieved state-of-the-art performance on the testing dataset. The average DSC on the testing data sets were as following: brainstem (0.88), chiasm (0.71), mandible (0.95), spinal cord (0.89), left optic nerve (0.74), right optic nerve (0.75), left sub-mandibular (0.81), right sub-mandibular (0.80), left & right parotid (0.85) and right parotid (0.83). **Conclusion:** WAU-net provides state-of-the-arts accurate contouring of multiple OARs, which can potentially facilitate the routine OARs delineation process for HN cancer.

Representation Matters: Our Responsibility in Cultivating Inclusion and Belonging in Radiation Oncology

WE-A-TRACK 1-05**Panel Discussion and Audience Q&A**

There has been a focus on generating awareness and cultivating equity, diversity, and inclusion (EDI) in the medical physics community, with significant efforts made by the AAPM and COMP at the last joint scientific meeting. However, there is still a need to exchange readily adoptable methods to improve EDI in recruitment, education, residency training, and professional practice. In this session, we will review how mentorship and intentional professional development can improve EDI in medical physics.

First, we will discuss how mentorship plays an important role in retaining underrepresented minorities (URM) in medical physics. We will provide strategies to develop holistic developmental relationships with URM mentees. Attendees will also be able to recognize unintentionally harmful and exclusionary practices that may discourage an URM's training, professional engagement, and career advancement.

Second, medical physicists involved in education, training, and management will learn about the concept of adverse impact and how adverse impact assessments can be used while reviewing screening criteria and procedures for residency applications. We will introduce structured interviews and their value in improving reliability, validity, and fairness, and examine how structure can be added to the recruitment interview process by implementing content-related components (e.g., standardized questions, behavioral or situational interviewing) and evaluation-related components (e.g., rating scales, interviewer training).

Then, we will highlight EDI initiatives adopted by our colleagues in radiation oncology, discuss the importance of diversity in the radiation oncology workforce, and identify effective strategies to improve EDI. This discussion will return to why diversity matters in both medical physics and in the general scope of healthcare.

Finally, the audience will engage with the speakers in a panel discussion and have the opportunity to exchange their own experiences with successful EDI strategies.

At the end of this session, participants will:

1. Learn about methods for fostering EDI in education, training, and professional practice.
2. Become familiar with mentorship strategies to advance developmental relationships with underrepresented minorities in medical physics.
3. Understand how adverse impact assessments and structured interviews can be applied as valuable tools for improving reliability, validity, and fairness in the recruitment process.
4. Gain insight on why diversity matters in healthcare, and learn about strategies used to improve diversity in the current radiation oncology workforce.

Clinical Applications & Dosimetric Considerations

The motivation for dual- or multi-energy CT (DECT or MECT) is that in x-ray computed tomography (CT), materials with different elemental compositions can have identical CT number values, depending on the mass density of each material and the energy of the detected x-ray beam. Differentiating and classifying different tissue types and contrast agents can thus be extremely challenging. In MECT, one or more additional attenuation measurements are obtained at a second, third or more energy. This allows the differentiation of at least two materials. Commercial DECT systems (only two energy measurements) are now available either using sequential acquisitions of low- and high-tube potential scans, fast tube-potential switching, beam filtration combined with spiral scanning, dual-source, or dual-layer detector approaches. The use of energy-resolving, photon-counting detectors is now being evaluated on research systems. Irrespective of the technological approach to data acquisition, all commercial MECT systems today provide dual-energy data. Material decomposition algorithms are then used to identify specific materials according to their effective atomic number and/or to quantitate mass density. These algorithms are applied to either projection or image data. Since 2006, a number of clinical applications have been developed for commercial release, including those that automatically 1) remove the signal from bony anatomy and/or calcified plaque; 2) create iodine concentration maps from contrast-enhanced CT data and/or quantify absolute iodine concentration; 3) create virtual non-enhanced images from contrast-enhanced scans; 4) identify perfused blood volume in lung parenchyma or the myocardium; and 5) characterize materials according to their elemental compositions, which can allow in vivo differentiation between uric-acid and non-uric-acid urinary stones or uric acid (gout) or non-uric-acid (calcium pyrophosphate) deposits in articulating joints and surrounding tissues. AAPM Report 291 provides an authoritative, open-access, peer-reviewed review of the topic of MECT for both the imaging and therapy communities. It describes the fundamental principles of MECT in an intuitive manner and with mathematical rigor, current and emerging manufacturer implementations, and current and emerging clinical applications.

Learning Objectives:

1. Understand the motivation for and fundamental principles of multi-energy CT
2. Appreciate the range of technical implementations of multi-energy CT
3. Recognize strengths and weaknesses of different technical implementation strategies
4. Identify clinical CT applications made possible by multi-energy CT

Advanced Imaging using Multitom Rax

The vast majority of medical Cone Beam Computed Tomography (CBCT) imaging occurs with the gantry rotating at a constant velocity in a circular trajectory, independent of the specific task and patient. Advancements in robotic X-ray systems have paved the way for variable velocity and non-circular exotic acquisition orbits to be investigated in clinical settings. The clinical drivers for such acquisitions include enabling patient-specific imaging, reducing overall imaging dose and providing the ability to tailor the image acquisition for a specific clinical task. Imaging patients with variable velocity and non-circular exotic orbits has applications in fields ranging from radiation therapy and ablation, to neuro- and orthopaedic surgery through to interventional radiology and beyond.

Learning Objectives:

1. To understand the clinical drivers for adaptive and exotic acquisition orbits on robotic X-ray systems
2. To learn the current exotic acquisition orbits being implemented
3. To examine the future directions of clinical imaging with robotic X-ray systems

AI for Intrafraction Motion Monitoring: Are We There Yet?**

The progress of artificial intelligence (AI) technologies has recently been exponential and shown to be both transformative and disruptive in many fields, which has impacted many aspects of human life. These AI technologies are now being researched, developed, and applied to healthcare, including radiation therapy. Imaging has become essential not only for the detection and monitoring of disease but also for improving the outcome of radiotherapy. Image-guided radiation therapy (IGRT) uses imaging during radiotherapy to improve the precision and accuracy of treatment delivery. Treatment machines are equipped with imaging technology to image patient anatomy before and during treatment. By comparing these images to the reference images taken during simulation, the patient's position and/or the radiation beams may be adjusted to more precisely deliver the radiation dose to the target. AI-based analytical and computational tools have been developed to enhance the role of quantitative imaging in IGRT and further improve the accuracy and precision of radiotherapy.

In the session, we will focus on the potential impact of AI on four important aspects of IGRT: image reconstruction, image augmentation, image registration, and intrafraction motion monitoring. This session will identify challenges and opportunities of AI, especially deep learning in IGRT, explore strengths and limitations of different AI models in IGRT, outline future trends of AI in IGRT, and highlight specific clinical applications.

Learning Objectives:

1. Learn the challenges in current IGRT and the technologies available or being developed for IGRT.
2. Learn how AI can be utilized to improve current IGRT practice.
3. Identify the rationale, significance, quality, and safety issues of AI in IGRT.
4. Understand the challenges, opportunities, strengths, and limitations of AI in IGRT.

Advancement of imaging research requires years of effort from dedicated research groups around the world. Such groups, working independently, typically suffer from limited local resources in terms of patient data and access to the “ground truth” required to properly train and test their algorithms. When these research groups report their methods in the literature, it is difficult for the research community to compare the relative merits of different approaches, since performance can depend on factors such as database composition, image quality, “truth” definition, and performance evaluation metric. Grand challenges allow for a direct comparison of different algorithms designed for a specific task, with all algorithms following the same set of rules, operating on a common set of data, and being evaluated with a uniform performance assessment approach. Comparisons among the methods of participating groups can help identify approaches that are the most promising for a specific task. The AAPM Working Group on Grand Challenges (WGGC) was created to promote the conduct of grand challenges in medical imaging by (1) developing recommendations for hosting computational challenges through AAPM activities designed to assess or improve the use of medical imaging in diagnostic and/or therapeutic applications, (2) vetting proposals from groups that wish to host a challenge in conjunction with the Annual Meeting, (3) facilitating the execution of these challenges, and (4) generating ideas for challenges to advance the field. Two challenges sponsored by the WGGC were conducted in the months leading up to the 2021 AAPM Annual Meeting and provided a unique opportunity for participants to compare their algorithms with those of other groups in a structured, direct way. Overviews of the Deep Learning for Inverse Problems: Sparse-View Computed Tomography Image Reconstruction (DL-Sparse-View CT) Challenge and the SPIE-AAPM-NCI DAIR Digital Breast Tomosynthesis Lesion Detection (DBTex) Challenge along with the DAIR Digital Breast Tomosynthesis Lesion Detection Challenge, Part 2 (DBTex2) will be presented along with presentations from the top-performing groups from the DL-Sparse-View and DBTex2 Challenges.

Learning Objectives:

1. To understand the role of grand challenges and public image datasets in medical imaging research.
2. To learn about the methods used by the top-performing participants in the DL-Sparse-View CT Challenge.
3. To learn about the methods used by the top-performing participants in the DBTex2 Challenge.

The DL-Sparse-View CT Challenge was supported by NIH grant numbers R01 EB026282 and R01 EB023968 and by a Grayson-Jockey Club research grant. The DBTex2 Challenge was supported by NIH grant number R01 EB021360.

Analytical Modeling of the Dynamic Collimation System Using Dual Trimmer Planes

L Bennett^{1*}, D Hyer¹, K Erhart², N Nelson³, P Hill³, K Patwardhan¹, T Geoghegan¹, B Smith¹, R Flynn¹, (1) University of Iowa, Iowa City, IA, (2) .decimal LLC, Sanford, FL, (3) University of Wisconsin Medical Radiation Research Center, Madison, WI

Purpose: Previous implementations of the Dynamic Collimation System (DCS) in the Astroid Treatment Planning System (TPS) modeled the trimmers as a single infinitesimally thin rectangular aperture. While this method is appropriate for a single brass aperture, it is insufficient to model DCS-based pencil beam scanning (PBS), which has two trimmer banks at different distances from the isocenter. This work introduces an analytical model that utilizes dual trimmer planes to enable more accurate dose calculation, with and without a range shifter present upstream of the trimmers. **Methods:** The lateral dose distribution from a single proton beamlet was modeled as the weighted summation of sub-beamlets (bixels). The interaction of protons with the apertures was accounted for by modifying bixel weights (fluences). Weights were modified according to the overlap of apertures with each sub-beamlet and were dependent on beam energy, range shifter interaction, and aperture location. Our model introduces multiple trimmer planes 6.5 cm and 10.65 cm from isocenter in the extended nozzle position and 19.65 cm and 23.80 cm from isocenter in the retracted nozzle position. The analytical dose calculation model was validated against a commissioned Monte Carlo model in TOPAS. **Results:** Without a range shifter present, 2D gamma passage rates at 1.0%/1.0mm were 100% between analytical and Monte Carlo for all energies considered (75 MeV, 100 MeV, and 150 MeV) and all trimmer positions relative to the central beamlet axis (1 mm, 5 mm) for both the single and dual trimmer plane models. With the range shifter present, the 2D gamma pass rates for all energies considered (80 MeV, 125 MeV, and 170 MeV) and all trimmer positions were >82% for the single plane model and >92% for the dual plane model. **Conclusion:** Using dual trimmer planes is necessary to accurately calculate dose for DCS plans using analytical dose algorithms.

Research reported in this abstract was supported by the National Cancer Institute of the National Institutes of Health under award number R37CA226518. Hyer, Flynn, and Hill are co-inventors on a patent that has been licensed to IBA.

Dose-Averaged LET in Proton Therapy for Patients with MRI Abnormalities and Its Role in Normal Tissue Complication Probability

A Bertolet^{1*}, R Abolfath², D Carlson³, R Lustig³, C Hill-Kayser³, M Alonso-Basanta³, A Carabe-Fernandez⁴, (1) Massachusetts General Hospital and Harvard Medical School, Boston, MA, (2) New Jersey Urology, West Orange, NJ, (3) University of Pennsylvania, Philadelphia, PA, (4) Hampton University Proton Therapy Institute, Hampton, VA

Purpose: To elucidate the role of LET in the appearance of abnormalities in MRI after undergoing proton radiotherapy. Results helped feed a normal tissue complication probability (NTCP) explicitly including LET as a predictor variable. **Methods:** We calculated dose-averaged LET (LET_d) in 26 meningioma patients that developed abnormalities in MRI studies following proton radiotherapy treatments. An analytical method (MicroCalc) based on the computation of the spectral fluence of primary protons, secondary protons and alpha particles was employed. MRI were registered to planning CT and LET_d values across voxels belonging abnormalities were scored. We divided dose (D) and LET_d ranges in bins and a priori probability of abnormality P(D,LET_d) for each bin was obtained as the fraction of voxels belonging abnormalities and belonging normal areas. This probability is modeled as a function of dose and the linear-quadratic (LQ) parameters $\alpha(LET_d) = \alpha_0 + \alpha_1 LET_d$ and $\beta = \beta_0$, which, in turn, depend on LET_d in this model. Data from patients were used to estimate these dependencies under the model. Finally, NTCP was modeled assuming independence between voxels. **Results:** For (D, LET_d) pair-values with a priori probability higher than 50% of abnormality, LET_d was found to increase roughly linearly as dose decreased, being above 8 keV/μm at doses below 1 Gy and about 3 keV/μm at a dose of 60 Gy. This points towards an enhancement of low dose effectiveness because of high LET_d. LQ parameters were estimated as $\alpha_0 = 0.011 \pm 0.02 \text{ Gy}^{-1}$, $\alpha_1 = 0.033 \pm 0.002 \text{ Gy}^{-1} \mu\text{m keV}^{-1}$ and $\beta_0 = 0.0015 \pm 0.0004 \text{ Gy}^{-2}$. **Conclusion:** We illustrated a practical method to infer the potential role that LET may play in the induction of normal tissue complications and on derived parameter estimates of an LET-dependent NTCP model. However, a larger patient cohort including patients without abnormalities are required to further validate these results.

Robust Optimization of Proton Therapy Treatments Using a Variable Range Uncertainty

M Cohilis^{1*}, E Sterpin^{1,2}, C Chang³, S Rivas¹, L Lin⁴, J Lee¹, K Souris¹, (1) UCLouvain, Brussels, BE, (2) KU Leuven, Leuven, BE (3) Emory University, Alpharetta, GA (4) Emory Proton Therapy Center, Atlanta, GA

Purpose: In proton therapy (PT), a range uncertainty of 2.6% is typically assumed when planning robust treatments with Monte Carlo dose engines. This number is based on a dominant contribution from tissues I-values. However, it was recently shown that expressing tissues as a mixture of water and “dry” material during the CT calibration process allowed for a significant reduction of this uncertainty. We thus propose an adapted framework for PT robust optimization. First, we move towards a spot-specific range uncertainty (SSRU) determination. Second, we use the water-based formalism to reduce range uncertainties and potentially better spare OAR. The methodology is applied to the treatment planning of a head and neck (H&N) primary tumor. **Methods:** For each spot, a ray-tracing method was used to propagate I-values uncertainties and obtain the corresponding range uncertainties. These were then combined with other sources of range uncertainties. Two plans of the same patient were optimized: the first one with the classical 2.6% range uncertainty, the second one with the SSRU. These plans were compared in terms of OAR mean dose reduction. Robustness evaluations were also performed, using the SSRU for both plans in order to simulate errors as realistically as possible. **Results:** The SSRU plan was found to have a very good robustness level at a 90% confidence interval while sparing OAR better than the classical plan. Mean dose reductions of 2.20 Gy and 4.27 Gy were respectively observed in the oral cavity and superior pharyngeal muscle for a similar target coverage. The classical plan showed an unnecessary robustness level, even when considering 100% of the simulated scenarios. **Conclusion:** Promising results of the SSRU framework were observed on a simplified H&N case. We believe the methodology could benefit even more for a full H&N treatment where more OAR will be close to the target volume.

The Effect of Treatment Planning Approach on Head-And-Neck IMPT for Patients with Implanted Dental Fixtures

Y Hu^{1*}, O Muller², R Foote¹, D Mundy¹, (1) Mayo Clinic, Department of Radiation Oncology, Rochester, MN, (2) Mayo Clinic, Department of Advanced Prosthodontics, Rochester, MN

Purpose: Proton dose perturbations from dental fixtures (e.g. amalgams, crowns, and implants) are unverified for clinical treatment plans. The effect of several treatment planning approaches for patients with installed dental fixtures is quantified. Four scenarios were measured and compared: (1) standard-operating procedure (SOP) treatment geometry (two anterior oblique and one posterior beam) with no fixtures in phantom; (2) SOP plan for patient with installed fixtures (e.g. spot delivery through fixtures prohibited); (3) SOP no-fixture plan delivered to phantom with installed hardware; (4) installed fixtures overridden and plan reoptimized without limitations for spot positions/delivery. **Methods:** An anthropomorphic head phantom with removable maxilla, mandible, and tongue inserts was simulated and clinically representative treatment plans were generated, delivering 54 Gy dose to a base-of-tongue (BoT) clinical target volume (CTV). An approximately 1.5 mm depth central groove occlusal amalgam and a PFM crown were installed on separate maxilla inserts and tongue inserts were 3D printed accommodating either a microdiamond diode (PTW 60019; Fricberg, Germany) or several axial or sagittal oriented pieces of EBT3 film (Ashland: New Jersey, USA). **Results:** For the amalgam, case (3) delivered to a SFO BoT treatment plan resulted in a dose shadow parallel with the field delivering through the fixture. The dose shadow corresponded to an approximately 12% decrease in dose directly behind the amalgam. Dosimetric losses were local, dropping to a 1% deviation from control within 1 cm of maximum in the direction of the affected beam. Further, the microdiamond diode, which was not set up directly in line with the amalgam, measured effectively no change in delivered dose. **Conclusion:** For SFO BoT plans, amalgams do perturb the beam, resulting in a shadowing effect, reducing the dose directly behind the amalgam in the direction of the affected beam. Losses were observed to be largely local to the implanted fixture.

WE-A-TRACK 6-05

The Relative Variability in Radiosensitivity Between Cell Lines Is the Same for Carbon Ions, Protons and X-Rays

D Flint^{*}, S Bright, B Turner, M Manandhar, M Ben Kacem, D Martinus, S Shaitelman, G Sawakuchi, University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: To demonstrate that the large variations in radiosensitivity between cell lines is the same relative size for higher LET radiation as for x-rays. **Methods:** We compiled clonogenic survival data we measured with data from the literature for human cancer cell lines (n=38) exposed to x-rays and protons (9.9 keV/μm) or carbon (C) ions (13.3-77.1 keV/μm), parameterizing each cell's radiosensitivity as the dose required to achieve 10% survival, D10%. For each radiation quality, we quantified the relative variability in radiosensitivity between cell lines using the coefficient of variation, COV(D10%). For each particle radiation quality, we compared the COV(D10%) to that for the same subset of cells exposed to x-rays via two-tailed z-tests. We further stratified the data into three histological subsets (brain, pancreatic and non-small cell lung cancer) based on tumor type, including only tumors for which no distinction is made in clinical dose prescription. Then, within each histological category, we compared the COV(D10%) values between radiation qualities. **Results:** Even for high LET C-ions, there were remarkable variations in radiosensitivity between cell lines, with COV(D10%) values of 28±6% at 77.1 keV/μm compared to 34±7% for x-rays. Consequently, we could not detect significant differences in the COV(D10%) values for x-rays and any particle radiation quality. The same was true even after we stratified the data into histologic subsets. Indeed, within histologic subsets, we still found remarkable differences in radiosensitivity at high LETs, with brain cancer cells varying 43±18% to 77.1 keV/μm C-ions, non-small cell lung cancer cells varying 24±7% to 60.5 keV/μm C-ions and pancreatic cancer cells varying 16±4% to 60.5 keV/μm C-ions, compared to 37±15%, 34±10% and 15±4%, to x-rays, respectively. **Conclusion:** Even for cell lines of the same histology, there are remarkable variations in intrinsic radiosensitivity that do not differ significantly between photon, proton or C-ion radiation.

WE-A-TRACK 6-06

A Beamlet-Based Optimization Algorithm for Arc Proton Therapy Planning

S Wuyckens^{1*}, G Janssens², E Sterpin^{1,3}, J Lee¹, K Souris¹, (1) UCLouvain, Molecular Imaging, Radiotherapy and Oncology (MIRO), Brussels, BE, (2) Ion Beam Applications SA, Louvain-la-neuve, BE, (3) KULeuven, Oncology Department, Leuven, BE

Purpose: Arc Proton Therapy (ArcPT) is an emerging technique that has the possibility of improving both the outcome and the efficiency of the treatment. This modality constrains the number of energy switches as it primarily determines the treatment delivery time. Therefore, the challenge lies in selecting as few energy layers as possible for each beam direction. In this study, we designed a beamlet-based algorithm for the optimization of ArcPT plans that distributes a number of energy layers similar to conventional therapy over more gantry angles. **Methods:** The ArcPT optimization problem is formulated with an objective function defined conventionally as the quantitative evaluation criterion for the delivered dose distribution combined with new objectives respecting constraints on the number of energy layers used over the arc. The proposed method was tested on a lung tumor case and evaluated according to these criteria: objective function value, layer sparsity and DVH metrics. **Results:** An ArcPT plan with 98.4% of the beams delivering only one energy layer per control point was successfully obtained with good dosimetry results, some of which are even better than the ones obtained with a conventional IMPT plan. Actually, the target D95 reached 96.5% of the prescription in ArcPT versus 95.6% in IMPT. Although the mean doses in the heart (0.4 Gy) and right lung (6.1 Gy) obtained with ArcPT slightly exceed those with IMPT (0.3 Gy and 5.6 Gy for the heart and right lung respectively), they still achieve the clinical goals. **Conclusion:** The algorithm proposed for ArcPT treatment plan optimization has successfully solved the energy layer selection problem by generating acceptable plans with good dosimetric results. The definition of our objective function will be completed with a sequencing energy term that favors small consecutive energy decrements to further reduce irradiation time.

Funded by the Walloon Region. Research agreement with Ion Beam Applications SA (IBA).

WE-A-TRACK 6-07

The Combined Effects of Protons and An Inhibitor of ATR Increase Micronuclei Formation and Potentiate Anti-Tumor Immunity

B Turner^{*}, S Bright, D Flint, G Sawakuchi, S Shaitelman, M Manandhar, M Ben Kacem, D Martinus, University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: High linear energy transfer (LET) protons are more densely ionizing than photons and low LET protons. Therefore, high LET protons create more clustered DNA damage and double strand breaks (DSBs). The double stranded DNA fragments generated in the form of micronuclei are the key activators of the cGAS-STING pathway, thereby potentiating anti-tumor immunity. The cGAS-STING pathway results in downstream activation of pro-inflammatory cytokines and signals that can lead to destruction of tumor cells. Here we show that the combination of high LET protons with an inhibitor of ATR (ATRi), a key protein in DNA damage response, amplify the production of precursors to antitumor immune activation, specifically cGAS-positive micronuclei (MN-cGAS+), more so than photons+ATRi. **Methods:** H1299 and PANC-1 cell lines were treated with 6 MV x-rays and 9.9 keV/μm (dose-weighted LET in water) protons alone or with an ATRi (1 μM, AZD6738). We then assessed MN and MN-cGAS+ 24 and 72 h after radiation+ATRi. The Micronuclei were assessed as the proportion of micronuclei or cGAS+ relative to the quantity of nuclei counted for each treatment tested. This was done using a custom auto-counting macro generated using ImageJ. **Results:** ATRi radiosensitized both

cell lines to photons and protons with sensitizations relative to photons alone of $1.126 \pm 0.049 / 1.003 \pm 0.025$ (H1299/PANC-1) (photons+ATRi) and $1.547 \pm 0.029 / 1.448 \pm 0.043$ (H1299/PANC-1) (protons+ATRi). At 72 h and 5 Gy for H1299 cells, protons+ATRi (0.5326 ± 0.015 MN/nucleus and 0.2426 ± 0.044 MN-cGAS+/nucleus) amplified MN and MN-cGAS+ compared to photons alone (0.3184 ± 0.033 MN/nucleus and 0.1716 ± 0.042 MN-cGAS+/nucleus), protons alone (0.4529 ± 0.007 MN/nucleus and 0.2444 ± 0.018 MN-cGAS+/nucleus) and photons+ATRi. Although of lower magnitude, the same trends were observed at 24 h/5 Gy and 72 h/2 Gy. Results for PANC-1 were also similar. **Conclusion:** In addition to radiosensitization from combining protons+ATRi, high LET protons+ATRi amplify MN-cGAS+, which has been reported to be a precursor of antitumor immune signaling.

This research was supported in part by RP170040, 1R21CA252411-01, Emerson Collective, and MD Anderson Cancer Center. Dr. Sawakuchi has research agreements with Alpha Tau Medical and Artios Pharma. Dr. Shaitelman has a research agreement with Exact Sciences.

Automated Ultrasound QC Methods

WE-A-TRACK 7-06

Q&A

The workshop will include five presentations covering a range of current topics in diagnostic ultrasound QA/QC. “Annual Survey” requirements will be presented, outlining steps and pitfalls of ACR-required ultrasound system tests. These include image uniformity and artifact surveys, geometric accuracy and system sensitivity tests, and display monitor evaluations. QC phantoms will be described for testing general purpose ultrasound scanners. This will be followed by descriptions of specialized phantoms and procedures for performance assessment of automated whole-breast screening ultrasound units. In addition, an overview of Doppler system testing using flow phantoms will be provided. Efforts to assess shear wave elastography and an initiative to estimate “pulse-echo quantitative ultrasound” parameters, including attenuation and backscatter coefficients and speed of sound, by the Quantitative Imaging Biomarkers Alliance (QIBA) and the American Institute of Ultrasound in Medicine (AIUM), will be introduced. Lastly, innovative software programs for automated QC will be described.

The targeted attendees are medical physicists and other medical professionals in diagnostic imaging and radiation oncology with interest in diagnostic ultrasound QC.

Learning Objectives:

1. To gain familiarity with common elements of a QA/QC program for diagnostic ultrasound scanners, including automated whole-breast screening ultrasound systems. QC tools, phantoms and automated software programs will be described.
2. To provide an overview of important phantom characteristics for evaluating Doppler ultrasound equipment and to outline Doppler system tests that can be performed using flow phantoms.
3. To introduce the AIUM/QIBA efforts in assessing shear wave elastography and the emerging pulse-echo quantitative ultrasound features.

Audience Q&A

Looking for that next career step? Do you have what it takes to be considered? Lots of factors can influence your advancement, ranging from expertise, problem-solving ability, and experience. Yet sometimes these factors that look-good-on-paper are not enough. Leadership at the next level means making a personal impact in addition to getting results.

In this session, MPLA will present its recommended leadership curriculum for where to efficiently put your effort for further developing your leadership skills based on your career stage. These core leadership skills should be transferable regardless of your work environment. MPLA will also present career planning steps to use in designing your path forward best suited to you. Additionally, the session will have a panel of medical physicist leaders discuss the need for passion in what you do, for creative as well as strategic thinking, and for the ability to make a strong case. The future of medicine is rapidly changing, so how can you be best equipped to play a role in defining and driving medical physics in your future?

Learning Objectives:

1. Apply the MPLA curriculum matrix of skills versus career stage
2. Value the need for medical physicists to foster both creative thinking and strategic thinking
3. Adapt lessons from a panel of medical physics leaders with their experiences of factors that affected their career advancement

Considerations for Commissioning and QA of SGRT Systems

Surface imaging is becoming a prevalent technology for many radiotherapy treatments, with its clinical applications expanding. The AAPM formed the TG-302 to provide recommendations on the common SGRT clinical applications and discuss its implementation. In addition, TG-302 surveyed AAPM members in 2018 on the prevalence and clinical uses of SGRT. This session will review the survey results to describe the current state of clinical use, including high-dose treatments such as stereotactic body radiotherapy (SBRT). Considerations for specific commissioning and quality assurance tests for SGRT systems will be reviewed. The recommendations of TG-302 regarding use of SGRT for breast radiotherapy and frameless brain SRS treatments will be presented, and some of the potential pitfalls that could occur during clinical application will be summarized.

Learning Objectives:

1. Summarize results of survey regarding the prevalence of SGRT
2. Learn how to commission and QA SGRT systems
3. Discuss the use of SGRT for breast deep-inspiration breath hold treatments including pitfalls
4. Discuss the use of SGRT for frameless brain SRS treatments including risk mitigation

Electrostatic Focusing Lens System for Low MeV-Ion Microprobe: A Simulation and Optimization Study

H Arya*, V Chirayath, Y Chi, University of Texas at Arlington, Arlington, TX

Purpose: Low MeV ion microprobe, that focuses an ion beam into submicron size at the cellular matrix plane, plays an important role in advancing fundamental mechanism study in particle-therapy. The dominant state-of-the-art beam focusing systems are electromagnetic quadrupole lens based, which can be hard to duplicate or of high cost. In this work, we investigated the focusing capability of the electrostatic quadrupole (EQ) lens system with a compact, easy-to-adopt, and cost-effective design goal. **Methods:** We have performed the investigation with three simulation tools: GICOSY (low accuracy but high efficiency) for raw optimization, SIMION 8.1 (high accuracy but low efficiency) for fine tuning, and WinTRAX for aberration studies. We optimized the lens system with considering the lens numbers, lengths, intervals, applying voltages, and aperture-lens distance (DAL) under a given input beam condition. We compared the performance of the optimized system to that of the state-of-art EQ sextuplet (EQS) system used in the RARAF center of Columbia University and our previously optimized EQ quadruplet (EQQ) system, in the aspects of system length (Ls), working distance (Dw), demagnification factor (Df) and aberrations. **Results:** An EQ triplet (EQT) lens system was optimized with superior performance than EQS and EQQ lens for a 3 MeV input proton beam with beam diameter of 30 μ m and angular divergence of 0.0067mrad. Specifically, comparing to Columbia EQS, Ls for EQT is $\sim$ 2 folds shorter (1.9 vs. 3.887 m), Dw is $\sim$ 1.4 times longer (170.2 vs. 126 mm) and Df is $\sim$ 2 times larger (198 vs. 94). Using the 'Q' value to comprehensively evaluate the focusing strength and aberration, EQT gains a Q of 30.4, while that for EQS and EQQ are 9.4 and 5.0, respectively. **Conclusion:** The results support our goal of compact, stable and high performance EQ design, providing promise to advance relevant radiobiological studies.

The Potential of Online-Adaptive Head and Neck Proton Therapy to Reduce Normal Tissue Complication Probability

A Lalonde*, M Bobic, B Winey, J Verburg, G Sharp, H Paganetti, Massachusetts General Hospital / Harvard Medical School, Boston, MA

Purpose: To evaluate the impact of daily online adaptation on normal tissue complication probability (NTCP) in the context of head and neck intensity modulated proton therapy (IMPT). **Methods:** IMPT treatment plans are created without setup margins for 10 retrospective head and neck patients with daily CBCTs (median=33). The plans are adapted at each fraction using an in-house developed online adaptation (OA) workflow based on GPU accelerated Monte Carlo dose calculation and a deep learning-based CBCT scatter correction algorithm. OA is performed by re-adjusting the intensity of a subset of highly weighted spots without changing their energy or position. For comparison, a second plan is created for each patient using robust optimization (RO) with a 3 mm set-up uncertainty on which no adaptation is performed during delivery. For both scenarios, dose accumulation is performed using deformable image registration between each daily CBCT and the planning CT. NTCP models for xerostomia, aspiration, dysphagia, oral mucositis, liquid and solid swallowing are applied to the accumulated dose distributions in order to quantify the toxicity risk associated with each treatment technique. **Results:** Both methods achieved similar target coverage over the course of treatment. NTCP calculated on the cumulative dose distributions showed a reduction in toxicity risk for aspiration, dysphagia, liquid and solid swallowing in all patients using OA over RO. The most noticeable differences were for aspiration, with median NTCP values of 28.4% and 17.1% for RO and OA respectively. Xerostomia and oral mucositis NTCP were also reduced over the whole patient cohort using OA over RO, with mean reductions of 4.7 and 8.3 percentage point respectively. **Conclusion:** This work demonstrates the potential of online adaptive proton therapy to expand the therapeutic window of head and neck IMPT by reducing the risk of long-term side effects while ensuring adequate target coverage.

Design and Initial Testing of An Isocenter Alignment Prototype for the Proton Dynamic Collimation System

T Geoghegan^{1*}, K Patwardhan¹, B Smith¹, R Flynn¹, J Yu², A Gutierrez², D Hyer¹, (1) University of Iowa Hospital and Clinics, Iowa City, IA, (2) Miami Cancer Institute, Baptist Health South Florida, Miami, FL

Purpose: The purpose of this work is to design and validate an isocenter alignment system for the Dynamic Collimation System (DCS), a proton collimator comprised of four nickel trimmers that move in synchrony with a scanned proton beam to sharpen the lateral penumbra. Accurate alignment of the DCS with the radiation isocenter is necessary as the lateral dose distribution is sensitive to the spatial relationship between the proton beam and the collimator. **Methods:** An alignment system was designed to be affixed to the base of the DCS and consists of a chromium-doped alumina scintillating screen (Chromox), a mirror, and a Raspberry Pi camera system. The camera system, which is mounted outside of the primary beam, views the scintillator via the mirror which is tilted at 45°. Each axis is aligned to radiation isocenter by irradiating a nickel trimmer with a uniform, 150 MeV scanned proton field (7x7 cm²) while acquiring a long exposure image of the Chromox screen. From the acquired images, the center of the trimmer is compared with the center of the radiation beam to determine the offset between the radiation and mechanical isocenter of the DCS. This calculated offset is passed along to the DCS control system such that the mechanical DCS coordinate system can be re-calibrated to match the radiation isocenter. This process is then repeated for each axis. **Results:** The alignment system was able to calculate the radiation isocenter offset within 1.1 mm as compared to a beams-eye-view x-ray image. **Conclusion:** Initial results indicate that the camera system is capable of aligning the trimmers to the center of a scanned proton field. Automation and further refinement of this system could result in an efficient QA alignment platform for the DCS

Research reported in this abstract was supported by the National Cancer Institute of the National Institutes of Health under award number R37CA226518. Hyer and Flynn are co-inventors on a patent that has been licensed to IBA.

Fast MCsquare-Based Independent Dose Verification Platform for Pencil Beam Scanning Proton Therapy

Y Zhang^{1*}, C Liu², M Ho³, J Park¹, W Hsi¹, X Liang¹, Z Li⁴, y song⁵, H Feng⁵, (1) University of Florida Proton Therapy Institute, Jacksonville, FL, (2) University of Science and Technology of China, Hefei, CN, (3) Johns Hopkins Medicine, Washington, DC, (4) Concord Medical Group, Guangzhou, Guangdong, CN, (5) Hefei Institute of Physical Science, Chinese Academy of Sciences, Hefei, Anhui, CN

Purpose: Secondary dose verification has not been introduced to proton therapy as a routine practice. The purpose of this study is to commission MCsquare (a multi-cores CPU-based dose calculation engine), integrate it into RayStation treatment plan system (TPS) to create a dedicated platform for fast, independent pencil beam scanning (PBS) dose verification. **Methods:** A MCsquare-based independent dose verification platform (MC2InRS) was developed to realize automatic dose re-calculation for clinical use, including data preparation, dose calculation, 2D/3D gamma analysis. MCsquare was commissioned based on in-air lateral dose profiles, integrated depth dose, and the absolute dose of different beam energies for Proteus@ONE. It was then integrated into RayStation using Python to build the independent dose verification platform - MC2InRS. MC2InRS was validated with measurement data using various targets and depths in a water phantom. This study also investigated fifteen clinical cases to demonstrate the feasibility and effectiveness of MC2InRS platform in clinic practice. **Results:** Between simulation and

measurement, the distal range differences at 80% (R80) and 20% (R20) dose levels for each energy were below 0.05 mm, and 0.1 mm, respectively, and the absolute dose differences were below 0.5%. 29 out of 36 QA planes reached a 100% gamma passing rate (GPR) for 2%/2mm criteria, and a minimum of 98.3% gamma was obtained in water phantom between simulation and measurement. For the 15 clinical cases investigated, the average 2D GPR (2%/2mm) was 95.4%, 99.3% for MCsquare vs. measurement, MCsquare vs. TPS, respectively. The average 3D GPR (2%/2mm) was 98.9%, 95.3% for MCsquare vs. TPS in water, and computed tomography (CT), respectively. **Conclusion:** A fast, independent dose verification platform – MC2InRS, has been developed to perform dose verification with high accuracy and efficiency for Pencil Beam Scanning (PBS). The feasibility of using MC2InRS in routine clinical practice has also been demonstrated.

BEST IN PHYSICS (THERAPY): New System for Fast and Independent Proton Beam Energy Measurement

F Milián^{1,2*}, O Villarreal¹, M Abujami¹, R Cirio¹, C Galeone³, S Giordanengo³, N Minafra⁴, V Monaco¹, E Verroì⁵, A Vignati², R Sacchi¹, (1) University of Torino, Physics Department, Turin, Italy, (2) State University of Santa Cruz, UESC, Ilheus, Brazil, (3) National Institute for Nuclear Physics INFN, Turin division, Turin, Italy, (4) University of Kansas, Lawrence, United States, (5) Trento Institute for Fundamental Physics and Applications, INFN, Povo, Italy

Purpose: A new system to measure the energy of clinical proton beams was developed. It is based on the precise measurement of the protons' time of flight (TOF) and a self-calibration procedure. Results from preliminary validation tests will be presented. **Methods:** A telescope was built using two Ultra-Fast Silicon Detectors segmented in 2.2 mm² strips and mounted on dedicated 8-channels front-end readout boards. A high-precision positioning system allows the TOF measurement at different configurations. Two linear stages are used for the transversal alignment of the second sensor while a third, 1 m long, linear stage moves one sensor to change the distance from 30 to 95 cm along the beam direction (axes Z). This displacement is measured with 10 µm of accuracy using an absolute optical encoder. The 16 signals from strips were acquired with a 5Gs/s digitizer and processed with a MATLAB application. To validate the self-calibration procedure, measurements were performed with a clinical proton beam at 7 different energies (69, 72, 104, 142, 183, 223, and 227 MeV), 4 distances (40, 60, 80 and 95 cm) and 12 milliseconds of data from 30 seconds of acquisition time. **Results:** The linear interpolations of the averaged TOFs as a function of the distance shown deviations of a few hundred keV for most of the energies and all the distances, corresponding to less than 1 mm range difference. The consistent energy values obtained for the four distances reflect the good calibration of the system. **Conclusion:** A new system able to measure independently the proton beam energy in a few seconds has been developed. This new technology, fast and precise, would radically improve the commissioning operations and could introduce new methods for beam control and validation in particle therapy.

We kindly acknowledge the following funding agencies and collaborations: INFN - CSN V (MoVeIT project); Dipartimenti di Eccellenza, Università degli Studi di Torino (ex L. 232/2016, art. 1, cc. 314,337); Ministero della Ricerca, PRIN 2017, progetto 2017L2XKTJ 4DInSiDe.

Simultaneous Proton Dose and LET Measurements Using Dual Storage Phosphors

J Setianegara*, T Mazur, D Yang, H Li, Washington University School of Medicine, St. Louis, MO

Purpose: To investigate the feasibility of using two optical storage phosphor dosimeters of different proton numbers (Zeff) for simultaneous proton dose and linear-energy-transfer (LET) measurements. **Methods:** A high Zeff commercial BaFBr:Eu²⁺ storage phosphor detector was investigated and compared with KCl:Eu²⁺, a low Zeff (Zeff=18) storage phosphor made in-house. BaFBr:Eu²⁺'s proton stopping-power-ratio (SPR) was calculated using the Bethe-Bloch theory with elemental data obtained via energy dispersive x-ray spectroscopy (EDS) analysis. Then, its optical characteristics were investigated using excitation and emission spectral analysis. Finally, its dosimetric response under varying proton irradiation conditions was measured under a reference proton SOBP geometry (Range: 15.0 g/cm², Modulation: 10.0 g/cm²) generated using a Mevion S250 proton therapy unit. The LET environment varied with depth in water and their values were calculated using analytical methods. The dosimetric responses of BaFBr:Eu²⁺ under varying irradiation conditions including dose linearity, dose-rate dependence, dynamic range, temporal profiles, radiation hardness and LET dependence were measured via photostimulated luminescence (PSL) intensity measurements. **Results:** EDS analysis revealed its exact elemental composition to be BaFBr_{0.85}IO_{1.5}:Eu²⁺ (Zeff=49) and subsequent analytical calculations showed a good, monotonic signal separation by virtue of the proton energy dependence of its proton SPR. Its PSL excitation and emission spectrum overlapped with KCl:Eu²⁺'s showing good cross-compatibility. In addition, it had good proton dose linearity, dose-rate independence and high reusability. It showed a strong LET-dependent PSL under-response across an LET spectrum from 0.64 keV/µm to 11.1 keV/µm that could be sufficiently explained using stopping-power-ratio variations. **Conclusion:** We have demonstrated that BaFBr_{0.85}IO_{1.5}:Eu²⁺ and KCl:Eu²⁺ constitute a pair of compatible storage phosphor dosimeters having desirable optical and dosimetric properties and having the ability to measure absolute proton doses (using PSL intensities from the near LET-independent KCl:Eu²⁺ dosimeters) and LET values (via the relative PSL under-response of the high Zeff BaFBr_{0.85}IO_{1.5}:Eu²⁺ dosimeters) simultaneously.

WE-B-TRACK 6-07

Development of An Imaging System for Proton Pencil Beam Spot Profile Determination

J Setianegara*, T Mazur, Y Hao, D Yang, H Li, Washington University School of Medicine, St. Louis, MO

Purpose: To develop an independent dosimetric imaging system consisting of an optical scanner and reusable storage phosphor dosimeters that can obtain two-dimensional (2D) dosimetric images of proton spots at sub-millimeter resolution. **Methods:** An in-house scanner was constructed using stepper motors that can achieve translations to sub-millimeter precision. BaFBr:Eu²⁺ storage phosphor detectors were then irradiated using proton pencil beams at maximum energy of 227.1 MeV. During optical readout, the detector panels were mounted vertically and actively translated relative to a static, focused stimulating laser light produced by a 594nm helium-neon laser. The intensities of the photostimulated luminescence (PSL) produced will correlate to the proton dose delivered at specific locations of the latent dosimetric image. Proton spots were delivered while varying the proton doses delivered from 1-150 monitor units (MUs), where 1MU corresponded to 6cGy peak proton dose. Typical dose delivery errors such as lateral displacements and beam divergence were simulated too. **Results:** The combined system managed to attain a sub-millimeter precision and close agreement with 1MU proton dose images collected with a commercial scintillator. Dosimeters showed good linearity and no saturation of up to 150MU proton dose. A signal-to-background ratios of at least 2400:1 was attainable at 150MU demonstrating the ability for proton halo measurements down to at least 0.04% of peak proton doses. The system was sensitive enough to detect ±1mm lateral displacements inline and crossline and ±0.30mm divergence in the Gaussian profile. **Conclusion:** We have developed an independent dosimetric platform that is able to perform profile and dosimetric checks of proton pencil beams at sub-millimeter precision and at high dosimetric accuracy. It was sensitive enough to detect beam delivery errors including lateral shifts and beam divergence. The demonstrated high dynamic range shows potential utility for versatile measurement applications such as proton beam halo measurements.

Frustrations in Ultrasound-guided Radiotherapy: Automated Solutions

Dr. Emma Harris

emma.harris@icr.ac.uk

The Joint Department of Physics, Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, London, UK

Ultrasound can image soft tissues with high resolution, in real-time and also offers volumetric imaging. These attributes make it ideal to guide radiation therapy. Ultrasound is also recognised as a user dependent modality, with the quality of the acquired images and the eventual interpretation of those images highly dependent on the skill and experience of the user. Clinical staff in the radiation therapy department often have little or zero experience with ultrasound. This has posed a significant barrier to the implementation of ultrasound in guidance in radiotherapy. The additional training and time required to use ultrasound, adds significant pressure to an already highly-pressured clinical environment and often under-resourced departments. On a practical level, ultrasound does not compare well with tools such as cone beam CT, now effectively single push button acquisition and complemented with a suite of image processing tools that automate image registration. It is eminently possible to improve the "user friendliness" of ultrasound. Alternative hardware which is more suited to the radiation therapy clinic, to improve speed of set up and provide a more seamless integration with radiotherapy workflow can be employed. In diagnostic ultrasound setting, new software tools are being developed to allow unskilled users to acquire images, and automatic segmentation of tissues is being addressed. This talk will review these new innovations and explore how a new generation of ultrasound guided radiation therapy can be successfully translated into the clinic.

Learning Objectives:

1. Understand the practical barriers to clinical implementation of ultrasound guided radiotherapy.
2. Knowledge of innovations in hardware that could be applied to ultrasound to improve integration of ultrasound with the radiotherapy workflow.
3. Knowledge of state-of-the-art machine learning approaches that are being applied to ultrasound to improve the ability of users to acquire good quality images and interpret images.

Ultrasound guidance during radioablation treatment of cardiac arrhythmias

Dr. Saskia Camps

saskia.camps@eba-med.com

External Beam Ablation Medical Devices (EBAMed) SA, Geneva, Switzerland

Heart arrhythmias are disruptions in the normal heartbeat, which can result in too fast, too slow or irregular heartbeats. As the occurrence of these arrhythmias is strongly linked to heart attacks and strokes, this can be a life threatening condition. Nowadays, catheter ablations are the main curative treatment option for atrial fibrillation and ventricular tachycardia. These procedures require hospitalization of the patient, can be lengthy and risky and they have shown varying outcomes depending on e.g. the arrhythmia type and skills of the treating physician. For this reason, there has been a growing interest for treating cardiac arrhythmia patients non-invasively and potentially more effectively by means of radiation.

To safely and effectively perform radioablation of the heart, several motion components which can affect the shape and position of the heart and therefore also the shape and position of the treatment target should be taken into account. One could think of motion resulting from the heartbeat of the patient, as well as of inter-fraction motion and intra-fraction drift of the heart. This talk will focus on how ultrasound imaging can be used to monitor these motion components in order to provide the clinicians with real-time information on the motion of the heart during radioablation treatment of cardiac arrhythmias.

Learning Objectives:

1. To learn more about the use of radiation for the treatment of cardiac arrhythmias.
2. To understand how ultrasound imaging can be used for motion monitoring during cardiac radioablation treatments.

Speaker #3

Platform for ultrasound-guided autonomous minimally invasive surgery: application to the knee

Dr. Maria Antico

m2.antico@qut.edu.au

Queensland University of Technology, School of Mechanical, Medical & Process Engineering, Science and Engineering Faculty, Brisbane, Australia

Ultrasound imaging can be employed to improve automation levels in minimally invasive surgery and eventually enable full automation by providing real-time situational awareness to medical robots via intra-operative, real-time, volumetric mapping of the surgical site.

This talk describes the development of a prototype automated image guidance system, combining high-refresh-rate, volumetric ultrasound (US) imaging (or 4D US) and advanced deep learning strategies for an autonomous robotic platform, currently being investigated for knee surgery. The feasibility of using 4D US for guidance in knee minimally invasive surgery was first proved through cadaver and volunteer studies. The workflow to enable automatic interpretation of 4D US imaging for robotic guidance was then developed and implemented. The essential steps include automatic image quality assessment, tissue segmentation and tracking (in combination with the assessment of uncertainties) and surgical tool tracking. The results obtained show US imaging's potential for quantitative autonomous tasks and for the creation of autonomous, intelligent robotic surgical systems that will hopefully soon make surgery more sustainable and improve people's quality of life.

Learning Objectives:

1. US imaging combined with deep learning strategies can provide a solution for real-time volumetric guidance for autonomous systems.

2. The algorithms developed and implemented can be extended to US images of other body districts.
3. The workflow elucidated provides solutions to the issues currently limiting the application of US imaging to quantitative autonomous tasks.

An X-Ray Fluence Modulation Apparatus for Cone-Beam CT

P Ghazi*, S Youssefian, T Ghazi, MALCOVA LLC, Baltimore, MD

Purpose: To develop and evaluate the performance an apparatus of fluence modulation and scatter shielding for cone-beam CT, and the corresponding method of image acquisition. **Methods:** The apparatus is composed of two assemblies, referred to herein as the dynamic Fluence Modulation (FM) and Scatter Shield (SS), that work in synchrony to form a narrow beam sweeping the entire field of view of the imaging system in each projection. The positioning of the FM with respect to the focal spot leads a change in the flux of x-rays incident on a patient – providing the means to optimize the dose depending on the size, shape and positioning of the organ of interest. Feasibility of this apparatus was verified through a series of Monte Carlo (MC) simulations, followed by incorporating the FM-SS assembly into an existing cone-beam CT system. A series of UHMW cylindrical phantoms were utilized to measure the detected signal level, scatter build-up, and the dose, in presence and absence of the FM-SS apparatus. **Results:** Implementation of FM-SS results in near scatter-free projections. The scatter-to-primary ratio dropped from 90% in the absence of the FM-SS to below 15% in its presence. The recorded dose, tallied throughout a phantom with a diameter similar to that of an average-size breast (14 cm), was dropped 32%. The variabilities in the recorded raw signal, resulting from the differences in the attenuation path length through a cylinder, was almost entirely resolved (coefficient of variation dropping from 850% to 20%). **Conclusion:** Utilization of the FM-SS apparatus and technique was demonstrated via simulations and physical implementation to result in: significant reductions in dose, reductions in scatter uptake in projections, and a reduction in the required dynamic range of the imager. This novel solution addresses the limitations of bow-tie filters, and high-scatter projections in cone-beam CT geometry.

The Evaluation of the Impact of Rotational Corrections on Translational Setup Errors

M Fu^{1*}, Z Cui¹, Y Zhang^{1,2}, Y Wang¹, W Qiu¹, J Zhu¹, (1) Department of Radiation Oncology Physics and Technology, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, Shandong province, CN, (2) School of Physics and Technology, Wuhan University, Wuhan, Hubei province, CN

Purpose: To compare the translational and rotational patients setup errors of different body regions with six-dimensional (6D) matching using CBCT, and therefore to quantitatively evaluate the impact of rotational corrections on translational setup errors. **Methods:** Daily online treatment 6D setup errors data from 302 patients for 4078 fractions treated by tomotherapy using Varian VitalBeam were obtained. Systematic and random errors were calculated and statistical methods were then applied. In addition, a phantom experiment was conducted. Also, 736 fractions from 40 patients received pelvic treatment were reevaluated offline by matching the CBCT scans to the planning CT scans with and without rotational corrections. With translational corrections only, unsuccessful registrations were classified and successful registrations were quantitatively analyzed. **Results:** Larger rotational setup errors were observed in the pelvis and breast regions. The changes in the anterior-posterior(y axis) and superior-inferior(z axis) directions were caused by uncorrected pitch. The changes in the superior-inferior (z axis) and lateral-medial (x axis) directions were caused by uncorrected yaw. The single uncorrected roll had little effect on the translational errors. The single uncorrected yaw had the greatest influenced on the translational errors. A shift change of nearly 3mm was caused by uncorrected 3° of yaw. Registration on bony tissue of 736 fractions from forty patients was successful for all offline 6D matches, 43.75% of which were unsuccessful with translational correction only. However, the rules of combinations in these rotational angles were summarized with the unsuccessful registration. The changes of translational shifts >1mm in 27.05% and >2mm in 3.38% of the rest successful registration were recorded. The changes of maximal translational shifts were 3.3mm. **Conclusion:** Translational setup errors have been affected by rotational corrections. Rotational corrections significantly improve the accuracy and efficiency of patient positioning before irradiation. It is of great significance for rotational corrections on high-precision radiotherapy.

Online Bayesian Geometric Calibration of CBCT Systems

O Dillon*, T Reynolds, R O'Brien, University of Sydney, Sydney, NSW AU

Purpose: C-arm x-ray imaging systems have found widespread clinical use, for example taking 2D projections to guide interventional surgeries. Accurate 3D reconstruction from 2D images requires precise calibration of geometric parameters. Geometric calibration is typically offline, which restricts 3D imaging to a narrow library of acquisition arcs on systems with highly reproducible geometry. We present a real time online geometric calibration framework utilising a treatment couch attachment applicable to patient adaptive scans and portable systems, and show results obtained with a commercial c-arm. **Methods:** We derived a Bayesian estimate of geometric parameters from observed markers. We designed a couch attachment that presents required markers during online imaging. A CIRS Dynamic Cardiac Phantom was imaged on a Siemens ARTIS pheno c-arm system with the couch attachment placed. First an automatic 3D acquisition with “gold standard” offline calibration was performed, then a manually controlled irreproducible acquisition. The first acquisition was reconstructed with uncalibrated, offline and online calibration geometry, the second with uncalibrated and online calibration as offline not applicable. The difference in parameter sets was quantified with Root-Mean-Square Deviation (RMSD) and the 5 3D images were inspected for calibration artefacts. **Results:** The RMSD between offline calibrated and uncalibrated geometry was 0.37° to 0.44° and 1.0mm to 3.7mm while RMSD between offline calibrated and online Bayesian calibrated was 0.0013° to 0.0017° and 0.4mm to 0.9mm. The manual acquisition uncalibrated geometry had the most artefacts, then inbuilt acquisition uncalibrated, then automatic and manual acquisition online calibration with minimal artefacts completely absent in the automatic acquisition offline calibration reconstruction. **Conclusion:** The online Bayesian calibration approach is able to

recover geometric parameters and produce reconstructions to nearly the quality of “gold standard” offline calibration, with the benefit of being applicable to adaptive acquisitions and portable systems.

Dictionary-Learning Iterative Reconstruction for Sparse Data, Slot-Scanning, Breast CT

C Zhao^{1*}, W Wang¹, A Leong¹, S Bambof², J W Stayman¹, (1) Johns Hopkins University, Baltimore, MD, (2) Fischer Imaging, West Hills, CA

Purpose: Breast CT improves the visualization of breast anatomy over conventional 2D mammography and has been widely investigated for the diagnosis and treatment of breast cancer. Slot-scanning mammography has potential advantages with the use of high-resolution linear detectors and reduced x-ray scatter; however, integrating such technology into a CT acquisition introduces acquisition time challenges. In this work, we explore an implementation of slot-scanning CT which uses sparsely sampled projection data. We propose a dictionary-learning (DL) iteration reconstruction method to handle the sparse data and to facilitate fast breast CT scans using the slot-scanning approach. **Methods:** We implemented a dictionary-learning penalized-weighted least squares (DL-PWLS) algorithm for breast CT. A global redundant dictionary with 16x16 voxel atoms was generated to emulate breast anatomical details. In each iteration, the image was extracted into patches that were estimated by a sparse combination of dictionary atoms. The DL-PWLS algorithm penalizes the difference between the reconstructed image and its representation assembled using the dictionary. The developed algorithm was tested using complete 360-view (49 kV, 243 mAs) projection data and 10% of data with 1D θ -sparsity (36 views) and 2D R, θ -sparsity (72 view but only 50% of the radial bins with 180° phase shifts between neighboring views). **Results:** The DL-PWLS algorithm demonstrates enhanced noise reduction and low-contrast tissue classification over traditional filtered backprojection (FBP) and PWLS algorithms. For sparsely sampled data, visualizations of microcalcifications and soft tissues as measured by structural similarity (SSIM) are further improved using the DL-PWLS reconstruction with 10% 2D R, θ -sparsity (SSIM = 0.77 and 0.84 for microcalcifications and low-contrast tissue). **Conclusion:** A DL iterative reconstruction algorithm is developed for breast CT. The DL-PWLS reconstruction in combination with doubly sparse data is expected to substantially shorten the breast CT scan time. The effective noise reduction also shows potential capability for patient dose reduction.

This work was supported, in part, by NIH grants R43CA224851 and R43CA239777, and an academic-industry partnership between Johns Hopkins University and Fischer Imaging.

Towards Megavoltage Cone Beam CT (CBCT) with Image Quality of Kilovoltage CBCT

J O'Connell*, C Lindsay, M Bazalova-Carter, University of Victoria, BC, CN

Purpose: Firstly, to develop fastCAT, a cone beam CT (CBCT) simulation platform capable of modeling the physics, geometries, and phantoms of commercial linacs with high computational efficiency. Secondly, the platform was used to conduct a simulation study investigating novel MV imaging beam and detector combinations. **Methods:** FastCAT combines GPU ray-tracing with Monte Carlo (MC) methods for improved simulation efficiency. FastCAT requires photon spectra and detector optical spread functions (OSFs) as input. 2.5 and 6 MV photon spectra were modelled in EGSnrc using carbon, aluminum, and tungsten targets. kV x-ray tube spectra were simulated analytically. OSFs were simulated in Topas for cadmium tungstate (CWO), gadolinium oxysulfide (GOS), and cesium iodide (CsI) detectors. FastCAT contrast and noise magnitude were validated using a Truebeam linac and a Catphan 504 phantom for 100 kVp and 6 MV CBCTs, respectively. The simulation study calculated CNRs for all detector/beam combinations using a contrast phantom containing rib and spongiosa bone, lung, and adipose tissue inserts. Detector modulation transfer function (MTF) for each beam/detector combination was calculated using an angled slit phantom. **Results:** Truebeam contrast and noise magnitude matched all fastCAT values within the 99% confidence interval. FastCAT simulation times were 51s and 77s for the kV and MV CBCT, respectively, significantly shorter than the estimated 1-year long full MC simulations. The simulation study showed CNRs for the carbon 2.5 MV/CWO combination were more than 1.5 times greater than the next best 120 kVp/CsI combination, while MTF 50 values were only 1.2% lower for the carbon 2.5 MV/CWO combination. **Conclusion:** Our finding makes a compelling case that clinical CBCT imaging could be greatly improved using carbon target beams with a CWO detector.

WE-lePD-TRACK 1-06

Evaluation of U-Net++ On Low Dose CT Enhancement

B Pan^{1*}, L Ren², (1) Duke Kunshan University, Kunshan, 32, CN, (2) Duke University Medical Center, Cary, NC

Purpose: Deep learning has been widely applied in traditional medical imaging tasks like segmentation and registration. Some fundamental CNN based deep learning methods have shown great potential in low dose CT enhancement. This study applied U-Net++ model to enhance CT images with low dose and compared the performance of U-net++ and symmetric residual convolution neural network (SR-CNN) quantitatively. **Methods:** 11 patient CT images were chosen as the ground truth in the training process. Under-sampled projections were simulated from the ground truth volumes with a uniform distribution. CBCT was then reconstructed from the under-sampled projections using the ASD-POCS TV algorithm with 40 iterations and was treated as the input of the models. The U-net++ model was improved based on U-net model by connecting the decoders, reserving better dense feature along skip connections. (shown in the figure 1). Deep supervision (DS) were used to make a combined loss between each upper node and the ground truth to enhance the image feature preserving capacity. U-net and SR-CNN were used as standard model for comparison. MSE loss and structure similarity (SSIM) loss were used in different attempts. The generated images were compared quantitatively using SSIM and peak signal-to-noise ratio (PSNR). **Results:** Both models succeeded to improve the quality of the low dose CT images. The U-net++ model trained with MSE loss had best average PSNR of 41.4 on the test dataset and average SSIM of 0.9993 in terms of the whole images. RS-CNN model trained using SSIM loss had the best average SSIM of 0.99996 and the average PSNR of 38.6. **Conclusion:** Deep learning method showed its potential dealing with the high dose caused by modern CT technique. Different CNN model could influence the quality of the generated image on different evaluation criterions.

A Geometry-Guided Deep Learning Technique for CBCT Reconstruction

K Lu^{1*}, L Ren², F Yin², (1) Duke University, Durham, NC, (2) Duke University Medical Center, Durham, NC

Purpose: Despite the success of using deep learning for CT reconstruction, deep-learning-based cone-beam CT (CBCT) reconstruction remains challenging due to GPU memory limitations. This study is to develop a novel deep-learning (DL) technique to perform CBCT reconstruction with significantly reduced computer memory requirement and demonstrate its feasibility through CBCT reconstruction with sparsely sampled projection data. **Methods:** The novel geometry-guided deep-learning (GDL) technique contains a GDL reconstruction module and a DL post-processing module. GDL replaces the traditional single fully connected layer with many small fully connected layers in the network architecture based on the projection geometry. GDL reconstruction module learns and performs projection-to-image domain transformation. The DL post-processing module further improves image quality after reconstruction. We demonstrated the feasibility and advantages of the model by comparing ground truth CT volumes with CBCT images reconstructed from simulated digitally-reconstructed-radiographs (DRRs) using 1) GDL reconstruction module only, 2) GDL reconstruction module with deep-learning post-processing module, 3) Feldkamp, Davis, and Kress (FDK) only, and 4) FDK

with deep-learning post-processing module. The differences are quantified by peak-signal-to-noise ratio (PSNR), structural similarity (SSIM) index, and root-mean-square error (RMSE). **Results:** Average values for PSNR, SSIM, and RMSE of reconstructed images are 14.092, 0.857, and 0.198 for FDK only, 18.086, 0.894, and 0.125 for GDL only, 23.015, 0.901, and 0.071 for FDK with post-processing, and 25.313, 0.930, and 0.054 for GDL with post-processing. Reconstruction time for all reconstruction methods is comparable (around seconds). The estimated memory requirement using GDL is reduced for more than 10,000-fold compared to DL methods using large fully connected layers for CBCT reconstruction. **Conclusion:** The GDL technique was demonstrated to be able to perform fast and accurate CBCT image reconstruction from sparsely sampled data with significantly reduced memory requirement compared to other existing networks.

Patient-Specific Estimates of Absorbed and Effective Dose in Pediatric 18FDG PET/CT Imaging Studies

R Nosrati^{1,2*}, C Kofler³, B Sexton-stallone², R MacDougall⁴, W Bolch³, F Fahey^{1,2}, (1) Harvard Medical School, Boston, MA, (2) Children's Hospital, Boston, MA, (3) University of Florida, Gainesville, Florida, (4) Canon Medical Systems USA, Tustin, CA

Purpose: To estimate patient-specific organ dose in children undergoing ¹⁸FDG-PET/CT scans and evaluate the correlation between CT size specific dose estimate (SSDE) and effective dose. **Methods:** Organ and whole body doses were calculated on 181 scans in 100 pediatric patients (females/males: 47/53; 11.4±5.2 YO) who underwent ¹⁸FDG-PET/CT scans on a Siemens mCT Biograph-64 scanner. PET/CT scans consisted of 75 diagnostic (Dx) partial body CT, 36 whole body (WB) low-dose attenuation correction (AC) CT, and 74 partial body AC-CT. The CT scan parameters were similar between Dx and AC scans except for Quality Reference mAs (QRM) which was 150 for Dx-CT and 20/35 for AC-CT. Tube current modulation (TCM) was applied to the CT acquisitions and modeled in the dose estimation. The UF/NCI phantom library was used to calculate CT and PET patient-specific organ dose. The FDG administered activity was based on the North American Consensus Guidelines. In addition, CT SSDE values were calculated based on the AAPM TG-220 formulation and the correlation between CT effective dose and SSDE was investigated. **Results:** The average PET effective dose was 7.63±2.06mSv. The mean WB-AC, WB-Dx-CT effective doses were 1.50±0.70mSv and 5.97±1.71mSv respectively. The mean total PET+CT effective dose for WB-AC-CT and WB-Dx-CT exams were 6.56±1.06mSv (range: 4.33-9.13mSv) and 11.11±2.29mSv (range: 7.61-16.78mSv) respectively. The four organs which received the highest PET dose were: bladder, heart, brain and liver; and, for the highest WB-AC-CTs, gonads, heart, bladder and small intestine. The estimated CT effective doses showed high correlation with SSDE ($R^2=0.9$) for all examination types (excluding neck); the correlation increased with the CT scan length, demonstrating almost perfect correlation for WB-AC scans ($R^2=0.99$). **Conclusion:** This work provides a reference library of organ dose for a wide range of age/weight of pediatric ¹⁸FDG-PET/CT patients. Also, a linear relationship between CT effective dose and SSDE was determined.

Learning Feature Fusion for Multi-Modality PET-CT Segmentation with An Interpretation Method

Z Chen¹, W Lu², X Qi³, S Tan^{1*}, (1) Huazhong University of Science and Technology, Wuhan, China (2) Memorial Sloan Kettering Cancer Center, Scarsdale, NY, USA (3) UCLA School of Medicine, Los Angeles, China

Purpose: The performance of a multi-modality PET-CT segmentation method heavily relies on the quality of the used information fusion strategy. We utilize the interpretation methods as tools to quantitatively measure the importance of information from each modality. We propose a novel feature fusion strategy according to the measured importance of information and design an iterative algorithm to automatically learn how to fuse information from different modalities. **Methods:** The co-segmentation framework consists of three stages. The first stage contains two parallel branches, and each is responsible for high-dimensional feature extraction either from PET or CT using an encoder-decoder style network. The second stage consists of an interpretable module, in which the perturbation-based interpretation method is used to measure the importance of different features. According to the measured importance of features, we obtain an effectively weighted features fusion strategy. The third stage is composed of cascaded convolutional blocks, which follow the interpretable module and are used to re-extract the semantic features and output the final segmentation mask. The algorithm is trained and tested on a PET-CT dataset with 84 patients, in which 60 are selected randomly for training, while the remaining 24 are used for test. **Results:** We use W-Net as the baseline, which is a classic co-segmentation method. Compared to the metrics (DSC=0.82, VE=0.36, CE=0.17) of the baseline, our method (DSC=0.85, VE=0.30, CE=0.15) achieves a superior performance. Meanwhile, we decompose our framework to investigate the contribution of the learned feature fusion strategy in the interpretable module. The backbone with the interpretable module performs much better than without the interpretable module. **Conclusion:** We propose a co-segmentation framework for PET-CT segmentation, and introduce the perturbation-based interpretation method to learn how to integrate features from multi-modality effectively. The proposed network with the learned feature fusion strategy achieved superior performance compared to the baseline.

Independent Verification of a Ge-68/Ga-68 Well Counter Accuracy Source Activity Mis-Calibration

W Erwin*, D Mitchell, UT MD Anderson Cancer Center, Houston, TX

Purpose: Annual efficiencies of our PET hot lab well counters using a new ⁶⁸Ge/⁶⁸Ga calibration rod source in 2020, were substantially lower than historical averages. An independent verification as to whether or not the stated activity of the new source was correct, was performed. **Methods:** A positron detection lab setup was employed for coincidence counting of the source. Two Harshaw 3" diam. x 3" thick NaI(Tl) detectors faced each other, separated by 18.6 cm and connected to Ortec pre-amplifiers (PAs). PA signals were input into Ortec amplifier and single-channel analyzers (SCAs) windowed around 511 keV. The two SCA logic pulses were input to an Ortec universal coincidence (UC) unit, and UC output logic pulses were then fed into an Ortec timer and counter. ²²Na coincidence efficiency (cpm/dpm) was determined using two 3-mm calibrated button sources centered between the detectors, and converted to that for ⁶⁸Ga based on positron yield. The 2020 and a 2015 source were then coincidence counted (cpm) and the results were converted to dpm. **Results:** The estimated dpm of the 2015 source was 7.6% lower than the decayed stated activity, but that for the 2020 source was 64.4% lower. A second new source sent by the manufacturer yielded an identical result (64.4% lower). All three sources were returned for investigation, and the manufacturer discovered an error in their source activity calibration method. A new source calibrated with a corrected method was sent, and the efficiencies of two well counters using that source (0.60 cpm/dpm) were within the range of those for the prior four years using the 2015 source (0.58 - 0.64). **Conclusion:** A coincidence counting method of measuring ⁶⁸Ge/⁶⁸Ga source activity, in addition to the well counter efficiencies based on that source, resulted in discovery and correction of an error in the manufacturer's activity calibration procedure.

Monte Carlo Study on PET Imaging Used as An Image-Guidance Tool in Very High-Energy Electron Therapy

A Bonfrate^{1,2*}, R M Jones^{1,2}, (1) University of Manchester, Manchester, UK, (2) Cockcroft Institute, Warrington, UK

Purpose: Monte Carlo (MC) study on the use of PET imaging as an image-guidance tool in Very High-Energy Electron (VHEE) therapy. **Methods:** Using the MC code TOPAS, the simulations were aiming to assess the number of positron emitters created along the beam path when irradiating DICOM images for abdomen. While no specific spot was targeted, the 250 MeV VHEE beam was going through a part of a lung and the heart. The main positron emitters created in biological tissue were scored, namely oxygen-15, carbon-11, nitrogen-13, phosphorous-30 and potassium-38 and the corresponding activity was then calculated. **Results:** The total number of positron emitters produced by the VHEE beam was averaging 110 emitters.Gy⁻¹.mm⁻³ and can reach a maximum of 330 emitters.Gy⁻¹.mm⁻³. The interface between tissue and air within the lungs can be observed as there is no creation of positron emitters in air. Moreover, the relationship between positron emitter production and material density allows PET imaging to discern structures with strong density differences such as air/tissue or tissue/bone. Finally, an in-beam PET system is required to prevent significant signal losses during acquisition due to the short half-life of oxygen-15 (2.03 min) which is the most abundant emitters. The overall production of positron emitters is lower with VHEE therapy than with proton therapy because it occurs indirectly by photonuclear reactions, whose cross-sections are small. However, the resulting total activity remains sufficient for detection with an average of 0.6 Bq.Gy⁻¹.mm⁻³ and a maximum of 1.8 Bq.Gy⁻¹.mm⁻³. **Conclusion:** The potential use of PET imaging as an image-guidance tool in VHEE therapy has been demonstrated as long as an in-beam PET system is used.

Predicting Breast Cancer Hormone Receptor Status with PET/MR Images Using Dual-Input Deep Convolutional Neural Network (DCNN)

S Choi^{1*}, H Cho², C Lee², E Kong³, (1) Electronics and Telecommunications Research Institute (ETRI), Yuseong-gu, Daejeon, KR, (2) Korea Research Institute of Standards and Science (KRISS), Daejeon, KR, (2) Korea Research Institute of Standards and Science (KRISS), Daejeon, KR, (3) Yeungnam University Medical School and Hospital

Purpose: The use of endocrine agents in breast cancer therapy depends on the response to estrogen hormone receptor. Tissue sampling and surrogate genetic testing are the gold standard methodology to figure out the hormone receptor (HR) status which are the basis of genetic expression of cancer cells. However, it is sub-optimal to personalized treatment plan due to its time consuming process. A simple deep convolutional neural network (DCNN) approach with dual-image (PET and MR) input has been proposed to classify the estrogen receptor (ER) status (positive/negative). The purpose of the study is to develop an automatic pipeline to predict prognostic factors. **Methods:** Dynamic contrast enhancement MR sequences and 18F-FDG PET imaging were performed using a synchronized PET/MR scanner. A total 212 patients were patients were retrospectively collected who had received immunohistochemistry (IHC) genetic testing after tissue sampling. We annotated the breast tumors by drawing binary masks on PET images and then warped them into the corresponding MR images for each patient. Image preprocessing includes MR and PET slice thickness and field-of-view matching. A total 2,565 image patches were independently trained with three different neural networks to predict the binary classes of ER positive and ER negative status. We used cross-validation scheme to avoid possible unseen coincidence when shuffling the dataset during training. **Results:** The resulted accuracies from three different DCNNs of single MR input, single PET input, and dual PET/MR input were 54%, 63%, and 76%, respectively, which demonstrates that combining the features of both PET and MR images can predict the ER status well, rather than solely training the images with one image type. **Conclusion:** Image-based prediction of hormone receptor status without IHC genetic testing would demonstrate that the extracted PET and MR image features from DCNN may include prognostic factors, which is a potential for radiogenetic imaging biomarker.

Change in ADC as An Indicator of Radionecrosis

M N Gwilliam*, T Muniz, J Xie, B Driscoll, M Butler, C Coolens, Princess Margaret Cancer Centre, Toronto, ON

Purpose: To investigate if Apparent Diffusion Coefficient (ADC) can identify radionecrosis (RN) which is a serious potential side-effect to stereotactic radiosurgery (SRS) and can be mistaken for tumour progression on imaging. There is an urgent need to develop tools that distinguish between necrosis, progression, and immunotherapy-induced pseudoprogression. **Methods:** A retrospective study of 74 patients treated for melanoma with ipilimumab (prescription: 4x infusion every 3 weeks) and longitudinal Diffusion-weighted, T1-with-contrast, and FLAIR MRI on a range of clinical systems is being undertaken. The preliminary cohort consists of 27 patients. 5 were excluded as diagnosis to treatment was >1 year. 8 patients had diffusion-weighted-imaging prior to and after SRS. The SRS to ipilimumab time was +43-170 days (mean 93). SRS prescriptions ranged from 15-21Gy/1-3 fractions according to published protocols. 7 patients were imaged <20 days prior to SRS, 1 at 118 days, and all at times from 20-200 (mean: 109) days post-SRS. Lesions were contoured by an experienced radiation oncologist. Additional ROIs were derived by contracting originals by 2mm in all directions, thus separating the tumour core from the peritumoral rim. The mean ADC value for each ROI prior to radiosurgery, was compared to its corresponding mean value after to obtain a change in ADC value for each ROI. RN and non-RN groups, identified by an experienced oncologist through examination of clinical reports, were compared with a t-test. **Results:** The change in ADC observed in core (peritumoral rim excluded) ROIs from prior to post treatment was significantly different between the RN and non-RN groups (p=0.047). This exaggerated a similar, not significant trend, observed when the whole tumour ROIs were examined (p=0.140). **Conclusion:** Increasing ADC in the inner-core may be predictive of RN in this study. Observed differences between the complete ROI and contraction ROIs should be considered in future investigations.

Characterization of Lobe-Wise Ventilation and Elasticity in Patients with Chronic Obstructive Pulmonary Disease

M Lauria*, B Stiehl, L Naumann, A Santhanam, D O'Connell, K Singhrao, J Goldin, I Barjaktarevic, D Low, University of California, Los Angeles, Los Angeles, CA

Purpose: Chronic Obstructive Pulmonary Disease (COPD) is a heterogeneous disease but is currently measured holistically by spirometry. This project aims to begin to describe the heterogeneous nature of COPD through ventilation and elasticity by characterizing these parameters for individual lobes. **Methods:** Eight patients with varying degrees of COPD and two patients without COPD were scanned 25 times using a free-breathing fast helical CT protocol. The 5DCT motion model was used to simulate end-exhalation and end-inhalation images from the 25 images and recorded breathing amplitudes. The DVFs between these pseudo-images were used to guide a biomechanical model to estimate elasticity and to calculate the Jacobian, which represents ventilation. The Pulmonary Toolkit was used to segment the lobes semi-automatically. The resulting lobe masks were used to analyze the Jacobian and elasticity distributions in each lobe, separately. A Ventilation Heterogeneity Index (VHI) was defined as the ratio of the minimum lobe Jacobian divided by the mean of the other lobe Jacobians. The relative volume of low-elasticity values (1-3 kPa), an elasticity range that is reflective of diseased lung tissue, was determined for each lobe. An Elasticity Heterogeneity Index (EHI) was

also defined to describe the ratio of the lobe with the maximum relative volume of low elasticity to the mean values of the other lobes. **Results:** Patients with severe COPD had a mean VHI of 0.00230 while patients with mild or no COPD had a mean VHI of 0.104. The EHI for patients with severe COPD was 1.69, denoting further heterogeneity than the 3.13 calculated for mild/non-COPD patients. **Conclusion:** We have measured a marked increase in heterogeneity in tissue elasticity and ventilation in patients with severe COPD. This work is one step towards personalizing treatment for patients with COPD to better spare the healthy tissue and maintain lung functionality.

Machine Learning Based Prediction of Big Inter-Fractional Changes in Lung Tumor Motion During Radiotherapy Course Using Robust Feature Selection

Q Wang*, L Dong, B Teo, H Lin, S O'Reilly, University of Pennsylvania, Philadelphia, PA

Purpose: During lung cancer radiotherapy, tumor motion amplitude may change due to various reasons. If motion amplitude varies greater than a clinical threshold (3 mm was used in this study), adaptive radiotherapy may be needed. In this work, we proposed an ensemble machine learning model to identify potential patients for adaptive radiotherapy after 4DCT simulation. **Methods:** We employed 5 conventional classification models (logistic regression, decision tree, support vector machine, random forest, and XGBoost) as base predictors. Then the results were used as inputs for a two-layer neural network to get a final prediction. For each first-level predictor, the inputs are based on 17 features (clinical factors and imaging features from planning CT) from 140 patients. To understand the correlation between each feature and the prediction task, we proposed a robust feature ranking method. We compared the ensemble learning model with each individual base predictor. To evaluate the model robustness, the error and area under receiver operating characteristic (ROC) curve were derived based on 1000-times 5-fold cross validation. **Results:** The feature ranking results showed that the initial tumor motion along the superior-inferior (SI) direction best correlates with the big tumor motion change. By sequentially removing the least important features, the prediction performance of base predictors was consistently improved. Furthermore, the proposed ensemble learning model effectively improved the best predictive accuracies of a single base predictor (Random Forest or Logistic Regression) from 0.78 to 0.83, and the best F1 score of XGBoost from 0.50 to 0.60. **Conclusion:** The proposed ensemble learning model can effectively detect a large change in tumor motion, which helps predict patients that may need adaptive radiotherapy. Experimental results demonstrated superior predictive performance over 5 base predictors. By involving a feature ranking strategy, the prediction accuracy of both base predictors and the overall prediction model are improved.

Powering Predictive Treatment Planning by a Seq2seq Deep Learning Predictor

D Lee*, Y Hu, L KUO, S Alam, E Yorke, A Rimmer, P Zhang, Memorial Sloan-Kettering Cancer Center, New York, NY

Purpose: To develop a novel deep learning algorithm, Seq2Seq, for predicting weekly anatomical changes of locally advanced lung tumor and esophagus during definitive radiotherapy, incorporate the potential tumor shrinkage into a predictive treatment planning paradigm for adaptive radiotherapy, and improve the therapeutic ratio. **Methods:** Seq2Seq starts with the tumor and esophagus observed on the planning CT to predict their geometric evolutions during radiotherapy on a weekly basis (week 1 to 6), and subsequently updates the predictions with new snapshots acquired via weekly CBCTs. Seq2Seq is composed of an encoder to parse the changes of images, and a decoder to reconstruct the prediction; both equipped with convolutional long-short term memory for sequence analysis. The longitudinal dataset (planning CT plus 6 consecutive weekly CBCTs) included 55 lung cancer patients, in which we used 11-fold cross-validation to comprehensively evaluate predictions for all patients. Dice coefficient and average Hausdorff distance (d_{hd}) between the predicted and actual weekly contours were calculated for accuracy evaluation. Simulating a workflow of weekly adaptation, six plans were optimized according to each weekly prediction, and made ready for weekly deployment to mitigate the clinical burden of online replanning. **Results:** Seq2Seq tracks structural changes well: DICE between predicted and actual weekly tumor and esophagus were $(0.82 \pm 0.10, 0.80 \pm 0.14, 0.79 \pm 0.13, 0.76 \pm 0.12, 0.74 \pm 0.13, 0.70 \pm 0.16)$, and $(0.72 \pm 0.16, 0.73 \pm 0.11, 0.75 \pm 0.08, 0.74 \pm 0.09, 0.72 \pm 0.14, 0.71 \pm 0.14)$, respectively, while d_{hd} were within 2mm. Evaluating dose to the actual weekly tumor and esophagus, a 5.3Gy reduction in esophagus mean dose while maintaining 60Gy tumor coverage was achieved with the predictive weekly plans, compared to the plan optimized using the initial tumor and esophagus alone, primarily due to noticeable tumor shrinkage during radiotherapy. **Conclusion:** It is feasible to predict the longitudinal changes of tumor and esophagus with the Seq2Seq network, which could lead to improving the efficiency and effectiveness of lung adaptive radiotherapy.

This work was partially supported by Varian Medical Systems.

WE-lePD-TRACK 3-05

Positron Emission Tomography (PET) Characterization for Biology-Guided Radiotherapy (BgRT)

Z Hu^{1*}, M Narayanan¹, V Ferri², A Iagaru², N Kovalchuk³, B Han³, L Xing³, L Vitzthum³, P Olcott¹, M Bieniosek¹, T Laurence¹, S Shirvani¹, D Chang³, M Surucu³, (1) Reflexion Medical, Inc., Hayward, CA (2) Stanford University School Of Medicine, Department of Radiology, Stanford, CA, (3) Stanford University School of Medicine, Department of Radiation Oncology, Stanford, CA

Purpose: To characterize the performance of the PET subsystem of the first Reflexion X1 machine installation using the NEMA NU-2 2018 standard. **Methods:** The X1 machine consists of two symmetrically opposing 90° arcs of PET detectors incorporated into the architecture of a ring-gantry linear accelerator rotating up to 60 RPM to aim radiotherapy beams using PET emissions of the tumors. Each PET arc has 32 detectors arranged in 2 rings with 90cm inner diameter and 5cm axial extent. Each detector is made up of 12x6 Lutetium-based crystals with a dimension of 4.14x4.14x20mm³. Sensitivity assessed using 2M coincidence events collected for each position. Spatial resolution tests utilized six point-sources arranged horizontally 1, 10 and 20cm away from the center axis, three in and three off the isoplane, measured simultaneously for 10 mins. Count loss assessed using 20 frames were scanned, 2M coincidence events each, with a 15 min break between scans. Image quality assessed using a phantom filled with FDG (4:1 sphere-to-background ratio). **Results:** X1 PET Subsystem sensitivity: 182.4 and 160.9 cps/MBq at the center and off-center positions, respectively. Spatial resolution: average FWHM values of 4.3, 5.1, and 6.7mm for the point sources at 1, 10, and 20cm off center, respectively. For count loss, max NECR: 2625.5 cps, max true coincidence rate: 5557.4 cps, and scatter fraction: 39.8%. Image-quality contrast values: 29.6%, 64.9%, 66.5%, 81.8%, 81.2%, and background variability: 14.8%, 12.4%, 10.3%, 8.8%, 8.3%, for the 13, 17, 22, 28, 37 mm sphere sizes, respectively. **Conclusion:** When operating in an imaging mode, spatial resolution and image contrast were equivalent to those of typical diagnostic systems, while sensitivity and count rate were lower due to design of the system which requires a far smaller detector area than a typical diagnostic system. Clinical efficacy when used in BgRT remains to be validated.

Comparison of 3D Deep Convolutional Neural Networks and Training Strategies for Ventilated Lung Segmentation Using Multi-Nuclear Hyperpolarized Gas MRI

J Astley*, A Biancardi, P Hughes, L Smith, H Marshall, J Eaden, N Weatherley, G Collier, J Wild, B Tahir, The University of Sheffield, Sheffield, United Kingdom

Purpose: Deep learning (DL) has shown competency in numerous image segmentation tasks, including delineating ventilated lung volumes from hyperpolarized gas MRI. We previously demonstrated the utility of a VNet convolutional neural network (CNN), trained on a combination of ^3He and ^{129}Xe scans, in producing segmentations that outperform conventional methods. Here, we compare the performance of several 3D CNNs with varying training strategies for segmenting ventilated lungs on a large multi-nuclear hyperpolarized gas MRI dataset comprising healthy subjects and patients with a range of pulmonary pathologies. **Methods:** The dataset contained 743 volumetric hyperpolarized gas MRI scans, with either ^3He (248 scans) or ^{129}Xe (495 scans) and corresponding expert segmentations, from 326 healthy subjects and patients with pulmonary pathologies. Five experiments were performed to train each CNN: (1,2) the model was trained on either ^{129}Xe or ^3He images; (3,4) transfer learning was applied to the pre-trained models in (1,2) to fine-tune the network for the opposite gas images; (5) the model was trained on combined ^3He and ^{129}Xe data. Experiments were performed on the UNet and VNet architectures with cross-entropy loss and PRELU activation functions. Each trained model was evaluated on a combined testing dataset of ^3He and ^{129}Xe images ($n=75$). Segmentation accuracy was evaluated via Dice similarity coefficients (DSCs), average boundary Hausdorff distances (Avg-HDs) and volume comparisons using Pearson correlation and Bland-Altman analysis. **Results:** The combined UNet model exhibited statistically significant improvements over the combined VNet model using DSC and Avg-HD metrics. Using Pearson correlation and Bland-Altman analysis, DL segmentation volume was highly correlated with the expert segmentations and exhibited minimal bias. **Conclusion:** We compared the performance of several 3D CNNs and training strategies for segmenting ventilated lungs on a large multi-nuclear hyperpolarized gas MRI dataset. The UNet CNN trained on both ^3He and ^{129}Xe data was the highest performing model.

First Beam QA and Commissioning Report of a Novel Biology-Guided Radiotherapy (BgRT) System

B Han^{1*}, N Kovalchuk¹, D Capaldi¹, E Simiele¹, A Purwar², J White², D Zaks², L Vitzthum¹, D Chang¹, L Xing¹, M Surucu¹, (1) Stanford University School of Medicine, Stanford, CA, (2) RefleXion Medical, Hayward, CA

Purpose: Reflexion X1, the first biology-guided radiotherapy (BgRT) system equipped with PET imaging, was installed at our institution. This study reports the QA and commissioning results of the X1 system following the TG-148 protocol. **Methods:** The X1 linac produces 6MV flattening filter free beams with a dose rate of 850cGy/min. The rotational treatment fields are modulated by a binary multi-leaf collimator (MLC) with 64 leaves with 6.25mm leaf width at 85cm SAD and IEC y-jaws switching between 1cm and 2cm. The mechanical tests were performed to verify the centering, alignment, and divergence of the MLC and y-jaws. The beam parameters were commissioned using a 3D water phantom and a diode detector. Beam quality, transverse and longitudinal profiles of each slice width were measured and compared with the beam model. The localization accuracies of the laser and kVCT to MV beam isocenter were checked using a ball cube phantom. **Results:** The source sweep test showed the y-jaw misalignment was 0.049mm. The y-jaw divergence was 0.36mm and the twist was 0.03°. The longitudinal field center variation along the x-axis was less than 0.03mm. The normalized MLC tongue-and-groove film result showed the x-axis out-of-focus value was 0.66%. The MLC alignment test showed an offset of 0.57mm and a twist of 0.15°. Comparing the measurement and TPS modeling, the PDD10 differences were 0.2% and -0.3%, and the mean transverse profile differences were 0.55% and 0.73% for the 40x2cm² and 40x1cm² fields, respectively. The FWHM differences of the longitudinal profiles were within 0.5mm. The localization accuracies of the laser and kVCT to MV isocenters were within 1mm. **Conclusion:** This evaluation represents the first QA and commissioning evaluation of the clinical BgRT system as a future reference.

IGRT-Based On-Line Dose Estimation in Proton Therapy

S Flampouri^{1*}, W LePain², M McDonald¹, (1) Emory University, Atlanta, GA, (2) Georgia Tech, Atlanta, GA

Purpose: In proton therapy, dose deposition is sensitive to both geometry and tissue density along the beam-path. This work investigates the feasibility of rapid daily dose estimation to guide patient setup. **Methods:** A reference CBCT (refCBCT) is a synthetic CBCT produced once by deforming first day CBCT to the planning CT, corrected by histogram matching to the planning CT. Same correction is applied to daily CBCT (iCBCT) for the shape of HU-to-RPSP. Software was developed to compare iCBCTs to refCBCTs and adjust proton dose based on corrected HU differences along each beam-path. Daily total dose was estimated by summing individual beam doses. 10 patients receiving bilateral neck radiation for oropharyngeal cancer were used for validation. Validation was performed by comparing estimated fractional dose to our off-line standard Monte Carlo calculation using a synthetic CT acquired by deforming the closest in time CT to iCBCT. **Results:** After acquiring iCBCT and its registration to the planning CT, dose estimation for 5-field bilateral HN plans took < 1min. Estimated doses for 4 fractions x 10 patients when compared with the standard dose calculations produced Gamma-Index (3mm/3%) with average pass-rates 97.4%, $\sigma = 0.8\%$. 95th percentile of voxel-by-voxel dose difference was <5% of the daily prescription. There was no statistically significant difference on how the method performed on the second and last treatment fractions. **Conclusion:** Using density-based dose deformation along each proton beam, a rapid and accurate fractional dose estimate for oropharyngeal radiation was obtained which could be used for real-time guidance on patient setup.

A Scatter-Rejection Method for Proton Computed Tomography

J Hour^{1*}, A Kapadia^{2,3}, (1) Duke University Medical Physics Graduate Program, Durham, NC, (2) Oak Ridge National Laboratory, Oak Ridge, TN, (3) Duke University Medical Center, Durham, NC

Purpose: Proton computed tomography (pCT) facilitates direct determination of the electron density distribution within a patient, enabling accurate proton therapy treatment planning. However, pCT has never been implemented clinically due to its low spatial resolution, largely an effect of multiple Coulomb scattering. Currently, this effect is accounted for by extrapolating each proton's most-likely-path and algebraically reconstructing the image. This method is an approximation and requires significant computing power. As an alternative, we have developed a simpler method in which detected protons scattered by an angle greater than a cutoff value θ_c are rejected, and standard cone-beam reconstruction algorithms are employed to generate images. **Methods:** Using GEANT4, a 250 MeV proton cone-beam was placed at a distance of 100 cm from the target object. Two silicon strip detectors were modeled to determine each proton's entry and exit positions with respect to the object for calculating scatter angle. Protons with scatter angle exceeding θ_c were rejected. A QA phantom was designed to determine reconstruction accuracy and spatial resolution, and an anthropomorphic head phantom (cropped from a full-body extended cardiac-torso, XCAT phantom) was used to evaluate dose. Scans were performed in 1° steps with 2×10^8 primary protons generated at each step. Images were reconstructed for $\theta_c = 0.1^\circ$, 0.5° , 1.0° , and unrestricted. **Results:** Spatial resolution and reconstruction accuracy generally improved with decreasing θ_c . At $\theta_c = 0.1^\circ$, resolution was 8 lp/cm for bone-water and 9 lp/cm for air-water. Reconstruction accuracy for bone and water was within 1% of the expected electron density. The absorbed dose in the head phantom was 43.85 mGy, which is below the median dose for head X-ray CT. **Conclusion:** Proton CT images exceeding clinical standards for spatial resolution, reconstruction accuracy, noise, and dose are achievable using a method in which detected protons scattered by an angle greater than some cutoff value are rejected.

Improving the Performance of a Proton Computed Tomography Scanner with An Empirical Artifact Correction Method

J Dickmann¹, C Sarosiek², S Goetz¹, M Pankuch³, G Coutrakon², R P Johnson⁴, R W Schulte⁵, K Parodi¹, G Landry^{6, 7, 1}, G Dedes^{1*}, (1) Ludwig-Maximilians-Universität München, Munich, Germany, (2) Northern Illinois University, DeKalb, IL, (3) Northwestern Medicine Chicago Proton Center, Warrenville, IL, (4) U.C. Santa Cruz, Santa Cruz, CA, (5) Loma Linda University, Loma Linda, CA, (6) University Hospital, LMU Munich, Munich, Germany, (7) German Cancer Consortium (DKTK), Munich, Germany

Purpose: To improve the accuracy of a prototype proton computed tomography (pCT) scanner in imaging of the stopping power relative to water (RSP) used for particle therapy treatment planning, by reducing image artifacts using an empirical artifact correction method. **Methods:** Inaccurate measurements of the water-equivalent pathlengths (WEPLs; RSP line integrals) degrade the performance of a prototype pCT scanner. An x-ray CT beam hardening correction was adapted to the requirements of pCT and used to calculate a correction function mapping distorted WEPLs to their corrected values. The function was optimized exploiting the linearity of the filtered backprojection operator and based on an experimental scan of a custom-built elliptical correction phantom with known RSP. The proposed method is simple and robust since it does not require knowledge of the correction phantom's geometry. It was applied in subsequent scans of a water phantom, a sensitometry phantom and a pediatric head phantom. **Results:** Application of the optimized correction function reduced an offset in the RSP maps and removed ring-shaped artifacts mainly stemming from protons stopping close to interfaces between segments of the energy detector. The scan of the water phantom was considerably more homogeneous. The mean absolute percentage RSP error reduced from 0.87% to 0.46%, which is an improvement by 47%. Artifacts visible in the head phantom were largely obviated. **Conclusion:** With the proposed method, the amplitude of artifacts of a prototype pCT scanner could be almost halved. This is to date the best RSP accuracy reported for a pCT scanner. There may also be an improvement compared to state-of-the-art dual-energy x-ray CT, for which errors of 0.7% were reported. Using pCT together with the empirical artifact correction method may help to reduce range calculation uncertainties in image-guided particle therapy.

Assessment of Clinical to High Energy Proton Radiography Viability Using TOPAS

B Broder^{1*}, M Freeman², (1) University of Chicago, Chicago, IL, (2) Los Alamos National Laboratory, Los Alamos, NM

Purpose: Proton radiography could provide instantaneous imaging for proton therapy, reducing position error and facilitating a more accurate dose calculation. Using a magnetic lens system, it has proven efficacious at high proton energies, but yields mixed results at lower energies. Here, a proton radiography system based on that at the Los Alamos Neutron Science Center (LANSCE) is modeled using the TOol for Particle Simulation (TOPAS). Clinical to high-energy protons irradiated head, rat, and mouse phantoms in simulation to determine the energy at which proton radiography becomes feasible. **Methods:** A proton flux of 108 particles traverses a magnetic lens system forming a Fourier plane (collimation point) and imaging plane downstream. Phantoms are simulated as stacked cylinders of tissue-equivalent material with varying diameters atop a 'plus sign' resolution object of bone-equivalent material; parameters changed per phantom to replicate approximate human, rat, and mouse anatomical dimensions. **Results:** Percent transmission was assessed through each bone and tissue combination; approximately 40% transmission was the threshold for visibility. While the bone was visible for all energies at the smallest tissue depth, it only became visible at the greatest depth starting at 530 MeV. Resolution across the bone edge was assessed at all energies and depths for the head phantom. Bone is visible with all energies at 4 cm thickness; at 8 cm, a sub-mm resolution image is obtained starting at 330 MeV, with resolution decreasing at higher energies due to edge effects; for 12 cm, at least 530 MeV is required for sub-mm spatial resolution; and 630 MeV required for 16 cm of tissue. **Conclusion:** Clinical 230 MeV protons are sufficient only for radiography of shallow tissues or preclinical applications. At least 630 MeV protons would be required to radiograph bone under 16 cm of tissue and image the full depth of an adult patient's head.

This project was also supported in part by the Graduate Fellowship in STEM Diversity as part of the GFSD Fellowship.

Histogram Analysis Method of Water Equivalent Path Length to Evaluate Dose Variation Due to Anatomical Change in Spot-Scanning Proton Beam Therapy

T Fujii^{1*}, S Takao^{2, 3, 4}, T Matsuura^{2, 3, 4}, S Hirayama¹, N Miyamoto^{2, 4}, K Umegaki^{2, 3, 4}, S Shimizu^{3, 4, 5}, H Shirato⁶, (1) Hitachi Ltd., 1-1 7-chome, Omika-cho, Hitachi-shi, Ibaraki, JP, (2) Division of Quantum Science and Engineering, Faculty of Engineering, Hokkaido University, Sapporo, Hokkaido, JP, (3) Proton Beam Therapy Center, Hokkaido University Hospital, Sapporo, Hokkaido, JP, (4) Department of Medical Physics, Hokkaido University Hospital, Sapporo, Hokkaido, JP, (5) Department of Radiation Medical Science and Engineering, Faculty of Medicine, Hokkaido University, Sapporo, Hokkaido, JP, (6) Department of Proton Beam Therapy, Faculty of Medicine, Hokkaido University, Sapporo, Hokkaido, JP

Purpose: Anatomical changes in a patient during radiation therapy can cause imprecise delivery of the irradiation dose, resulting in an increased dose to normal tissue and a reduced dose to tumor tissue. We have developed a method that uses the deviation in the water equivalent length (Δ WEL) along the spot beam path to quickly check for anatomical changes and then estimate the resulting dose differences (Δ Dose) from the planned dose distribution. It is designed for use in spot-scanning proton beam therapy (SSPT). **Methods:** To determine whether the WEL can be used to predict dose changes due to respiration, we investigated the correlation between the Δ WEL obtained with the proposed method and the Δ Dose obtained from freely available 4D-computed tomography (CT) data. Three Δ WEL analysis methods were evaluated: 1) Δ WEL map, 2) Δ WEL spot, and 3) monitor-unit (MU)-weighted Δ WEL spot. Treatment plans were prepared for a simulated target implanted into a chest defined by a 4D CT dataset provided by DIR-Lab. The Δ WELs between the planned CT paths and the comparison target CT paths were calculated spot by spot using DICOM-Radiation Therapy software. Linear regression fits between the Δ WEL histogram (median and 95% width) and Δ Dose (root mean square deviation (RMSD) and 3% dose pass rate) were calculated for the three analysis methods. **Results:** The combination of RMSD and Δ WEL showed a relatively high correlation expressed as the coefficient of determination ($0.3631 < R^2 < 0.8894$) while the combination of the 3% dose pass rate and Δ WEL showed a low correlation ($0.0002 < R^2 < 0.3428$). **Conclusion:** These results show that the Δ WEL spot histogram can provide information for predicting the dose deviation to the target and for judging whether to continue or terminate the treatment course.

A Novel Reconstruction Method for 3D Cone Beam CT Images in Proton Therapy Using RTK

J Lindsay^{1*}, A Bryce-atkinson¹, M Taylor^{1, 2}, S Meara^{2, 1}, M Aznar^{1, 2}, M van Herk^{1, 2}, (1) The University of Manchester, Manchester, GB, (2) The Christie NHS Foundation Trust, Manchester, GB

Purpose: CBCT reconstruction research requires access to different algorithms. Offline reconstruction for the Varian ProBeam CBCT system has not been reported. We aim to: 1) develop a novel offline reconstruction method for ProBeam CBCT and 2) simulate ultra-low-dose CBCT images. **Methods:** Straightforward reconstruction of ProBeam projection images with RTK results in significant artefacts. Our reconstruction pipeline includes processing on projection images as well as the reconstructed CBCT. 10 air calibration images are used to correct for bowtie filter, source, and detector shifts during gantry rotation (flood field flex). Beam hardening by the bowtie filter is corrected using an empirically-derived attenuation space map. RTK version 1.4 is used for filtered backprojection and slice averaging is then applied. The pipeline was validated by comparison to clinically-reconstructed CBCT images. To test the simulation of ultra-low-dose images, a Catphan 503 phantom was scanned at 9 mAs exposures (35-811 mAs/projection, 100 kV, SDD 370 cm). The signal-noise relationship was measured from phantom projection data to inform the amount of non-uniform Gaussian noise to be added to simulate low dose scans. Ultra-low-dose CBCTs at 30% and 10% exposure were simulated using datasets from paediatric patients treated on ProBeam. **Results:** The exposure and hardening corrections completely eliminate artefacts. The processed reconstructed images show excellent visual agreement with clinically reconstructed CBCT images. SNR measured in simulated phantom projection data shows good agreement with that in acquired images. Simulated low-exposure scans of paediatric patients are noisier but maintain good visibility of bone and some soft tissue, even at 10% exposure. **Conclusion:** We successfully implemented offline reconstruction for Varian Probeam CBCT images. Correcting for flood field image flex is essential in large-geometry imaging systems. Our methods allow optimisation of CBCT acquisition and reconstruction, especially relevant for paediatric treatments, and can be easily applied to other scan types e.g. 4DCBCT.

Performance of Dose Restoration in Head and Neck Cancer for Adaptive IMPT

E Borderias-Villarreal^{1*}, V Taasti², W Van Elmpt², X Geets^{1,4}, E Sterpin^{1,5}, (1) MIOU-UC Louvain, Brussels, BE (2) Maastricht Clinic, Maastricht, NL (3) Imagerie Moleculaire et Radiotherapie Experimentale, Brussels, BE (4) KU Leuven, Leuven, BE

Purpose: Proton plans are very sensitive to patient anatomical changes due to the nature of proton interaction with tissue. Initial plans tend to distort throughout the treatment fractions due to anatomical changes occurring during treatment. Dose restoration (DR), a fully-automated adaptive strategy which aims to keep the dose distribution constant in every fraction, has proven powerful in lung and pelvic locations. The objective of this work was to test the performance of DR in head and neck (HN) patients. **Methods:** Ten clinically planned HN patients underwent between 4 and 6 repeated-CTs (rCTs) during treatment. Robust DR using the same robust optimization parameters as in planning phase (setup-error=3mm, range-error=3%) was performed for all rCTs (n=50). Isodose contours generated from the initial dose and patient-specific minimum and maximum objectives were used in the DR workflow to re-optimize the plan and reproduce the initial dose in every rCT. Robust evaluations (1mm, 3%) of non-adapted and of restored plans were compared for each rCT. Differences to clinical plan on the planning CT scan in DVH-metrics (nominal and worst-case values) were analysed for non-adapted and for restored plans. **Results:** An improvement in DVH-metrics and robustness was seen for the restored plans compared to non-adapted plans. For non-adapted plans, 28% (14/50) of rCTs did not fulfill the CTV coverage criteria (i.e. D98% > 95% Dprescription (Dp)) and therefore needed offline adaptation. By implementing DR, the median of the D98% over the 50 rCTs was increased by 0.61 Gy and 0.17 Gy in the primary tumour CTV (Dp=70Gy) and the nodal target CTV (Dp=54.25Gy), respectively. Because of large anatomical changes and/or inaccurate patient repositioning, 14% (7/50) of rCTs still needed offline adaptation to ensure an optimal treatment. **Conclusion:** DR has the potential to reduce offline adaptation rate by 50%. However, a minority of rCTs (14%) still need to be visually inspected and fully-automation might not be possible for these HN patients.

Modelling Toxicity Risk and Uncertainty in Breast Radiotherapy with Bayesian Networks

P Ciunkiewicz^{1*}, M Roumeliotis², K Stenhouse², P McGeachy², P Grendarova³, S Quirk², S Yanushkevich¹, (1) University of Calgary, Calgary, Alberta, CA, (2) Tom Baker Cancer Centre, Calgary, Alberta, CA, (3) Alberta Health Services, Calgary, Alberta, CA

Purpose: To predict post-treatment normal tissue toxicity in patients undergoing accelerated partial breast irradiation (APBI) therapy and to quantitatively identify which diagnostic, anatomical, and dosimetric features are contributing to these outcomes. **Methods:** A retrospective study of APBI treatments was performed using 32 diagnostic, anatomical, and dosimetric features pertaining to various phases of the patient's treatment journey. These features were used to inform and construct a Bayesian network (BN) based on both statistical analysis of feature distributions and relative clinical importance. The target feature for prediction was defined as a measurable worsening of telangiectasia, or subcutaneous tissue induration, or fibrosis when compared against the observed baseline. Parameter learning for the network was performed using data from the 299 patients included in the ACCEL trial. Predictive performance of the BN was measured and compared against a variety of conventional machine learning (ML) approaches. **Results:** Cross validated performance of the BN for predicting toxicity was consistently higher across all binary classification metrics when compared against ML techniques including decision trees, naive Bayes, ensemble trees, and support vector machines. The measured BN receiver operating characteristic area under the curve (ROC-AUC) was 0.938±0.028 against the best ML result of 0.910±0.032 using 5-fold cross validation across 100 trials. The volume of the clinical target volume and baseline fibrosis measurements were found to have the highest mutual dependence with normal tissue toxicity in the network, representing the strongest contribution to patient outcomes. **Conclusion:** The BN outperformed conventional ML techniques in predicting tissue toxicity outcomes and provided deeper insight into which features are contributing to these outcomes. With additional data and further development of the network topology, stronger predictive performance is possible. BNs are a powerful tool for many predictive and diagnostic clinical tasks, particularly for applications with limited data availability or completeness.

The authors acknowledge funding and regulatory support from the Institutional Clinical Trials Unit and an Investigator Initiated Trial grant supported by the Alberta Cancer Foundation that facilitated the conduct of the ACCEL trial.

Multi-Domain Statistical Modeling of Treatment Tolerance in Patients with Gastric and Esophageal Adenocarcinoma

A Toronka^{*}, M Defreitas, B Konkel, M Nedrud, I Zaki, A Valentine, S Cubberley, F Yin, M Bashir, K Lafata, Duke University, Durham, NC

Purpose: To investigate associations between demographic, clinical, and CT-based estimates of muscle and fat mass with treatment tolerance in patients with gastric or esophageal cancer. **Methods:** We retrospectively identified 142 patients with gastroesophageal adenocarcinoma treated with neoadjuvant chemotherapy +/- radiation. Clinical endpoints were defined as: treatment breaks in neoadjuvant therapy; reduction in neoadjuvant therapy dose; admission to the Emergency Department (ED) / inpatient encounters; and neoadjuvant treatment completion. Demographic and clinical features included age, gender, race, ethnicity, BMI, smoking status, pack years, TNM Stage, and treatment site. A deep learning model using the UNET architecture was developed to segment visceral fat (VF), subcutaneous (SF), and muscle on CT images from T12-L5. These values were used to derive: average transverse area of VF, SF, and muscle; ratio of VF/SF area; ratio of muscle area to total fat (VF+SF) area; skeletal muscle index (muscle area/[patient height]²). Univariate statistical associations between each clinical endpoint and the demographic, clinical, and imaging features were analyzed using T-tests or Chi-squared tests, as appropriate, with Bonferroni correction. Multivariate machine learning models were then developed for each clinical endpoint, where Regularized Logistic Regression, Support Vector Machine (SVM), and Random Forest (RF)

formalisms were compared. Model training and hyperparameter tuning was achieved with 5-fold cross-validation, and model generalization was evaluated based on a stratified Monte Carlo sub-sampling technique. **Results:** On univariate analysis, age was associated with breaks in neoadjuvant therapy ($p=0.047$), and VF/SF was associated with ED admissions ($p=0.023$). On multivariate analysis, SVM modeling achieved the best performance regarding breaks in neoadjuvant therapy ($AUC=0.64$) and neoadjuvant treatment completion ($AUC=0.64$). In contrast, RF modeling achieved the best performance for ED admissions ($AUC=0.64$) and dose reductions ($AUC=0.54$). **Conclusion:** Our preliminary analysis suggests that demographic, clinical, and imaging features may be associated with adverse outcome in patients with gastric and/or esophageal cancer.

Influence of Sub-Lethal Damage Repair On Biological Effectiveness of Proton with the Consideration of Dose Delivery Time Structure in Scanning Proton Therapy

K Kasamatsu^{1*}, H Hosoi², S Tanaka^{3,4}, K Miyazaki³, S Takao^{3,4}, N Miyamoto^{3,4}, K Umegaki³, T Hashimoto⁵, K Nishioka⁵, S Shimizu^{4,5}, T Matsuura^{3,4}, (1)Hokkaido University, Graduate School of Biomedical Science and Engineering, Sapporo, Japan (2)Hokkaido University, School of Engineering, Sapporo, Japan (3)Hokkaido University, Faculty of Engineering, Sapporo, Japan (4)Hokkaido University Hospital, Department of Medical Physics, Sapporo, Japan (5)Hokkaido University, Faculty of Medicine, Sapporo, Japan

Purpose: To evaluate how the sub-lethal damage repair influences on the biological effectiveness of proton in prolonged scanning irradiation. Previous studies revealed the reduction of biological effectiveness caused by the repair effect in passively-scattered irradiation where the dose rate is independent of position over target volume. However, the effect in scanning irradiation was not clarified because of the different dose delivery time structure. **Methods:** Spread-out Bragg-peak (SOBP) irradiation was simulated in water phantom with one- and two-field plans. Three scenarios (instantaneous, passively-scattered and layered-scan) were considered with corresponding models of dose delivery time structures for each irradiation technique. The repair effect was evaluated with the biological dose (dose $\times$ relative biological effectiveness (RBE)) obtained from linear quadratic model combined with theory of dual radiation action. McNamara model was used to include the LET dependence of RBE. In addition, the simulation using clinical plans with one and two fields (post-operative seminoma and prostate tumor, respectively) were carried out. **Results:** Dose delivery time structure which differs for each scenario was found to be an important factor for evaluating the repair effect. In the passively-scattered scenario, relative dose decrease against the instantaneous scenario was about 3.3% over SOBP with 19 min of total irradiation time. On the other hand, layered-scan scenario resulted in the variable dose decrease with 3.5% and 0.5% at the proximal and distal side of SOBP, respectively. The variability of dose decrease was mainly caused by the spatial dependence of dose delivery time structure in scanning irradiation. The similar results were obtained from the clinical plans indicating the potential distortion of biological dose distribution in layered-scan scenario. **Conclusion:** Consideration of the dose delivery time structure in scanning proton irradiation is important for the evaluation of the repair effect.

WE-lePD-TRACK 5-04

A Mechanistic Model for the Calculation of Oxygen Dependent DNA Damage After Radiation Exposure

H Zhu^{1*}, J Li², X Deng¹, R Qiu², Z Wu², H Zhang², (1) Department of Radiation Oncology, Sun Yat-sen University Cancer Center, Gangzhou, Guangdong, CN, (2) Department of Engineering Physics, Tsinghua University, Beijing, CN

Purpose: Cellular responses at different oxygen concentrations (OCs) continues to be of significant research interest in cancer radiobiology. Therefore, this study aimed to develop a mechanistic model for the analysis of cellular responses at various OCs. **Methods:** A DNA damage model (the different cell oxygen level DNA damage [DICOLDD] model) that examines the oxygen effect was developed based on the oxygen fixation hypothesis, which states that dissolved oxygen can alter the reaction kinetics of DNA-derived radicals generated by ionizing radiation. Radiation induced DNA-derived radicals were simulated using the Monte Carlo method, and the decay of DNA-derived radicals was described using differential equations. The DICOLDD model was fitted to previously published experimental data obtained under different irradiation configurations. Furthermore, the DICOLDD model was validated by calculating yields of DNA double strand breaks (DSBs) after exposure to 137Cs as well as cell survival fractions (SFs) after exposure to different particles. **Results:** Generally, DSB yields calculated after exposure to 137Cs at different OCs correspond to statistical uncertainties of previous experimental results. Calculated cell SFs exposed to photons, protons, and alpha particles at different OCs concur with those obtained in previous studies. Moreover, the DICOLDD model was applied for the calculation of DNA damage yields after irradiation with 0.5–50 MeV protons. Our results demonstrated that the variation in DSB yields was less than 10% when the cellular OC decreased from 21% to 5%. Additionally, DSB yields changed drastically when OC dropped below 1%. **Conclusion:** We developed a DNA damage model to evaluate the oxygen effect and evidenced that it provides a mechanistic description of the reaction kinetics of DNA-derived radicals induced by ionizing radiation. Therefore, the DICOLDD model could be a powerful tool for the analysis of cellular responses at different OCs after exposure to different types of radiation.

Contribution of Nuclear Fragmentation to Dose and Relative Biological Effectiveness (RBE) Across Common RBE Models in Carbon Radiotherapy

S Hartzell^{*}, F Guan, P Taylor, C Peterson, R Howell, S Kry, The University of Texas, MD Anderson Cancer Center, Houston, TX

Purpose: Variable RBE in carbon radiotherapy may be calculated using several models, including the microdosimetric kinetic model (MKM), stochastic MKM (SMKM), and Local Effect Model I (LEM), which have not been thoroughly compared. This work compares how models handle the nuclear fragmentation of carbon beams to provide insight to where model differences arise. **Methods:** Geant4 Monte Carlo was used to simulate various monoenergetic and SOBP carbon beams incident on a water phantom. From these, input parameters for each RBE model (microdosimetric spectra, double strand break yield, kinetic energy spectra, dose fragment contributions) were calculated for each contributing fragment of the carbon beam (namely H, He, Li, Be, B, and secondary C). The spectra for each fragment was used to calculate the linear (α) and quadratic (β) portions of each RBE model, which were combined with α and β values of reference radiation and physical dose to calculate RBE. The contribution of RBE by each fragment was then compared across models. **Results:** Calculations found that secondary fragment contributions could exceed 20% of total physical dose. When calculated using identical beam parameters, RBE varied greatly in magnitude across models and was typically lowest using MKM. When compared across fragments, RBE typically decreased with atomic number when $Z < 3$ and increased when $Z \geq 3$ for RBE(MKM) and RBE(SMKM). Using LEM, RBE increased with Z until $Z=6$, where RBE dropped sharply. Trends of RBE by fragment varied by region (entrance vs. SOBP) for microdosimetric models only. **Conclusion:** This study demonstrated that secondary fragments could contribute notably to physical dose, indicating that fragmentation is an important factor in treatment delivery. Similar trends were seen in fluctuations of RBE by atomic number for microdosimetric models, which differed from those of RBE(LEM). Further insight into model differences may drive future cell studies and increase consistency in model use.

WE-lePD-TRACK 5-06

Robust Alternating RBE- and LET-Weighted Beam Orientation and Fluence Map Optimization for Intensity Modulated Proton Therapy

P Ramesh^{1*}, Q Lyu¹, W Gu², D Ruan¹, K Sheng¹, (1) UCLA School of Medicine, Los Angeles, CA, (2) University of Pennsylvania, Philadelphia, PA

Purpose: Empirical relative biological effectiveness (RBE) models and dose averaged LET surrogates have been separately used to estimate the biological dose in proton therapy. Neither method adequately captures the factors influencing RBE values for treatment planning. Here we incorporate McNamara RBE (RBE(M)) and LET in a beam orientation (BOO) and fluence map optimization (FMO) framework with alternating objective functions. **Methods:** Based on our previously developed robust sensitivity-regularized and heterogeneity weighted BOO (SHBOO) framework, we formulated the optimization problem using two different methods. The

first method optimized RBE(M)-weighted dose, updating RBE(M) values with each round of optimization until they converged (RBEwFMO). The second alternated between RBE(M)-weighted and LET-weighted doses, until the RBE values converged (RBELETwFMO). We compare their performance with a physical dose optimizer assuming RBE(1.1) (PHYSFMO). Three head and neck patients were planned with the three techniques and compared on dosimetry and robustness. **Results:** Compared to PHYSFMO, CTV homogeneity and Dmax were improved by an average of 0.02 and 1.4 GyRBE for RBELETwFMO, and 0.03 and 2.3 GyRBE for RBEwFMO. D98% was improved by RBEwFMO by 0.6 GyRBE. Slight decrease in mean and maximum RBE dose was seen in the larynx, esophagus, and constrictors with RBEwFMO and RBELETwFMO. Regarding robustness, worst [Dmax, V95%, D95%, D98%] for CTVs improved by [4.2%, 31.9%, 5.5%, 4.7%] with RBEwFMO and [2.4%, 33.2%, 6.7%, 5.4%] with RBELETwFMO under range and setup uncertainties. For OARs, the worst [Dmax, Dmean] improved by an average of [3.1, 0.8] GyRBE for RBEwFMO and [5.3, 2.0] GyRBE for RBELETwFMO under setup uncertainties. **Conclusion:** The three optimization techniques deliver comparable physical doses for the head and neck cases. Beside modest OAR RBE dose sparing improvement, CTV coverage and overall robustness were substantially improved with RBEwFMO and RBELETwFMO, showing potential benefit for directly incorporating McNamara RBE in proton treatment planning.

WE-lePD-TRACK 5-07

Improving the Uniqueness of Numerically Extracted Proton Pencil-Beam Energy Spectrum from Integral Depth Dose

W Yao*, University of Maryland School of Medicine, Baltimore, MD

Purpose: Proton pencil-beam energy spectrum is an essential parameter for calculations of dose and linear energy transfer(LET). We extract energy spectrum from measured integral depth dose(IDD) by decomposing the measured IDD into IDD of mono-energetic protons. The decomposition is unique if the mono-energetic IDD are linearly independent, but this condition may not be satisfied especially at low energy when the proton range < the step size that is used in generating the mono-energetic IDD. In this work, we examined the condition of linear independence and improved the uniqueness. **Methods:** Spectra with single and double peaked Gaussian distribution were used to simulate multi-energetic proton beams. The IDD of the beam was synthesized from mono-energetic IDD with its energy spectrum. The energy interval of mono-energetic IDD is 0.05 MeV so that the calculation error of LET will not be larger than 0.5 keV/μm. Optimal decomposition algorithms were performed on the synthesized IDD. The uniqueness of the extracted energy spectrum was examined by the difference of the extracted energy spectrum from the original. To improve the uniqueness and meanwhile save the memory and computation, we used multiple resolution mono-energetic IDD. The step sizes of the IDD of mono-energetic pencil beams are 1 and 0.1 mm. **Results:** The difference of the extracted and original Gaussian energy spectrum peaked at 75 and 80 MeV was <1%. The difference increased as the energy decreased. With 1 mm step size of IDD, we obtained well extracted Gaussian spectrum peaked at and larger than 30 MeV, and with 0.1 mm step size of IDD, peaked at and larger than 20 MeV. **Conclusion:** High resolution mono-energetic IDD are necessary to extract low energy spectrum from measured IDD. Use of energy interval larger than 0.05 MeV in the mono-energetic IDD will be investigated to optimize the calculated dose and LET.

Design and Testing of a Novel Phantom for Camera Calibration of Skin Tones with SGRT

V Bry*, N Bice, N Kirby, D Saenz, N Papanikolaou, K Rasmussen, UT Health San Antonio MD Anderson Cancer Center, San Antonio, TX

Purpose: Surface guided imaging relies on exposure to a patient's surface and anatomical topographic information to accurately track patient positioning for setup and to manage motion during treatment. Camera sensitivity parameters permit adjustments according to different reflections on the skin surface. In this study we attempt to quantify Integration time (μs) and Signal Amplification, or Gain (%) values with the CRAD Catalyst HD for four different skin tones. **Methods:** Four ceramic skulls (Fun Express) were painted using four different shades of a matte mousse makeup foundation (Rimmel). We chose the darkest and lightest shades and two shades in between to simulate a variety of skin tones. A head cushion was molded to provide reproducible setup and positioning. Phantom was setup with and without the head rest and automatic camera sensitivity parameters were evaluated at multiple gantry angles (180°, 225°, 135°, and 360°). **Results:** The average integration time generated by the automatic settings for no headrest in order from Lightest to Darkest tones were 2685μs, 2700μs, 4008μs, and 6608μs and the addition of a headrest decreased these values to 2562μs, 2686μs, 2007μs and 2109μs. The average Gain generated by the auto settings for no headrest in order from Lightest to Darkest tones were 167%, 363%, 314%, 321% and the addition of a headrest changed these values to 178%, 326%, 89%, 50%. **Conclusion:** It is important to quantify camera sensitivity parameters for a variety of skin tones so that clinicians can rely on surface imaging for accurate positioning of patients at treatment time. Use of makeup foundation is a novel method for evaluating maximum imaging signal for a variety of skin tones. We demonstrated that darker skin tones required much greater integration time values than lighter skin tones to maximize surface reflection.

EPID-Based Detection of Anatomical Changes During Radiotherapy Treatment for Head-And-Neck and Prostate Cancer Patients

N Dang¹*, V Leandro Alves¹, M Ahmed², J Siebers¹, (1) University of Virginia Health System, Charlottesville, VA, (2) Vanderbilt University Medical Center, Nashville, TN

Purpose: To quantify and analyze the effectiveness of an EPID-based cine transmission dosimetry to detect gross anatomical errors of cancer patients during radiotherapy treatment. **Methods:** Cine EPID patient transmission images were simulated for 360° 6MV VMAT fields from a TrueBeam linac with an aS1024 EPID imager system for 10 head-and-neck and 19 prostate patients. Simulations were performed to determine the ability to distinguish in-tolerance (1-3 mm/1-3 degree) from out-of-tolerance (10-20 mm/15-20 degree) miss-alignments, and in-tolerance inter-fraction patient pose variations from large out-of-tolerance anatomical changes or a different patient. Predicted EPID image frames mimicked the ~10 Hz EPID image acquisition, with an EPID frame for each 100 msec delivery interval. An image distance metric was used to classify the in-tolerance and out-of-tolerance EPID frame images. The beam error classification was made by checking the failed-frame rate with respect to a threshold. The error detection system was tested with patient datasets which have 8-13 CTs acquired on different days throughout the treatment course. **Results:** Results showed good performance for all classification types of errors. The areas under ROC curves (AUCs) are 0.88 for the miss-alignment scenario and 0.91 for the incorrect patient scenario. The system readily detects substantial anatomical changes between treatment days due to rectal gas. **Conclusion:** This simulation study indicates that this gross error detection system is a promising tool for detecting patient pose errors with EPID dosimetry in real-time mode. Such a system could detect errors that were previously undetectable.

Modeling the Geometric Relationship Between Targets and OARs for Patient-Specific Plan Quality Evaluation in Head and Neck Radiotherapy

E Aliotta*, C Della-Bianca, K Ohri, M Aristophanous, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: Head and neck (HN) radiotherapy presents highly variable treatment geometries, which make optimal patient-specific organ at risk (OAR) dose objectives difficult to define. We sought to develop models of expected HN OAR doses based on geometric relationships between OARs and planning target volumes (PTV) to facilitate quantitative patient-specific plan quality evaluation. **Methods:** Fifty-five treatment plans (VMAT or IMRT) from 41 patients were retrospectively analyzed. Primary and boost plans were assessed independently. For parotids, submandibular glands, and oral cavity, fractional volumes within 1, 5, 10, 20, 30, 40, and 50mm of the nearest PTV surface (including all dose levels) were computed for each plan. Linear, quadratic, and cubic polynomial fits were then generated to relate each distance metric with mean OAR dose (normalized to the lowest prescription dose in each plan). Optimal distance metrics were then selected for each OAR to minimize the mean absolute error (MAE) of the fit. The optimal polynomial order was set to 1 (linear) unless higher order models significantly improved MAE ($P < 0.05$). **Results:** The optimal parotid model ($N=103$ parotid contours including left and right) was a linear fit to the 10mm distance metric, which modelled mean parotid dose with MAE=4.2% (95% confidence interval, 95CI=0.2-10.6%). For oral cavity ($N=55$), the optimal model was a linear fit to the 20mm distance metric (MAE=6.9%, 95CI=1.1-15.1%) and for the submandibular glands ($N=106$), it was a quadratic fit to the 5mm distance metric (MAE=8.6%, 95CI=0.4-23.0%). MAE values did not change substantially ($<0.4\%$) upon five-fold cross-validation. Target coverage was consistent across plans (D95% range: 98-103%, V95% range: 97-100%). **Conclusion:** Simple models based on OAR-PTV distance metrics can produce accurate models of mean OAR doses in HN treatment plans. These models can be easily implemented in treatment planning systems to objectively assess plan quality against cases with similar treatment geometries.

An Uncollided Energy Fluence Convolution Method for EPID Image Prediction

N Dang^{1*}, A Harju², A Maslowski², J Siebers¹, (1) University of Virginia Health System, Charlottesville, VA (2) Varian, Palo Alto, CA

Purpose: To determine the dosimetric accuracy of EPID images computed based upon Varian Acuros predicted exit fluence. **Methods:** AcurosPD is an application prototype that calculates the uncollided energy fluence transmitted through a patient image-set, and incident upon on the portal imager panel. In this work, we developed a method that convolves this output to estimate the recorded dose image on the EPID panel. The method uses Monte Carlo generated energy deposition kernels to account for the primary and scattered components of the EPID response separately via convolution with the corresponding AcurosPD calculated transmitted energy fluence. Different mono-energetic dose kernels were calculated to account for the EPID's energy-dependent responses to primary photons and for photons that penetrate phantoms of different thicknesses (1, 5, and 10 cm). The fluence output of AcurosPD is been structured into 19 energy groups ranging from 0.01 to 6 MeV. The convolved results were validated by comparing with the open field measurement from 6 MV flattened beams at 150 cm source to detector distance. **Results:** The results show good agreement for most of the field sizes and phantom thicknesses with the relative differences within 5%. For the 2x2 field size, the energy spectrum reweighting is needed to achieve acceptable agreement between prediction and measurement. **Conclusion:** The EPID image prediction can be performed by the Acuros energy fluence calculation together with the proposed convolution method. The inclusion of thickness-dependent scatter kernels improves the prediction accuracy.

An Automatic, Uncertainty Model-Guided, Target-Generating Algorithm Improves Target Volumes in Lung SBRT

A Yock*, A Knutson, E Osmundson, Vanderbilt University Medical Center, Nashville, TN

Purpose: This work presents the improvement in lung SBRT internal target volumes generated with an automatic algorithm that used voxelized position uncertainty models derived from individual 4DCT simulation scans. **Methods:** For 19 previously treated lung SBRT targets, deformable image registration was applied to all respiratory phases of 4DCT simulation scans. From the resulting deformation vector fields, voxelized models of gross tumor volume motion were created and fed into an in-house, target-generating algorithm to produce a new internal target volume, the aITV. The efficacy of the aITV was evaluated by comparing its volume and the coverage it provided to each gross tumor volume voxel with those of the clinically-utilized ITV. In addition, the magnitude of an isotropic margin that could be added to the aITV and yield a volume equivalent to the clinical ITV was determined. **Results:** The target-generating algorithm was used to create aITVs that covered at least 95% of the tumor voxels at least 95% of the time according to the voxelized motion model. The aITV increased the coverage of the 5th-percentile-most-covered voxel 50.2% (range -4.9% to 95%) ($p < 0.001$) with a volume that was 29.6% less than the clinical ITV (range 11.4% to 57.3%) ($p < 0.001$). Furthermore, an extra 1.8 mm isotropic margin (range 0.5 to 3.2 mm) was able to be added to the aITV and still not yield a volume greater than the clinical ITV. **Conclusion:** An automatic, uncertainty model-guided, target-generating algorithm was used to create lung SBRT internal target volumes that, when compared to the clinically-utilized ITV, provided both a significant increase in tumor voxel coverage and a significant decrease in volume. The greater efficacy of this target has the potential to increase the therapeutic ratio for lung SBRT treatments, and the algorithm can be extended to other radiotherapy treatment sites exhibiting positional uncertainties.

WE-lePD-TRACK 6-06

Miniaturized Scintillator Dosimeter for Small Field Dosimetry

M Gonod^{1*}, C Chacon Avila², M Suarez², J Crouzilles³, S Laskri³, J Vinchant³, L Aubignac¹, T Grosjean², (1) Centre Georges-Francois Leclerc, Dijon, 21, FR, (2) FEMTO-ST Institute - Optics Departement - UMR 6174 - University of Bourgogne Franche-Comte, Besancon, Doubs, 25(3) SEDI-ATI Fibres Optiques, Evry-Courcouronnes, 91

Purpose: A miniaturized inorganic scintillator detector (MSD) is demonstrated in the analysis of the small static photon fields used in external radiotherapy **Methods:** The detector is constituted by a 0.25 millimeter diameter and 0.48 millimeter long inorganic scintillating cell efficiently coupled to a narrow 125 micron diameter silica optical fiber using a photonic interface. Response of our MSD is tested under a 6MV photon beam of a linac for various field sizes (from 1x1cm² to 4x4cm²). The MSD measurements are compared to those obtained with two high-resolution reference detectors commonly used in small field dosimetry: a micro-diamond detector and a silicon diode. The spurious Cerenkov signal is rejected with a spectral filtering **Results:** The MSD shows a linear response regarding the dose, repeatability within 0.1% and radial directional dependence of 0.36% (standard deviations). Beam profile 5cm depth with the MSD and the micro-diamond detector shows a mismatch in the measurement of the full widths at 80% and 50% of the maximum which does not exceed 0.25mm. The deviation of the percentage depth dose between the MSD and micro-diamond detector remains below 2.3% within the first fifteen centimeters of the decay region for field sizes of 1x1cm², 2x2cm² and 3x3cm² (0.76% between the silicon diode and the micro-diamond in the same field range). The 2D dose mapping of a 0.6x0.6cm² photon field evidences the strong 3D character of the radiation-matter interaction in small photon field regime. Our detector is a right compromise between high resolution, compactness, flexibility and ease of use. The MSD overcomes problem of volume averaging, stem effects, and despite its water non-equivalence it is expected to minimize electron fluence perturbation due to its extreme compactness. **Conclusion:** MSD has the potential to become a valuable dose verification tool in small-field radiation therapy, in Brachytherapy, FLASH-radiotherapy and microbeam radiation therapy.

WE-lePD-TRACK 6-07

Small-Field Dosimetry in Single-Isocenter Stereotactic Irradiation for Brain Metastases Using a Detector-Specific Field Output Correction Factor

T Ono^{1*}, M Nakamura², M Uto¹, T Mizowaki¹, (1) Department of Radiation Oncology and Image-applied Therapy, Graduate School of Medicine, Kyoto University, Kyoto, Japan, (2) Division of Medical Physics, Department of Information Technology and Medical Engineering, Human Health Sciences, Kyoto University Graduate School of Medicine, Kyoto, Japan

Purpose: In small-field dosimetry such as stereotactic irradiation for brain metastases, the measurement dose may include large uncertainties. Recently, IAEA-TRS483 has reported detector-dependent correction factors for small irradiation fields that are expected to reduce the uncertainty of the measured dose in small irradiation fields. This study aimed to evaluate the measured doses considering the correction factors in single-isocenter stereotactic irradiation for brain metastases. **Methods:** A total of 14 sites: 9 cases of single brain metastasis and 2 cases of multiple brain metastases (including 2 sites and 3 sites) were included in this study. Single-isocenter stereotactic irradiation plans were created with a dynamic conformal arc using XVMC (calculation grid size: 1 mm) in Elements Multiple Brain Mets SRS (Brainlab). The dose was measured with a water-equivalent phantom using a cc04 chamber (IBA). The multi-leaf collimator (MLC) field size of each target was calculated for each control point (CP) using Python. Each correction factor was calculated from the MLC field size referred to in the IAEA-TRS483 report. Finally, the plan correction factor was calculated from the average correction factor weighted by the monitor unit for each CP. The measured doses with and without the correction factor were compared with the values calculated by the XVMC, and the differences were evaluated as the mean value $\pm$ standard deviation. **Results:** The difference between the measured and calculated doses was $-3.2\% \pm 1.5\%$ (range: -5.3 – 0.6%) without correction and $-1.8\% \pm 1.2\%$ (range: -3.6 – 1.0%) with correction, indicating that the difference between the measured and calculated doses decreased with correction. **Conclusion:** The measured doses considering the correction factors were evaluated in single-isocenter stereotactic irradiation for brain metastases. A more reliable evaluation of the dose in patients is expected by considering the output correction that takes into account the detector characteristics in small-field dosimetry.

In Pursuit of Meaningful and Efficient Automatic Quantification of Clinical CT Exams

WE-CD-TRACK 2-07

Audience Q & A

The American College of Radiology (ACR) quality control manuals have represented standardized programs for quality and safety for many years. The most recent stereotactic breast biopsy QC manual is from 1999; this session will include an introductory vision for an updated stereotactic and/or x-ray image-guided breast biopsy QC manual that is now in development. This session will also include an introductory vision for QC manuals for nuclear medicine and PET, which are also now in progress. Summer 2021 will also see introduction of a new MR Accreditation Program (MRAP) phantom in a medium size. This medium phantom will accommodate clinical head coils that are too small for the large phantom, necessitating extra handling of MR coils in order to conduct required MRAP QC. This session will include key updates to the MRAP related to the new medium phantom. This session will conclude with a discussion of a new ACR project focused on the pursuit of meaningful and efficient automatic quantification of clinical CT exams.

Learning Objectives:

1. Understand the vision for the ACR stereotactic breast biopsy QC manual revision in progress;
2. Understand the vision for the ACR NM and PET QC manuals in development;
3. Learn requirements for using the new medium phantom in the ACR MR Accreditation Program;
4. Learn key elements of ACR's project to identify and develop processes for automatically quantifying and reporting indices of clinical image quality in CT.

Clinical Implementation of Fully-Automated Comprehensive Quality Assurance Tool Using In-Vivo EPID Image Analysis for Varian Halcyon

A Chalise*, C Bojcheko, University of California San Diego, La Jolla, CA

Purpose: An automated, comprehensive in-vivo system to detect changes in patient anatomy and machine output was developed using a novel analysis of in-vivo EPID images for every fraction of treatment on a Varian Halcyon. The in-vivo approach was used to identify errors that go undetected by routine quality assurance (QA) to compliment daily machine performance check (MPC), with minimal additional physicist workload. **Methods:** Images for all fractions treated on Halcyon were automatically downloaded and analyzed at the end of the treatment day. For image analysis, we select a high-dose region that has been shown to be a predictive metric for changes in the PTV mean dose (PTV_μ). Flags are raised for: (Type-A) patients whose PTV_μ exceeds 10%, to protect against large errors, and (Type-B) patients with three consecutive fractions higher than 3%, to protect against systematic trends. A detailed report for flagged patients is e-mailed to a physicist for further investigation. Furthermore, daily averages and standard deviations are uploaded to Total QA, our QA portal, in addition to MPC that are signed-off by physicist daily, ensuring comprehensive QA for Halcyon. To guide clinical implementation, beginning on 12-15-2020, a retrospective study was conducted for treatments from Nov-2018 till Dec-2020, grouping errors by treatment site. **Results:** From retrospective data of 1033 patients, no Type-A errors were found and only 31 patients (3 %) had a Type-B error. Most of these deviations for Type-B were due to Head/Neck weight loss. For 3 months of use, no flags have been raised by the system that required immediate intervention, indicating the system is running nominally. **Conclusion:** This system protects against errors that can occur in-vivo to provide a more comprehensive QA. This fully automated framework can easily be implemented in other centers with a Halcyon and only requires a standard desktop computer and analysis scripts.

Supported by grant funding from Varian Medical Systems.

WE-C-TRACK 3-02

Establishment of a Standard High-Energy X-Ray Beam for Replacement of Cs-137

E King*, L DeWerd, University of Wisconsin-Madison, Madison, WI

Purpose: To establish a standard high-energy x-ray beam to act as a surrogate for Cs-137. **Methods:** To achieve an x-ray beam with a high average energy, a combination filter of tin, copper and aluminum was chosen. A Varex NDI-451Be x-ray irradiator, with a maximum energy of 500 kV, was used for developing this beam. A beam model of the irradiator was created with the EGSnrc user code BEAMnrc, which was benchmarked with percent depth dose (PDD) and half-value layer (HVL) measurements. The beam model allowed the spectrum of the standard x-ray beam to be simulated to iterate the filtration. The filter thicknesses were optimized to increase the average energy of the spectrum while allowing the beam intensity to stay above an acceptable level. An air kerma rate that is higher than our highest energy, highest filtered NIST-matched x-ray beam was chosen as the beam intensity metric. **Results:** The standard x-ray beam that was created has a thickness of 5.36 mm of tin, 1.28 mm of copper, and 2.01 mm of aluminum. It creates a spectrum with an average energy of 265 keV and a HVL of 6.64 mm of copper. The air kerma rate at 1 m is 2.735 mGy/s which is above the air kerma rate of our highest filtered NIST-matched beam indicating an acceptable beam intensity. **Conclusion:** This work establishes a standard high-energy, more highly filtered x-ray beam than what is currently available. As clinics and research institutions are phasing out Cs-137 irradiators in favor of x-ray irradiators, a standard high-energy x-ray beam for calibration use becomes increasingly more critical.

WE-C-TRACK 3-03

Evaluation of MRI-Only Treatment Planning (MRTP) Quality for Gynecologic HDR Brachytherapy Using PETRA Sequence

CY Lee*, E Kaza, TC Harris, DA O'Farrell, MT King, RA Cormack, I Buzurovic, Brigham and Women's Hospital, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Purpose: Interstitial HDR brachytherapy uses MRI for the clinical target volumes (CTV) and the organs at risk (OARs) delineation for treatment planning. CT is utilized for needle localization, as opposed to MRI, which often does not provide sufficient contrast to visualize needles. An optimized 'Pointwise Encoding Time Reduction with Radial Acquisition' (PETRA) MRI sequence is a promising candidate for implementing an MRI-only treatment planning (MRTP). The feasibility of administering MRTP in gynecological patients was evaluated against the clinical treatment plan (CTP). **Methods:** Five gynecological cancer patients with interstitial needle implants were treated with the CTP generated using the standard CT/MRI-based method employing 3D SPACE images. To generate a plan using MRTP approach, an optimized 3D axial PETRA MRI (TR/TE 3.3/0.07) was acquired on a 3T MAGNETOM Vida (Siemens Healthcare, Erlangen, Germany). The MRI-only needle digitization was performed on Oncentra Brachy (Elekta Brachytherapy, Netherlands) Treatment Planning System using both PETRA and SPACE images for better visualization of the needles through tissues and the interstitial template, respectively. The MRI-based plan was generated by activating and assigning the same dwell times as in the CTP. The quality of the MRI-based plan was evaluated against the CTP by comparing the DVH and EQD2 metrics for the CTV and the

OARs (rectum, bladder and sigmoid). D90 and D2cc were used for the CTV and OARs, respectively. **Results:** In these five patients, the maximum relative differences in the DVH metrics were 5%, 11%, 12%, and 5% for the CTV, rectum, bladder and sigmoid, respectively. These differences correspond to the maximum relative EQD2 metric difference of 6% for all CTVs and OARs. **Conclusion:** The optimized PETRA shows the potential to make MRTP feasible in this pilot cohort of gynecological cancer patients. A larger cohort of patients is required to confirm these preliminary observations.

WE-C-TRACK 3-04

Monte Carlo Dose Calculations for Patient-Specific QA Based On Machine Log Files

H Parenica^{1*}, C Kabat¹, P Papaconstadopoulos², N Kirby¹, P Myers¹, T Wagner¹, N Papanikolaou¹, S Stathakis¹, (1) UT Health San Antonio MD Anderson Cancer Center, San Antonio, Texas, (2) The Netherlands Cancer Institute, Amsterdam, Netherlands

Purpose: Two-dimensional detector arrays are commonly used to verify IMRT dose delivery. An area of interest is the use of machine log files for machine and patient-specific quality assurance. We aim to develop an application that uses a true Monte Carlo model to calculate dose based on machine parameters extracted from log files from patient plan delivery. **Methods:** A model of the Elekta VersaHD linear accelerator was developed using the EGSnrc codes. This model was validated to be within 1%/1 mm accuracy of measured PDDs and profiles. A tool was created in MATLAB that extracts information from machine log files from delivered beams and “injects” it into the patient’s DICOM RP file, replacing the initial parameters used to calculate the “planned” dose. Plans were created from log files from 10 patients’ IMRT QA deliveries. These plans were converted to the inputs required by BEAMnrc/DOSXYZnrc using a MATLAB script developed in-house. Doses were calculated using Source 21 in DOSXYZnrc. Results were compared to measurements made with the PTW Octavius phantom and evaluated in Verisoft with a gamma criterion of 3%/2mm. **Results:** The 3D gamma passing rates for log file-based plans calculated in DOSXYZnrc ranged from 95.7% to 99.9%, and all statistical uncertainties were below 3%. In 9 out of 10 patients, doses calculated in DOSXYZ showed better agreement with measured values than the doses calculated in Pinnacle. **Conclusion:** Using plans with parameters from log files, we can obtain a more accurate representation of the dose that was delivered to the patient and determine the differences from the dose that was initially planned. The “DICOM Injection” tool can provide greater insight on the impact of machine errors in delivered plan quality. When used with Monte Carlo, users have the potential to see an accurate representation of the dose delivered to the patient.

The project described was supported by the National Center for Advancing Translational Sciences, National Institutes of Health, through Grant TL1 TR002647. This project was also supported by the Cancer Prevention and Research Institute of Texas (CPRIT) Research Training Award (RP170345).

WE-C-TRACK 3-05

Multi-Institution Plan Complexity Characteristics Based on IROC Phantoms

V Desai^{1*}, S Kry², (1) UW Health, Madison, WI, (2) MD Anderson Cancer Ctr., Houston, TX

Purpose: To evaluate how much treatment plan variability exists across institutions developing plans to satisfy common objectives. **Methods:** IROC phantoms provide consistent anatomy and plan objectives, but the institution is allowed to develop a plan based on their treatment techniques. Four standard IROC phantoms (head-and-neck, prostate, lung, and spine) were evaluated based on 24 complexity metrics for more than 1700 plans developed across the radiotherapy community. Statistical tests were used to assess the spread within, and differences between, the complexity of phantom plans. These metrics were also evaluated on a single institution database containing 627 clinical patient plans over the same 4 anatomical sites. A k-means clustering algorithm was applied to the principal components of the 24 complexity metrics to determine whether any distinct plan clusters existed. **Results:** For the 4 IROC phantoms, median complexity results were distinct from one another: the H&N phantom and spine phantom were most complex, the prostate and lung least complex, consistent with the complexity of the phantom anatomy. However, there was also a large spread of results for each phantom in terms of solution complexity. These two trends were also seen for the clinical plans. The k-means algorithm demonstrated that complexity metrics successfully stratified the IROC phantom data into two groups, namely prostate/lung and H&N/spine. However, these clusters demonstrated low inter-cluster variance and high intracluster variance. Additionally, step-and-shoot and sliding window plans were quite distinct in terms of complexity, while VMAT plans were not. **Conclusion:** Consistency in planning across the community is relatively low as substantial plan variability was seen for common plan objectives on identical treatment geometries. In addition, plan complexity metrics were not uniquely descriptive of a particular class of plans, even for a single phantom geometry, suggesting they may have limited utility as plan descriptors for QA.

WE-C-TRACK 3-06

Predicting Ion Chamber Disagreements for Patient-Specific Quality Assurance of VMAT Plans Using Machine Learning

P Wall^{*}, M Lafreniere, E Hirata, O Morin, G Valdes, A Witztum, University of California San Francisco, San Francisco, CA

Purpose: To develop and validate a machine learning model for predicting ion chamber disagreements used in patient-specific quality assurance (QA) of VMAT plans at a multi-site institution. **Methods:** A dataset of 579 VMAT treatment plans and associated QA measurements was retrospectively collected at our institution. 30 classes of complexity features representing different failure modes (totaling 293 raw features) were extracted from each DICOM RT-Plan file using in-house software. QA outcomes, represented by the percent difference between planned dose and ion chamber measured dose, were extracted from a RedCAP database used in our clinic. An XGBoost model was trained (10-fold cross-validation) to predict ion chamber measurement disagreements using the complexity features as input. A grid search over a range of values was used to optimize maximum tree depth and learning rate hyperparameters, after which the tuned model was tested on a previously unseen dataset. **Results:** The beam model, edge metric, monitor unit factor, small aperture score at 25 mm, and modulation complexity score were found to be the five most important features for predicting ion chamber disagreements by total gain. The initial model was able to predict all but 24 of the 579 testing samples within $\pm 3\%$ across the 10 testing folds. The average training and testing mean absolute error (MAE) were $0.73 \pm 0.14\%$ and $1.10 \pm 0.17\%$. The 24 samples predicted outside of 3% error were remeasured after which the model was retrained and reoptimized. All testing samples were subsequently predicted within 3% error and the testing MAE was improved to $1.01 \pm 0.08\%$. **Conclusion:** This is the first predictive model developed for ion chamber disagreements in patient-specific QA and was shown to be accurate within 3%. The model has been implemented in our clinical workflow and prospectively validated on 147 plans with MAE < 1%.

WE-C-TRACK 3-07

Sensitivity Evaluation of Patient Specific Quality Assurance - Independent Assessment of Quality

J Lehmann^{1,2,3*}, M Hussein⁴, S Siva⁵, A Moore^{3,6}, T Standen¹, B Subramanian⁷, P Greer^{1,3}, CH Clark^{4,8,9}, (1) Calvary Mater Newcastle Hospital, Newcastle, AU (2) University of Sydney, Sydney, AU (3) University of Newcastle, Newcastle, AU (4) National Physical Laboratory, Teddington, UK (5) Peter MacCallum Cancer Centre, Melbourne, AU (6) TROG Cancer Research, Newcastle, AU (7) GenesisCare, Bundoora, AU (8) University College London Hospital, London, UK (9) National Radiotherapy Trials Quality Assurance Group, London, UK

Purpose: The quality of radiation delivery has been shown to impact clinical outcomes significantly. External dosimetry audits are widely implemented as additional independent tools to ensure safe delivery of treatments, however have found problems despite facilities passing the audit plans with their own patient specific quality assurance (PSQA). This work presents a new concept for dosimetry audits which assesses the sensitivity of a facility’s clinical PSQA to detect relevant errors. **Methods:** Treatment delivery errors which produce clinically significant changes to treatment plans, yet are within or close to the specifications of the treatment

delivery system, were designed and introduced into Spine SBRT treatment plans from participating facilities. Each facility submitted one plan using a provided data set and planning guidelines. They received twelve versions of the plan back, on which they then performed their standard clinical PSQA. Identical errors were used for all facilities and the impact of the errors in the plans was assessed individually. **Results:** Seventeen facilities from Australia, the UK and the US participated in the study, using six different radiation treatment planning systems and the two major radiation treatment delivery systems. Of the twelve versions of a participant's plan, between two and eight passed the local PSQA. Six of the error plans (from four facilities) which had caused a >10% increase in radiation dose to an organ at risk still passed the PSQA. If the threshold was reduced to >5% this rose to 18 plans (seven facilities). **Conclusion:** Going beyond the current approach to test a facility's ability to deliver a selected test case, this novel audit methodology could improve the precision of institutional PSQA, thus improving quality in every facility, impacting many patients. The developed system is administered fully remotely, which provides advantages in cost, environmental impact and logistics.

This work has been supported by a Hunter Cancer Research Alliance (HCRA) Radiation Oncology, Cancer Imaging & Technology (ROCIT) Flagship Program grant (Newcastle, Australia).

Ultrasound-Based Neurotherapeutics and Imaging of Cardiovascular Disease and Cancer

WE-C-TRACK 4-03

Q&A

Therapeutic ultrasound is older than ultrasound imaging and yet has not translated to the clinic until only recently. Focused ultrasound (FUS) has been shown to facilitate drug delivery through the opening of the blood-brain barrier (BBB). Protein and gene delivery will be shown in the neuroprotection and neurorestoration of the nigrostriatal pathway through the combined use of FUS and AAV-GDNF in an early-stage Parkinson's disease (PD) mouse model. Our group has demonstrated that only the striatum that received a combination of AAV-GDNF and FUS exhibited protection against a subsequent MPTP insult while the mice with already existing and stable MPTP lesions exhibited signs of both behavioral and morphological amelioration following AAV-GDNF and FUS with up to 76% restoration, especially in the neuronal terminals. A second study will also be presented for the treatment of Alzheimer's disease (AD) in a mouse model expressing both amyloid and tau. In this case, FUS targets the hippocampus and both amyloid and tau are shown to be reduced with behavioral working memory also improved in the FUS-treated group only. FUS has thus the capability of overcoming certain limitations of pharmacological agents that are incapable of permeating the BBB at clinically relevant dosages; thereby opening new avenues for disease-modifying strategies in undertreated neurodegenerative disorders such as PD and AD.

FUS can also affect brain cognition, either with but also without opening the BBB and merely exerting mechanical and/or thermal effects on the brain or peripheral nerves and driving neuronal modulation. Examples of lateralized motor and sensory responses will be shown in mice and improvement in motor and cognitive performance in non-human primates (NHP) will be shown as well as pain suppression in human subjects by targeting the median nerve.

Finally, FUS is used for ablation of tumors in the clinic and in this lecture, an elastographic technique developed by our group, Harmonic Motion Imaging, will be demonstrated in its capability of identifying the type, targeting and treating breast and pancreatic tumors while also monitoring and assessing the procedure before and after chemotherapy based on the change in the underlying tumor stiffness as a result of the treatment.

Learning Objectives:

1. To understand the mechanisms of inducing neurorestoration through protein and gene delivery by opening the blood-brain barrier.
2. To understand the mechanisms of neuromodulation using therapeutic ultrasound in the brain and peripheral nerves.
3. To understand the imaging capabilities of monitoring elasticity changes in tumors to assess responses to chemotherapy and ultrasound ablation.

Q&A & Panel Discussion

Proton therapy (PT), especially pencil beam scanned proton therapy (PBS-PT), has been increasingly used to treat cancer patients. PT has a physical advantage, and thus in some cases a demonstrated clinical advantage over standard radiation therapy with photons. Despite the physics advantage, PT poses many challenges. Therefore, while at least 15% of all patients who receive radiation are expected to benefit from proton therapy, less than 1% receive this form of treatment. In this symposium we will present recent advances in treatment planning, modeling, and delivery technology that may broaden the accessibility of proton therapy from a “luxury” treatment option for relatively few selected patients to all patients who are expected to benefit from it.

In the first talk, we will discuss the unanticipated adverse events in PT induced by its high linear energy transfer (LET) at the end of proton ranges via a newly developed tool, dose-LET volume histogram (DLVH). The need of understanding LET effect for PT from patient outcomes combining both dose and LET for evaluation and treatment planning will be discussed.

In the second talk, we will discuss the 4D adaptive PT to account for the intra-fractional anatomical changes in PT to treat mobile tumors. 4D adaptive proton therapy will enable an automated seamless workflow by integrating imaging, treatment planning, and treatment quality assurance into a real-time adaptive PT treatment loop.

In the third talk, we will discuss the model-based selection of those patients who are expected to benefit from proton therapy, which can be considered an alternative evidence-based method for randomized studies. This approach has been implemented for patient selection in the Netherlands. Positive experiences as well as challenges will be reported.

In the fourth talk, we will cover recent advances in combined photon and proton optimization. The role of combined treatments for maximizing the benefit of limited proton resources for a population of patients will be analyzed. Situations in which individual patients benefit from a combination of protons and photons will be discussed.

In the fifth talk, we will discuss technological advances that have recently enabled the installation of proton therapy in spaces designed for conventional radiotherapy and future developments to the level of standard radiation therapy. This will dramatically increase the availability of proton therapy to more patients and reduce the disability adjusted life year.

In the last part of the symposium, we will have a Q&A session for some further in-depth discussion between session organizers, speakers, and audience.

Learning Objectives:

1. Describe advanced concepts of integrating the variable linear energy transfer (LET) in the adverse events study.
2. Identify the most important factors requiring treatment adaptation.
3. Describe the motivation behind model-based patient selection.
4. Name two advantages of combining proton and photon therapy.
5. What are the main drivers of proton therapy cost?

MRI for Adaptive Treatment Planning and Delivery

WE-C-TRACK 6-01

A Physics-Aware Deep Neural Network for Real Time Volumetric MRI in Support of MR-Guided Radiotherapy

L Liu^{1*}, L Shen¹, A Johansson², J Balter³, Y Cao³, L Xing¹, (1) Stanford University, Palo Alto, CA, (2) Uppsala University, (3) University of Michigan, Ann Arbor, MI

Purpose: To investigate the feasibility of real time volumetric MRI using a physics-aware deep neural network, in support of MRI-based 3D motion tracking for MR-guided radiotherapy. **Methods:** A deep neural network was proposed to generate volumetric MRI from orthogonal Cine MRI, which can be acquired on MR-Linac systems real time. The network consisted of a 2D generation module that synthesized oblique slices from two orthogonal slices and a 3D refinement module to generate final high quality volumetric images. A physics module that utilized prior knowledge of imaging physics was used to bridge 2D and 3D domains. The proposed method was evaluated for 6 patients with intrahepatic carcinoma. Each patient received two golden-angle radial MRI examinations that were more than 1 month apart, where one examination was used for network training and another for evaluation. Time series of 100 volumetric images with a sampling rate of 340 ms were reconstructed via retrospective binning and served as the ground truth. Orthogonal Cine MRI were sampled from volumetric MRI and served as network inputs. A reference MRI with gross tumor volume (GTV) contours was deformed to match the time series. Deformed GTV centroid positions and contours were compared between ground truth and network prediction. **Results:** Across the 6 patients evaluated, the averaged distance between predicted and ground truth GTV centroids was less than 1 mm in all 3 directions (anterior-posterior, inferior-superior and lateral). The averaged 95-percentile Hausdorff distances between predicted and ground truth GTV contours was 4.6 mm, which was similar to the cross-plane imaging resolution (4 mm). **Conclusion:** Physics-aware deep neural network enabled real time volumetric MRI with sufficient accuracy for 3D motion tracking. The proposed technique is robust to longitudinal patient changes and has the potential of reducing treatment margins and improving treatment delivery precision on a MR-Linac system.

BEST IN PHYSICS (MULTI-DISCIPLINARY): Multi-Task MR (MT-MR) for Free-Breathing Simulation in Abdominal Radiotherapy Treatment Planning

J Chen^{1,2*}, P Han^{1,2}, F Han³, Z Hu^{1,2}, N Wang^{1,2}, W Yang⁴, D Ling⁴, S Palmer⁴, A Christodoulou^{1,2}, D Li^{1,2}, Z Fan⁴, (1) Cedars-Sinai Medical Center, Los Angeles, CA, (2) University of California, Los Angeles, Los Angeles, CA, (3) Siemens Medical Solutions USA, Inc., (4) Keck School of Medicine of USC, Los Angeles, CA

Purpose: MR simulation in the abdomen region is challenging because of respiratory motion. Multiple scans with different contrast weightings are ideally needed for better delineation of the tumor target and organs-at-risk (OARs). However, conventional diagnostic MR sequences often use variable motion compensation strategies (e.g. respiratory gated or breath holds) and are susceptible to inter-scan misalignment. Emerging motion resolved volumetric MR (i.e. 4D-MR) techniques are limited to a single contrast weighting. In this study, we present a free-breathing MR sequence, namely multi-task MR (MT-MR), that produces multi-contrast, motion-resolved volumetric images for abdominal radiotherapy simulation. **Methods:** Our technique builds upon the recently proposed MR Multitasking imaging framework that uses low-rank tensor modeling and exploits the correlation between images of different motion states and contrast weightings to achieve accelerated acquisitions. During each repetition time, a combination of saturation recovery pulses, idle gaps and T2 preparation pulses allows T1, proton density and T2 contrast weightings to be successively generated. MR data are collected using FLASH readouts with a Cartesian spiral-in sampling pattern, which allows for denser coverage of k-space center region and reduced eddy-current effect. This sequence was validated on an abdomen digital MR phantom as well as 7 healthy volunteers at 3.0T with a 1.6SI x 1.6LR x 3.2AP mm³ resolution. Additionally, we acquired 2D real-time MR images as a motion reference in 4 of the 7 volunteers. **Results:** The digital simulation confirmed the image accuracy of our MR technique. In vivo scans demonstrated our capabilities in producing motion-resolved, volumetric multi-contrast abdomen MR images from a free breathing scan under 10 mins. Differences between the respiratory motion range resolved by MT and the 2D real-time MR image reference are within 0.65mm. **Conclusion:** MT-MR is a multi-contrast, motion resolved MR simulation sequence that may provide versatile, useful information for abdominal radiotherapy treatment planning.

WE-C-TRACK 6-03

Real-Time MRI Motion Estimation Through an Unsupervised K-Space-Driven Deformable Registration Network (KS-RegNet)

H Shao*, Y Zhang, UT Southwestern Medical Ctr at Dallas, Dallas, TX

Purpose: Real-time MRI is highly desired for intra-treatment target localization to guide radiotherapy. However, imaging acquisition constraints limit the amount of K-space data that can be acquired for real-time MRI. We developed an unsupervised, K-space-driven, end-to-end deformable registration network (KS-RegNet) for real-time MRI motion estimation from fully-sampled priors and under-sampled K-space data. **Methods:** KS-RegNet solves deformation-vector-fields (DVF) to deform prior MRIs (for instance, a fully-sampled setup MRI) to real-time new MRIs, through direct data fidelity matching in K-space. The network takes in complex-valued prior MRIs and real-time under-sampled K-space data, and outputs DVFs for real-time motion tracking. Without access to high-quality 'gold-standard' real-time MRIs, the loss function directly measures similarity between K-space transformation of the DVF-morphed prior MRI and the real-time new K-space signal. Inverse-consistency is incorporated into the network design to reduce the DVF solution space and improve its accuracy. A dynamic cardiac MR set with raw K-space data from 16 patients were used to train and evaluate KS-RegNet (12/1/3 for training/validation/testing). Radial sampling masks were generated to down-sample the K-space to 10% - 30% of full sampling. The real-time MRIs estimated by KS-RegNet, respect to each under-sampling mask, were compared against the fully-sampled gold-standard images via metrics including mean-squared-error (MSE) and relative-error (RE). **Results:** Under 10% sampling, KS-RegNet generated dynamic MRIs with average MSE and RE of 0.95e-4 and 16.2%, as compared to 1.79e-4 and 21.3% for prior MRIs (without deformable registration), and 7.63e-4 and 47.6% for non-uniform fast-Fourier-transform (NUFFT) images. The corresponding results were 0.83e-4/15.0% and 2.86e-4/28.9% for KS-RegNet and NUFFT by 20% sampling, and 0.76e-4/14.3% and 1.41e-4/20.3% by 30% sampling, respectively. KS-RegNet solved each DVF within 200 ms, meeting clinical demands for real-time imaging. **Conclusion:** KS-RegNet allows motion estimation from substantially under-sampled K-space acquisition, paving the way for real-time MRI motion tracking and treatment adaptation.

The study was supported by funding from the National Institutes of Health (R01CA240808) and from the University of Texas Southwestern Medical Center.

The Optimal Imaging Plane Determination for Motion Monitoring in MRI Guided Radiation Therapy

Y Zhang^{1*}, N Yue¹, X Zhang¹, Y Zhou², K Nie¹, (1) Rutgers Cancer Institute of New Jersey, New Brunswick, NJ, (2) Fudan University Zhongshan Hospital, Shanghai, China

Purpose: To develop a framework that can identify optimal imaging plane to monitor tumor motion in MRI guided radiation therapy using combined motion trajectory and plan dose information. **Methods:** A total of 10 patients with 6 lung and 4 liver patients underwent IMRT or SBRT were retrospectively analyzed. The target volumes were identified from the maximum inhale and exhale breathing cycles. Voxel-based motion trajectories were obtained by deforming images between these two respiratory phases. The voxelized dose gradient was also calculated between the 50%-100% prescription dose regions. A heatmap was constructed by calculating the products between these two gradient vectors, with higher values representing the motion directions more parallel to the dose gradient directions. The heatmap identified regions that could result more clinical-relevant plan failure thus close motion monitoring for those regions would be needed. Principle component analysis (PCA) was further conducted to identify the primary imaging plane that can capture major clinical-relevant motions. The tumor motion extracted from the optimal imaging angle was then compared to that monitored with the standard image plane used clinically. **Results:** From the heat maps generated from all the cases, there was no specific direction or region consistently showing high values. The PCA-determined imaging planes were also patient-specific. Our proposed method was able to capture larger in-plane motion with an average of 2.8 mm(range [1.6-6.8 mm]) compared to 2.1 mm([1.2-5.7mm]) as seen in clinical used image plane. The through-plane motion was also reduced from 2.4mm [0.8-6.6mm] to 1.7mm [0.3-4.2 mm]. **Conclusion:** The proposed method used the respiratory tumor motion trajectory combined with plan dose to determine the optimal imaging angle before the treatment. Results showed the proposed method had overall better motion tracking performance when compared against the imaging planes used in routine clinic.

WE-C-TRACK 6-05

Time-Resolved Estimated Synthetic CTs Based on Orthogonal Cine MRI for Low-Field MR-Linac Treatments

M Rabe^{1*}, C Paganelli², H Schmitz¹, G Meschini², M Riboldi³, J Hofmaier¹, J Dinkel¹, M Reiner¹, K Parodi³, C Belka^{1,5}, G Landry^{1,3}, C Kurz^{1,3}, F Kamp^{1,6} (1) Department of Radiation Oncology, University Hospital, LMU Munich, Munich, GER (2) Dipartimento di Elettronica, Informazione e Bioingegneria, Politecnico di Milano, Milano, IT (3) Department of Medical Physics, Ludwig-Maximilians-Universitaet Muenchen (LMU Munich), Garching (Munich), GER (4) Department of Radiology, University Hospital, LMU Munich, Munich, GER (5) German Cancer Consortium (DKTK), Partner Site Munich, Munich, GER (6) Department of Radiation Oncology, University Hospital Cologne, Cologne, GER

Purpose: To develop and experimentally validate a method to create continuous time-resolved estimated synthetic CTs (tresCTs) based on 3DCT and orthogonal cine MRI data for MR-guided radiotherapy. **Methods:** A breathing porcine lung phantom was consecutively scanned at a CT scanner and a 0.35T MR-Linac. A mid-exhale breath-hold 3DCT was deformably registered to a mid-exhale 3DMRI. The 3DMRI was deformably registered to orthogonal cine MRI series (sagittal/coronal orientation) at 7.3Hz, intersecting different injected tumor-mimicking gelatin nodules. The time-resolved deformation vector fields were extrapolated to 3D and applied to the deformed 3DCT to create 82s-long tresCTs at 3.65Hz. A 4DCT scan served as ground truth (GT). Ten tresCTs were created for ten tracked nodules with different motion patterns in two lungs. Each intersected nodule, expanded by a 5mm margin, was used as PTV for stereotactic step-and-shoot IMRT treatment planning (8x7.5Gy) on the GT-4DCT mid-exhale image to mimic gated MR-Linac plan generation. Each plan was recalculated on all GT-4DCT phases and one tresCT image per breathing phase, randomly sampled from different breathing cycles. Phase-dependent DVH parameter and dose differences were quantified. **Results:** Median nodule motion amplitudes were 8mm (range 3-16mm), with median centroid position deviations between GT and tresCTs of 2.3mm. For all ten

nodules and breathing phases (100 dose comparisons), the median absolute differences of D98%, D50% and D2% were 2.1%, 0.8% and 0.5% for the PTV. The dose difference analysis with a 2% prescription dose acceptance level (10% dose threshold) yielded a median pass rate of 97.4%. Dose deviations in the vicinity of the GTVs were observed, where phase-dependent lung density variations were not accurately modeled. **Conclusion:** Dose differences between GT and tresCTs were at a clinically acceptable level. Hence, tresCTs could be used for time-resolved dose accumulation to guide inter- and intra-fractional treatment adaptation in the future.

This work was supported by the German Research Foundation (DFG) within the Research Training Group GRK 2274 "Advanced Medical Physics for Image-Guided Cancer Therapy". The Department of Radiation Oncology of the University Hospital of LMU Munich has a research agreement with ViewRay.

WE-C-TRACK 6-06

Treatment Window Determination for Cardiac Synchronized VMAT

J Poon^{1,2*}, RB Thompson³, MW Deyell¹, D Schellenberg⁴, K Kohli⁴, H Clark⁴, S Thomas², (1) University of British Columbia, Vancouver, BC, CA, (2) BC Cancer - Vancouver, Vancouver, BC, CA, (3) University of Alberta, Edmonton, AB, CA, (4) BC Cancer - Surrey, Surrey, BC, CA

Purpose: The use of SABR for treatment of ventricular tachycardia is negatively affected by target motion. The effect of motion can be reduced by treating only during the quiescent interval of the cardiac cycle using a technique such as cardiac synchronized VMAT (CSVMAT). In this work, cardiac magnetic resonance (CMR) cine images for an illustrative patient with impaired left ventricle (LV) function were analyzed to track LV contour point motion and determine an optimum treatment window. **Methods:** CMR data included breath-hold scans for 2 short-axis slices and 2-, 3-, and 4-chamber view long-axis slices. Image data and myocardial tissue masks for 30 cardiac cycle phases were converted to endocardial and epicardial contours. Coherent point drift, a non-rigid point set registration algorithm, was used to assign contour point correspondences across all cardiac phases. The motion profile of the target was then determined according to the displacement of the associated contour points. From this temporal motion profile, a CSVMAT or gated treatment window can then be designed to minimize target displacement. **Results:** Minimum, mean, and maximum displacements for each segment were displayed in a 17-segment bullseye plot for either the short-axis or long-axis direction. Displacement due to cardiac motion was generally greater towards the basal end of the LV compared to the apex. Choosing basal segment 6 as the target, an optimal beam delivery window of 200 ms (for a 1 s cardiac cycle) reduces the maximum target displacement during delivery from 18.4 mm to 4.2 mm. For mid-cavity segment 12, maximum displacement is reduced from 7.0 mm to 1.2 mm. **Conclusion:** A method of estimating LV wall displacement due to cardiac motion was developed. This method may be used to create optimal treatment margin guidelines for cardiac radioablation targeting specific areas of the LV.

This work was supported by a Vancouver Coastal Health Research Institute (VCHRI) Innovation & Translational Research Award. Authors Steven Thomas, Kirpal Kohli, and Justin Poon have filed a patent application for CSVMAT.

Auto-Detection of Structural Similarity Index Map from Daily MRI as An Indicator for MR-Guided Online Adaptation Replanning

Abdul K Parchur, Sara Lim, Haidy Nasief, Eenas Omari, Ying Zhang, X. Allen Li*, Medecol College of Wisconsin, Milwaukee, WI

Purpose: MRI-guided adaptive radiation therapy(MRgART), particularly daily online adaptive replanning (OLAR), can substantially improve radiation therapy delivery, however, can be labor-intensive and time-consuming. Currently, whether to perform OLAR for a treatment fraction is determined subjectively. In this work, we develop a machine learning classifier based on structural similarity index map (SSIM) to quickly, automatically, and objectively determine whether OLAR is necessary for a daily MRI set. **Methods:** The classifier was developed based on a total of 70 daily MRI sets acquired on a 1.5T MR-Linac during MRgART of 14 pancreatic cancer patients each treated with 5 fractions. For each daily MRI set, OLAR and reposition plans were created and the superior plan for the daily fraction was determined per clinical dose-volume criteria. SSIM was extracted for each daily MRI set with respect to its reference (e.g., planning) MRI in six regions enclosed by: 50%, 80%, 100%, 50–80%, 50–100%, and 80–100% isodose surfaces, respectively. A series of histogram features, i.e., mean, median, moment (2nd order), skewness's, kurtosis, and full width at half maximum (FWHM), along with a new parameter MMF ratio=Mean/(Moment*FWHM)*10⁵, were extracted from each SSIM. A linear regression, t-SNE, and 5-fold cross-validation ensemble classifier was determined to predict if OLAR is necessary for a daily MRI set. **Results:** Higher significant difference was observed for SSIM features extracted from the 50–100% isodose surface regions based on initial linear regression analysis ($p = 0.007$) and t-SNE projection between OLAR vs. reposition. The developed ensemble classifier in term of MMF ratio can predict 90% reposition and 95.9% OLAR with five-fold cross validation. The prediction accuracy was 94.2% and AUC was 0.97. A simplified decision tree with six-nodes was created. **Conclusion:** An ensemble-based classifier using SSIM was developed, allowing to automatically and objectively determine if OLAR is necessary for a treatment fraction during MRgART.

D. Ruan, UCLA School of Medicine:
The Two Sides of the AI Coin

This session is intended for clinicians who are asking themselves how artificial intelligence may change their clinical tasks. Recent research has shown that artificial intelligence algorithms can solve tasks with an accuracy comparable to a human interpreter. Similarly, scripting has been shown to automate some repetitive tasks. Most clinicians would question if the promises of research abstracts will hold in day-to-day clinical work where many practical considerations are essential in addition to the pure accuracy of automation algorithms. The session will explore how AI algorithms can be integrated with the clinical workflow by using scripting to enable them in commercial software, with the ultimate question of if AI research can indeed become a tool that keeps up to its promise to improve productivity.

Another function of this session is to explain in layman terms what AI and scripting can and can't do, and how we see the field changed by automation in the upcoming future. It is not intended as a collection of research or clinical topics; instead, an example of how AI and clinical duties can be bridged by scripts to include automation algorithms in our clinical lives, for tasks where current research can replace human thinking. The session's objectives are balanced on both the advantages and pitfalls of automation through AI, presented to a clinically minded audience.

Each speaker will give an overview of an AI application, covering integration with the clinical software and describing their experience in adapting these changes to daily clinical hurdles. It should not focus on mathematics but on the experience with implementing these in the clinic. A panel discussion will be held to answer questions.

Learning Objectives:

1. Present planning tasks that can be automated by current research to a clinical audience
2. Describe the pros and cons of automation from the end-user's perspective
3. Detail the hurdles encountered when implementing AI algorithms on real clinical datasets

Towards Contour Quality Assurance of Cardiac Structures with Automatic Segmentation

C Uche¹, H Geng², J Yu³, E Gore⁴, Y Xiao⁵, (1) University of Pennsylvania, Philadelphia, PA, (2) University Of Pennsylvania, Philadelphia, PA, (3) NRG Oncology Statistics and Data Management Center, Philadelphia, PA, (4) Medical College of Wisconsin, Milwaukee, Wisconsin, (5) University of Pennsylvania, Philadelphia, PA

Purpose: This study aims to determine the clinical readiness of two auto-segmentation approaches for cardiac structures contouring quality assurance. **Methods:** Five experienced radiation oncologists delineated the pericardium, atria, and ventricles of 469 RTOG0617 CT scans using a consistent guideline. We developed atlas-based automatic contouring (ABAC) library using 100 randomly sampled CT scans. The CT scans of 200 patients (including the 100 scans for ABAC) were trained on an in-house developed convolutional neural network (CNN) model. The remaining patients were used to assess the performance of the two models, based on the Dice similarity coefficient (DSC), Hausdorff distances (HD), and mean distance-to-agreement (MDA). For dosimetric comparison, the mean dose (Dmean), and the maximum dose (Dmax), were computed for all the cardiac structures. Relative dose-volume factors, including V5 - V60, were analyzed to study the effect of dose heterogeneity. Spearman correlation enabled us to evaluate the relationships between geometric and dosimetric metrics. **Results:** Compared with ABAC, the geometric metrics (DSC, HD, and MDA) of CNN for the cardiac structures depicted a better alignment with the physician-drawn contours. Auto-segmentation with CNN also attained relatively lower Dmean, Dmax, and V5 to V60 to the cardiac structures. However, significant mean and maximum dose differences between the two auto-segmentation methods in the atria and ventricles highlighted a non-negligible disparity between the two auto-segmentation approaches. Analysis of the geometric and dosimetric metrics showed no clear relationship with the automatic contours due to dose heterogeneity. **Conclusion:** Although auto-segmentation shows promise to reduce cardiac structures' contouring inconsistencies, the heterogeneous distribution of radiation doses within the heart segments negates the use of geometric metrics as suitable surrogates for dosimetric parameters. Thus, auto-segmentation would continue to require a thorough validation of a qualified expert to ensure its safe clinical use.

WE-D-TRACK 1-02

Automated ICC Tool for a Novel Planning Incident Learning Environment

D Ferguson*, E Hirata, A Witzum, University of California, San Francisco, San Francisco, CA

Purpose: Initial chart checks (ICCs) are integral to ensuring safe and accurate delivery of radiation. Over a third of treatment plans at our three-site institution are submitted for ICC within a day of treatment, creating a large and urgent workload. We developed a tool to automate a large proportion of the ICC by connecting our TPS (Raystation) and record and verify system (Mosaik), with the goal of reducing the likelihood of errors reaching the patient and introducing automated reporting in a new planning incident learning environment (PILE). **Methods:** Plan parameters from the TPS and Mosaik database were extracted and compared using in-house code. Automated checks were written to match those documented in the ICC list, with the output presented through a graphical user interface (GUI) in the TPS and through a web interface (WI). The TPS GUI can be used by dosimetrists prior to plan approval, and the WI can be used by physicists to complete the ICC. **Results:** A tool was developed to automate a portion of ICCs. Using this, the average time to complete an ICC was reduced by approximately 50%. Additionally, each time the tool is used, an entry in the PILE is created, enabling the tracking and remedying of repeating issues. A retrospective analysis of plans in Mosaik identified minor (non-reportable) errors in plans that would have been flagged by this tool. **Conclusion:** A chart check tool was developed and integrated into the workflow to automate ICCs where possible, simultaneously reducing the likelihood of errors reaching the patient and reducing the physicists' time burden. The output of each ICC is stored in the PILE database, allowing trends in behaviors to be identified and providing a framework for how each ICC can provide information to further improve our

WE-D-TRACK 1-03

Plan Quality Assessment of the Leksell Gamma Knife Lightning Dose Optimizer

D Wieczorek^{1*}, R Kotecha², A Gutierrez³, M Hall⁴, M Tom⁵, S Davis⁶, M McDermott⁷, M Mehta⁸, R Tolakanahalli⁹, (1) Miami Cancer Institute, Miami, FL, (2) Miami Cancer Institute, (3) Miami Cancer Institute, Baptist Health South Florida, Miami, FL, (4) Miami Cancer Institute, (5) Miami Cancer Institute, Miami, (6) Miami Cancer Institute, Miami, FL, (7) Miami Neuroscience Institute, (8) Miami Cancer Institute, Baptist Health South Florida, (9) Miami Cancer Institute, Miami, FL

Purpose: To compare plan quality metrics of manual versus Elekta Lightning™-based inversely optimized radiosurgery plans for Gamma Knife. **Methods:** Clinically treated plans for 100 consecutive patients (115 lesions; 67 metastatic and 48 benign) were replanned with the Lightning™ dose optimizer (based on a convex linear programming formulation). Plans were generated to match or exceed the following metrics in order of importance: Target Coverage, Paddick Conformity Index (PCI), delivery treatment time, and Gradient Index. Plan quality metrics in addition to delivery parameters such as spatial distribution of shots, collimator sizes and optimization times were investigated. **Results:** Overall, 76% (87/115) of Lightning plans showed a statistically significant improvement in plan quality. As compared to manual plans, Lightning plans showed significant improvements of 2.0% in the median PCI ($p < 0.01$), 4.7% in median GI ($p < 0.01$) and an increase in median number of shots by 60.3% ($p < 0.01$). Target coverage and delivery treatment time differences were not statistically significant. Regarding plan specifics, Lightning plans showed a significant increase in use of 16mm ($p < 0.01$) and blocked shots ($p < 0.01$) while also showing a significant decrease in 8mm ($p < 0.01$) and 4mm ($p < 0.01$) shots when compared to manual plans. Use of multiple shots per coordinate was substantially more frequent in Lightning plans. The Lightning optimizer did fail to produce clinically acceptable results in 4/115 (3.5%) cases. Median optimization time for Lightning plans was 4.0 min (Range: 1.0 – 15.0 min). **Conclusion:** Lightning offers a significant reduction in efforts for treatment planning while achieving comparable plan quality of an expert planner. Lightning plans employ non-intuitive increased use of blocked sectors and shot-in-shot technique to achieve high quality plans. A handful of Lightning plans severely failed in matching clinical plans and warrants further investigation.

Power Transformations on Multivariate Non-Normal Radiotherapy Plan Quality Measures

R Wijaja^{1*}, A Roy¹, M Gopalakrishnan², B Mittal², (1) The University of Texas at San Antonio, San Antonio, TX, (2) Northwestern Memorial Hospital, Chicago, IL

Purpose: To investigate the application of power transformations on skewed plan quality measures used by multivariate quality control charts in radiotherapy. **Methods:** We compute multivariate risk-adjusted control charts for treatment plan quality control, which employ the resulting residuals of a risk-adjustment model that uses a set of organ-at-risk (OAR) dose-volume histogram (DVH) points as proxies for plan quality. The risk-adjustment model adjusts the DVH points for a set of patient- and treatment-specific risk factors. Given an ordinary least squares (OLS) regression-based risk-adjustment model, an assumption is that the data is normally distributed, which is typically not the case for DVH data. Thus, we employ the Box-Cox transformation that is a power transformation to reduce the impact of skewness in the DVH points. The control charts are evaluated on 69 head-and-neck cases with the brainstem serving as the primary OAR. **Results:** In the multivariate control chart with Box-Cox transformation, two patients (43 and 49) are signaled as out-of-control (OC), while the chart without Box-Cox transformation signals three patients (24, 43, and 49) as OC. The DVHs show that patient 49 is a high-quality plan, while patients 24 and 43 are poor quality plans with high brainstem dose. Replanning led to a sizable improvement in patient 43's brainstem dose while patient 24 could not be improved without sacrificing tumor dose criteria. The risk-adjustment model and the control chart fails to account for the skewed DVH data without the Box-Cox transformation, leading to a false signal for patient 24. **Conclusion:** A power transformation is necessary for non-normal DVH data for statistical modeling and quality control. The proposed Box-Cox transformation can scale and adjust the skewness of DVH data, leading to an improved performance of control charts for quality control in radiotherapy.

Artificial Intelligence for Dose-Volume Histogram Based Clinical Decision-Making Support System in Radiation Therapy Plans for Brain Tumors

P Siciarz^{*}, B McCurdy, S Alfaifi, S Rathod, E Van Uytven, R Koul, CancerCare Manitoba, Winnipeg, MB, CA

Purpose: To create and investigate a novel, clinical decision-support system using artificial intelligence (A.I.). **Methods:** The A.I. model was developed based on 79 radiotherapy plans of brain tumor patients that were prescribed a total dose of 60 Gy delivered in 30 fractions (2 Gy per fraction) with volumetric-modulated arc therapy (VMAT). Structures considered for analysis included planning target volume (PTV), brainstem, cochleae, and optic chiasm. Data for model training consisted of five dosimetric and five geometric features extracted from radiation therapy plans. The model aimed to classify the target variable that included class-0 corresponding to plans for which the PTV treatment planning objective was met and class-1 that was associated with plans for which the PTV objective was not met due to the priority trade-off to meet one or more organs-at-risk constraints. One model was selected for further investigation amongst those evaluated: Support-Vector Machine, Elastic-Net, Logistic-Regression, and Random-Forest using double-nested cross-validation and an area under the curve (AUC) metric. The model predictions were explained both globally and locally with Shapely additive explanation (SHAP) interaction values. **Results:** The highest-performing model was Logistic Regression achieving an accuracy of 93.8±4.1% and AUC of 0.98±0.02 on the testing data. The SHAP analysis indicated that the $\Delta D99\%$ metric for PTV had the greatest influence on the model predictions and was approximately 3.5 times more significant than the second most important feature – $\Delta D1\%$ for optic chiasm. The least important feature was $\Delta DMAX$ for the left and right cochleae. **Conclusion:** The trained model achieved satisfactory accuracy and can be used by medical physicists in a data-driven quality assurance program as well as by radiation oncologists to support their decision-making process in terms of treatment plan approval and potential plan modifications. Model explanation analysis showed that the model relies on clinically valid logic when making predictions.

Feasibility of Time-Resolved DVH Based Treatment Delivery Verification of VMAT with EPID

P Greer^{1*}, R David², J Wolf¹, (1) Calvary Mater Newcastle, Newcastle, (2) CCLHD, Gosford, NSW, Australia, Gosford, AU

Purpose: EPID presents a potentially efficient and comprehensive option for verification of VMAT with no setup time. However dosimetric verification of VMAT with EPID is usually performed using integrated EPID images therefore the time-resolved dose delivery is not verified. Moreover gamma based analysis is difficult to interpret for the clinical significance of any errors. This work investigates the feasibility of performing time-resolved dose-volume histogram (DVH) based analysis of VMAT with EPID. **Methods:** Feasibility was assessed with a 2-arc (200 degrees rotation) VMAT lung SBRT plan modelled as 40 subarcs of 10 degrees. Dose in flat phantom for each subarc at 10 cm depth, gantry zero, was calculated with Eclipse V15.6.05. Image frames at 13 frames per second were collected during in-air delivery by a framegrabber computer with in-house acquisition software and interpolated to form 10 degree subarc images. These were then converted to dose at 10 cm depth in flat phantom using an in-house EPID to dose conversion model and dose ratio (DR) matrices to Eclipse dose generated. These DR matrices were backprojected through the original patient CT dose using ray-tracing to give a measured-weighted dose. Dose volume histogram comparisons were then performed. **Results:** The 2D dose maps (n=40) were evaluated with traditional planar gamma evaluation methods with gamma pass rates (mean±SD) of 99.9±1.1% at 2%,2 mm criteria. The DVH curves generated from measured-weighted dose were virtually indistinguishable with the original planned DVH. **Conclusion:** This study successfully demonstrated feasibility of time-resolved DVH based verification of VMAT with EPID. Using EPID subarc measurements during VMAT the DVHs are

reproduced.

6-DoF Robotic Motion Phantom: An Open-Source Project for Quality Assurance of Real-Time Image-Guided Radiotherapy Technologies

C Sengupta^{1*}, S Alnaghy², D Nguyen^{1,3,4}, A Kyme⁵, K Makhija¹, T Moodie⁶, D Mason⁷, V Caillet¹, K Shi¹, R O'Brien¹, J Booth⁴, S Tomka¹, P Keall¹ (1) ACRF Image X Institute, The University of Sydney, Sydney, NSW, AU, (2) Centre for Medical Radiation Physics, University of Wollongong, NSW, AU, (3) University of Technology Sydney, Ultimo, NSW, AU, (4) North Sydney Cancer Centre, Royal North Shore Hospital, NSW, AU, (5) School of Biomedical Engineering, The University of Sydney, NSW, AU, (6) Crown Princess Mary Cancer Centre, NSW, AU, (7) Nepean Cancer Care Centre, NSW, AU

Purpose: The geometric and dosimetric impact of tumor translation and rotation, or 6-degree-of-freedom (6-DoF) motion, in radiation therapy is becoming increasingly important. Since there is currently no commercial 6-DoF solution that could reproduce patient-measured motion, we designed, built and programmed a robot-based system for 6-DoF Image-guided Radiation Therapy (IGRT) research and Quality Assurance (QA). To enable advancement of intrafraction motion management in our community, we have made the complete package open-source. The purpose of this work is to describe the applications of the 6-DoF system, the research results and the open-source repository. **Methods:** The 6-DoF system consists of a six-axis robotic arm (Universal Robot, UR3), an acrylic phantom, a custom-base plate to mount the robotic phantom onto the treatment couch and a software application which controls the robotic phantom to reproduce the patient-measured tumor motion. The integrated system is capable of accurately mimicking patient-measured tumor traces to provide precise 6-DoF QA for real-time IGRT approaches. The repository contains everything required to assemble a similar 6-DoF system: source code, CAD files for the phantom and hardware tools, robot specifications, bill of materials, documentation, and user-guide to operate the system, and, step-by-step QA procedure. **Results:** The 6-DoF system has been used successfully for several applications including geometric QA tests for the real-time tumor tracking technology, Kilovoltage Intrafraction Monitoring (KIM) in two multi-center clinical trials, for prostate and liver cancer patients and evaluation of the dosimetric impact of prostate rotational motion using films. **Conclusion:** The development of this system has enabled us to perform 6-DoF QA processes for KIM and it has great potential to perform QA for other real-time radiotherapy systems. Full details of the system and its application have been shared on GitHub for the benefit of the medical physics community: <https://github.com/ACRF-Image-X-Institute/6-DoF-Robotic-Motion-Phantom>.

A Method to Estimate a Fan-Beam CT NPS Using Two Basis Functions with a Limited Number of Noise Realizations

H Jang*, M Han, M Ko, J Baek, Yonsei University, Incheon, 28KR

Purpose: Traditionally, noise power spectrum (NPS) is estimated by ensemble averaging of multiple realizations of noise-only images. However, with a limited number of images, the estimation accuracy of NPS becomes lower. Recent works proposed NPS estimation methods using radial 1D-NPS as its basis, but these methods couldn't reflect the non-stationary noise property of a fan-beam CT image. In this work, we proposed a more accurate NPS estimation method that reflects the non-stationary noise property of a fan-beam CT image. **Methods:** Each angular spoke of the 2D-NPS can be expressed as a sum of two basis functions with different cutoff frequencies determined from complimentary projection magnification factors. Therefore, the proposed method uses two basis functions by reflecting view angle dependent variations of cutoff frequencies in each angular spoke of the 2D-NPS. To examine the non-stationary property of NPS in a fan-beam CT image, NPS was estimated at 3 different local regions centered at (-100mm, 0), (0, 0) and (0, -100mm). The weighting factors of the two basis functions were estimated by minimizing the mean squared error (MSE) from the realized NPS image calculated from 10 noise realizations. We compared the estimation accuracy of NPS calculated from 10 noise realizations, previous method, and proposed method. Analytical NPS was used as a reference. **Results:** The NPS estimated by the proposed method showed high similarity to analytical NPS, while the NPS estimated by the previous method couldn't reflect the non-stationary noise property of a fan-beam CT image. **Conclusion:** In this work, we proposed a more accurate method using two basis functions to estimate the NPS which reflects the non-stationary noise property of a fan-beam CT image. The NPS estimated by the proposed method showed higher similarity to analytical NPS compared to the NPS estimated by the previous method.

An Assessment of Uncertainties in Pediatric CT Organ Dosimetry When Scan Parameters and Individual Body Morphometry Are Unknown

C Kofler^{1*}, E Olguin², E Stepusin³, D Long⁴, M Kwan⁵, D Miglioretti⁶, R Smith-bindman⁷, W Bolch⁸, (1) University of Florida, Gainesville, FL, (2) University of Florida, Gainesville, FL, (3) Chicago, IL, (4) Memorial Sloan Kettering Cancer Center, New York, NY, (5) Kiser Permanente Northern California, Oakland, CA, (6) University of California Davis, Davis, CA, (7) University of California San Francisco, San Francisco, CA, (8) University of Florida, Gainesville, FL

Purpose: In many epidemiology studies of patient CT exposures, details regarding patient-specific body morphometry and/or exam-specific technique factors are typically absent, and thus various assumptions are employed during organ dose reconstruction. The purpose of this study is to highlight the importance of these parameter sets in estimating effective and organ doses from a CT scan. **Methods:** The University of Florida/National Cancer Institute (UF/NCI) computational phantom library (12 reference phantoms and 351 non-reference phantoms) were used to compute organ doses within a population of 2,815 American pediatric patients undergoing CT imaging from 1998 to 2013 in which both patient height/weight and exam-specific scan lengths were available. Next, patient morphometry and scan length data were incrementally removed and replaced with various estimates to assess uncertainties in CT dosimetry when these data are unavailable. **Results:** Using the effective diameter of the patient to estimate height and weight resulted in up to an 82% overestimation of the effective dose. Matching to a reference phantom resulted in up to a 54% overestimation of effective dose. Estimating height based on patient age and weight based on effective diameter resulted in effective dose being underestimated by a maximum of 8% and overestimated by a maximum of 10%. Estimating height and weight based on patient age resulted in effective dose being underestimated by a maximum of 25% and overestimated by a maximum of 12%. Using a default scan length in place of a patient-specific scan length resulted in up to a >200% overestimate or a 51% underestimate of the effective dose. **Conclusion:** The differences in organ and effective doses found in this study highlight the need for patient- and exam-specific information when estimating organ and effective doses from CT imaging in pediatric patient populations.

Diagnostic Reference Levels (DRLs) and Achievable Doses (ADs) for the 11 Most Commonly Performed Pediatric CT Examinations in the United States (USA) as a Function of Patient Age and Size Using 1.5 Million Examinations in the American College of Radiology (ACR) CT Dose Index Registry

K Kanal^{1*}, P Butler², M Chatfield², J Wells³, E Samei³, M Simanowith², D Golden², D Gress², J Burleson², W Sensakovic⁴, K Strauss⁵, D Frush³, (1) University of Washington, Seattle, WA, (2) American College of Radiology, Reston, VA, (3) Duke University Medical Center, Durham, NC, (4) Mayo Clinic, Phoenix, AZ, (5) Children's Hospital Medical Center, Cincinnati, OH

Purpose: To develop diagnostic reference levels (DRLs) and achievable doses (ADs) for the 11 most commonly performed pediatric CT examinations in the United States (USA) as a function of patient age and size using the American College of Radiology (ACR) CT Dose Index Registry. **Methods:** Data on the 11 most commonly performed pediatric CT examinations acquired between 2016 – 2020 from 1637 facilities were analyzed. For head, neck and extremity examinations, doses were analyzed based on patient age; for body examinations, doses were analyzed based on both patient age and effective diameter. Data from 1,562,016 examinations provided medians (AD) as well as 75th percentiles (DRL) for CTDIvol, DLP and SSDE. Results were compared with DRLs from other countries. **Results:** Of all facilities analyzed, 65.2% of the facilities were community hospitals, 16.8% were freestanding centers, 9.5% were academic facilities and 3.5% were dedicated children's hospitals. Head CT was the most frequently performed examination in the study (56.1%) followed by the abdomen/pelvis CT (28.1%). ADs and DRLs (for both CTDIvol and DLP) for all examinations generally increased as a function of age and patient effective diameter. For head without contrast examinations, the CTDIvol AD and DRL ranged from 19-46 mGy and 23-55 mGy, respectively increasing with age. For abdomen/pelvis without contrast examinations, the CTDIvol ADs and DRLs ranged from 2.1-24 mGy and 2.6-28 mGy, respectively with increasing effective diameter. Although international pediatric DRL methodology and results vary, our results fall within the ranges reported across other countries. **Conclusion:** DRLs and ADs as a function of patient age and effective diameter were developed from a wide range of USA practice environments for the 11 most common CT pediatric examinations using data from over 1.5 million pediatric examinations. These determinations can serve as practical benchmarks for accountability and for improvement in pediatric CT practice.

Fast Monte Carlo Simulation of Non-Isotropic X-Ray Source for CT Dose Calculation

S Wang^{1*}, A Imran¹, D Pal², E Zucker¹, A Wang¹, (1) Stanford University, Stanford, CA, (2) GE Healthcare, Menlo Park, CA

Purpose: To accurately and efficiently estimate individualized patient dose in CT scans with Monte Carlo (MC) simulations. **Methods:** A GPU-based MC tool with the ability to model a non-isotropic source was developed from MC-GPU v1.3. Unlike the isotropic source in the original MC-GPU, the anode heel effect and bowtie filtration are realized in this tool. The heel effect leads to photon intensity variation for azimuthal angles that can be modeled as a probability function, while the bowtie model is based on analytic attenuation. The bowtie is represented by two basis materials so that with inputs of material attenuation coefficients and thickness combinations at different fan angles, photon transmission and filtered spectra for each fan angle can be calculated for a given source spectrum. Using a precomputed lookup table of the bowtie, the photon's direction and energy can be efficiently randomly selected using the alias method. An air scan was used to validate the simulation tool by comparing against the analytically calculated ground truth image. For individualized patient dose maps, we generated spatial maps of both material type and mass density based on the CT numbers as the inputs for the MC tool along with necessary scanner-specific parameters. **Results:** The simulation was performed on a workstation with two Nvidia Titan RTX GPUs. The average processing speed was $\sim 3.5e7$ photons/sec (original MC-GPU with isotropic source: $4.7e7$ photons/sec). In the air scan validation, the average relative error in a spectral test was 0.86% for 25-80 keV and the average relative errors in energy-integrated detection were 1.69% and 0.92% for bowtie filtration and heel effect, respectively. **Conclusion:** In this work, a near real-time MC dose tool is introduced which has the potential to provide realistic and individualized dose map from non-isotropic sources. Ongoing work will include tube current modulation and automatic organ segmentation.

Longitudinal QC Testing of CBCT and Helical MDCT Systems with a Unified Image Quality and Dose Phantom

M Mahesh^{*}, M Fernandez, A Uneri, J Boone, J Siewerdsen, Johns Hopkins University, Baltimore, MD

Purpose: The first clinical use of a phantom for unified quality control testing of both cone-beam CT (CBCT) and helical MDCT is reported, with automated analysis and structured reporting of quantitative imaging performance and dose in longitudinal studies spanning 6 clinical systems (3 CBCT + 3 MDCT) for 6 months. **Methods:** The phantom (CorgiTM, The Phantom Lab) was used in monthly QC of 3 CBCT systems – Synergy XVI (Elekta), O-arm (Medtronic), and Artis Zee (Siemens) – and 3 MDCT systems – Edge (Siemens), Precision (Canon), and Aquilion One (Canon). Automated software provided one-click analysis and structured reporting of voxel value linearity, contrast-to-noise ratio (CNR), image uniformity, spatial resolution (MTF in axial and non-axial planes), noise, noise-power spectrum (NPS), and cone-beam artifact (signal modulation about two parallel disks). For each system, image quality tests were performed for standard Head (with 13.5 cm diameter phantom) and Body protocols (phantom within a 32 cm annulus). **Results:** The results demonstrate a unified system for more rigorous, quantitative, objective QC across a broad spectrum of CBCT and MDCT systems in clinical applications ranging from image-guided radiotherapy, image-guided surgery, interventional radiology to diagnostic radiology and cardiology. Quantitative tests revealed factors not conventionally evaluated and had positive impact on QC of each system – example, quantitative analysis of spatial resolution (MTF, rather than subjective evaluation and line-pair tests that do not probe the limits of spatial resolution on modern CBCT or MDCT systems), the extent to which spatial resolution is isotropic (MTF in axial and non-axial planes), and NPS analysis that was valuable in identifying shortfalls in detector and system geometry calibration. **Conclusion:** The phantom, test procedures, and automated analysis of quantitative QC metrics provide a valuable basis for more standardized, rigorous, and quantitative QC in CBCT and with helical MDCT.

Boone JM & Siewerdsen JH have licensing agreement with The Phantom Lab (Greenwich NY) for the phantom used in the work.

Uneri A has a consulting agreement with The Phantom Lab (Greenwich NY) for software development.

A Scanner-Specific Simulation Platform for Virtual Imaging Trials in Deep Si-Based Photon-Counting CT

S Sharma^{1*}, D Pal², E Abadi³, P Segars⁴, J Hsieh⁵, E Samei⁶, (1) Duke University, Durham, NC, (2) GE Healthcare, Menlo Park, CA, (3) Duke University, Durham, NC, (4) Duke University, Durham, NC, (5) GE Healthcare, Milwaukee, WI, (6) Duke University, Durham, NC

Purpose: Deep Si-based photon-counting CT (Si-PCCT), a candidate emerging CT detector technology, is expected to provide multiple benefits by virtue of fast charge collection times, reduced K-fluorescence crosstalk, and ease of manufacturing. To translate Si-PCCT to clinical use, its performance needs to be comprehensively evaluated and optimized in a task-specific manner. Often performed through large-scale imaging studies on human subjects, such evaluations are impractical for Si-PCCT due to the lack of access to clinical prototype systems. This limitation can be overcome by using computational anthropomorphic phantoms and imaging simulators, in a process known as virtual imaging trials (VITs). To enable such VITs, we present a scanner-specific simulation platform to simulate realistic clinical images for Si-PCCT systems. **Methods:** A hybrid simulation platform for VITs (DukeSim) was extended to model the scanner-specific geometry

and components of a PCCT prototype, including models incorporating energy-dependent response and crosstalk characteristics for a deep Si-based detector. To simulate images, a potential pilot system was emulated to image a high-resolution (0.1 mm) virtual patient with a lung lesion. The obtained projections with energy-binned photon counts were processed to introduce Poisson noise, summed across energy bins, and corrected for beam hardening before reconstruction. To demonstrate the utility of this platform, the reconstructed images were utilized to qualitatively and quantitatively compare the spatial resolution performance of PCCT to conventional energy-integrating CT (ECT), including their relative performance for estimation of morphological radiomics features. **Results:** The platform successfully simulated realistic images for prototype Si-PCCT designs. The evaluation of spatial resolution revealed superior performance of Si-PCCT over ECT both qualitatively and quantitatively, with a dramatic improvement of accuracy (30.7% mean) in the estimation of morphological radiomics features. **Conclusion:** The developed simulation platform simulated realistic images for a pilot Si-PCCT system, enabling the qualitative and quantitative evaluations integral to performing clinical VITs.

Accurate and Efficient Measurement of Channelized Hotelling Observer-Based Low-Contrast Detectability on the ACR Accreditation Phantom

M Fan*, T Vrieze, T Thayib, C McCollough, L Yu, Mayo Clinic, Rochester, MN

Purpose: To optimize channel filters and many other parameters in channelized Hotelling observer (CHO) so that the low-contrast detectability can be accurately and efficiently estimated for the widely used American College of Radiology (ACR) accreditation phantom. **Methods:** A large number of repeated scans is typically required in CHO calculation to provide accurate and precise estimate of index of detectability (d'). The main goal of optimization is to minimize the number of repeated scans and make it practically feasible. To provide a reference standard for optimization, an ACR phantom was repeatedly scanned 100 times at three dose levels (24, 12 and 6 mGy). Images were reconstructed with two kernels (FBP Br44 and IR Br44-3). d' as a function of number of repeated scans was determined for different channel filter options, different number of low-contrast objects, different number of background regions of interest (ROIs), and different number of slices per each object. The bias of d' was quantified using the d' calculated from all 100 repeated scans as reference. The variation of d' at each condition was estimated using a resampling method combining bootstrapping and random sampling among all 100 repeated scans. **Results:** Optimized parameters in CHO calculation were determined: 9 non-overlapping slices per object, 4 objects per low-contrast object size, 2 background ROIs per object, and 4 channel filters. The bias and standard deviation were estimated at different numbers of repeated scans using these parameters. If only one single scan was used in the CHO calculation, the bias of d' was within 6%. However, the uncertainty remains high (16-21%). In order to limit the uncertainty to be 10%, 2-3 repeated scans were still required at routine dose levels. **Conclusion:** With optimized parameter settings in CHO, efficient and accurate measurement of low-contrast detectability on the commonly used ACR phantom becomes feasible.

The Development of Metrics to Gauge Treatment Outcomes from Mechanical Ablation with Focused Ultrasound

WE-D-TRACK 4-04

Q&A

Ablation is among the primary tools for interventional procedures. Focused ultrasound is gaining traction for noninvasive ablation in oncological and urological applications. Early stage focused ultrasound technologies relied on heating to achieve ablation, but more recent developments indicate ultrasound-induced mechanical effects can also be utilized to achieve the desired clinical outcomes. Acoustic cavitation is the most prominent mechanical effect induced by ultrasound for therapeutic purposes. Histotripsy is a focused ultrasound technology that generates cavitation spontaneously to disintegrate soft tissues. Histotripsy has some advantages over its thermal counterparts, including its ability to ablate large and highly vascularized and large tumors with specialized sources. Cavitation also plays a role for breaking down kidney stones. Burst wave lithotripsy (BWL) is an experimental treatment that uses sinusoidal focused ultrasound pulses to noninvasively fragment urinary stones into small pieces that can naturally pass through the urinary tract. Cavitation induced by the BWL pulse produces stress at the surface of the stone that contribute to erosion of the material, but also can lead to complications from off target damage. The noninvasive application of each of these therapies requires imaging peri-treatment guidance and monitoring, and post-treatment assessment of efficacy. The choice of imaging modality depends on the intended therapeutic mechanism of action.

This session will provide an overview of the mechanical effects of ultrasound as a therapeutic modality. Focused ultrasound instrumentation will be discussed for oncological and urological applications. Standard and novel methods for image guidance of therapeutic ultrasound will be introduced, including the relevant imaging metrics to gauge therapeutic efficacy.

Learning Objectives:

1. Understand the origin of ultrasound-based therapeutic mechanical mechanisms
2. Understand how cavitation impacts stone fragmentation and tissue injury for burst wave lithotripsy, and the role of cavitation in ablation of soft tissues with histotripsy

3. Recognize the origin of cavitation-generated acoustic emissions, and how the emissions are processed to monitor cavitation-based therapies

Autosegmentation and Image Analysis in MRI-guided Radiation Therapy

WE-D-TRACK 6-01

Auto-Correction of Inaccurate Auto-Segmentation for MRI-Guided Adaptive Radiotherapy

J Ding^{1*}, Y Zhang¹, A Amjad¹, J Xu², D Thill², X Li¹, (1) Medical College of Wisconsin, Milwaukee, WI, (2) Elekta Inc., St. Charles, MO

Purpose: Fast and accurate auto-segmentation on daily image is essential for MR-guided adaptive radiotherapy (MRgART). However, the state-of-the-art auto-segmentation based on deep learning (e.g., deep convolutional neural networks, DCNN) has a limited success particularly for complex structures, e.g., bowels. To address this issue, we develop a method to quickly and automatically correct for unacceptable auto-segmented contours for MRgART. **Methods:** An improved active contour model (ACM) based on level set was implemented to utilize the probability maps from standard DCNN models to set per-pixel parameters and initialize contour evolution. The ACM method was tested on the DCNN auto-segmented bowel contours (initial contours) for 46 abdominal T2w-MRI sets. All MRI images were pre-processed with bias correction and contrast enhancement. For each image slice, bowel region was divided into multiple subregions with each including a bowel loop. The ACM contour correction was performed on the initial contour in each subregion. The correction performance was measured by comparing the Dice Similarity Coefficients (DSC) for the corrected contours with those for the initial contours. Manually delineated contours were used as ground truth. **Results:** The DSC for the ACM-corrected contours was increased compared to those for the initial contours. For bowel contours with initial DSC<0.5, the mean DSC was increased from 0.307 to 0.574 after correction, with 16% of the corrected contours reaching DSC≥0.8. For contours with DSC=0.5–0.8, the mean DSC was increased from 0.694 to 0.773 after correction, with DSC≥0.8 in 47% of cases. The execution time of the correction on a subregion was less than 10 seconds. **Conclusion:** A fully-automated contour correction method based on ACM was performed to quickly correct for inaccurate deep learning auto-segmentation and its effectiveness was demonstrated for complex anatomy, e.g., bowels. The method can be integrated into the segmentation step to improve and accelerate the process of MRgART.

Multi-Parametric Ultra-Quality 4D-MRI Synthesis Using VoxelMorph-Based Deformable Image Registration

H Xiao^{1*}, T Li¹, R Ni¹, G Ren¹, W Liu², W Wang², Y Zhang², H Wu², H Lee³, H Chang³, L Cheung³, J Cai¹, (1) The Hong Kong Polytechnic University, Hong Kong, CN (2) Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Radiation Oncology, Peking University Cancer Hospital & Institute, Beijing, CN (3) The University of Hong Kong, Hong Kong, CN

Purpose: To develop a novel multi-parametric ultra-quality 4D-MRI technique through deep learning synthesis using a VoxelMorph-based deformable image registration (DIR) model. **Methods:** Twenty-seven liver tumor patients undergoing radiotherapy were collected from Beijing Cancer Hospital with IRB approval. Each patient received a T1w 4D-MRI scan using TWIST volumetric interpolated breath-hold examination (TWIST-VIBE) sequence. Patients also received multi-parametric 3D MR scans, including T1w, T2w, and diffusion-weighted MR imaging (DWI) with b-value of 50 and 800. 4D-MRI frames at the same respiratory phases with 3D MR scans were selected, and a VoxelMorph-based model was trained to obtain the deformations between selected frames and other frames. The deformations were then applied to those 3D MRIs to synthesize multi-parametric ultra-quality 4D-MRIs at corresponding respiratory phases. Contrast-to-noise ratio and full-width-half-maximum (FWHM) of the profile along lung-liver interface were calculated on different MRIs to quantitatively evaluate image quality, and tumor motion trajectories were measured to determine motion errors and subsequently the motion accuracy of synthetic 4D-MRIs. **Results:** CNR of the original T1w 4D-MRI was 6.62±3.85, and it increased to 10.54±5.64, 12.83±7.66, 25.36±14.26, and 30.42±14.02 in the synthetic ultra-quality T1w, T2w 4D-MRI, 4D-DWI (b=50), and 4D-DWI (b=800), respectively. FWHM of the liver-lung profile reduced from 6.7±2.9 mm to 4.7±2.4 mm, 3.1±1.3 mm, 6.4±4.5 mm, and 4.5±1.4 mm in the synthetic ultra-quality T1w and T2w 4D-MRI, 4D-DWI (b=50), and 4D-DWI (b=800), respectively. In addition, relative tumor motion errors were much smaller than the voxel sizes of the 3D-MRIs. **Conclusion:** This study demonstrated the feasibility of a novel multi-parametric ultra-quality 4D-MRI with deep learning-based DIR. This method overcomes many limitations of current 4D-MRI techniques and holds great promises for clinical applications.

Radial MR Fingerprinting for Accelerated High Resolution Quantitative Prostate MRI in Radiation Therapy

V Yu^{1*}, E Subashi², C Wu³, P Koken⁴, M Doneva⁵, R Otazo⁶, O Cohen⁷, (1) Memorial Sloan Kettering Cancer Center, New York, NY, (2) Memorial Sloan Kettering Cancer Center, New York, NY, (3) New York, NY, (4) Philips Medical Systems, (5) Philips Medical Systems, (6) Memorial Sloan Kettering Cancer Center, New York, NY, (7) Memorial Sloan Kettering Cancer Center

Purpose: magnetic resonance fingerprinting (MRF) provides simultaneous T1/T2 quantitative maps, allowing for longitudinal assessment of treatment response and disease progression. We examine the feasibility of a golden-angle radial MR fingerprinting for radiotherapy applications in prostate with a dedicated MRI simulator. **Methods:** A 2D steady-state-free-precession(SSFP) MRF sequence with inversion preparation was used with golden angle radial trajectory readout. All scans were performed on a 3T Philips scanner equipped with a flat tabletop for MRI simulation. MR fingerprinting imaging parameters are as follows: in plane resolution 1.1x1.1 mm², slice thickness=5mm, [echo time(TE),repetition time(TR)] = [8.1ms,4ms], variable flip angle=0-60 degrees. The acquisition schedule contains 500 time points, and 3 golden-angle-radial-spokes per time point. The radial MRF sequence was tested with the NIST imaging phantom and the measured T1/T2 values were validated against the ground truth values. Prostate MRF images of a healthy volunteer subject were acquired. T1/T2 maps were calculated by dot product matching to the simulated MRF dictionary. Standard relaxation mapping methods, namely Variable-flip-angle(VFA) for T1 and Multi-single-echo-spin-echo(MSE) for T2, were performed for comparison. The prostate gland(P), peripheral zone(PZ) and transition zone(TZ) regions of interest were delineated, and the statistics and distribution of the quantitative mapping values were analyzed. **Results:** T1/T2 quantitative maps were obtained covering the whole prostate gland in 3 minutes. The generated parameter maps on the NIST Phantom were in good agreement with expected T1/T2 values. All values from standard method or MRF were in agreement with published literature. The MRF-T1 average values for [P,PZ,TZ]=[1960ms,2171ms,1858ms]. Compared with VFA, MRF-T1 values were lower but achieve significantly lower standard deviations. The MRF T2 mean value for [P,PZ,TZ]=[52.7ms,68.4ms,47.4ms]. MSE-T2 resulted in higher average values and superior image quality at the cost of longer scan time. **Conclusion:** feasibility of prostate radial MRF in the RT MRI simulation has been demonstrated.

This work was partially supported by the NIH/NCI Cancer Center Support Grant/Core Grant (P30 CA008748). PK and MD are employees of Philips Healthcare.

Synthetic Magnetic Resonance Imaging from Computed Tomography Simulation Scans Using Deep-Learning Models for High-Dose-Rate Prostate Brachytherapy

H Kang^{1*}, M Abuhamad², A Solanki¹, J Roeske¹, (1) Loyola University Medical Center, Maywood, IL, (2) Loyola University Chicago, Chicago, IL

Purpose: For high dose rate prostate (HDR) brachytherapy at our institution, both CT and MRI are acquired to identify catheters and delineate the prostate, respectively. We propose to build a deep-learning model to generate synthetic magnetic resonance imaging (sMRI) with enhanced soft-tissue contrast from computed tomography (CT) scans. sMRI would assist physicians to accurately delineate the prostate without needing to acquire additional planning MRI. **Methods:** 58 paired post-implant CT and T2-weighted MRI sets acquired on the same day for HDR prostate patients were retrospectively curated to train and validate the conditional Generative Adversarial Networks (cGAN) algorithm Pix2pix to generate sMRI. CT and MRI images were fused using a mutual information rigid registration algorithm in the Eclipse treatment planning system. The CT images for each patient were resampled to match to the dimensions of the MRI scan. Pix2pix was then trained to generate sMRI from the CT images using the MRI images as the ground truth. The performance of the algorithm was quantitatively evaluated using the metrics of mean absolute error (MAE), mean squared error (MSE) and cosine similarity (CS) over 400 images. MAE and MSE are 0 and CS is 1 when sMRI and MRI images are identical. **Results:** sMRI images with enhanced soft-tissue contrast and catheter visualization were generated using Pix2pix for HDR prostate patients. The following performance metrics were obtained: MAE = 0.062±0.008, MSE = 0.008±0.002, CS = 0.987±0.006. Qualitatively, sMRI closely resembled the patient MRI in both soft tissues and bony anatomies in the region of near the prostate. **Conclusion:** It is feasible to generate sMRI from CT scans clearly visualizing soft tissues, the boundary of the prostate, and catheters inside the prostate. To our knowledge, this is the first time both the boundary of the prostate and catheters have been visualized on sMRI.

Synthetic MRI-Aided Delineation of Organs at Risk in Head-And-Neck Radiotherapy

X Dai^{*}, Y Lei, T Wang, J Zhou, J Roper, M McDonald, J Beitler, J Bradley, T Liu, X Yang, Emory University, Atlanta, GA

Purpose: Eliminating the labor-intensive, time-consuming, and observer-dependent manual delineation of organs-at-risk (OARs) is highly desired in radiotherapy treatment planning. This study aimed to tackle the challenges remaining in achieving reliable expert performance among current auto-delineation algorithms through developing a novel synthetic MRI-aided method. **Methods:** MRI provides superior soft-tissue contrast compared to CT. By taking the complementary contrasts provided by CT and MRI into account, the accuracy of OAR delineation can be improved. In the study, synthetic MR images were firstly synthesized from CT images utilizing a cycle-consistent generative adversarial network. A novel model namely, mask scoring regional convolutional neural network, was implemented to obtaining delineation of organs through extracting and combining the features of CT and synthetic MRI. The performance of the proposed method was quantitatively assessed using both in-house and public datasets containing CT scans from head-and-neck (HN) cancer patients. Metrics including Dice similarity coefficient (DSC), 95th percentile Hausdorff distance (HD95), mean surface distance (MSD), and residual mean square distance (RMS) were calculated to evaluate the outperformance of our proposed method against current state-of-the-art algorithms. **Results:** A mean DSC of 0.77, mean HD95 of 2.90 mm, mean MSD of 0.89 mm, mean RMS of 1.44 mm were achieved by our proposed method across all of 18 OARs in our in-house dataset which contains images from 70 patients, which outperforms the current state-of-the-art algorithms by 6%, 16%, 25%, and 36%, respectively. A mean DSC of 0.86 was achieved for all 9 OARs on public dataset which has 48 patients, which is 6% better than the competing methods. **Conclusion:** In this study, a synthetic MRI-aided deep learning framework for automated delineation of OARs in HN CT has been developed. The proposed method will have a high impact in rapid OAR contouring in routine HN cancer radiotherapy treatment planning.

Learn from What You Drew - a Deep Learning Assisted Fast Semi-Automatic Segmentation for Complex Anatomy On MRI

Y Zhang^{*}, Y Liang, A Amjad, E Ahunbay, E Paulson, W Hall, B Erickson, X Li, Medical College of Wisconsin, Milwaukee, WI

Purpose: Existing auto-segmentation has limited success for complex organs (e.g., bowels). Consequently, time-consuming slice-by-slice review and editing is often required. To address this issue, we propose a deep learning based, fast, semi-automatic contouring method that predicts a contour on a slice using the user-approved contour from the previous slice. **Methods:** To demonstrate the idea, the deep learning method was trained and tested for stomach and small bowel contours on T2-weighted MRIs acquired from 48 patients with abdominal tumors. All the MRIs were pre-processed (e.g., bias corrected, normalized, and cropped) and carefully delineated (ground truth). The network backbone used was UNet with 3-channel input, including an image slice (to be segmented), and the image and contour of previous slice. Data augmentation by randomized 3D rotation, scaling and different image pair sampling using 1, 2, or 3 slices intervals was used in the model training. Patient-based leave-one-out-cross-validation was employed to evaluate the model performance. Quality of the predicted contour was evaluated quantitatively using Dice similarity coefficient (DSC) and qualitatively by a human rater with scores of 1, 2 and 3 indicating acceptable, minor editing, and major editing, respectively. **Results:** The average 2D-DSC of the predicted contours for each patient was in the range of (0.82-0.96) / (0.74-0.93) with a median value of 0.90/0.88 for stomach/small bowel contours. The percentage of the predicated contours with scores of 1 to 3 was 82.4 ± 10.5%, 14.6 ± 8.9% and 3.1 ± 4.8% for stomach and 72.7 ± 19.0%, 23.4 ± 15.2% and 3.9 ± 5.7% for small bowel. **Conclusion:** The proposed method can robustly predict a contour on an MRI slice based on the contour from previous slice for complex structures (e.g. stomach and small bowel). It can be integrated into existing workflows, facilitating fast and accurate segmentation, which is particularly important for MR-guided adaptive radiation therapy.

A Prior Knowledge Guided Deep Learning Model for GTV Auto-Segmentation On 4DMRI in MR-Guided Adaptive Radiotherapy of Pancreatic Cancer

Y Liang, Y Zhang^{*}, W Hall, E Paulson, X Chen, B Erickson, X Li, Medical College of Wisconsin, Milwaukee, WI

Purpose: Fast and consistent GTV segmentation in non-contrast enhanced daily 4DMRI is challenging for MR-guided Online Adaptive Radiation Therapy (MRgOART) for abdominal tumors. In this work, we develop a prior knowledge guided deep learning model specifically for auto-segmentation of pancreatic GTV on daily 4DMRI for MRgOART. **Methods:** Seventy-three pairs of verification and daily mid-position MRI sets acquired from 12 pancreatic cancer patients using 4D Vane sequence on a 1.5T MR-Linac during MRgOART were used to train and test the deep learning model with patient-based leave-one-out cross-validation. The model used the verification MRI and GTV mask (obtained before the first fraction) as a guidance for the daily MRI. A region of interest (ROI) was selected as the minimum bounding box of the verification GTV contour plus a margin of 15 mm to account for inter-fractional variations. Model input size was 128×128×3 with 3 channels corresponding to verification MRI, verification GTV mask, and daily MRI. Data augmentation methods such as translation, rotation, flip, guidance-target inversion, and rigid registration error introduction were applied for robust model training. Model performance was evaluated using dice similarity coefficient (DSC). **Results:** With the small size of the 4D Vane MRI dataset, the proposed model achieved an average DSC of 0.66±0.13 for all the cases studied. While for the 8 cases

with GTV >5 cc, the average DSC was 0.71, comparable to the inter-observer variation of DSC = 0.71 estimated in a previous study. The proposed model took less than 1 second to create the GTV contour on a daily MRI set. **Conclusion:** We developed a prior knowledge guided deep learning model to segment the pancreatic GTV in the daily non-contrast enhanced MRI using a composite image-mask input. The proposed model achieved clinically relevant DSC for cases with GTV >5 cc.

Deep Learning Model for Scatter Correction in Dedicated Breast CT

J Pautasso^{1*}, M Caballo¹, K Michielsen¹, I Sechopoulos^{1,2}, (1) Dept. of Medical Imaging, Radboud University Medical Center, Nijmegen, NL. (2) Dutch Expert Centre for Screening (LRCB), Nijmegen, NL

Purpose: To develop a deep learning (DL) model for scatter correction of dedicated breast CT (BCT) projection images. **Methods:** 118 digital breast phantoms were obtained by automatic segmentation of as many BCT patient images and augmented via random translation of the breast in the image field of view to a total of 470 samples. The samples were used to simulate the primary and scatter projections of a clinical BCT system using Monte Carlo (MC) simulations. Twelve projections were simulated for each sample, one every 30° covering a full 360° acquisition. The projections simulated from 450 samples were used to train the DL model to predict the scatter from the input primary+scatter projections. The model was trained end-to-end by unifying information from four orthogonal projections, to account for breast size and position. It was then tested on the remaining samples, and on acquired projections of a physical breast phantom. The scatter-corrected projections of this phantom were reconstructed, and then compared to the uncorrected reconstruction and a reconstruction from MC-corrected projections. **Results:** Inside the breast, the mean percentage error (min, max) between the MC-simulated and the DL-predicted scatter was -1% (-10%, 4%) and the mean standard deviation of the error within a projection was 6% (2%, 13%). In a homogeneous region of the physical phantom reconstruction, the mean ΔHU between ROIs close to the perimeter and the center were 86, 24, -64 for the uncorrected, MC-corrected, and DL-corrected images, respectively. **Conclusion:** The proposed DL model showed promising results for scatter correction in BCT images. Moreover, its performance allows for almost real-time processing, correcting 300 projections in 17 seconds on a standard PC. Future work will involve the evaluation of different DL architectures and learning algorithms to further improve the precision of the method, and additional evaluation with physical phantoms and patient images.

Scatter Correlation and Correction for Cone-Beam CT Using Dual-Layer Flat Panel Detector

S Gu*, B Qi, H Gao, Tsinghua University, Beijing, CN

Purpose: Scatter remains a big challenge and dominating factor of affecting dual-energy CT performance. The goal of this work is to study the correlation and correction of the x rays scattering between the layers for Cone-Beam CT using a prototype dual-layer flat-panel detector. **Methods:** A physical model about the relationship of the scatter distribution between layers is proposed, it may be described by a function related to the average scatter energy. Since the average scatter energy and the projection value are both related to the size of the phantom, we approximately assume the correlation is a function of the low and high projections. The dual layer detector consists of a top and bottom CsI scintillator with the same thickness of 550 μm, no extra filter in-between the two layers, the active area of 43.2*43.2 cm², and the pixel size of 150 μm. Experiments were performed using 120 kV X-ray voltage, 2*2 detector binning mode, and a multi-energy CT phantom (Gammex, Model 1472). The projections of the phantom in short, long axis, and the separate head part were acquired using cone beam and fan beam respectively. The difference between cone beam and fan beam transmission images is considered to be the contribution from scatter. **Results:** Three groups of the experiments show that scatter distribution from top (Is1) and bottom (Is2) layers satisfy the relation $Is2 = \alpha Is1$, where α follows our physics model. The correlation coefficients of the bottom distribution and the normalized top distribution are 99.3%, 99.7%, 93.4%, respectively. **Conclusion:** A scatter correlation model is proposed to describe the relationship of the scatter between two layers. The preliminary experimental results are basically consistent with the expectation, further validation of the scatter correlation model and scatter correction are underway with MC simulations and real experiments.

This project was supported in part by grants from the National Natural Science Foundation of China (No. U20A20169 and No. 12075130).

Correcting Cone-Beam CT for Patient-Generated Scatter Using Bayesian Monte Carlo Extrapolation

S Blake*, O Dillon, R O'Brien, ACRF Image-X Institute, University of Sydney, Sydney, NSW, AU

Purpose: Cone-beam computed tomography (CBCT) is used in image-guided radiotherapy to ensure correct patient positioning prior to treatment delivery. However, patient-generated x-ray scatter degrades CBCT image quality. Monte Carlo (MC) simulations offer the most physically accurate means to predict scatter signals, which can improve CBCT images via subtraction in projection space. Unfortunately, MC simulations can be too computationally costly for clinical application. We present a novel Bayesian Monte Carlo extrapolation (BMCE) algorithm that uses Bayesian statistics to mitigate the statistical noise present in MC-estimated scatter signals. The BMCE scatter correction method is then used to correct a 200-projection CBCT scan of a lung cancer patient. **Methods:** The BMCE method uses MC simulations to estimate the scatter component of each CBCT projection by transporting a 120 kVp x-ray beam through the planning 4DCT volume. Statistical noise present in the MC-simulated scatter signals was then corrected using an iterative Bayesian extrapolation postprocessing algorithm. Finally, the Bayesian-extrapolated scatter signals were subtracted from CBCT projections and images were reconstructed in 3D and 4D using the Feldkamp-Davis-Kress (FDK) algorithm. The quality of the CBCT images corrected using our BMCE algorithm was quantified in terms of contrast-to-noise ratio (CNR) and Hounsfield unit (HU) integrity. Image quality was then compared to images reconstructed without any scatter correction. **Results:** The BMCE scatter correction algorithm increased CNR for 3D and 4D reconstructions by factors of 3.4 and 3.8 respectively, and decreased the root mean square error (RMSE) between the HU-calibrated 3DCBCT reconstruction and the planning 3DCT by 30% relative to the 3DCBCT image reconstructed without any scatter correction. **Conclusion:** We demonstrate that Bayesian extrapolation of scatter signals estimated using Monte Carlo simulations with low numbers of primary x-rays can render otherwise noisy scatter distributions suitable for implementation in a CBCT scatter correction algorithm.

Gas Bubble Motion Artifact Reduction Through Simultaneous Motion Estimation and Image Reconstruction

K Wang*, H Shao, Y Zhang, J Wang, UT Southwestern Medical Center, Dallas, TX

Purpose: Motion of gas bubbles in abdominal region can produce significant artifacts during on-board CBCT scanning, which adversely affects the imaging quality

and limits the process of CBCT-based adaptive planning and image-guided radiotherapy. In this study, we aim to test the effectiveness of the simultaneous motion estimation and image reconstruction technique (SMRIE) for improving CBCT image quality and HU accuracy for abdominal scan. **Methods:** Two 3D abdominal CT images for a same patient acquired with 3 mins time interval were used in this study and the deformation vector field (DVF) between these two scans were calculated. Based on the calculated DVF, we simulated n ($n=0, 2, 4, 6, 8$) different DVFs through adding random motion vectors, and the corresponding n different CT images were generated. A $n+2$ phases 360° CBCT projection was then simulated through combining the projection images from the $n+2$ CT images, where projections from every continuous $360^\circ/(n+2)$ are from the same CT. Then we applied SMEIR algorithm onto the generated multi-phase CBCT projection, the motions of gas bubbles between these phases were iteratively predicted through inverse-consistent 2D-3D registration following motion compensated simultaneous algebraic reconstruction technique (SART), and the motion induced artifacts were corrected in the meanwhile. **Results:** When using SART for CBCT reconstruction, gas bubble motion artifacts in the simulated CBCT image showed the same pattern to those in the real abdominal CBCT scan. By introducing SMRIE technique, the boundary of structures and HU inaccuracy of gas bubble region are well corrected in the reconstructed CBCT image compared with SART reconstruction result. **Conclusion:** We introduced SMRIE technique for gas bubble motion artifact reduction, the improved image quality in the result demonstrated that SMRIE technique is promising for on-board CBCT gas bubble motion artifact reduction.

WE-lePD-TRACK 1-05

Scatter Correction for Cone Beam CT Using Half-Beam Blocker and Local-Filtration Scatter Estimation

H Cui*, X Jiang, Y Yang, University of Science and Technology of China, Hefei, CN

Purpose: We propose a half beam blocker-based scatter correction method combined with local filtration algorithm to remove the scatter-induced artifacts in single-scan cone-beam CT(CBCT) imaging. **Methods:** A head phantom and an electron density phantom were scanned in our in-house developed CBCT platform. A half beam blocker composed of lead strips was inserted between the x-ray source and the phantom, and used to block about half of the beam area. The shaded regions behind lead strips were considered as scatter signal. The scatter signal was smoothened with a threshold-based local filtration algorithm. Finally, the scatter free projections were produced by subtracting the estimated scatter from the unblocked half projections, and were used for volumetric reconstruction with FDK algorithm. The scatter corrected CBCT images were compared with fan beam CT and those without scatter correction. **Results:** Compared with the CBCT without correction, the error of CT number was reduced from more than 200 HU to less than 7 HU for the electron density phantom, and from more than 148 HU to less than 14 HU for the head phantom. The spatial uniformity was improved by a factor of 3. **Conclusion:** The proposed scatter correction method obtained accurate CT numbers and improved image spatial uniformity, without additional effort of another scan. This method has promising application in CBCT guided radiotherapy for better adaptive radiation dose calculation.

WE-lePD-TRACK 1-06

Reducing Scan Time and Dose: Motion Compensated Reconstruction for Adaptive 4DCBCT

B Lau^{1*}, O Dillon¹, T Reynolds¹, P Keall¹, J Sonke², S Vinod³, R O'Brien¹, (1) ACRF Image X Institute, University of Sydney, Sydney, NSW, AU, (2) Netherlands Cancer Institute, Amsterdam, (3) University of New South Wales, Sydney, NSW, AU, (4) Liverpool Hospital Sydney, Sydney, NSW, AU

Purpose: Prior to thoracic radiotherapy treatments, patients are commonly aligned using conventional 4DCBCT scans (1320 projections over 4 minutes). The ADAPT clinical trial performs adaptive 4DCBCT scans by modulating gantry rotation speed and projection acquisition in response to real-time changes in the patients breathing rate with as low as 200 projections. This study determines reconstruction algorithms that best complement adaptive 4DCBCT acquisitions for reducing imaging dose and scantime whilst maintaining or improving image quality compared to conventional 4DCBCT acquisitions from 20 ADAPT clinical trial patients (NCT04070586). **Methods:** Adaptive acquisitions from 20 patients treated for lung cancer as part of the ADAPT clinical trial were used in this study. Each patient dataset consisted of a planning 4DCT and 3 4DCBCT scans acquired on two treatment fractions (conventional 1320, adaptive 600 and adaptive 200 projections scans were acquired). All scans were reconstructed using Feldkamp-Davis-Kress (FDK) as a comparator, and the adaptive scans are reconstructed using McKinnon-Bates (MKB), Motion Compensated MKB (MCMKB) and motion compensated FDK (MCFDK). Reconstructed image quality was quantified using Structural Similarity Index (SSIM), Signal-to-Noise-Ratio (SNR), Contrast-to-Noise-Ratio (CNR), Tissue Interface Sharpness at the diaphragm (TIS-D) and tumor (TIS-T). **Results:** 200 and 600 projection adaptive 4DCBCT acquisition delivered 85% and 55% less imaging dose and 62% and 4% shorter scan times, respectively. Motion compensated reconstruction maintained or improved image quality metrics comparable to conventional reconstructions. The 200 projection adaptive scan with MCFDK (SNR=21.0±9.9, CNR=13.0±4.9, TIS-D=0.8±0.9, TIS-T=0.8±0.6) and MCMKB (SNR=22.1±10.7, CNR=14.1±5.3, TIS-D=1.3±1.1, TIS-T=0.9±0.3) reconstructions improved image quality metrics compared to conventional scans (SNR=11.9±4.2, CNR=9.5±3.1, TIS-D=0.58±0.3, TIS-T=0.4±0.1). **Conclusion:** Combining adaptive acquisition with motion compensation allows significant reductions in 4DCBCT scan times to be realized in the clinic on a standard linac.

This study is funded by NHMRC grant 1138899 and partly by a Cancer Australia grant number 1123068. RO is supported by a Cancer Institute NSW career development fellowship and PK is supported by an Australian NHMRC Senior Principal Research Fellowship.

A Generative Adversarial Network (GAN)-Based Technique for Synthesizing On-Board Imaging Artifacts in the Extended Cardiac-Torso (XCAT) Phantoms

Y Chang^{1*}, Z Zhang¹, Z Jiang¹, Y Lai², L Ren¹, (1) Duke University, Durham, NC, (2) University of Texas Southwestern Medical Center, Dallas, TX

Purpose: Simulating on-board imaging in digital phantoms is valuable for evaluating and optimizing of on-board treatment techniques like adaptive therapy. This study aims to synthesize CBCT imaging artifacts for different acquisition conditions in XCAT phantoms by developing a GAN-based deep-learning technique. **Methods:** An artifact simulation model is developed using CT images and image acquisition conditions as inputs, and is trained to generate CBCT images with the conditions-specific imaging artifacts. Then, XCAT phantoms are input to the model with user-desired image acquisition conditions to simulate CBCT artifacts in XCAT. The model was trained in two steps: (1) simulate cone and under-sampling artifacts for different projection numbers (450, 150, or 100); (2) simulate scatter and beam-hardening artifacts. Cone-beam projections of the CT volumes were generated by ray-tracing and used to reconstruct CBCTs using FDK-backprojection, which were used for the output for step 1 and input for step 2. The second-step model outputs corresponding CBCTs reconstructed using Monte-Carlo (MC) projections. We incorporated 15 patients and 5 XCAT phantoms for model training, validation, and testing. We evaluated the model performance with peak-signal-to-noise-ratio (PSNR), structural-similarity (SSIM), cross-correlation and NPS (noise power spectrum) correlation coefficient (NCC). **Results:** For the under-sampling and cone artifacts simulation, the PSNR reached 38.58/37.24/36.92, and the SSIM reached 0.987/0.978/0.966 for the testing patient with 450/225/100 projections, respectively. The cross-correlation and NCC achieved at least 0.99 for all projection numbers. Qualitatively, the model successfully simulated the streak artifact due to under-sampling and cone artifact in the XCAT phantom. For scatter simulation, the PSNR reached 28.05, and SSIM reached 0.904 for the testing patient. The cross-correlation was 0.927, and NCC was 0.984. **Conclusion:** The results demonstrated the feasibility of synthesizing CBCT artifacts in the 4D-XCAT phantom using the proposed method. This crucial development enhances the value of XCAT phantoms for evaluating and optimizing various on-board imaging and treatment delivery techniques.

High Spatial Resolution Simultaneous Quantitative T1rho and T2 Mapping at 3T

Q Peng^{1*}, C Wu², (1) Department of Radiology, Albert Einstein College of Medicine and Montefiore Medical Center, Bronx, NY, (2) Department of Medical Physics, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: Quantitative T1ρ and T2 MR mapping are promising MRI techniques for biochemical evaluation for soft-tissue, particularly articular cartilages, brain white matter, and tumors. Both techniques suffer from long scan duration. We present a novel approach in which T1ρ and T2 MRI are acquired and reconstructed simultaneously with quadrupled spatial resolution and nearly halved scan time compared to traditional approaches. **Methods:** All experiments were performed using a 3T MR scanner (Ingenia, Philips) equipped with a 1Tx/16Rx knee coil. A 3D Magnetization-Prepared Angle-Modulated Partitioned k-Space Spoiled Gradient Echo Snapshots (3D MAPSS) sequence was implemented for high resolution 3D T1ρ and T2 mapping. To improve sensitivity, reduce artifacts, and reduce total scan duration, T1ρ preparation with adiabatic RF pulses, synovial fluid suppression, unpaired RF phase cycling, optimized spin-lock time or TE sampling schemes, and combined T1ρ and T2 imaging and map generation were implemented in a novel sequence termed “FastMAPSS”. The single combined sequence had high spatial resolution of 0.3×0.5×2 mm³ with 5:55min scan duration, while the standard T1ρ and T2 sequences had 0.44×0.77×4 mm³ acquired within 5 min each. **Results:** SNR efficiency was greatly improved, and artifacts were maximally suppressed in the FastMAPSS sequence when integrating T1ρ and T2 mapping in one sequence and employing synergistically complementary curve fitting in the same equation for both maps using the complex MRI data. The combined T1ρ and T2 acquisition also avoided the need to co-register T1ρ and T2 images. As a result, high-resolution MRI (0.3×0.5×2 mm³) with laminar specificity on a 3T clinical scanner was achieved by simultaneous T1ρ and T2 mapping of the whole-knee cartilage in less than 6 minutes. **Conclusion:** The combined T1ρ and T2 FastMAPSS MRI sequence allowed quadrupled spatial resolution with nearly halved scan time compared to the traditional approaches.

Evaluating and Improving the Bloch Fitting Method for the Analysis of AcidoCEST MRI

T Li^{1,2*}, K Jones¹, A Kotrotsou¹, S Zhang¹, M Pagel¹ (1) UT MD Anderson Cancer Center, Houston, TX. (2) The University of Texas Health Science Center at Houston Graduate School of Biomedical Sciences, Houston, TX

Purpose: The Bloch-McConnell equations can be used to fit CEST spectra to estimate the proton chemical exchange rates (k_{ex}) and pH of a sample. This study aims to test the improvement of the fitting algorithm when the fitting parameters are fixed with T₁, T₂, B₁ and B₀ experimental values. **Methods:** Two-hundred iopamidol samples were prepared with 5 concentrations (5-50 mM), 5 T₁ values (0.4-3.9 sec) and 8 pH levels (6.25-7.30, equally spaced). Thirty-six CEST scans were performed on each sample using a FISP acquisition sequence and a cross-combination of six saturation powers (0.5-6 μT) and six saturation times (0.5-6 sec) with a Bruker 7T preclinical scanner. The set of 36 CEST scans was repeated at five temperatures (31-43 °C). In addition, T₁, T₂, B₁ and B₀ maps were also acquired. Image analysis and Bloch-fitting was performed with MATLAB. **Results:** The changes in the iopamidol amide contrasts in Z-spectra with CEST agent concentrations, T₁ values, sample pH values, saturation powers and saturation times match well with previous studies. Our Bloch fitting algorithm can detect the increase of amide k_{ex} with increasing sample pH and temperatures. Reducing the number of parameters fitted in the Bloch-fitting process by fixing the parameters with experimentally measured values does not significantly affect the fitting results of mid-to-high pH (>6.55) iopamidol samples, but can increase the sensitivity to the pH changes of low pH (<6.55) samples. Including T₁, T₂ and B₁ experimental information also significantly reduces the computation time. **Conclusion:** Our Bloch-fitting algorithm is capable of detecting the changes of k_{ex} of iopamidol protons at different pH levels. The inclusion of experimental information in the Bloch-fitting process improves the accuracy and precision of the fitting result and shortens the fitting time.

3D Brain Tumor Segmentation Through Multimodal Weighted Network in MRI

Z Zhou^{1*}, R Wang², J Yang³, J Guo⁴, (1) University of Central Missouri, Warrensburg, MO, (2) Xidian University, CN, (3) Xidian University, Xi'an, CN, (4) Xidian University

Purpose: Accurate brain tumor segmentation in Magnetic resonance imaging (MRI) images plays an important role in image-guided surgery and treatment planning, while unreliable may cause mislead surgery. We aim to develop a new multimodal weighted network (MW-Net) for three-dimension (3D) brain tumor segmentation. **Methods:** Totally 285 patients including 210 high grade and 75 low grade gliomas from Brats 2018 dataset are used in this study. The registration is performed on four available modalities such as T1, T1Gd, T2 and FLAIR on each case. In MW-Net, 3D-U-Net which is developed based on U-net are used as base model, which consists of convolutional, pooling and upsampling layers in 3D way. The activation function is ReLU, and the loss function is cross entropy. Adam function is used to tune the model parameters. Then four modalities with the corresponding weights fed into the shared 3D-U-Net model. A backpropagation algorithm is employed to train MW-Net. In testing stage, the 3D brain image is directly fed into trained MW-Net and the 3D segmentation results can be obtained. Dice coefficient (Dice), Positive Predictive Value (PPV) are sensitivity (SEN) are used as evaluation criterion. The better segmentation results can be obtained with higher Dice, SEN and lower PPV. **Results:** Five-fold cross validation is performed in this study. The evaluation results for MW-Net on Dice, PPV and SEN are 0.8824, 0.8823, and 0.8963, respectively, while 3D-U-Net are 0.8524, 0.8995, and 0.8475. **Conclusion:** A new multimodal weighted network (MW-Net) for three-dimension (3D) brain tumor segmentation was developed. The experimental results demonstrated that MW-Net can obtain better segmentation performance compared with available methods.

MRI Super-Resolution Via Real-World-Like Training Set Preparation

B Huang^{1*}, H Xiao², T Li², Y Yang¹, Y Yang¹, J Cai², (1) University of Science and Technology of China, Hefei, Anhui, P.R.China, (2) The Hong Kong Polytechnic University, Hong Kong, HK

Purpose: Current super-resolution (SR) methods suffer from poor performance on real-world MR images due to the simple translation model (e.g., Gaussian blur) used when preparing low-resolution (LR) images for training. We propose a deep learning-based (DL-based) method that generates more realistic LR images and use them to train our SR network to achieve better performance on real-world LR MR images. **Methods:** A two-step workflow was used: (a) dataset preparation via the proposed method. (b) SR network training. In the first step, a Generative Adversarial Network (GAN) was constructed to simulate the downsampling process. The generator of the proposed GAN is comprised of six convolutional layers without non-linear activation layer to simulate the low-pass filtration. The receptive field of the discriminator is 7-by-7. During the adversarial training, the generator output fake LR MR images that mimicked the real LR MR images on patch-level. Matched LR and HR MRI pairs were not needed since the receptive field of discriminator is small. An Enhanced Deep Super-Resolution (EDSR) network was used for SR.

A total of 2624 axial HR and LR images from 20 patients scanned with TWIST-VIBE sequence were used for training. Two experiments were conducted using different methods to prepare LR MR images: proposed GAN and conventional Gaussian filtration. Real LR images in this dataset were used to evaluate the SR network. **Results:** Severe artifacts were observed with the SR network that was trained with Gaussian blurred LR images. Better resolution enhancement was observed with the SR network that was trained with the data prepared by the proposed adversarial training method. This visual difference was verified by SSIM and PSNR. The SSIM improved by 0.111 ± 0.016 and the PSNR improved by 2.76 ± 0.98 dB. **Conclusion:** The proposed method outperformed the Gaussian blur method by demonstrating better resolution enhancement and fewer artifacts on real-world MRI.

Towards a Probabilistic Neurochemical Atlas of the Human Cerebellum Using ZOOM MRSI

N Farley*, Purdue University, Indianapolis, IN

Purpose: Magnetic Resonance Spectroscopic Imaging (MRSI) combines the principles of spectroscopy and anatomical imaging to create images mapping relative metabolite concentrations within each pixel. However, traditional MRSI sequences lack the necessary resolving power needed to distinguish functional subregions of the cerebellum (such as white and grey matter boundaries). This work's purpose is to create a probabilistic neurochemical model of the cerebellum using ZOOM MRSI, a novel sequence developed by our group which obtains 2.5mm in-plane resolutions in 9 minutes and 36 seconds. **Methods:** Six healthy volunteers gave informed consent to be subjects for this experiment, which involved in-vivo scans in the cerebellum for two and the posterior cingulate for the other four. The scans were performed on a Siemens Prisma 3 Tesla (Siemens, Germany) scanner with a 64-channel receive only head coil. ZOOM MRSI was performed on each subject via metabolite-cycled semi-LASER localization (TE = 32ms, TR = 2s). Localizations were placed on the central cerebellar slice and posterior cingulate slice within the transverse plane. MATLAB (R2016b, MathWorks, Natick, MA) was used as the reconstruction software, with LCModel (Version 6.3-1M) being utilized for metabolite quantification. Normalized metabolite levels were calculated using the water-scaled signal intensity of each metabolite. Lastly, test/retest reliability will be evaluated with Intraclass Coefficient (ICC), Percent Volume Change (PVC), and Pearson Correlation Coefficient (PCC). **Results:** Coronal, sagittal, and axial images of the Montreal Neurologist Institute-152 template were fitted with ZOOM MRSI images and found to have significant overlap. Additionally, normalized maps for Glutamate+Glutamine for two healthy subjects (for two different scans) were also developed. **Conclusion:** ZOOM MRSI advantages over conventional MRSI methods is demonstrated through its reliable quantification for tNAA, tCr, tCho, Glx, and myo- ins in a voxel of isotropic size equivalent to 62.5uL. This is due to the sequence's improved resolution and spectral quality.

Classification of Tumor Progression and Radiation Necrosis Following Gamma Knife for Brain Metastases Using Radiomic Features and Clinical Variables

D Mitchell*, S Buszek, B Tran, H Liu, D Luo, S Ferguson, C Chung, UT MD Anderson Cancer Center, Houston, TX

Purpose: To develop a classification tool to differentiate between tumor progression and necrosis following Gamma Knife treatment for brain metastases based on both radiomic features and clinical variables. **Methods:** Under IRB approval, this analysis includes a retrospective cohort of 154 patients treated with Gamma Knife for brain metastases who had contrast-enhanced T1-weighted MR images acquired using 3-D spoiled gradient echo (SPGR) sequences and surgical resection of the suspected lesion. Lesions were segmented using semi-automated methods, and tumor/necrosis was determined pathologically (100% necrosis vs. tumor present). 3-D radiomic features ($3 \times 3 \times 3$ -mm spatial normalization, 64-bin intensity discretization) were extracted using PyRadiomics and clinical variables via chart review. Z-scores were used to normalize feature values. Feature reduction was performed using principal component analysis (components represented 95% explained variance). Fifteen classification models and ensembles were trained, and performance was assessed using 5-fold cross-validation. **Results:** 100 radiomic features were selected a priori and extracted. Ten clinical variables were implemented, including gender, race, age at diagnosis, time from Gamma Knife treatment, histology, time between primary and metastasis diagnoses, metastasis location, Gamma Knife dose, and Gamma Knife treatment volume. A RUSBoosted trees ensemble yielded a classification accuracy of 66.2% (AUC = 0.71). 12 out of 17 necrosis cases were correctly predicted, and 90 out of 137 tumor progression cases were correctly predicted. **Conclusion:** These results are promising for the development of a reliable classification tool for tumor progression and radiation necrosis using data that is readily clinically available. Such a tool could have significant value by assisting with clinical decision making. Further investigation of classifiers and parameter optimization may yield higher performance.

Prediction of pH Using AcidoCEST MRI and Machine Learning

T Li^{1,2*}, J Cardenas-Rodriguez³, M Pagel^{1,2} (1) UT MD Anderson Cancer Center, Houston, TX. (2) The University of Texas Health Science Center at Houston Graduate School of Biomedical Sciences, Houston, TX. (3) Data Translator, Oro Valley, AZ

Purpose: To test and evaluate the performance of a machine learning (ML) algorithm in predicting pH from CEST spectra of iopamidol. **Methods:** Two-hundred iopamidol samples were prepared with 5 concentrations (5-50 mM), 5 T₁ values (0.4-3.9 sec) and 8 pH levels (6.25-7.30, equally spaced). Thirty-six CEST scans were performed on each sample using a FISP acquisition sequence and a cross-combination of six saturation powers (0.5-6 μ T) and six saturation times (0.5-6 sec) with a Bruker 7T preclinical scanner. The set of 36 CEST scans was repeated at five temperatures. For each CEST scan, 81 images were collected at different saturation frequencies. In addition, T₁, T₂, B₁ and B₀ maps were also acquired. All 36,000 CEST spectra from the 200 samples and the T₁, T₂, B₁ and B₀ data for each phantom sample were used to the train and validate the ML algorithm. **Results:** ML is able to produce reliable pH prediction from iopamidol CEST spectra. As expected, the accuracy of pH prediction increases as the increase of saturation powers and times. However, to our surprise, the ML algorithm can achieve a 95% accuracy even for spectra acquired with 0.5 μ T power and 0.5 sec time, which is not easily achievable by other analysis methods. This advantage of ML likely arises from that no assumptions need to be made about what parts of the spectra are useful. We also demonstrated that the pH prediction accuracy can be retained when the number of saturation frequencies is decreased from 81 to 27, therefore eliminating the need for data acquisition for redundant frequencies. **Conclusion:** Employing a ML algorithm is an effective method in predicting pH based on iopamidol spectra across a wide range of pH and saturation parameters. The accuracy of pH prediction can be retained when the saturation frequency list is truncated.

WE-lePD-TRACK 3-01

A Framework of Utilizing Biological Models for Iso-Toxic Adaptive Replanning in MR-Guided Radiotherapy

P Prior*, E Quashie, A Tai, X Li, Medical College of Wisconsin, Milwaukee, WI

Purpose: MR-guided online adaptive radiotherapy (MRgOART) allows iso-toxic treatments, i.e., adjusting fraction target dose to take advantage of daily anatomic and/or biologic changes while maintaining the same doses to organs at risk (OAR). This work describes a framework for iso-toxic planning in MRgOART using biophysical models. **Methods:** This framework includes (1) converting fractional adaptive plan optimized based on the daily anatomy to biologically effective dose (BED) distribution, (2) calculating composite BED dose distribution for total or a portion of the fractions delivered, (3) converting the composite BED plan to the physical dose distribution with the original fractionation, and (4) calculating tumor control probability (TCP) and normal tissue complication probability (NTCP) using the dose volume histograms and the tumor/organ specific model parameters derived from published dose-response data. Data collected from selected pancreatic cancer cases treated with SBRT using MRgOART were used to demonstrate the utility of the proposed framework. The fractional target dose was rescaled such that the same OAR maximum doses (Dmax), or doses to 0.03 or 1.0 cm³ (D0.03cc or D1cc), were maintained. Comparison was made with respect to the treatment planning goals (TPGs) and the sum daily dose (SDD) of D0.03cc & D1cc and the ratio of SDD to TPGs was calculated. **Results:** The proposed framework allowed to calculate BEDs for increased/decreased fraction doses based on daily anatomy change (e.g., OAR moved away from the target), and to estimate fraction doses for the remaining fractions considering total BED. For example, the ratio of SDD to TPGs were < 0.65 in one case, which would allow to increase fraction dose in subsequent fractions or to deliver an extra fraction. **Conclusion:** A framework for iso-toxic adaptive planning is developed to account for biological effect of different fraction doses and to optimize the therapeutic ratio in MRgOART.

Changes in Prostate Volume and Dosimetry with Stereotactic MR-Guided Adaptive Radiotherapy

E Huynh*, C Williams, Z Han, L Singer, M Huynh, R Mak, D Cagney, J Leeman, Brigham and Women's Hospital, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Purpose: MR-guided adaptive radiotherapy enables visualization of the prostate and surrounding anatomy at each treatment fraction and ability to adapt the treatment plan to account for interfraction variations in anatomy. This study investigates changes in prostate volume throughout treatment and its impact dosimetrically. **Methods:** Prostate cancer patients were treated with MR-guided adaptive SBRT (MRIdian, Viewray Inc.) at our institution between 06-2020 and 02-2021 to 36.25Gy in 5 fractions. The “original” plan was re-optimized at each treatment based on daily anatomy to improve target coverage and meet organ-at-risk (OAR) metrics. A “predicted” plan was generated at each fraction by re-calculating the original plan on the day-of anatomy, estimating what would have been delivered without adaptive capabilities. Dose to the PTV (V36.25) and OARs (rectum, bladder, urethra) were assessed. Differences between simulation and treatment fractions for prostate volume and PTV V36.25 were calculated. **Results:** A cohort of 13 patients treated in 65 fractions was analyzed. The median prostate volume was 29.3cc (range: 16.2-104.6cc) at time of simulation. Increases in prostate volume were observed for 51/65 fractions. At the first treatment, the prostate volume was similar to simulation (median difference of -0.2cc (range: -1.5-0.49cc)). However, the median volume increased from simulation at successive fractions (fractions 2, 3, 4 and 5) by 1.1cc (range: 0.18-6.8cc), 1.2cc (range: 0.02-6.52cc), 1.0cc (range: -0.81-8.2cc) and 0.8cc (range: -1.79-7.71cc), respectively. As prostate volume increased, the predicted plan PTV V36.25 decreased by a median of -2.2% on the first fraction, and -10%, -8.9%, -6.6%, -8.4% on successive fractions. Adaptive planning improved PTV V36.25 on 54/65 fractions; remaining fractions required sacrificing PTV coverage to meet OAR metrics. **Conclusion:** MR-guided prostate SBRT revealed a consistent increase in prostate volume after first fraction of treatment, which can impact PTV coverage. Adaptive re-optimization can significantly improve PTV coverage while minimizing toxicity to OARs.

Deep Learning-Based Automatic Plan Prediction for MR-Guided Adaptive Radiotherapy

L Buchanan, Y Zhang*, X Chen, X Li, Medical College of Wisconsin, Milwaukee, WI

Purpose: Fast and automated plan generation is desirable for MR-guided adaptive radiation therapy (MRgART). Recently, significant progress has been made in predicting an optimal dose distribution using deep learning approaches. As a next step for automatic planning, we investigate the feasibility of predicting a deliverable plan for a target dose distribution based on deep learning. **Methods:** A conditional generative adversarial network (cGAN) was trained to predict the MLC leaf sequence corresponding to a target dose distribution. The training data were 50 ground truth dose distributions and corresponding IMRT plans that were optimized during MRgART in a treatment planning system (TPS) for 10 pancreatic cancer patients (each with 5 fractions). The model input was the dose distribution from each individual beam and the output was the predicted corresponding field segments with specific shape and weight. The predicted plan was then generated and transferred back to TPS to calculate the corresponding dose. Patient-based leave-one-out-cross-validation was employed and the model performance was evaluated by calculating the gamma passing rate of the ground truth dose vs. the dose from the predicted plan. **Results:** The average gamma passing rate (95%, 3mm/3%) among 10 test cases was 88%. With relaxed passing criteria (95%, 5mm/5%), the average passing rate was 96%. In general, we observed 95% of the prescription dose to PTV achieved with a slight increase of dose to OARs. Complete plans were predicted in <15 seconds using a GTX 1660TI GPU. **Conclusion:** We have developed a deep learning method to predict IMRT plans rapidly and automatically for pancreatic cancer. With further developments using large datasets, the method may be implemented to accelerate MRgART process or to facilitate real-time MRgART.

Dose Accumulation Comparison Between Adapt-To-Shape and Adapt-To-Position for MRL Adaptive SBRT Prostate Patients

CD Johnstone*, T Tadic, V Malkov, D Letourneau, and J Winter. Princess Margaret Cancer Centre, Toronto, ON, CA

Purpose: To use dose accumulation to directly compare two strategies for online adaptation on an MR-Linac (MRL): the adapt-to-position (ATP) isocentric shift approach versus the full re-optimization adapt-to-shape (ATS) approach for prostate SBRT treatment. **Methods:** This study analyzed 12 prostate SBRT patients treated at our centre with 30 Gy in 5 fractions on a 1.5 T MRL using 9-field IMRT with MR-based reference planning. The ATP workflow adapts the beams following translation-only rigid registration of the prostate. The ATS workflow generates a new treatment plan to match the daily anatomy using deformable image registration (DIR) and manual online contour editing by a Radiation Oncologist. Treatment plans on the localization MR images were created for all fractions using both ATP (simulated) and ATS (clinical) workflows. All plans were imported into a commercial treatment planning system to perform DIRs and accumulate dose on the reference MR images. Clinical goal DVH metrics for accumulated ATP and ATS dose distributions were compared with Student's t-tests. **Results:** Mean ($\pm$ STD) CTV D98 was not significantly different between ATP (3132 ± 129 cGy) and ATS (3180 ± 90 cGy), and satisfied the > 2850 cGy clinical goal for 11 of 12 patients for ATP and all patients for ATS. DVH goals for femurs (D5 < 1200 cGy), rectum (D1cm3 < 3000 cGy, D20 < 2000 cGy, D50 < 1000 cGy) and bladder (D5cm3 < 3000 cGy) were not significantly different between ATP and ATS. Organ-at-risk clinical goals were not met in 6 patients (12/72 goals) for ATP and 2 patients (3/72 goals) for ATS. **Conclusion:** Dose accumulation demonstrates that CTV coverage and OAR sparing are statistically equivalent for ATP and ATS workflows. The

ATP workflow may be preferred for MR-guided adaptive treatments to eliminate need for online recontouring and thus reduce the overall treatment time.

WE-lePD-TRACK 3-05

Feasibility of Dynamic Contrast Enhanced MR Perfusion for Glioblastoma On a Low-Field MRI-Linac System

D Maziero^{1*}, R Stoyanova², YC Chang², A Breto², JC Ford¹, EA Mellon¹, (1) Sylvester Comprehensive Cancer Center, University of Miami Health System, United States, Miami, FL, (2) University of Miami Miller School of Medicine, Miami, FL

Purpose: The purpose of this study is to evaluate the feasibility of measuring dynamic contrast enhanced (DCE) perfusion in glioblastoma on an MRI-Linac at 0.35T. **Methods:** Images were acquired on a glioblastoma patient prior to first radiotherapy treatment on a 0.35T MRI-linac system using 15-channel surface array coils. A 3D gradient recalled echo sequence was used to acquire continuous 45-volumes with 18 axial slices of the brain during gadoteridol infusion. Each volume and total acquisition time were 9.75s and 7min19s, respectively. The tumor lesion was segmented on post-contrast enhancement T1-weighted images. An extended volume of interest (VOI) was created by expanding the margins of the tumor contour by 8mm to incorporate peritumoral voxels to the analysis. Constrained Non-Negative Matrix Factorization (cNMF) method was applied to the DCE curves in the VOI. The cNMF was set to seek for 3 solutions with the condition that the weights of a given pattern should be more than 40% in a given voxel to label it accordingly. Finally, the signal-vs-time curves, from voxels in a given solution were averaged and analyzed using Tofts' pharmacokinetic model. **Results:** The average VOI signal intensity late in the DCE time series was 21% higher relative to the pre-contrast signal. The three temporal curves identified by cNMF and their spatial distribution were consistent with the patterns of: (VAS)-blood vessels, characterized by rapid contrast wash-in and wash-out; (TC1)-well perfused tumor tissue, contrast fast wash-in and gradual wash-out and (TC2)-possibly hypoxic/necrotic tumor tissue, characterized by slow and continuous contrast uptake. The transfer constant K_{trans} for patterns TC1 and TC2 were 0.82 and 0.47 min⁻¹, respectively. **Conclusion:** To the best of our knowledge, this is the first report of DCE perfusion on a 0.35T MRI-linac system. This technique can be used to evaluate early tumor perfusion response for adaptive radiotherapy of glioblastoma.

Longitudinal Evaluation of Plan Quality Metrics During the Course of Pancreatic Online Adaptive MRI-Guided Radiotherapy

J Ginn^{*}, O Green, D Yang, A Curcuro, S Badiyan, L Henke, H Kim, A Price, Washington University School of Medicine, St. Louis, MO

Purpose: To evaluate plan quality longitudinally over the course of pancreatic MRI-guided adaptive stereotactic body radiation therapy (SBRT). **Methods:** A script was developed to retrospectively extract SBRT plan quality metrics from dose volume histogram files generated during MRI-guided adaptive radiotherapy treatments on a ViewRay MRIdian Linac. Plan quality metrics, including conformity index (CI), ratio of the 50% isodose to the 100% prescription isodose (R50), and ratio of the 36% isodose to the 100% isodose (R36), were computed. At our institution, a planning target volume optimization (PTVopt) structure is generated for each adaptive case by subtracting away an organ-at-risk+5mm planning risk volume from the planning target volume. The CI was computed relative to the PTVopt. These plan quality metrics were computed for the initial plan prepared prior to treatment, as well as for each adapted plan. A paired t-test was used to compare initial plan quality to all subsequent adapted fraction metrics. A Cronbach's alpha was calculated for each of the 3 dosimetric indices to determine consistency within adaptive fractions across all patients. **Results:** Plan quality metrics were evaluated retrospectively for 42 pancreas patients. Initial results indicate that plan quality was stable throughout the course of radiotherapy. The average CI across all patients ranged from 1.03 to 1.05 throughout the course of treatment. The difference between the initial and all subsequent adapted CI values were not statistically significant. All dosimetric indices had Cronbach's alpha ≥ 0.96 , indicating high overall consistency across all adapted fractions. However, some differences between initial and adapted R50 and R36 values were statistically significant. **Conclusion:** Initial results indicate that plan conformity was consistent throughout adaptive MRI-guided radiotherapy. However, lower isodose falloff varied more throughout the course of therapy. Work is underway to investigate other plan quality metrics and organ-at-risk sparing.

Super Resolution for Improving 2D Cine-MRI Resolution During MR-Guided Radiotherapy of Pancreatic Cancer Patients

B Lewis^{1*}, J Chun², J Shin^{1,2}, Z Ji¹, J Park³, J Kim², T Kim¹, (1) Washington University in St. Louis, Saint Louis, MO, (2) Yonsei University College of Medicine, Seoul, KR, (3) University of Texas Southwestern, Dallas, TX

Purpose: Spatiotemporal resolution of MR images is limited by hardware and acquisition parameters, especially at low magnetic fields where long imaging times are required to improve SNR and feature identification. These factors are vital to target tracking and beam gating during MR-guided radiotherapy (MRgRT). Super resolution (SR) reconstruction with deep-learning frameworks provides the ability to generate SR images from low resolution (LR) images. This study applies the SR framework to 2D cine MRI acquired on an MRgRT system during pancreatic cancer treatment. **Methods:** Real time 4 frames-per-second (FPS) cine MR images were collected retrospectively for fifty pancreatic cancer patients treated on the ViewRay MR-linac system. A previously trained super resolution framework was used to generate SR images from the original 3.5x3.5mm² pixel images, with a new resolution of 0.9x0.9mm². SR images were compared to the original LR using inherent metrics including: NIQE, PIQE, and BRISQUE. Inherent image metrics score from 0 to 100, 0 indicates an ideal image. SR images were also compared to paired high resolution (HR) 3D images using SSIM and anterior wall intensity gradient as a surrogate for edge sharpness. **Results:** SR images had statistically significant improvements for inherent metrics, compared to the LR images. SR images scored a mean ($\pm$ SD) of 3.17 $\pm$ 0.18 for NIQE, 34.58 $\pm$ 3.38 for PIQE, and 29.65 $\pm$ 2.98 for BRISQUE. LR images scored a mean ($\pm$ SD) of 7.40 $\pm$ 0.69 for NIQE, and 69.46 $\pm$ 1.52 for PIQE, and 42.48 $\pm$ 0.98 for BRISQUE. SR images also had greater SSIM values and sharper line profiles compared to LR images with SSIM of 0.633 $\pm$ 0.063 and 0.587 $\pm$ 0.067, and gradients of 17.71 $\pm$ 3.17 and 14.39 $\pm$ 3.51, for SR and LR images, respectively. **Conclusion:** Super resolution images provided improved image quality and target identification without introducing artifacts or anatomical inconsistencies. This leads the way for real time SR image generation during MRgRT for target tracking and gating.

Forecasting Absolute Lymphocyte Count Depletion During and After Radiation Therapy Using Deep Learning

S Ebrahimi^{1*}, G Lim², B Hobbs³, S Lin⁴, R Mohan⁵, W Cao⁶, (1) University of Houston, Houston, TX, (2) University of Houston, Houston, TX, (3) The University Of Texas At Austin, Austin, TX, (4) UT MD Anderson Cancer Center, Houston, TX, (5) UT MD Anderson Cancer Center, Houston, TX, (6) UT MD Anderson Cancer Center, Houston, TX

Purpose: Numerous studies have shown that severe radiation-induced lymphopenia (RIL - depletion of absolute lymphocyte count (ALC)) adversely impacts patient survival after radiation therapy (RT) of most solid tumors. In this study, we aimed to identify pre-RT patient characteristics and dosimetric features that could predict radiation-induced lymphocyte depletion in esophageal cancer patients during and after the course of RT to identify patients who may benefit from treatment plan reoptimization, use of a different modality, or a pharmacological intervention and ultimately improve outcomes. **Methods:** Data of 860 esophageal cancer patients who received concurrent chemoradiotherapy were used for this study. All patients were treated with protons or photons radiation modalities with a dose of 50.4 Gy.

Pre-, weekly during RT and post-RT ALCs, clinical characteristics and dosimetric parameters were extracted from data bases. A hybrid deep learning model using deep neural network and long short-term memory (LSTM) network was applied to predict ALC depletion trend using baseline value of ALCs measured before or during early stages of RT course. **Results:** Several important prediction metrics were employed to evaluate the performance of the proposed model compared to other commonly used prediction methods. The results showed that the proposed model achieved predictions with the mean squared error (MSE) of 0.046 for 258 patients in test set. Inclusion of ALC after the first week reduced the MSE to 0.014. Moreover, this model outperformed off-the-shelf prediction methods by at least 30% reduction in MSE of weekly ALC predictions. **Conclusion:** The proposed model performed well in predicting radiation-induced lymphocyte depletion. The ALC prediction would enable physician to identify patients at high risk of severe radiation-induced lymphopenia and potentially benefit from modified treatment approaches. Furthermore, if measured ALC were to be available after the first few fractions, it could be used for improved confidence in risk prediction.

Imaging Biomarkers for Radiation-Induced Airway Changes in a Swine Model

E Wallat^{1*}, A Wuschner¹, M Flakus¹, J Reinhardt², G Christensen², J Bayouth¹, (1) University of Wisconsin, Madison, WI, (2) University of Iowa, Iowa City, IA

Purpose: To investigate changes in imaging biomarkers as precursors to atelectasis post-RT in a swine model and develop a dose-response relationship for bronchial stenosis. **Methods:** A cohort of three swine were analyzed. The swine underwent a research course of 60 Gy in 5 fractions delivered to a targeted airway in the left inferior lung. The right lung was used as control as it was left unirradiated. Airway segmentation was performed on the pre- and three months post- radiation therapy (RT) maximum inhale phase of the four dimensional (4D) computed tomography (CT) scans. Segmentation repeatability was assessed by calculating the percent relative standard deviation of the inner cross-sectional area (A_i) for each airway. A decrease in A_i was assumed to be a surrogate of bronchial stenosis. **Results:** Repeatability analysis showed good repeatability for both timepoints ($r > 0.99$, small deviations $< 5\%$). Airways ($n=30$) in the right (unirradiated) lung for all swine showed no significant changes in A_i post-RT compared to pre-RT. Airways ($n=28$) in the left (irradiated) lung of all swine were found to have a decreased A_i post-RT compared to pre-RT, which was significantly ($p < 0.001$) correlated (Adjusted $R^2 = 0.95$) with dose, and independent of pre-RT inner radius. Additionally, while the square root of wall area (i.e. thickness) decreased significantly ($p = 0.0001$) with dose, the wall area percent increased significantly ($p = 0.04$) with dose. **Conclusion:** This work shows there is a significant correlation between radiation dose and bronchial stenosis as well as wall area percent. Airway toxicities beyond the proximal bronchial tree have mostly been ignored in treatment planning. These results support the hypothesis that airway dose should be considered during treatment planning in order to preserve functional lung and reduce lung toxicities. Further work should be performed in order to verify these effects in humans and the consequences on pulmonary function.

This work was supported by the National Institutes of Health grant CA166703.

Overall Survival Prediction Via an Interpretable Machine Learning Model for Patients with Oropharyngeal Cancer

X Pan^{1*}, T Feng², X Qi³, C Liu⁴, (1) Xi'an University of Posts and Telecommunications, Xi'an, Shaanxi, CN, (2) Xi'an University of Posts and Telecommunications, Xi'an, Shaanxi, CN (3) UCLA School of Medicine, Los Angeles, CA, (4) Xi'an University of Posts and Telecommunications, Xi'an, Shaanxi, CN

Purpose: Treatment outcome prediction is first step towards plan adaptation and personalized treatment. We aimed to explore and use interpretable machine learning (ML) methods, with a hope of adding more prognosis value, to predict overall survival of patients with Oropharyngeal Cancer (OPC). **Methods:** 200 patients with OPC from TCIA database were pooled and analyzed. 70 cases were used for training, 30 cases were used for evaluation, the remaining cases were used as an independent validation cohort. Survival prediction model was created using Support vector machine (SVM), based on imaging features of gross tumor volume (GTV) extracted from planning CT using Pyradiomics. Patient characteristics, including ECOG_Performance, smoking/drinking status, et al were also considered as potential predictors to construct the prediction models. The shapley value (SV) of each feature was calculated according to the alliance game theory to determine its importance in the prediction model. A positive SV corresponds to the prediction result of the instance is positive, while a negative SV means a negative contribution to the prediction. The final prediction model performance was evaluated using the area-under-ROC-curve (AUC). **Results:** The prediction model achieved AUC=0.83 combining both feature categories. Additionally, the correlations between both features categories and survival model can be captured by the SV from the interpretable ML model with interpretable graphs. The top five features that were most correlated with overall prediction were ECOG_Performance, smoking_PY, original_shape_Maximum2DDiameterRow, original_gldm_DependenceNonUniformityNormalized, wavelet-HLH_glszm_SizeZoneNonUniformityNormalized, etc. **Conclusion:** We demonstrated the predictive value of combined patient characteristics and imaging features for OPC patients. The mostly relevant features to patient survival and their contribution to the predictive model were determined via interpretable machine learning models, which hold great promises of addition prognostic value compared to blackbox radiomics analysis. The interpretable ML could greatly improve the application of ML model in medical and clinical applications.

Predicting Pathological Complete Response Through Automatic Belief Rule Base in Gastric Cancer

Q Wang^{1*}, J Wu², Z Wang³, M Liu⁴, M Ma⁵, Z Zhou⁶, (1) Shaanxi Normal University, (2) Shaanxi Normal University, (3) Peking University Cancer Hospital & Institute, CN, (4) Shaanxi Normal University, (5) Shaanxi Normal University, (6) University of Central Missouri, Warrensburg, MO

Purpose: Neoadjuvant chemotherapy (NAC) has been proved as an effective way to improve survival time in gastric cancer treatment. Accurate predicting pathological complete response (pCR) status after NAC plays an important role in making the personalized treatment plan. We aim to develop a new automated belief rule base (AutoBRB) model to predict pCR after NAC in gastric cancer. **Methods:** Totally 55 patients' clinical data (Peking Cancer Hospital, Beijing, China) are used in this study. Since belief rule base (BRB) can integrate clinical domain knowledge and be interpretable, it is used in this study. However, it is always hard to initialize the model parameters. As such, a new automatic BRB (AutoBRB) is developed in this study. In AutoBRB, the referential values, adopted to construct the rule base, are initialized through the information gain ratio, and the corresponding belief degrees are initialized through a new grid strategy. To obtain optimized model, a differential evolutionary algorithm is employed to train the model parameters, and an adaptive searching strategy is adopted to set the confidence threshold. Furthermore, the final output is inferred through an evidential reasoning approach where the belief degrees are obtained and used for making the decision. In the experiments, accuracy, sensitivity, specificity, and area under the curve (AUC) are used as the evaluation measures. **Results:** The mean and standard deviation value of AutoBRB on the accuracy, sensitivity, specificity, and AUC are 0.8962 ± 0.0562 , 0.8530 ± 0.1161 , 0.9394 ± 0.0683 , and 0.9488 ± 0.0345 , respectively, while BRB is 0.7659 ± 0.0560 , 0.9046 ± 0.0756 , 0.6273 ± 0.1081 , 0.9179 ± 0.0450 . **Conclusion:** A new AutoBRB model for predicting pCR after NAC in gastric cancer was developed in this study. The experimental results demonstrated that AutoBRB is superior to BRB and other available methods.

Prediction of Cardiotoxicity for Breast Cancer Patients Using Light Gradient Boosting Machine

Z Jiang^{1*}, P Diaio², Y Liang³, K Dai⁴, H Li⁵, H Wang⁶, Y Chen⁷, M Lu⁸, Y Kuang⁹, (1) University of Nevada, Las Vegas, Las Vegas, NV, (2) Sichuan Cancer Hospital, Chengdu, Sichuan, CN, (3) Sichuan Cancer Hospital, Chengdu, Sichuan, CN, (4) Sichuan Cancer Hospital, Chengdu, Sichuan, CN, (5) Sichuan Cancer Hospital, Chengdu, Sichuan, CN, (6) Sichuan Cancer Hospital, Chengdu, Sichuan, CN, (7) Sichuan Cancer Hospital, Chengdu, Sichuan, CN, (8) Sichuan Cancer Hospital, Chengdu, Sichuan, CN, (9) University of Nevada, Las Vegas, Las Vegas, NV

Purpose: To predict the increased risk of severe cardiotoxicities in breast cancer patients receiving chemoradiotherapy could be challenging due to the variations of current methods used to evaluate the cardiotoxicity symptoms, individual susceptibility and early markers of injury. In this study, we developed, for the first time to our knowledge, a Light Gradient Boosting Machine (LightGBM)-enabled predictive model to integrate patients' chart from electronic medical records (EMRs) for early prediction of severe cardiotoxicities. **Methods:** A total of 179 breast cancer patients were included. The patients were randomly partitioned to the training set and the validation set for LightGBM predictive model development and validation. The training features extracted from each patient include age, cancer stage, tumor size, tumor location, medical history, chemotherapy drugs, targeted therapy drugs, hormone therapy drugs, distant metastases, surgery, radiation therapy position, radiotherapy dose, electrocardiograph (ECG) signal score and left ventricular ejection fraction (LVEF) value before chemoradiotherapy. The utility of the LightGBM model constructed in predicting severe cardiotoxicities was evaluated by ROC analysis in the validation set. **Results:** The AUC value of the LightGBM predictive model achieved in the validation set was 0.82. The sensitivity, specificity, F1 score, precision, and overall accuracy of LightGBM model in the validation set were 78.6%, 81.8%, 81.5%, 84.6% and 80.0%, respectively. The feature important analysis showed that age, the LVEF value before chemoradiotherapy, cancer position, targeted therapy, tumor stage and hormone therapy were the most valuable risk predicting factors. **Conclusion:** The LightGBM framework proposed herein affords a means to use EMR data to individualize the prediction of severe cardiotoxicities at point of care of patients with breast cancer receiving chemoradiotherapy, which can facilitate the identification of patients for whom early intervention are warranted before the therapy, thus potentially improving the utility of chemoradiotherapy for breast cancer from a precision treatment perspective.

Ultrasound Histogram Assessment of Radiation-Induced Breast Toxicity in Breast Cancer Radiotherapy: A Longitudinal Study of Acute Toxicity

B Zhou^{*}, X Yang, J Lin, S Kahn, K Godette, M Torres, T Liu, Emory University, Atlanta, GA

Purpose: To develop an ultrasound histogram technique capable of evaluating radiation induced acute toxicity in patients receiving radiotherapy (RT) for early-stage breast cancer. **Methods:** Thirty-one patients who underwent conservative breast surgery followed by hypofractionated RT were enrolled in the IRB-approved study. RT involves 15 fractions of whole breast irradiation with simultaneous integrated boost. Each participant received longitudinal breast ultrasound at four timepoints: prior to RT, last day of RT, 3 weeks and 10 weeks post RT. Ultrasound scans were performed using a clinical ultrasound scanner with a 12-MHz linear probe on the irradiated breast and contralateral breast at 5 locations (3, 6, 9, 12 o'clock and tumor bed). The scans on the contralateral breast served as controls. RT-induced breast toxicity was graded in 3 levels (11 patients rated as mild, 10 as moderate, and 10 as severe) based in ultrasound B-mode images. Normalized echo-intensity histograms were computed for the regions of interest including the skin and subcutaneous tissue. The histogram difference (Bhattacharyya distance) between irradiated and contralateral breasts was calculated to capture radiation-induced tissue changes. **Results:** Bhattacharyya distance increased from mild to severe toxicity in all locations. Bhattacharyya distance also increased from mild to severe toxicity at various timepoints (Mild: 0.28 ± 0.06 Pre-RT, 0.32 ± 0.10 Last-RT, 0.32 ± 0.09 at 3-week post-RT, 0.31 ± 0.13 at 10-week post RT; Moderate: $.39 \pm 0.12$ Pre-RT, 0.37 ± 0.17 Last-RT, 0.38 ± 0.15 3-week post-RT, 0.4 ± 0.14 10-week post-RT; Severe: 0.42 ± 0.11 Pre-RT, 0.47 ± 0.1 Last-RT, 0.42 ± 0.14 3-week post-RT, 0.50 ± 0.14 10-week post-RT). **Conclusion:** Radiation-induced breast toxicity remains a major obstacle to effective RT. This study has shown that ultrasound histogram analysis is feasible and may be developed into a low-cost imaging method for radiation-induced tissue toxicity monitoring and assessment.

Unique Changes on Functional Magnetic Resonance Imaging Maps Following D2 Receptor and Cholinergic Specific Knock-Out of TorsinA

H Liu^{*}, J Desimone, Y Liu, University of Florida, Gainesville, FL

Purpose: The objective of this study was to compare how loss of torsinA function in D2R and cholinergic cells within the striatum impairs motor deficits, sensory evoked blood oxygen level dependent (BOLD) functional magnetic resonance imaging (fMRI), sensory-evoked functional connectivity, and tissue microstructure using in vivo high field magnetic resonance imaging. **Methods:** We used two genetic mouse models characterized by conditional knock-out of torsinA in either D2R-expressing striatal neurons or striatal cholinergic interneurons for motor behavior assessment (accelerated Rotarod and Beam-walking). Furthermore, we acquired in vivo sensory-evoked fMRI and in vivo diffusion magnetic resonance imaging (dMRI) to assess tissue microstructural changes across the whole brain, as this technique has shown promise in studying neurodegeneration. **Results:** The findings demonstrate that knock-out of torsinA from d2R-expressing striatal cells and striatal cholinergic interneurons have profound effects on sensory-evoked BOLD fMRI, sensory-evoked functional connectivity, and motor deficits: (1) The within-group effects on the β -coefficients. In all groups, BOLD activation was significantly increased within the sensorimotor cortex, cingulate, retrosplenial area, parietal cortex, striatum, globus pallidus, thalamus, cerebellar cortex, and brainstem. (2) The seed-based correlation of functional connectivity with the striatum during sensory-evoked fMRI. Dyt1 d2KO and Ch2KO mice showed abnormal functional connectivity in sensory-evoked functional MRI compared to their control littermates. (3) Correlation between fMRI and behavior deficits, with the region of significance between-group difference found for the sensory-evoked BOLD activation and sensory-evoked functional connectivity. **Conclusion:** The study determines how systemic level changes in brain function, connectivity, and microstructure are influenced by knock-out of torsinA using high field 11T fMRI and dMRI. The findings demonstrate that knock-out of torsinA from d2R-expressing striatal cells has profound effects on sensory-evoked BOLD fMRI, sensory-evoked functional connectivity, which have high correlation with the subjects' motor deficits.

Development and Validation of a TOPAS Monte Carlo Model of a Dynamic Collimation System for Pencil Beam Scanning Proton Therapy

N Nelson^{1*}, W Culbertson¹, D Hyer², T Geoghegan², K Patwardhan², B Smith², R Flynn², J Yu³, S Rana³, A Gutierrez³, P Hill⁴, (1) University of Wisconsin-Madison, School of Medicine and Public Health, Department of Medical Physics, Madison, WI, (2) University of Iowa, Department of Radiation Oncology, Iowa City, IA, (3) Miami Cancer Institute, Department of Radiation Oncology, Miami, FL, (4) University of Wisconsin-Madison, School of Medicine and Public Health, Department of Human Oncology, Madison, WI

Purpose: To develop and experimentally validate a TOPAS Monte Carlo model of the Dynamic Collimation System (DCS) and the IBA dedicated nozzle (DN). The DCS is an energy layer-specific collimator specifically designed for low energy pencil beam scanning proton therapy and consists of four nickel trimmer blades that translate and rotate as a function of beam position located downstream from a polyethylene range shifter. **Methods:** Uncollimated integral depth dose (IDD) curves,

in-air spot profiles, and absolute dose measurements were used to commission a source model of the IBA DN system in TOPAS. Collimated pristine and range shifted IDD curves and in-air and in-phantom 2D spot profiles were acquired to benchmark the model's performance for a variety of collimator configurations. The water equivalent thickness (WET) of the range shifter was determined by the shift in the depth of the 80% dose point distal to the Bragg peak between the range shifted and pristine uncollimated beams. **Results:** Uncollimated IDDs 1D gamma pass rates were 99.4% and 91.2% at the 1%/1mm and 0.5%/0.5mm evaluation criteria, respectively. For the pristine collimated beams, the average 1%/1mm gamma pass rates across all collimator configurations investigated were 99.8% for IDDs and 97.6% and 95.2% for in-air and in-phantom lateral profiles. All range shifted IDDs passed at 100% while in-air and in-phantom lateral profiles had average pass rates of 99.1% and 99.8%, respectively. The measured and simulated WETs of the polyethylene range shifter were determined to be 40.9 and 41.0mm, respectively. **Conclusion:** A TOPAS Monte Carlo model of the DCS and IBA DN system was developed and validated against uncollimated and collimated IDD and lateral profile measurements. As the DCS moves towards clinical implementation, this model will be used to assess the accuracy of analytical algorithms used in commercial treatment planning systems and help guide future dosimetric investigations.

Research reported in this abstract was supported by the National Cancer Institute of the National Institutes of Health under award number R37CA226518. Hyer, Flynn, and Hill are co-inventors on a patent that has been licensed to IBA.

3D Dosimetry of Lung and Cardiac Shielding for Total Body Irradiation

M Glenn*, K Wallner, S Luk, M Phillips, Y Tseng, R Ermoian, M Kim, University of Washington, Seattle, WA

Purpose: Despite technological improvements in treatment planning, dosimetry for total body irradiation (TBI) remains relatively crude. This work employs a unique 3D TBI beam model to inform how different shielding parameters may affect patient dose distributions. **Methods:** An 18 MV clinical beam model was commissioned in RayStation to accommodate classical AP/PA TBI at an extended distance using spoilers and compensators. The low-energy photon spectrum and electron contamination were modified to ensure optimal agreement between the TPS-computed and measured tissue phantom ratios (TPR). Validation measurements were performed using solid water in the standing TBI setup. TPS calculations of the newly-validated model were cross-checked with hand calculations for clinical cases: 3 CT scans of patients without gross disease were planned for the standing treatment position with a total dose of 1200 cGy in 6 fractions. Lung shielding was simulated in RayStation with varying margins (0-2 cm) as well as cases for which the cardiac silhouette was blocked or unblocked. Each case was examined for changes in mean heart and lung dose, lung V10Gy and V12Gy, and point doses behind the blocked tissues. **Results:** The modeled TBI beam agreed with measured TPRs within 2% at 1 cm depth and 0.4% beyond a depth of 3 cm. The average difference in calculated MU between the 3D TBI model and hand calculations for the three patients was 1.7%, confirming agreement with our current clinical practice. Increasing the lung block margins systematically increased the average lung dose by 10%, whereas V10Gy increased nearly two-fold, from 31% to 60%. The mean heart dose increased by 7.5% when the cardiac silhouette is unblocked, while the cardiac V12Gy increased by 25%. **Conclusion:** 3D TBI planning for extended distance is feasible and can provide dosimetric information that traditional planning methods lack, especially regarding lung and heart doses.

WE-lePD-TRACK 5-03

RayStation Photon Beam Modeling Challenges for Small Targets Treated with VMAT and Dynamic Conformal Arcs

J Huang*, S Frigo, University of Wisconsin- Madison, Madison, WI

Purpose: A TrueBeamSTx 6FFF beam model geared toward treating small targets with VMAT and dynamic conformal arcs (DCA) was created. However, a revision was necessitated due to IMRT QA failures. The purpose of this abstract is to describe the needed changes and required validation, as well as to discuss the challenges encountered in creating an adequate model for two distinct treatment techniques. **Methods:** Since its clinical release, our beam model was predominately used for small VMAT targets (2-4 cm in diameter). However, IMRT QA failures, where the calculated dose was higher than measured, were occurring. Of 70 total plans, 15 (21.4%) plans exhibited median dose differences of >3.0%, with an average median dose difference of -2.3%. To improve absolute dose agreement, several MLC parameters were adjusted. Subsequent validation work included film, ion chamber, and Delta4 measurements for representative DCA and VMAT plans. **Results:** Post-revision, profile agreement in the low-dose shoulders for simple DCA plans worsened based on film measurements. Original DTA values were 0.1-0.2 mm and the average 5%/0.5mm gamma passing rate was 95.5% for a range of target sizes. Corresponding values for the revised model were 0.1-0.3 mm and 90.9%. For VMAT deliveries, the absolute dose agreement within targets improved, with the average discrepancy decreasing from -1.7% to -0.6% for TG-119 type validation plans. Post-revision, the average median dose difference for IMRT QA was -0.5% (59 plans), with all passing clinical criteria. **Conclusion:** Our experiences highlight the challenges with creating a single beam model that is accurate for a range of target sizes and treatment techniques. For small targets, a compromise between DCA profile accuracy and VMAT absolute dose accuracy was needed. Ultimately, a model revision was performed to optimize the model based on actual clinical utilization.

WE-lePD-TRACK 5-04

Sensitivity of IMRT and VMAT Dose Calculation to Changes in MLC Parameters

S Gardner*, S Wang, K Snyder, C Smith, B Miller, I Chetty, Department of Radiation Oncology, Henry Ford Cancer Institute, Henry Ford Health System, Detroit, MI

Purpose: To evaluate the sensitivity of IMRT/VMAT dose calculation to changes in dosimetric leaf gap(DLG) and MLC-transmission for a suite of test plans. **Methods:** A set of 5 test shapes were used to generate IMRT and VMAT plans for dose calculation sensitivity analysis. Three test shapes were selected from the TG-119 report: CShape, H&N, and Prostate. Additional test shapes were used as well: H&N_2, which contains an SIB volume, and Pelvis, which mimics prostate with pelvic lymph node irradiation. IMRT and VMAT plans were generated in Eclipse using AAAv15.6 algorithm for both 6 MV and 10 MV. Each plan was calculated on phantom image set for each DLG and MLC-transmission setting evaluated (3 settings were used for each energy). The sensitivity for each parameter was taken to be the difference in point dose relative to the baseline dose calculation. The sensitivity was also compared to the modulation factor (MU per Gy delivered for each plan). **Results:** For 6MV, the mean dose sensitivity (normalized to 1 mm change in DLG) was 2.4% (VMAT) and 4.1% (IMRT). For 10 MV, DLG sensitivity was 2.0% (VMAT) and 5.0% (IMRT). For 6 MV, the mean dose sensitivity (normalized to 1% absolute change in MLC-transmission) was 1.4% (VMAT) and 3.1% (IMRT). For 10 MV, MLC-transmission sensitivity was 1.3% (VMAT) and 3.4% (IMRT). The dose sensitivity (for both DLG and MLC-transmission) was largest for the plans with largest modulation factor-CShape and Pelvis IMRT plans. **Conclusion:** For both 6 and 10 MV, IMRT planning exhibited higher sensitivity to changes in MLC parameters – DLG and MLC-transmission. Further, the plan modulation factor (defined as the MU/Gy) appears to be correlated with the plan sensitivity to changes in MLC parameters. The sensitivity analysis in this study is a potential reference for physicists when tweaking MLC parameters during machine commissioning.

WE-lePD-TRACK 5-05

The Lifetime of a Monitor Unit Ion Chamber

A Cetnar*, D DiCostanzo, The Ohio State University - James Cancer Hospital, Columbus, OH

Purpose: This study shares our clinical experience of the lifetime of Varian Kapton sealed ion chambers as a retrospective review. The data provided shows the average lifetimes of the ion chambers in our institution for nine clinical linear accelerators, so other physicists can be informed of the average lifetime and prepare

for replacement. **Methods:** The lifetime of ion chambers (N=11) has been analyzed using daily quality assurance, monthly quality assurance, delivered treatment field data, and machine applied gain values pulled from configuration files saved after each output adjustment. We investigate the length of time before replacement, beam hours, and filament hours captured during routine preventative maintenance inspections. The estimated clinical monitor units (MU) delivered, cumulative MU after ion chamber replacement, and output adjustments are also analyzed. Data for all clinical linear accelerators was exported and analyzed using a combination of Microsoft Excel and custom Python programs. **Results:** The average number of MU delivered per machine before ion chamber replacement was 13.9 Million (STDEV 4.1 Million). The average amount of time before the first ion chamber replacement was 1,731 days (STDEV 567) which is approximately 4.75 years. The average increase in the applied gain to the ion chamber before replacement was 8.7% (STDEV 3.4%) with a maximum increase over the life of the ion chamber of 13.1%. **Conclusion:** The average lifetime of an ion chamber is approximately 14 million clinically delivered MU. We have found replaced chambers have greater initial changes in output than would be anticipated based on current literature for output changes, and we would recommend this be closely monitored after replacement. We did not observe a plateau in the output changes over time as suggested by other reports.

Dosimetric Characterization of Orthopaedic Carbon Fiber Implants for Photon and Proton Radiotherapy

J Pursley^{1*}, N Depauw¹, S Lozano-Calderon², C Patel¹, (1) Department of Radiation Oncology, Massachusetts General Hospital, Boston, MA, (2) Department of Orthopaedic Surgery, Massachusetts General Hospital, Boston, MA

Purpose: Impending/actual pathologic femoral fractures secondary to metastatic bone disease, lymphoma, or multiple myeloma often require intramedullary fixation followed by radiotherapy. Traditionally, titanium-alloy (TA) rods are used but recently, carbon fiber (CF) has emerged as an alternative. Due to its low atomic number, there is reduced CT-imaging artifact and dose perturbation when planning postoperative radiation. Herein, we characterize the dosimetric properties of CF implants compared to TA for proton and photon radiotherapy and develop recommendations for treatment planning. **Methods:** TA and CF samples were acquired from an implant manufacturer as flat pieces 5cm x 5cm and 1.1cm thickness. CT scans were acquired in a solid water phantom with the implants in a custom-made Lucite holder. Material characteristics were evaluated on CT scans with and without metal artifact reduction (MAR). Relative stopping power (RSP) was determined from the range pull-back of each sample in a 20cm range proton beam. Photon transmission measurements were made in a solid water phantom and compared to the RayStation planning system. Photon plans for patients with implants were evaluated for dose perturbation. **Results:** CF caused no visible CT artifacts and MAR was not necessary for Hounsfield Unit determination (median 364 HU) or contouring, while TA (median 3071 HU) caused substantial artifacts, which were improved, but not eliminated by MAR. The proton water-equivalent-thickness and RSP was measured as 35.4mm and 3.204 for TA and 15.7mm and 1.414 for CF. For 6 MV photons, the measured transmission was 89.3% for TA and 98% for CF. CF RSP calculation and transmission from CT HU showed a physical density overestimate compared to measurements. **Conclusion:** With a density similar to bone, CF implants cause no imaging artifacts and minimal dose perturbation compared to TA. Overestimation of RSP and transmission from CT caused slight, but acceptable dose uncertainty (<1.5mm proton range).

Dr Lozano-Calderon has been a paid speaker for CarboFix Orthopedics Ltd, Amgen, and Daiichi Sankyo.

Validation of Monte Carlo Simulated Tc-99m Absorbed-Dose-To-Water Inside a Custom SPECT/CT Phantom Using Active and Passive Dosimeters: A Novel Approach to Benchmarking Monte Carlo Methods for Targeted Radionuclide Therapy Dosimetry

A Bertinetti^{1*}, M Rodriguez², B Palmer¹, C Hammer¹, J Hull¹, H Vija², W Culberson¹, (1) University of Wisconsin-Madison, Madison, WI, (2) Siemens Healthineers

Purpose: Targeted radionuclide therapy (TRT) is a growing field within the realm of radiation therapy despite its shortcomings in dosimetry. This work aims to introduce a novel method for benchmarking TRT Monte Carlo simulations using a custom-made SPECT/CT phantom and active and passive dosimeters. **Methods:** A cylindrical, acrylic SPECT/CT phantom of diameter 8" and length 8" capable of housing an IBA EFD diode, SNC600c farmer type ion chamber, and TLD-100 microcubes was designed and built for the purpose of assessing internal absorbed-dose-to-water at various points within a solution of ^{99m}Tc. The phantom is equipped with removable inserts that allow for numerous detector configurations. All detectors were calibrated using a 250 kVp NIST traceable x-ray beam in either Virtual Water or a water tank. Three experiments were conducted with exposure times ranging from 11 to 21 hours with starting activities of approximately 350 mCi. Automation of the electrometer allowed for data collection over the extended acquisition time. Measurement data was appropriately corrected for pressure and temperature fluctuations, or energy dependence, and subsequently compared to Monte Carlo simulations using the egs_chamber user code in EGSnrc 2018. **Results:** In general, both the diode and ion chamber measurements agreed with the predicted Monte Carlo simulated doses within k=1 calculated uncertainty values. TLD measurements generally produced an under response relative to the predicted doses. **Conclusion:** Our results show that measurements can be obtained with generally good agreement of Monte Carlo simulations for the active dosimeters, and within at least 20% for the passive dosimeter investigated. Future work will incorporate beta emitting radionuclides and modified attachments to the current phantom to assess the feasibility of measuring dose from these commonly used TRT agents.

Incorporating Organ Deformation in Biological Modeling and Patient Reported Outcome Study for Permanent Prostate Brachytherapy

S To^{1*}, P Mavroidis¹, R Chen², A Wang¹, T Royce¹, T Zhu¹, J Lian¹, (1) University of North Carolina, Chapel Hill, NC, (2) University of Kansas, Kansas City, KS

Purpose: Permanent prostate brachytherapy has inherent intraoperative organ deformation due to the inflatable trans-rectal ultrasound probe cover. Since the majority of the dose is delivered with reduced prostate deformation, the dosimetry approved at the time of implant may not accurately represent the dose delivered to the target and organs at risk. We aimed to evaluate the biological effect of the prostate deformation and its correlation with patient-reported outcome. **Methods:** We prospectively acquired ultrasound images of the prostate pre- and post-probe cover inflation for 27 patients undergoing Iodine-125 seed implant. Coordinates of implanted seeds from the approved clinical plan were transferred to the undeformed prostate to simulate the actual dosimetry using a machine learning-based deformable image registration. DVHs of both plans were reduced to Tumor Control Probability (TCP) and Normal Tissue Complication Probability (NTCP) with assumed generalized equivalent uniform dose distribution. The change in patient-reported rectal and urinary symptoms six months post procedure were correlated with NTCP using area under the curve (AUC) and odds ratio (OR). **Results:** From the deformed clinical plan to the undeformed plan, the average TCP decreased from 98.9% to 94.2% and the average NTCP changed from 0.4% and 26.7% to 18.0% and 17.3% for the urethra and rectum, respectively (p<0.05). For the diarrhea symptom NTCP>20%, the undeformed plan showed AUC=0.75, OR=8.9 (1.3-58.8) while the deformed plan showed AUC=0.56 and OR=1.4 (0.2-9.0). For the urinary control NTCP>15%, the undeformed plan showed AUC=0.70, OR=6.9 (0.6-78.0) while the deformed plan showed AUC=0.51 and no reported OR since all NTCP were below 6.6%. **Conclusion:** With the consideration of organ deformation, TCP decreased while urethra NTCP showed worse sparing and rectal NTCP showed better sparing. The NTCP of the undeformed plan shows a strong correction with patient-reported diarrhea and urinary control, while the original clinical plan does not.

Prediction of Radiation Pneumonitis for NSCLC Using Crop Convolutional Neural Network Based Model

D Kawahara^{1*}, N Imano¹, R Nishioka², A Saito¹, Y Nagata¹, (1) Hiroshima University, Hiroshima, JP, (2) Medical and Dental Sciences Course, Graduate School of Biomedical & Health Sciences, Hiroshima University, Hiroshima, JP

Purpose: To predict grade 2 radiation pneumonitis (RP) in locally advanced non-small cell lung cancer (NSCLC) patients with high accuracy by using convolutional-neural network (CNN) model. **Methods:** Three CNN models were created: the whole body region, normal lung (nLung) region, and nLung region overlapping the region over 20 Gy (nLung $\cap$ 20Gy) were fed into 3D CNN model. Models were evaluated on 54 patients and were independently tested on 23 newly treated patients. The risk of RP was categorized into two groups (Group I: more than RP grade 2 and Group II: within RP grade1). The model was optimized using Adam. Fivefold cross-validation was applied to verify its predictive performance. The precision, accuracy, and sensitivity by generating confusion matrices and the areas under the receiver operating characteristic curve (AUC) for each model were evaluated. **Results:** The accuracy, specificity, sensitivity, and AUC were 53.9%, 80.0%, 25.5%, and 0.58, respectively for whole body method and 60.0%, 81.7%, 36.4%, and 0.64, respectively for nLung method. For the nLung $\cap$ 20Gy method, the accuracy, specificity, sensitivity, and AUC were improved to 75.7%, 80.0%, 70.9%, and 0.84, respectively. The segmented input data can be learned effectively and useful for CNN model. **Conclusion:** The CNN model which the input image was segmented and considered dose distribution can help to predict grade 2 RP for NSCLC after definitive radiotherapy.

Development of Radioimmunotherapy for Brain Tumors Using In-Vitro Assays

Y Walter*, A Hubbard, C Thiegs, K Djam, H Kramer, A Benoit, E Yank, O Salas, M Schwengler, S Mckinley, J Lewison, A Ekpenyong, Creighton University, Omaha, NE

Purpose: In the last decade, anticancer agents that act as immune-checkpoint inhibitors have been approved and deployed successfully in treating some cancers such as melanoma, leading to the emergence of immunotherapy as a possible fourth pillar of cancer treatment in addition to surgery, radiotherapy and chemotherapy. For primary brain tumors such as glioblastoma, which show high radioresistance as well as high chemoresistance, there is an urgent need to develop synergistic strategies combining immunotherapy with traditional modalities. The purpose of our work is to develop new combination modalities for glioblastoma which currently has a dismal 5-10% 5-year survival rate. **Methods:** Having recently used a commercially available Electric Cell Impedance Sensor (ECIS) to quantify the migration of various cancer cell lines following chemotherapy and following radiotherapy (2 Gy, 10 Gy and 20 Gy) using a cell irradiator, Faxitron CellRad, we now focus on quantifying cell migration following combinations of radiotherapy with temozolomide (TMZ), and other approved immunotherapeutic agents. **Results:** Our preliminary results show that irradiated T98G cells (Glioblastoma, brain cancer cells) attach and migrate significantly more ($p < 0.0001$) than non-irradiated cells in the first 20-40 hours post irradiation. Irradiated cells (5 Gy and 20 Gy) show markedly different proliferative and migratory patterns in the course of 7 days following irradiation (Figures 1 and 2 in supplement). Along with clonogenic assays, therapeutic windows suggested by these results will be explored and presented. **Conclusion:** Our preliminary results suggest that real time cell migration assays can be used to explore therapeutic windows for optimal combination of immunotherapy and radiotherapy especially in the case of highly radioresistant and chemoresistant cancers such as glioblastoma.

WE-lePD-TRACK 6-04

Characterization of the Response of 9L Orthotopic Brain Tumors to 3D Conformal Radiation Therapy Using Contrast Enhanced MRI

G Valadie*, S Brown, J Ewing, G Divine, N Tavarekere, K Farmer, G Cabral, Henry Ford Hospital, Detroit, MI

Purpose: Our long-term goal is to evaluate early predictors of tumor radiation response. As a first step, the response of 9L orthotopic brain tumors were measured following MRI guided planning of stereotactic radiotherapy (SRS) in order to determine the dose to cure 50%, TCD50. **Methods:** 118 Fischer-344 rats were implanted with 105 rat 9L cells in 10 μ l using males and females. Tumors either grew untreated or were treated with 20 or 25 Gy to the 95% isodose as follows. Around 8 days post-implantation, rats were imaged with contrast enhanced MRI (MRI-CE) and irradiated using a Small Animal Radiation Research Platform (SARRP) from Xstrahl Inc. (Suwanee, GA) operating at 220 kV and 13 mA with an effective energy of ~ 70 keV and dose rate of ~ 2.5 Gy per minute. Rat orientations were assessed using cone-beam CT; tumor locations were co-registered using the MRI-CE images. Treatment planning using MuriPlan software from Xstrahl Inc. allowed delivery of four non-coplanar arcs with an identical isocenter. Rats were monitored daily for physical and behavioral abnormalities. Study endpoints were animal survival at 200 days with no weight loss exceeding 20% of maximum animal weight. **Results:** The TCD50 was established from Kaplan-Meier survival analysis as between 20 and 25 Gy. Animals with large tumors assessed from MRI-CE on the day of treatment did not survive long, as expected. For example, tumors > 150 mm³ correlated inversely with survival for animals treated with 25 Gy (Wilcoxon Rank Sum test). Cox Proportions-Hazards modeling did not suggest an effect of sex with the caveat of the wide confidence intervals. **Conclusion:** The radiation response of orthotopic 9L tumors was characterized using clinically relevant treatment techniques. One future direction is to evaluate the predictive value of pre-treatment vascular measures (blood flow, vascular permeability, etc.) on radiation response.

Research reported in this publication was also supported by National Cancer Institute of the National Institutes of Health under award number R01-CA218596

WE-lePD-TRACK 6-05

Comparison of Dose Escalation Strategies for Head and Neck Cancer Patients Using a Radiobiological Model of Reoxygenation

M Guerrero^{1*}, E Smith², (1) University of Maryland School of Medicine, Baltimore, MD, (2) Yale University

Purpose: Hypoxia is a big challenge for tumor control in head and neck cancers. With advanced imaging techniques, individual patient hypoxic regions can be identified. Several clinical trials perform dose-escalation based on pre-treatment hypoxia, typically boosting hypoxic tumor areas. However, longitudinal imaging studies showed that the location of hypoxic cells changes throughout treatment. The purpose of this work is to quantify the potential loss of biological effect due to changes in hypoxia during treatment in dose-escalation studies based on initial hypoxia only and compare this strategy to one based on patient imaging at weeks 0 and 2 of treatment. **Methods:** A previously published reoxygenation model based on LQ survival formulas with reoxygenation parameter Δ is extended to allow for dose-escalation with dose $d(H)$ per fraction for initial hypoxic cells. The new model allows for some hypoxic cells to miss the escalated dose depending on parameter "m" ($m=0$ no missed cells, $m=1$ all cells missed). Using published radiobiological parameters and hypoxia reduction factor (HRF) of 1.5-2.5, we calculate the EQD2 when hypoxia is present for 70Gy delivered in 35 fractions with $d(H)(2.2-2.6Gy)$ to the hypoxic region. **Results:** For an HRF of 1.5, the biological effect with escalated dose per fraction up to 2.6Gy cannot sufficiently compensate hypoxia if there is no reoxygenation ($\Delta=0$). As Δ is increased to 0.2 and beyond (20% or more hypoxic cells re-oxygenate after each fraction), the EQD2 becomes comparable to the non-hypoxic values. Based on previous results, the dose-escalation of the whole tumor after 20Gy based on hypoxia imaging at 2 weeks yields comparable or higher EQD2 values for more modest escalated doses to the whole tumor. **Conclusion:** The new model allows to evaluate and compare strategies for dose-escalation to compensate for hypoxia during treatment and quantifies limitations of dose-escalation based on initial hypoxia.

WE-lePD-TRACK 6-06

Towards the Biological Meaning of the Site in Microdosimetry: Relation to DNA Compactness

A Bertolet^{1*}, J Ramos-Mendez², H Paganetti¹, J Schuemann¹, (1) Mass General Hospital and Harvard Medical School, Boston, MA, (2) University of California San Francisco, San Francisco, CA

Purpose: To study the biological meaning of site in microdosimetry and DNA direct damage at different degrees of DNA compactness under alpha particle irradiation. **Methods:** To associate the concept of site in microdosimetry with a biological endpoint, we performed TOPAS-nBio simulations of direct damage caused by alpha particles to two DNA arrangements in a water sphere of 500 nm radius: (i) straight linear plasmids of DNA, i.e., double helix arranged in parallel, with axial separations of 2.8 nm, 4.2 nm, and 5.6 nm; and (ii) supercoiled plasmids of DNA (pBR322) available in TOPAS-nBio. DNA geometries were uniformly irradiated by an isotropic source of alpha particles with initial energies between 1 and 15 MeV/u. Scored double strand breaks (DSBs) were defined as damage (i.e., energy imparted above 17.5 eV) in two base pairs separated by less than 10 base pairs. Yield of DSBs per Gy per giga base pair (Gbp) were obtained and reported as a function of the corresponding dose-mean lineal energy (y_D) and dose-mean specific energy ($z_D(r)$) for sites of variable size. **Results:** Yields of DSBs in the linear plasmids, regardless of the separation between them, showed the same linear relation with y_D . Yields of DSBs for supercoiled plasmids were greater than for linear plasmids but also exhibited an approximately linear relation. Yields as a function of $z_D(r)$ from both linear and supercoiled configurations were aligned for radii equal to 385 nm and 293 nm, respectively. **Conclusion:** Compacted DNA have neighbor base pairs closer than uncoiled DNA, which makes a track more likely to damage two of them. This associates with smaller volumes in which the pattern of energy deposited is relevant, i.e., smaller sites. Therefore, prediction of direct DNA induction from microdosimetry can be separated into two components: y_D (radiation quality-dependent) and site radius (DNA geometry-dependent).

This work was supported by the National Institutes of Health (NIH)/National Cancer Institute (NCI) grant no. R01 CA187003.

Extracting Organ-Specific Radiobiological Model Parameters from Clinical Data for Radiation Therapy Planning of Head and Neck Cancers

E Quashie*, A Tai, P Prior, M Awan, C Schultz, X Li, Medical College of Wisconsin, Milwaukee, WI

Purpose: Different radiation therapy (RT) strategies, e.g., conventional fractionation, hypofractionation, stereotactic body radiotherapy (SBRT), adaptive RT, and re-irradiation are often used to treat head and neck cancers. Combining and/or comparing these strategies require to calculate biological effective dose (BED). The purpose of this study is to develop a practical process to extract organ-specific radiobiologic model parameters that may be used for BED calculations in individualized RT planning for head and neck cancer. **Methods:** The dose volume constraint data for 12 organs at risk (OAR) corresponding to no grade ≥ 3 toxicity for SBRT, hypofractionated and conventional fractionation treatments were compiled from various sources such as TG101, QUANTEC and clinical trial database. These data cover 10 fractionation schemes. A linear-quadratic-linear (LQ-L) model was used to extract model parameters (e.g., α/β , γ/α and d_t) from fitting the Iso-BED curves of those dose volume constraints for the OARs using an in-house python code. The obtained model parameters were integrated into a practical workflow in MIM software. Their practicality was tested for treatment planning of re-irradiation. **Results:** The LQ-L model fitted the data well as indicated by smooth transition curves from SBRT to conventional fractionation data. The organ-specific model parameters were obtained, for example, $\alpha/\beta=2.57\text{Gy}$, $\gamma/\alpha=9.07\text{Gy}$ and $d_t=7.65\text{Gy}$, and $\alpha/\beta=2.34\text{Gy}$, $\gamma/\alpha=9.67\text{Gy}$ and $d_t=6.80\text{Gy}$ for spinal cord and brainstem, respectively. The composite dose plans for retreatment of head and neck cancers with considering the obtained model parameters show up to 10% difference in physical dose constraints from traditional EQD2 method with $\alpha/\beta=3.0\text{Gy}$. **Conclusion:** A practical process was developed to obtain organ-specific radiobiological model parameters from clinical data and was shown to generate more clinically relevant model parameters for calculating BED distributions compared to those extracted from cell line survival data. The practicality of the obtained parameters was demonstrated in creating composite plans for retreatment.

Microsoft Teams® as An Operational Tool for Evaluation of Machine Performance and QA Tasks

M Gopalakrishnan*, S Kucuker Dogan, B Zawislak, T Teo, I Das, Northwestern Memorial Hospital, Northwestern University Feinberg School of Medicine, Chicago, IL

Purpose: Maintaining machine performance and service database in an academic department with multiple machines, different locations and various vendors is a challenging task. Microsoft Teams®, used for virtual meeting is explored for tracking machine status and performance. **Methods:** Microsoft Teams®, a collaborative workspace hub for conversations, document sharing, assigning and completing tasks is utilized for machine related communications in the department. An equipment dashboard was created for each machine to assign tasks and alert physicist for necessary services. Physicist completes and add notes for the task which would then trigger an email to members alerting the status of the service, maintenance and QA. A timeline for each of the above tasks is maintained for assessing workflow in the system. As part of machine performance QA, this data is reviewed during the weekly physics meetings where all the machine related QA issues are discussed and remedial actions evaluated. **Results:** Department maintains 5 Linacs, 2 CT scanners, GK ICON and host of other peripheral equipment at two locations with mixed vendors and different vintage. Teams® dashboard provides every information that is entered to the entire department and have reduced the bottleneck. It provides instantaneous information for the service issues, report and summarize the incidence of each machine in real-time. This information is vital for communication and for future planning. Machine related issues for different components including downtime, maintenance reports, service calls, physics support are visible and tracked. Visibility, communications, and overall management of equipment issues has dramatically improved after utilizing Microsoft Teams®. **Conclusion:** Microsoft Teams® has been successfully implemented as a platform to track QA and service issues without investing huge amount of money or writing a code. It is concluded that Teams can be used in any department for providing essential communication and exchange of information among staff.

WE-E-TRACK 1-02

Successful VMAT Commissioning in Low- and Middle-Income Country (LMIC) in the Era of COVID-19 Using Remote Connectivity

S Wadi-Ramahi^{1*}, F Waqqad^{2,3}, A Alsharif³, (1) University of Pittsburgh Medical Center, Hillman Cancer Center, Pittsburgh, PA, (2) Radiation Oncology Center, King Abdullah University Hospital, Irbid, Jo, (3) Radiation Oncology Dept, Afia Nuclear Medicine and Radiation Oncology Center, Amman, Jo

Purpose: Outlining a systematic process to successfully commission VMAT in Jordan in a time of restricted travel and increased virtual connectivity. **Methods:** Process started on 9/2019 with a 2-days physical visit to initiate trust and discuss scope of work. Observing clinical workflow was intended for a week-long visit to follow. After COVID19, VPN access to both center's Mosaic and TPS to evaluate treatment setup, reproducibility and reviewing IMRT cases was given. Due to time difference, there was no interruption in clinical workflow when the systems were accessed. Extensive conference calling and email communication to discuss findings. Confidential communication with administration is important. Remote commissioning began with agreeing on a detailed time-table with clear assigned responsibilities. Remote supervision through VPN, videoconferencing, group chats and emails. **Results:** Workflow baseline unveiled opportunities for improvements that were accepted and implemented. TPS re-acceptance (TG119 and TecDoc1583) was done by local physicists. Various QAs were implemented using TG142. Linac VMAT acceptance testing was done followed by virtual training by vendor. Lastly, 20 different disease site VMAT plans were done, using actual patient scans for different disease sites, for QA purposes resulting in recommending 3%/3mm for gamma analysis. Clinical protocols written for dose objectives and QA methodology. All work was remotely followed and supervised. **Conclusion:** COVID-19 has taught us a very important lesson: Professionals from high-income countries can effectively help clinics in LMICs through virtual connectivity. This process can be adapted to after-COVID to reduce cost. Other lessons learned: 1. A short visit is a must to meet the team, 2. Written communication should be clear. Lapses in communication may greatly hinder the project, 3. Always start with measuring the clinical-workflow baseline. Implementing change to improve and assessing local staff's effective participation is critical, 4. Agree on a clear timetable with assigned responsibilities.

Remote MRI Physics During a Pandemic: Challenges and Opportunities

K Vigen*, L Henze Bancroft, J Garrett, F Korosec, J Holmes, University of Wisconsin-Madison, Madison, WI

Purpose: Prior to the COVID-19 pandemic, our MRI physics group often provided in-person clinical MRI exam physics support, including monitoring exams of patients with certain MR Conditional and unlabeled implants; managing artifacts; suggesting protocol modifications; and providing basic MRI system troubleshooting. This work will describe the transition to an almost entirely virtual MRI physics model during the pandemic, including example cases. **Methods:** To minimize risk to patients and staff, our MRI physics team adopted a virtual support model immediately after the pandemic started. Remote support tools included remote PACS viewers, secure access to the MRI host computer, and a prototype remote MRI console viewer installed on a single hospital MRI scanner. **Results:** Prior to the pandemic, 3.5 cases per week required in-person MRI physics support. The majority of exams requiring physics support were shifted to the MRI system with the remote MRI console viewer. Following the initial decrease in all MRI exams at the onset of the pandemic onset, MRI volumes at our institution recovered to pre-pandemic levels; our virtual model has been able to support nearly all cases requiring MRI physicist presence: 5 exams in the first 4 weeks of the pandemic shutdown, up to 5.6 cases per week by late summer, normalizing to 3.8 cases per week since that time. MRI physicists can work remotely, with onsite after-hours visits for QC, pulse sequence and protocol development, and basic troubleshooting. **Conclusion:** We have shifted the majority of in-person clinical MRI physics activities to a virtual model. This helped our institution navigate initial and subsequent phases of the pandemic by enabling remote work and minimizing facility occupancy, while maintaining a high level of MRI physics services. We anticipate continuing to use these tools for efficient MRI physics support across our network spanning several imaging facilities in the community.

Our department received research support from GE Healthcare.

Did the COVID-19 Pandemic Disproportionally Affect Patients Receiving Radiation Therapy at a Public Safety-Net Hospital Compared with Patients Treated at a Private Hospital in the Same Metropolitan Area?

J Cui*, J Cui, W Yang, A Zhuang, O Ragab, D Hong, S Bian, E Chang, R Jennelle, Keck School of Medicine of USC, Los Angeles, CA

Purpose: To compare the number of radiotherapy treatments delivered to patients at two departments at an epicenter of the COVID-19 pandemic. One is a public safety-net hospital serving a socioeconomically disadvantaged and under-insured population. The other is a private hospital serving patients with private insurance. **Methods:** On March 11, 2020, the World Health Organization declared COVID-19 a global pandemic. Considering the response to COVID-19, the number of External Beam Radiation Therapy (EBRT) and Gynecologic High-Dose-Rate (HDR) brachytherapy treatments delivered between May 2020 and Feb 2021 (during pandemic) was compared to treatments delivered between May 2019 to Feb 2020 (pre pandemic). We also reported differences in patient access to telemedicine, COVID-19 screening, and clinical trials at the two centers. **Results:** At the safety-net hospital, there were 8291 EBRT treatments pre-pandemic and 7475 during the pandemic, which reflects a 10% decrease. At the private hospital, the numbers were 10662 and 8231 respectively, a 23% decrease. At the safety-net hospital, the HDR treatments were 45, 32, 26 for cylinder, interstitial, tandem-and-ovoid respectively pre pandemic and 38, 14, 56 during the pandemic. The total number of HDR treatments were 103 and 108 respectively. The decrease in interstitial therapy was balanced by an increase in hybrid tandem-and-ovoid with needles when needed. For the private hospital, Gyn HDR increased from 14 to 32, likely due to detrimental impact of treatment delay on Gyn cancers. During the pandemic, clinical trials were administratively paused at the safety-net hospital to allow for reassignment of resources directed to the care of critically ill COVID-19 patients. The private center enrolled 9 patients during the pandemic, same number as pre-pandemic. **Conclusion:** Our analysis demonstrates that the COVID-19 pandemic did not disproportionately affect patients' accessibility to RT at a safety-net hospital versus a private hospital. However, access to clinical trials was severely impacted.

Medical Physics During COVID-19: The North American Perspective | Audience Q&A

B Parker^{1*}, (1) The University of Texas M.D. Anderson Cancer Center, Galveston, TX

Medical physics was not immune to the impact of the COVID-19 pandemic, and the profession required creative methods to adapt to working in this new age. This presentation first will introduce a recent publication on the global medical physics response to the pandemic (Medical Physics During the COVID-19 Pandemic: Global Perspectives in Clinical Practice, Education, and Research) and then focus on the North American response in the areas of clinical practice, education, research, and regulatory and accreditation. It will conclude with lessons learned and opportunities identified from the COVID-19 experience.

Learning Objectives:

1. Understand the impact the pandemic had on various aspects of the profession
2. Review the North American medical physics response for various aspects of the profession
3. Identify lessons learned and opportunities to improve future responses for similar emergent situations

Audience Q & A

Updates on CT Dosimetry Abstract

Accurate measurement and assessment of CT Dose indices is vital for equipment constancy and acceptance testing, estimating patient absorbed doses, and comparison of imaging protocols across scanners. In this educational session, updates on several key topics in CT dosimetry will be discussed. Recent scientific and regulatory developments in CT dosimetry offer new indices to better approach patient dose and new approaches to measure dose outside of the “traditional” 4 cm or less beam width scenario.

The first talk will be focused on Size Specific Dose Estimate (SSDE) updates, including how SSDE may be calculated for examinations focused on the head as described by AAPM Report 293. In addition, prospects for scanner implementations of SSDE following approval of a new IEC standard will be discussed. The 2nd presentation will review the findings of AAPM Report 200 and highlight options for measuring dose indices in long phantoms to ensure scatter tails for wide beam geometries are captured. Further discussion of dose index measurement under non-conventional scenarios will follow in the third talk, which will focus on approaches to measure CT dose from helical acquisitions. Finally, approaches to measuring CT dose in air will be discussed, including approaches described by manufacturers in technical manuals when measurements in phantoms alone are not sufficient to assess CTDIvol.

Learning Objectives:

1. Understand how SSDE is calculated in head and body and how it will be implemented on scanners in the future.
2. Understand how CT dose may be measured in a long phantom as described by AAPM report 200
3. Understand how CT dose may be measured without a CTDI phantom or when axial acquisition modes are not available.

Quantitative Lung Ultrasound, Beyond Artifact Imaging

WE-E-TRACK 3-04

Q&A

Ultrasound imaging is one of the most used imaging modalities due to its portability, relative low cost and use of non-ionizing radiation. Despite these advantages, variability in image acquisition and interpretation, as well as the complexity of the image that result from the many interactions of ultrasound with tissue, and a lack of compensation for system dependent factors, have limited a more extended use. Additionally, conventional ultrasound methods are not well suited to imaging organs such as the lung, because of large amounts of scattering by the air-filled alveoli. This session will discuss technological developments that are expanding the frontiers of ultrasound imaging, enhancing it with quantitative measuring features. The goal of this expansion is to overcome some of these limitations by offering clinicians tools to quantify physical characteristics of tissue such as its scattering properties (reflectivity) and sound speed (related to compressibility), which can be used as biomarkers or surrogates of tissue healthy or disease status. Invited speakers will provide the physical basis of these quantitative ultrasound techniques, and present recent applications in liver, breast, and other tissues. The challenges of extending this approach to the lung, where new sources of contrast must be established so that new biomarkers of lung diseases can be developed, will also be discussed. Proffered talks will expand on these applications by presenting the state of the art of ultrasound imaging research.

After this session, attendees will be able to:

1. Describe the physical principles of novel scattering and sound speed-based quantitative ultrasound techniques.
2. Discuss recent applications of these techniques in liver, breast, lung, and other tissues.
3. Describe how the proposed techniques can be used to solve specific clinical needs.
4. Identify the main challenges of incorporating these novel quantitative ultrasound techniques in their clinical practice

Targeted attendees are scientists and medical physicists and other medical professionals with interests in the development of quantitative imaging, particularly quantitative ultrasound, and its clinical translation.

Discussion

This symposium will celebrate the life and accomplishments of John Robert (Jack) Cunningham O.C., B.Eng., M.Sc., Ph.D., FCCPM, FAAPM, FCOMP, one of the great pioneers in Medical Physics. His breadth and depth of Medical Physics experience and knowledge have resulted in multiple, wide-ranging contributions extending from operating a radon plant in the 1940s, to evaluating range-energy relationships for electrons from a betatron in the early 1950s, to the development of radiation therapy apparatus including the design and construction of cobalt-60 machines in the 1950s and 60s, to generating radiation-related basic quantities for dose calibration protocols in the 1970s and 80s. He co-authored *The Physics of Radiology* along with Harold Johns, "the Johns and Cunningham book," generally considered as the "bible" in Medical Physics. However, his greatest and most impactful contributions started in the 1960s with his early development of dose calculation algorithms for use with computerized, clinical, radiation treatment planning programs. The algorithms used calculations of primary dose summed with differential scatter doses using quantities known as scatter-air ratios (SARs). His programs were made commercially available beginning in the 1970s evolving through various commercial enterprises, starting with Atomic Energy of Canada Limited (AECL) and moving through to Theratronics, MDS Nordion, and Nucletron. The principles and concepts were implemented in various other commercial systems as well.

In view of his significant contributions to Medical Physics and the resulting impact on many patients around the world, Jack has received multiple awards, including the AAPM Coolidge award in 1988, the inaugural COMP Gold Medal in 2006 and the Order of Canada, the top award given by the Canadian government for those "who exemplify citizenship and whose contributions enrich the lives of their contemporaries". A more detailed review of Jack's career can be found in *Medical Physics*: <https://doi.org/10.1002/mp.14050>.

In honor of Jack Cunningham and out of recognition of his intense desire to develop elegant physics solutions to clinical problems, this symposium will focus on radiation treatment planning-related algorithms by considering the past, evaluating the present and projecting into the future. The speakers are all acquaintances of Jack and have interacted with him at a variety of levels.

Learning Objectives

1. Learn about the contributions Jack Cunningham made to the field of Medical Physics.
2. Learn about the dose calculation algorithms developed by Jack Cunningham and their implementation in commercial treatment planning systems.
3. Learn about the state-of-the-art treatment planning and dose determination algorithms by considering the past, evaluating the present and projecting into the future.

WE-E-TRACK 5-04

Q&A

The stellar clinical results of the early clinical applications of cardiac radioablation¹⁻³ mirror the enthusiasm for the early applications of lung cancer SABR that has now demonstrated efficacy compared with surgery and conventional radiotherapy in phase III trials.⁴⁻⁵ Lung SABR is now a mainstream treatment. In order for cardiac radioablation to navigate the path from early adopters to the mainstream, the enthusiasm for the broader implementation must be accompanied by multidisciplinary education, clinical evidence and practice guidelines to maximize patient safety and procedure efficacy. There are many opportunities for imaging and therapy medical physicists to contribute to the development of new and better technology to image, target and monitor treatment response. This symposium will cover:

- Cardiac radioablation R&D needs at the juncture of electrophysiology and radiation therapy
- Research opportunities from academia: A summary of the state-of-the-art cardiac radioablation medical physics R&D opportunities, including cardiac imaging and gating
- Open questions in the radiobiology of cardiac radioablation and the promise of particle therapy
- The challenges and opportunities to contribute to improved cardiac radioablation patient treatments and outcomes

Learning Objectives:

1. To understand electrophysiology and radiobiology relevant to a medical physicist planning to implement cardiac radioablation
2. To learn the current technology approaches implemented for cardiac radioablation
3. To appreciate the future opportunities for medical physicists to define cardiac radioablation practice

3D Printed Patient-Specific HDR Brachytherapy Applicator for Penile Cancer Plesiotherapy

H Lee*, B Hryckushko, Z Xiong, M Folkert, N Desai, A Garant, T Chiu, UT Southwestern Medical Center, Dallas, TX

Purpose: To develop a custom 3D printed HDR plesiotherapy applicator for localized squamous cell carcinoma on the glans penis. **Methods:** A rigid shell-like applicator having eight channels for standard plastic catheter insertion was designed such that it could slide onto the penis. A spiral pattern was designed at the distal end to accommodate the spherical curvature of the glans while achieving a large radius of curvature for smooth source wire transfer. This applicator was printed on a SLA 3D printer to achieve a highly smoothed finish for standard plastic catheter insertion. Before putting on the applicator, a custom-made silicone bolus/sleeve (4mm-thickness) was placed to provide space from the source to reduce the surface dose and for patient comfort. Tests were conducted to ensure the standard plastic channel diameter and radius of curvature were appropriate for guide tube insertion and source delivery. **Results:** With the bolus and applicator placed, a patient with a rcT1a penile cancer was imaged on a CT scanner with wires placed in the channels for treatment planning digitization. For a penis of diameter ~30mm, a 36mm applicator with a 26mm silicone bolus provided sufficient immobilization with minimal air gaps. Brachytherapy planning was performed with a prescription dose of 40 Gy in 10 fractions at the surface, and 35 Gy at 5mm depth, bidaily. Dose coverage to the targeted glans was 94%(D90). During the course of treatment, a highly reliable and reproducible setup (5-10 minutes setup time) was made possible. 6-month follow-up monitoring showed no significant changes in urinary and sexual function. **Conclusion:** A 3D printed patient specific applicator with a silicone bolus was shown effective in providing a reproducible setup and dose delivery for HDR brachytherapy plesiotherapy.

A Fast and Accurate Analytical Dose Calculation Method for Seed-Loaded Stent

T Xiong^{1*}, B Liu^{2,3}, J Lu⁴, S Li⁴, X Bai^{1,2}, F Zhou^{1,2}, Q Wu⁵, (1) Department of Physics, Beihang University, Beijing, CN (2) Image Processing Center, Beihang University, Beijing, CN (3) Beijing Advanced Innovation Center for Biomedical Engineering, Beihang University, Beijing, CN (4) Center of Interventional Radiology & Vascular Surgery, Department of Radiology, Zhongda Hospital, Medical School, Southeast University, Nanjing, CN (5) Duke University Medical Center, Durham, NC

Purpose: The safety and clinical efficacy of 125I seed-loaded stent for the treatment of portal vein tumor thrombosis have been shown. However, the dosimetry characteristics of the seed-loaded stents remain unclear and there is no fast dose calculation technique available for seed-loaded stent. This paper aims to explore a fast and accurate analytical dose calculation method which takes into account the effect of stent and tissue inhomogeneity. **Methods:** An accurate model of the seed-

loaded stent was established using 3D modeling software and subsequently used in the MC simulation to calculate the dose distribution around stent. The dose perturbation caused by the presence of the stent was analyzed and dose perturbation kernels (DPKs) were derived. Then, the dose calculation method from AAPM TG43 was adapted and integrated with the DPK and inhomogeneity correction factor (ICF) correction to calculate dose distributions analytically. To validate the proposed method, extensive comparisons were performed with other methods in water phantom and voxelized CT phantoms of three patients. **Results:** The stent has a large effect on the dose distributions and reduces the dose up to 47% for single seed stent and 13% for 16-seed stent. In water phantom, dose distributions from MC simulations and the proposed method showed a good agreement with the relative error less than 3.3%. In voxelized CT phantoms, the relative errors of TG43 method can be up to 33% while those of the proposed method were less than 5%. For a dose matrix with 256×256×46 grid for 16 seeds-loaded stent, it only takes 17 seconds compared with 25 hours for MC simulation. **Conclusion:** With its good agreement with MC calculation and computational efficiency, the proposed method is adequate for dose evaluation and optimization in seed-loaded stent implantation treatment planning.

Defining Dose Thresholds to the Optic Disc and Macula to Predict Vision Complications: A COMS Retrospective Study

C Oare*, B Gerbi, K Dusenbery, D Koozekanani, S Sun, C Ferreira, University of Minnesota, Minneapolis, MN

Purpose: Despite the long history of COMS (Collaborative Ocular Melanoma Study) eye plaques, limited consensus for dose thresholds exists for the optic disc and macula. A retrospective study was conducted to identify a correlation between complications and doses to optic structures for ocular melanoma patients. The primary objective of this work was to define dose-side effect relationships and identify dose thresholds for radiation retinopathy, vision decline, blindness, and cataract formation. **Methods:** A cohort of 52 patients treated with COMS plaques at our institution between 2004-2019, with adequate follow up data, were used in a single institution retrospective study. Patient demographics, dosimetry, and clinical outcomes were recorded. A univariate analysis and relative risk estimates were performed to analyze dose-side effect relationships for the optic disc, lens, and macula. A logistic regression was performed to identify dose percentiles for retinopathy, vision decline, blindness, and cataracts. **Results:** Doses to the optic disc and macula had significant relationships ($p \leq 0.05$) with incidence of radiation retinopathy, moderate vision decline (5 or more Snellen lines), and onset of blindness. Moreover, significant ($p \leq 0.05$) relative risk estimates exist for radiation retinopathy, vision decline, and blindness for doses greater than 35 Gy to the optic disc, and 55 Gy to the macula. Finally, a macula dose of 55 Gy will result in less than 13% of patients experiencing radiation retinopathy or vision loss. Optic disc doses of 24 and 33 Gy would result in less than 13% of patients experiencing retinopathy or vision loss, respectively. **Conclusion:** Based on the results of the study, it can be concluded that dose-effect relationships exist for the optic disc and macula with respect to radiation retinopathy, vision loss, blindness. To improve a patient's quality of life beyond treatment, further work is needed to expand upon dose reduction strategies for patients undergoing eye plaque brachytherapy.

WE-E-TRACK 6-04

Determination of the RBE of the Xofigo Axxent Source for Cervical Cancer Applications

A Walter*, K Nickel, R Kimple, L DeWerd, University of Wisconsin-Madison, Madison, WI

Purpose: To measure the relative biological effectiveness (RBE) of the Xofigo Axxent electronic brachytherapy source on HeLa cells with the bare S7600 Axxent source (BS) and source-in-titanium applicator (SIA). **Methods:** HeLa cells were suspended in 1 mL of cell culture media and placed into 1.5 mL microcentrifuge tubes. Cells were irradiated at a radial distance of 2 cm from the source and given doses ranging from 0-6 Gy for both the BS and SIA. The source was pulled back a distance of 3 mm for the SIA irradiations. Doses from the BS and SIA were determined using an Exradin A26 ionization chamber, TLD-100 microcubes, and the TOPAS Monte Carlo code. Irradiations were also performed in Co-60 using 15 mL tubes placed in a virtual water phantom at an SAD of 75 cm and depth of 1.5 cm to obtain reference dose points. Following irradiation, each suspension was seeded in a 6-well plate, with an equal concentration of cells per well. The plates were incubated for 1 week, stained with crystal violet, and the surviving colonies were counted. Survival curves were plotted and fit using a linear-quadratic equation. **Results:** The RBE values determined for the BS were found to be 1.19, 1.22, and 1.27 for the surviving fractions of 1%, 10%, and 37% respectively. The RBE determined for the SIA was found to be 1.17, 1.19, and 1.22 for the surviving fractions of 1%, 10%, and 37% respectively. **Conclusion:** The RBE of the Axxent source is approximately 20% greater than that of Co-60, which is representative of current external beam treatments. Additionally, filtration of the Axxent source from the applicator causes a reduction in dose rate and small reduction in the RBE of the Axxent source.

The sources and applicator used for this work were provided by Xofigo, a subsidiary of iCAD Inc.

Commissioning and Clinical Implementation of a Hybrid TG-43 Technique for Shielded Brachytherapy Applicators

E Choi, C Collins*, M Rivard, Brown University/Rhode Island Hospital, Providence, RI

Purpose: Commercial brachytherapy (BT) treatment planning systems (TPSs) rely on TG-43 calculations that treat all materials as water and fail to accurately accommodate shielded BT sources and applicators. While this works fine for conventional applications such as HDR prostate and GYN BT, treatment of superficial lesions and those in proximity to organs-at-risk will benefit from more sophisticated treatment delivery techniques. This includes the cylindrical AccuBoost breast and Leipzig skin BT applicators. Model-based dose calculation algorithms and applicator models for these devices are not readily available. Innovations using the TG-43 formalism make it possible for BT TPSs to approximate dose distributions in the vicinity of these shielded, high-Z applicators. **Methods:** This study created models for the AccuBoost and Leipzig BT applicators to function within a conventional BT TPS. Published Monte Carlo-derived dose distributions in Cartesian coordinates (along-away) were transformed into polar coordinates (radius and polar angle) for derivation of TG-43 dosimetry parameters through customized values of the dose-rate constant, radial dose function (RDF), 2D anisotropy function, active length, and calibrated source strength. RDF and 2D anisotropy function values were chosen to have sub-millimeter/sub-degree changes, permitting characterization of high-gradient dose regions (i.e., >40%/millimeter). These models were formatted as XML+MD5 files for TPS entry (Oncentra v.4.6.0, Elekta), then used to generate treatment plans for source/applicator commissioning. DICOM RD files were prepared and exported for direct comparison with published Monte Carlo-derived dose distributions. **Results:** Though the TPS limited the 3D dose calculation grid to voxels of at least 1.0 mm, high accuracy of absolute dose was observed with agreement typically within 0.2% and greater than 99.9% of the dose points being within 2%. Voxels outside 2% agreement were located in the high-gradient dose regions where volume averaging was not insignificant. **Conclusion:** This innovative method produced dosimetry results that were deemed acceptable for clinical use.

Adaptive Workflow for a Patient-Specific 3D-Printed Template with Direction Modulated Brachytherapy (DMBT) Tandem Applicator for HDR Cervical Interstitial Brachytherapy

J Sohn*, M Polizzi, E Fields, W Song, Virginia Commonwealth University, Richmond, VA

Purpose: We propose a novel workflow that utilizes a couple of emerging and certainly innovative technologies of direction modulated brachytherapy (DMBT)

tandem applicator along with rapid 3D printing for a patient-specific template augmented for a further improvement in dosimetric conformity and needle positioning accuracy. **Methods:** The proposed workflow consists of three steps to produce an optimized needle configuration with a DMBT tandem. The first step is composed of pre-and each inter-fraction MR imaging to acquire high-risk CTV and delineate the vaginal space for creating the patient-specific template. The second step includes the two-step inverse optimization to (1) determine optimal needle numbers and needle paths and (2) perform volume optimization with DMBT tandem and needle paths. The final step includes rapid 3D printing and QA. This process is iterative and the 3D printed template may be re-optimized using the patient's latest imaging. **Results:** We present a highly adaptable workflow and utilized it for a retrospective patient case. A conformal plan with optimal needle tracks and DMBT tandem was created, and a 3D vaginal template with the tandem and needle tracks was printed. A dosimetric planning comparison is provided to illustrate the additional plan quality improvement achievable with the proposed novel two-step optimization and 3D printing workflow. Radiation Oncology departments with access to MRI and 3D printers can implement this process to reduce inter and intra-fractional needle placement uncertainties. **Conclusion:** The proposed workflow attempts to optimally utilize the rich anatomic information present in the daily MRI by the power and the flexibility of needle positioning offered through 3D printed tracks in combination with the DMBT tandem that allows superior intensity modulation over conventional tandems. The combination of the two technologies, and powered by the daily MRI, offers a truly adaptive workflow that generates the most conformal plans for each fraction.

The senior author has Varian funding for the project.

Commissioning of the Ring Applicator and Quantifying Dwell Position Offset with Varian Bravos HDR Remote Afterloader

A Baghwala¹*, R Boopathy², (1) Radiation Physicist II, Houston Methodist Hospital, The Woodlands, TX, (2) Assistant Professor Division of Radiation Physics, OHSU School of Medicine, Portland, OR

Purpose: Despite new technology offered through BRAVOS afterloader from Varian, the issue of discrepancy between planned source dwell position and delivered in the ring applicator still exists. Purpose of our study was to propose a methodology and quantify the offset due to snaking effect in ring applicators before clinical use. **Methods:** 6 Ring applicators (2 sets of 30/45/60 degrees) from Eckert & Ziegler were used. The applicators are taped to Gafchromic™ EBT3 film and irradiated to 400MUs with a 16MeV electron beam on a linac with the x-ray marker BV 320mm inserted. A treatment plan was created and delivered with 10 equally spaced 1cm source dwell positions at a nominal dwell time of 2 seconds. Combination of applicator image and dwell positions in same radiograph helps in confirming the structural integrity and identifying the tip of the lumen better to compare the expected vs delivered source dwell positions. Films were scanned using Epson Expression 11000XL scanner and the analysis was done in Eclipse Brachytherapy 2D Entry. **Results:** Arc length was measured from the center of each delivered source/dwell position to the center of the ring. Subtracting with 0.25 (source center from distance tip) gives the path length. Subtracting the path length with applicator length (150 cm) will give us the shift in delivered source position. Results show an average of 5mm (σ +/-0.6mm) difference between planned and delivered source dwell position. The results also revealed that the offset increases with the angle of arc length. Applying a consistent correction offset of 4mm to all planned dwell position improved the positional accuracy to less than 1mm (σ +/-0.07mm). **Conclusion:** The data from this study warrants the need for robust applicator commissioning. Quantifying one consistent offset for ring applicators instead of multiple offset values will improve efficiency/workflow without compromising the safety/delivery accuracy.

Scintillator Based Patient Specific QA in the Age of MRgRT

This educational program will cover the changing landscape of patient-specific QA, including experience of implementing new solutions into the clinic, as well as developing new technologies. Specific topics include: 1) Moving from measurement-based pre-treatment QA with Gamma Analysis in phantom to DVH based metrics 2) Moving from measurement-based pre-treatment QA to trajectory file-based QA 3) Moving from a simple 'Type A' independent dose calculation to a 'Type B' (convolution/superposition) or 'Type C' (Monte Carlo) based independent dose calculation algorithm 4) Patient-specific QA for new technologies and online adaptive radiotherapy 5) Scintillator based patient-specific QA in the age of magnetic guided radiation therapy (MRgRT).

Learning Objectives:

1. The benefits of DVH based analysis in patient-specific QA.
2. The strengths and weaknesses of log file-based QA
3. The latest advancement in the area of independent dose calculation algorithm.
4. The challenges of patient-specific QA in the era of online adaptive radiation therapy
5. New measurement-based methods in the presence of magnetic field

Q&A

Scientific publishing is evolving rapidly and AAPM's journals are adapting to stay at the forefront of serving our patients and our profession. Authors and readers alike will benefit from hearing from the Editors-in-Chief and Deputy Editors of Medical Physics and the Journal of Applied Clinical Medical Physics (JACMP) about their latest work to modernize their publications as platforms for dissemination of important new medical physics knowledge.

As an open access journal, JACMP provides worldwide reach to authors and attracts readers who lack access to publications using a traditional subscription model. Open access publishing is affected by a number of trends of which both prospective authors should be aware. Authors will also benefit from learning about the taxonomy used by JACMP for its content. As modern publishing evolves from a print-only medium to a digital multimedia environment, JACMP has launched new initiatives such as video abstracts which will also be highlighted in this session.

A new editorial model for Medical Physics that provides a more horizontal construct for leadership and participation in the review process has been employed that includes 15 Deputy Editors. The Deputy Editors provide expertise that encompasses the entire taxonomy of topics published in Medical Physics, and the global reach of Deputy Editors includes Asia, North America and Europe. This presentation will expand on the benefits of this new editorial model, and the dynamic challenges it must address for the premier journal of our profession.

The Medical Physics journal publishes Research Articles and Technical Notes on a range of medical physics topics, which include Therapeutic interventions; Diagnostic Imaging (Ionizing and Non-Ionizing); Quantitative Imaging and Image Processing, Emerging Imaging and therapy Modalities; and Computational and Experimental Dosimetry. These article types and categories will be briefly presented in terms of the continuing expansion of our field.

Learning Objectives:

1. Explain the new editorial approach and review process for Medical Physics.
2. Discuss trends impacting open access publishing in the field of medical physics.
3. Apply correct journal taxonomy to manuscripts submitted for publication to Medical Physics and JACMP.
4. Describe the benefits of video abstracts.

M Mills receives compensation for serving as Editor-In-Chief of JACMP. A Cetnar has nothing to disclose. J Boone receives compensation for serving as Editor-In-Chief of Medical Physics. S Benedict receives compensation for serving as Therapy Editor of Medical Physics.

High-Resolution Ultrasound Imaging Through Self-Supervised Learning

X Dai*, Y Lei, T Wang, M Axente, J Roper, D Xu, J Lin, J Bradley, T Liu, X Yang, Emory University, Atlanta, GA

Purpose: This study aims to develop a deep learning-based algorithm to reconstruct high-resolution 3D ultrasound (US) images from sparsely acquired 2D images without any extra atlas database. **Methods:** In conventional US imaging, in-plane spatial resolution is generally much higher than through-plane resolution. Under the assumption of isotropy of US imaging in biological tissue, the mapping from through-plane low-resolution to high-resolution images should be identical as that

for in-plane images. Therefore, the mapping can be learned using paired low-resolution and high-resolution in-plane images. Given the acquired 2D images which have high in-plane spatial resolution, the in-plane low-resolution images can be obtained through down-sampling. In this study, a model which is constructed by two independent cycle consistent generative adversarial networks (cycleGANs) is built to learn the mapping from low-resolution to high-resolution images and generate high-resolution through-plane images from original sparsely distributed 2D images. We performed a leave-one-out cross validation method to evaluate the proposed high-resolution method using a 3D breast database with 70 patients. Metrics including mean absolute error (MAE), peak signal-to-noise ratio (PSNR), and visual information fidelity (VIF) were computed to quantify the performance of our proposed method. **Results:** In the experimental studies with a spatial resolution enhancement factor of 3, for all patients, a mean and standard deviation of MAE value of 0.90 ± 0.15 , a PSNR value of 37.88 ± 0.88 dB, and a VIF value of 0.69 ± 0.01 were achieved by our proposed method, significantly outperforming the commonly used bicubic interpolation. **Conclusion:** In this study, a novel self-supervised learning framework has been investigated for reconstructing high-resolution 3D US images from sparsely acquired 2D images. Without using any extra atlas images, our proposed method achieves significant improvement on through-plane resolution. Its self-supervision capability could accelerate high-resolution US imaging, and this imaging tool will have a high impact on US-guided intervention.

WE-F-TRACK 3-02

A Novel Wireless Mechanical Oscillator for Power Doppler-Based Needle Tip Identification in Brachytherapy

N Orlando^{1,2*}, J Snir³, K Barker², D Hoover^{3,4}, A Fenster^{1,2,4}, (1) Department of Medical Biophysics, Western University, London, ON, CA, (2) Robarts Research Institute, Western University, London, ON, CA, (3) London Regional Cancer Program, London, ON, CA, (4) Department of Oncology, Western University, London, ON, CA

Purpose: Brachytherapy (BT) is a form of radiation therapy, which relies on the insertion of needles to deliver radiation. Accurate needle tip identification is key for safe and effective BT, as errors can result in radiation delivery that deviates from the planned dose. Typically, standard brightness (B)-mode ultrasound (US) imaging is used for needle tip identification; however, artifacts can limit the visibility of needles. We propose a novel wireless mechanical oscillator for needle perturbation in a power Doppler (PD)-based needle tip identification method to overcome these limitations and improve needle tip identification accuracy in BT. **Methods:** Our wireless mechanical oscillator is capable of oscillating at a fixed and controllable frequency and amplitude, featuring a cylindrical end-piece designed specifically for use with BT needle mandrins. We evaluated our method using a tissue equivalent phantom with a standard clinical needle implant pattern and an implant pattern designed to maximize needle shadowing. Needle tips were identified with B-mode US alone, with B-mode and PD US together, and with PD US alone by reducing B-mode gain to 0, simulating the clinical case of non-visible needles. Performance was quantified using a tip error metric computed using the clinical standard of ideal reference needles. **Results:** Absolute mean $\pm$ standard deviation tip error was 0.33 ± 0.27 mm (B-mode), 0.39 ± 0.23 mm (B-mode+PD), and 0.77 ± 0.89 mm (BlindedPD) for the standard clinical needle implant and 0.80 ± 1.70 mm (B-mode), 0.34 ± 0.47 mm (B-mode+PD), and 0.43 ± 0.62 mm (BlindedPD) for the shadowed needle implant. **Conclusion:** Our PD US method provided equivalent tip identification accuracy for the standard clinical needle implant and superior accuracy for shadowed needles, including the ability to visualize needles that could not be seen using B-mode US alone due to shadowing. Our wireless oscillator is easy to use and requires no modification to the clinical workflow, providing promise for the clinical utility of our method in BT procedures.

WE-F-TRACK 3-03

A Novel End-To-End Deep Learning Based Beamformer for Flexible Array Ultrasound Transducer

X Huang*, M Lediju Bell, K Ding, Johns Hopkins University, Baltimore, MD

Purpose: The flexible array transducer is a promising tool for image-guided tumor tracking in radiotherapy. Comparing with the traditional ultrasound transducer, it is user-independent and can avoid contact pressure that may cause an anatomical change. However, due to its flexible geometry, the conventional delay-and-sum (DAS) beamformer may apply incorrect time delay to the radio-frequency (RF) data and produce B-mode images with low quality and considerable distortion. Here, we propose a novel end-to-end deep learning approach that may alternate the conventional DAS beamformer when the transducer geometry is unknown. **Methods:** Our deep neural networks (DNNs) are designed based on the popular U-Net, Pix2Pix GAN, and Cycle GAN structures. They are trained with Field II simulation and real scanning RF data from transducers with different geometries and the corresponding properly beamformed images. The DNNs are expected to learn the proper time delays for each channel and generate the undistorted high-quality B-mode images directly from RF data. They are then tested with RF data from a transducer with random unknown geometry, and the results are evaluated using full-width-at-half-maximum (FWHM), contrast-to-noise ratio (CNR), and aspect ratio of the round-shaped cyst. **Results:** We compare the DNN results to the standard DAS results using different data. For point targets, the average FWHM of DNN results is 2.1 mm lower than that of DAS results. For anechoic cyst targets, the DNN results improve the CNR by 0.79 dB and aspect ratio by 0.23. For abdominal phantom and in vivo scans, the DNN approach improves the CNR by 1.80 dB and 2.18 dB, respectively. The U-Net structure has the overall best performance. **Conclusion:** The evaluations show that when the transducer geometry is unknown, the proposed DNNs can effectively reduce the distortion and improve the lateral resolution and contrast of the B-mode images compare with the conventional DAS beamformer.

X-Ray Acoustic Computed Tomography of Linac Photon Beams: Medium Dependent Experiments

G Gonzalez^{1*}, S Wang², P Pandey², K Prather¹, J Caron¹, S Ahmad¹, L Xiang², Y Chen², (1) University of Oklahoma Health Sciences Center, Oklahoma City, OK (2) University of California, Irvine, CA

Purpose: The goal of radiotherapy is to deliver dose to the tumor while sparing organs at risk (OAR). Some cases can become challenging due to organ motion or breathing. X-ray induced acoustic tomography (XACT) offers an alternative for image guided radiotherapy (IGRT) without using additional imaging dose. This study compared XACT images from different medium. **Methods:** A low frequency single element transducer was used to acquire XACT signals on water and oil from a 4 cm square photon field. The transducer was fixed in front of the radiation field at an appropriate distance and depth of measurement. Beam delivery was performed using a Varian TrueBeam with 10X-FFF energy and 4 microsecond linac pulse to trigger acquisition. The XA signals passed through a shielded preamplifier, then collected in an oscilloscope with high averaging. Data collection was performed at every 6° collimator angle, for a total of 60 signals. MATLAB was used for signal processing and image reconstruction using simple backprojection. 2D images were obtained for the field in both water and oil medium. The frequency spectrum was compared for both medium and background signals. **Results:** The reconstructed square field was clearly visible in oil, while the image from water was considerably weaker presenting artifacts. Each signal contains rarefactions where the middle corresponds to the boundaries of the field. The signal intensity reached 1mVpp in water, while in oil it was 15mVpp. The frequency spectrum in oil presented larger response at lower frequencies, having at 50kHz a ratio of 11 to the water medium. **Conclusion:** This XACT system was able to reconstruct the image of the photon field. Signal strength is highly dependent on the acoustic properties and radiation absorption of the medium. Further analysis of frequency response could give insight on using dual mode ultrasound to improve image quality.

4D MR Reconstruction Based on Real-Time 3D Ultrasound for Image-Guided Radiotherapy

S Jupitz*, J Holmes, B Bednarz, University of Wisconsin, Madison, WI

Purpose: Utilizing a hands-free, MR-compatible 3D ultrasound transducer, we developed a method to bin multiphase 2D MR slices into MR volumes in time—effectively reconstructing a 4D MR dataset. The resulting dataset provides spatial and temporal information for image-guided radiotherapy applications. **Methods:** Simultaneous multiphase 2D sagittal MR slices and 3D ultrasound images of the liver were acquired from four healthy volunteers as well as end-exhale 3D MR images on a clinical 3T MRI. The imaging session was repeated for two volunteers. Liver vessels in ultrasound were tracked throughout the session. Ultrasound motion datapoints were temporally matched to 2D MR images. Deviations from the mean greater than 1.5 standard deviations were rejected as outliers. The remaining datapoints were sorted into 14 equidistant amplitude bins. Likewise, datapoints were sorted according to MR slice position. Thus, subsets of images were created for each amplitude-slice position bin pair. The image with the median position within each subset was selected to represent the group. Selected images were reorganized to create static MR volumes at each amplitude. This technique and resulting reconstructions were evaluated quantitatively and qualitatively. End-exhale 3D MR provided ground-truth for comparison to the binned 3D MR at end-exhale as measured in diaphragm position discrepancy. Difference maps were assessed for volunteers with two imaging sessions. **Results:** The average diaphragm position discrepancy was 2.14 ± 0.92 mm. Qualitative analysis showed reasonable out-of-plane diaphragm continuity. Difference maps demonstrated good agreement, especially for the liver. Ultrasound tracking revealed extreme baseline drift in one dataset. The change in breathing motion was effectively captured with this system indicating this workflow can determine whether an imaging session recorded consistent, representative respiratory signals. **Conclusion:** Simultaneous ultrasound was effectively used to reconstruct multiphase 2D MR images into 4D datasets. This technique could be applied to clinical datasets to assess target motion and deformation from respiration.

This work was supported by NIH grant R01CA190298 as well as the University of Wisconsin-Madison Graduate School Pandemic Affected Research Continuation Initiative (PARCI).

An Unsupervised Ultrasound Liver Motion Tracking Using Deep Convolutional Neural Network

Y Lei*, X Dai, S Momin, J Roper, E Schreibmann, P Patel, J Bradley, T Liu, X Yang, Emory University, Atlanta, GA

Purpose: The capability of providing video-rate volumetric images with zero ionizing radiation dose makes ultrasound (US) imaging suitable for intra-fraction motion tracking in radiotherapy. This study aims to develop a deep learning-based algorithm for liver motion tracking using US images. **Methods:** We propose an unsupervised deformable image registration network for US liver motion tracking. A Markov-like network is used to extract features from sequential US frames (one tracked frame is followed by untracked frames) to estimate a set of deformation vector fields (DVF) through the registration of the tracked frame and the untracked frames. This network is optimized in an unsupervised manner, namely, without the need for ground truth DVFs. The positions of the landmarks in the untracked frames are finally determined by transforming the landmarks in the tracked frame according to the estimated DVFs. The performance of the proposed method was evaluated on the testing dataset by calculating the tracking error between the predicted and ground truth landmarks on each frame. **Results:** The proposed method was assessed on the MICCAI CLUST 2015 dataset, which contains 63 2D and 22 3D US image sequences respectively from 42 and 18 subjects collected using 7 US scanners with 8 types of transducers. The experimental results show that our proposed method achieved a mean tracking error of 0.70 ± 0.38 mm on the 2D sequences and 1.71 ± 0.84 mm on the 3D sequences. **Conclusion:** We have proposed and investigated a new deep learning-based algorithm for liver motion tracking using US images and demonstrated its feasibility for real-time motion tracking. This imaging tool has strong potential for US-guided motion tracking during liver radiotherapy.

WE-F-TRACK 3-07

Motion Management in Abdomen with An Integrated Ultrasound and Abdominal Pressure Plate Device

W Li*, Y Huang, X Chen, Y Yang, University of Science and Technology of China, Hefei, Anhui, CN

Purpose: Radiotherapy to tumors in the abdomen is challenging because of the significant organ movement and deformation caused by respiration. We developed a motion management strategy using ultrasound (US) integrated with an abdominal compression plate (ACP), where the US was to monitor motion after the abdomen was compressed with the ACP. **Methods:** Twenty-one volunteers were immobilized using an in-house developed device that integrated an US probe with an ACP. For each subject, abdominal US data was successively collected with and without an ACP. Experiments were repeated three experiments to verify the reproducibility. A template matching algorithm based on normalized cross correlation was implemented for motion tracking. And the failure rates of the liver, pancreas and stomach tracking were analyzed. On the basis of the obtained organ locations in the US, linear correlation models between liver and pancreas/stomach were established to predict the motion of pancreas/stomach using liver as a surrogate. **Results:** The liver motion amplitudes for individual subjects with ACP compression were significantly reduced with ACP compression in both superior-inferior (SI) ($p < 0.0001$) and anterior-posterior (AP) ($p < 0.0001$) directions. The failure rates in liver, pancreas and stomach tracking were reduced from 1 %, 2.54% and 2.79 % to 0.03%, 0.73% and 1.07% after ACP compression respectively. The correlation coefficients between liver and pancreas/stomach were 0.98/0.97 without ACP and 0.96/0.94 with ACP in SI and were 0.68/0.68 and 0.43/0.42, respectively, in AP. **Conclusion:** While slightly reducing the linear correlation between organs, ACP effectively inhibits the abdominal motion and improves the reliability of organ tracking in US. The US and ACP combined device can work as an effective motion management strategy in abdominal radiotherapy.

J. Robar, Nova Scotia Health Authority: Personalized Brachytherapy with Integration of 3D Printing Technologies

Brachytherapy is undergoing a dramatic transformation. There are tremendous advancements and automation across imaging, applicators, treatment planning, and QA. The future of brachytherapy will likely be shaped by these emerging technologies and this symposia is to take an in-depth look at what is on its horizon. First, we'll review the application of deep learning (DL) in brachytherapy. Undoubtedly, DL based approaches has become an effective and handy tools in tackling some of the most time-consuming tasks. Specifically, its role in image processing/registration, applicator/needle digitization, organ segmentation, and plan evaluation and toxicity prediction will be looked at. Second, we'll review the rise of cleverly designed shielded applicators that enable intensity modulated brachytherapy (IMBT). IMBT utilizes high-density shields to provide at least one additional degree of freedom in the dose delivery process (e.g., directional beam) and can result in marked improvement in plan quality. Third, we'll review a number of recent advances that improves the brachytherapy treatment planning in different aspects. For example, improved solution algorithms for new treatment technologies (IMBT), catheter placement and total number of catheters to improve treatment plan quality, robust optimization to mitigate the effects from uncertainty, and machine learning to automate the parameter tuning in optimization models. Finally, we'll review the state of the art in 3D printing and clinical applications as this technology has progressed in an impressive pace in the last few years. There are vast range of materials and printers to consider, and at least, one commercial solution available. It is poised to revolutionize the field and hence is a timely topic.

Learning Objectives:

1. Review of Deep Learning, Automation in Brachytherapy, including QA
2. Review of Intensity Modulated Brachytherapy and Plan Optimization
3. Review of 3D Printing in Brachytherapy and QA

A Bilateral Neural Network for Loco-Regional Recurrence Prediction in Head and Neck Squamous Cell Cancer

L Chen*, K Wang, C Shen, D Sher, J Wang, UT Southwestern Medical Center, Dallas, TX

Purpose: Accurate estimation of the risk of loco-regional recurrence (LRR) for patients with head and neck squamous cell cancer (HNSCC) prior to treatment is essential to physicians for making personalized treatment management. In this work, we proposed a bilateral neural network to predict LRR through using pre-treatment CT, PET and clinical data. **Methods:** In the proposed scheme, there are two classification convolutional neural network (cCNN) modules: the first cCNN module (cCNN_1) uses region of interest (ROI) containing tumor and its surrounding tissues as input while the second cCNN module (cCNN_2) uses tumor itself as input. cCNN_1 pays attention on the information of the tumor position and tumor contrast compared to surrounding tissues, while cCNN_2 concerns more on the tumor inside and tumor boundary. The features learned by these two networks are complementary, which are then fused with clinical data for the final LRR prediction. Additionally, due to the highly-imbalanced characteristics of the dataset (with vs. without LRR), we proposed a new loss function termed as focal-dual loss which focuses more on the samples hard to classify and also tries to decrease the probabilities that a data point is assigned to an incorrect class to train the classification model. This study included the images and clinical variables of 316 patients with HNSCC received radiation treatment, among which 60 patients experienced LRR. Five folder cross validation was used to evaluate the performance of the proposed scheme. **Results:** The sensitivity, specificity, accuracy, and area under the receiver operating characteristic curve (AUC) values obtained by the proposed scheme were 0.77, 0.75, 0.75 and 0.80 respectively, outperforming conventional cCNNs only using ROI or tumor itself, and radiomics approaches. **Conclusion:** The proposed method combining clinical feature and CT & PET imaging features learned from two cCNN modules provides a more accurate way to predict HNSCC LRR.

An Automated Multi-Objective Model with Hyperparameter Optimization for Treatment Outcome Prediction in Metastatic Melanoma

Z Zhou¹, M Zhou², Z Wang³, X Chen^{2*}, (1) University of Central Missouri, Warrensburg, MISSOURI, (2) Xi'an Jiaotong University, Xi'an, Shaanxi, China, (3) Peking University Cancer Hospital & Institute, Beijing, CN

Purpose: Accurately predicting immunotherapy response is of great importance to improve treatment effectiveness in metastatic melanoma. We aim to develop a new automated multi-objective model with hyperparameter optimization (AutoMO-HO) for treatment outcome prediction. **Methods:** Totally 50 patients who exam contrast-enhanced computed tomography (CECT) are used in this study. The images with both pre- and one-cycle post-treatment are obtained for extracting delta-radiomic features by calculating the difference between pre-treatment and one-cycle post-treatment radiomic features. To obtain more discriminative and complementary features, one-cycle post-treatment radiomic features are combined with delta-radiomic features to predict treatment response. To obtain the balanced sensitivity and specificity as well as higher confidence output, an automated multi-objective model (AutoMO) is applied in this study. However, there are several hyperparameters to be set manually before training, leading to the non-optimal model performance. As such, Bayesian optimization is introduced to automatically find the optimal model hyperparameter, and a new model termed as AutoMO-HO is developed based on AutoMO in this study. In AutoMO-HO, the training stage consists of two phases, they are Bayesian hyperparameter optimization through the Tree Parzen estimator algorithm and Pareto-optimal model set generation. In testing stage, the evidential reasoning (ER) strategy is used to fuse the output of each Pareto-optimal model to obtain more reliable results. Finally, the label with the maximal output confidence is taken as final output label. Accuracy, AUC, sensitivity and specificity are used for evaluation. **Results:** In this study, five-fold cross validation is performed. Accuracy, AUC, sensitivity and specificity of AutoMO-HO can achieve 0.88, 0.91, 0.96 and 0.88, respectively, while AutoMO without hyperparameter optimization is 0.84, 0.87, 0.82 and 0.85. **Conclusion:** A new automated multi-objective model with Bayesian hyperparameter optimization (AutoMO-HO) for predicting immunotherapy response is developed in metastatic melanoma. The experimental results demonstrated that AutoMO-HO can obtain better performance than AutoMO.

Changes in Post-Treatment Cardiac PET Avidity Predict Overall Survival in Lung Cancer Patients Treated with Chemoradiation

T Santangelo^{1*}, F Forghani¹, C Rusthoven¹, R Castillo², E Castillo³, B Jones¹, T Guerrero³, Y Vinogradskiy¹, (1) University of Colorado, Denver, CO, (2) Emory University, Atlanta, GA, (3) Beaumont Health Research Institute, Houston, TX

Purpose: The relationship between thoracic radiation to the heart and overall survival (OS) has been recently demonstrated in non-small cell lung cancer (NSCLC) patients. Functional imaging, and in particular PET/CT, has been used to provide an early predictor for clinical outcomes. The purpose of this study was to use a

large, co-operative group clinical trial (ACRIN 6668) data-set to evaluate whether PET-CT changes in the heart are predictive of OS. **Methods:** We retrospectively evaluated data for 239 patients enrolled on the ACRIN 6668 study which evaluated the prognostic value of pre-treatment tumor PET-CT information for stage 2-3 NSCLC patients treated with chemo-radiation. 77 Eligible patients for the current analysis included patients for whom pre and post-treatment PET/CT data was acquired. The heart was contoured for each patient's PET-CT scan and the mean Standard Uptake Value (SUVmean) was calculated for each heart contour. The SUVmean cardiac change was calculated as post-treatment SUVmean minus pre-treatment SUVmean. The ability of cardiac SUVmean change to predict for OS was assessed using multivariable Cox modeling (controlling for cofactors of age and stage) and by comparing OS for patients with positive or negative cardiac SUVmean change. **Results:** The median OS was 469 days (range 144-1640 days). SUVmean cardiac change from pre to post-treatment was predictive of OS on multivariate analysis ($p=0.016$, Hazard ratio=0.81, 95% confidence interval=[0.68-0.96]). Median survival for patients with a negative SUVmean change (i.e. a post-treatment decrease in cardiac SUV) was 413 days while patients with a positive SUVmean change had a median OS of 585 days ($p<0.01$). **Conclusion:** The data demonstrates that cardiac SUV changes are significantly associated with OS in NSCLC patients. If validated in a prospective cohort, our data show the potential for cardiac metabolic changes to be an early predictor for clinical outcomes.

Measuring Radiation-Induced Changes in Perfusion with Dynamic Contrast-Enhanced 4DCT and Non-Contrast Lung Density Analysis in a Novel Swine Model

A Wuschner^{1*}, E Wallat¹, M Flakus¹, J Reinhardt², G Christensen², A Baschnagel¹, J Bayouth¹, (1) University of Wisconsin, Madison, WI, (2)Iowa City, IA

Purpose: To measure radiation-induced changes in perfusion using dynamic contrast-enhanced CT and correlate these changes to a non-contrast imaging biomarker in a novel swine population. **Methods:** Five Wisconsin Mini-Swine(WMSTM) received 60 Gy in 5 fractions following a clinical SBRT schedule using an MRI-guided LINAC. A dynamic contrast-enhanced 4DCT was taken prior to and 3 months post-RT. Vasculature was masked to enable the analysis of the non-vessel lung parenchyma and the vessels separately. All post-RT scans were deformably registered to the pre-RT scan using B-spline registration to allow voxel-wise comparisons. Analysis was performed in 10 Gy dose bins. Dose contours were copied onto the contralateral lung which received <5Gy for comparison. In each contour, measurements of the baseline HU measurement in the non-vessels and the max HU value of the vessels were obtained at pre and 3 months post-RT. **Results:** Statistically significant($p=0.001$) increases in the mean HU value in the non-vessel lung parenchyma were observed in the ipsilateral lung. The percent increases depended linearly with EQD2 dose ($R=0.989$). Additionally, statistically significant decreases ($p<0.05$) in the peak mean HU inside vessels were observed in each dose bin of the ipsilateral and contralateral lungs. The HU-increases outside the vessels strongly correlated ($R^2=0.85$) to HU-reductions inside the vessels suggesting radiation-induced vasculature leakage. The slope of the HU increase outside vessels vs. HU decrease inside vessels curve was -0.87. Additionally, there was an apparent threshold dose above which this leakage occurred of approximately 25Gy. **Conclusion:** This work suggests there is radiation-induced vessel leakage that occurs above a threshold dose of 25Gy. Additionally, this leakage can be predicted using a non-contrast biomarker (HU change outside vasculature). This presents the potential to develop non-contrast imaging bio-markers for radiation-induced change in perfusion to guide functional avoidance treatment planning.

Quantitative Radiomics Approach to Assess Acute Radiation Dermatitis in Breast Cancer Patients

S Park^{1*}, J Park², J Kim², C Choi², J Kim², (1) Department of Radiation Oncology, Veterans Health Service Medical Center, Seoul, Republic of Korea (2) Department of Radiation Oncology, Seoul National University Hospital, Seoul, Republic of Korea

Purpose: We applied a radiomics approach to skin surface images to objectively assess acute radiation dermatitis in patients undergoing radiotherapy for breast cancer. **Methods:** A prospective cohort study of 20 patients was conducted. Skin surface images in normal, polarised, and ultraviolet (UV) modes were acquired using a skin analysis device before starting radiotherapy ('before RT'), approximately 7 days after the first treatment ('RT D7'), on 'RT D14', and approximately 10 days after the radiotherapy ended ('after RT D10'). Eighteen types of radiomic feature ratios were calculated based on the values acquired 'before RT'. We measured skin doses in ipsilateral breasts using optically stimulated luminescent dosimeters on the first day of radiotherapy. Clinical evaluation of acute radiation dermatitis was performed using the Radiation Therapy Oncology Group scoring criteria on 'RT D14' and 'after RT D10'. Several statistical analysis methods were used in this study to test the performance of radiomic features as indicators of radiodermatitis evaluation. **Results:** As the skin was damaged by radiation, the energy for normal mode and sum variance for polarised and UV modes decreased significantly for ipsilateral breasts, whereas contralateral breasts exhibited a smaller decrease with statistical significance. The radiomic feature ratios at 'RT D7' had strong correlations to skin doses and those at 'RT D14' and 'after RT D10' with statistical significance. **Conclusion:** The energy for normal mode and sum variance for polarised and UV modes demonstrated the potential to evaluate and predict acute radiation, which assists in its appropriate management.

Quantum Reinforcement and Deep Learning for Decision Support in Response-Adapted Lung Cancer Radiotherapy

D Niraula^{1*}, J Jamaluddin², M Matuszak², R Ten Haken², I El Naqa¹, (1) Moffitt Cancer Center, Tampa, FL, (2) University of Michigan, Ann Arbor, MI

Purpose: To develop a robust decision support framework for personalized recommendations in response-adapted lung cancer Radiotherapy based on quantum computing and deep learning estimated tumor and normal tissue responses. **Methods:** Combined quantum reinforcement learning (QRL) and deep learning (DL) techniques were implemented for creating the proposed framework. DL models were used to create an Artificial Radiotherapy Environment, consisting of a transition function for governing the patients' state dynamics as a function of dose, and an RT outcome estimator of local control and grade 2 radiation induced pneumonitis for a given state. RT state features were selected from a multi-objective Bayesian network: IP10, GLSZM-ZSV, cxcrl-Rs2234671, Tumor-gEUD, and Lung-gEUD. Decisions were modeled as quantum states to reflect the associated uncertainty in treatment outcomes, and QRL was used for optimizing the decision-making process. Two new approaches were developed to improve the robustness of the framework: (1) a quantum controller circuit to evaluate the framework on a quantum processor and (2) a constrained DL approach to guide the RT outcome estimator learning of radiation response. We trained our framework on 67 non-small lung cancer patients treated with RT and then validated it on the independent data of 20 prospective patients. **Results:** The constrained DL modeling improved the learning of experimentally observed monotonic radiation response outcomes. The framework constructed with QRL and quantum controller using 5-qubit IBMQ quantum processor demonstrated improved performance over the ones trained in 3-qubit and 5-qubit quantum simulators. The RMSE values between the clinical dose decision and framework recommendations were 0.81 (0.78-0.84) Gy/frac, 0.93 (0.84-0.99) Gy/frac, and 0.86 (0.84-0.93) Gy/frac, respectively. The validation results showed reasonable performance in the institutional prospective dataset with an RMSE value of 0.96 (0.80-1.07) Gy/frac. **Conclusion:** This work demonstrates a robust QRL-DL framework for response-adapted lung cancer radiotherapy.

WE-F-TRACK 6-07

Computational Prediction of Symptomatic RP Based on Planning Computed Tomography Images Using Topologically Invariant Betti Numbers Prior to Stereotactic Body Radiation Therapy

K Ninomiya^{1*}, H Arimura¹, T Yoshitake², T Hirose², Y Shioyama³, (1) Kyushu University, Fukuoka, JP (2) Kyushu University Hospital, Fukuoka, JP (3) SAGA HIMAT Foundation, Saga, JP

Purpose: Stereotactic body radiation therapy (SBRT) is commonly administrated for inoperable patients with early stage non-small-cell lung cancer. However, some patients, whose lung tissue is vulnerable to radiation, could experience radiation induced pneumonitis (RP). Therefore, we have developed a symptomatic RP prediction model by characterizing the vulnerability of lung regions based on planning computed tomography (pCT) images using topologically invariant Betti numbers (BNs) prior to SBRT. **Methods:** Two-hundred sixty-six patients who underwent SBRT were selected for this study. A total of 236 (20 with $\geq$ grade 2 symptomatic RP) and 30 cases (8 with $\geq$ grade 2 symptomatic RP) were used for training and independent test of the RP prediction models, respectively. A lung region on an axial plane of the pCT image, which included a centroid of a gross tumor volume, was analyzed for characterizing the vulnerability of lung regions. A total of 47,616 image features were obtained from 512 BN maps that may represent topologically invariant heterogeneous characteristics of lung cancer by applying histogram- and texture-based feature calculations. A BN-based signature was constructed using the least absolute shrinkage and selection operator logistic regression model. Support vector machine (SVM) models were utilized to build the RP prediction model using the BN-based signature in a leave-one-out cross validation. The performance of the BN-based model was compared to the SVM model trained with the conventional signature consisting of original pCT image features (pCT-based model) regarding a robustness index (RI) which defined higher total and lower difference of area under receiver operating characteristics curves (AUCs) in the validation and test. **Results:** The RIs for BN- and pCT-based models were 1.544 (AUC in the validation: 0.800, test: 0.778) and 1.191 (AUC in the validation: 0.750, test: 0.608), respectively. **Conclusion:** The BN-based model could be feasible for prediction of symptomatic RP prior to SBRT.

A Hybrid Method for Prostate Segmentation in Transrectal Ultrasound Based on Redefined Closed K-Segment Principal Curve and Improved Differential Evolution-Based Artificial Neural Network

T Peng^{1*}, J Zhao², J Cai³, (1) The Hong Kong Polytechnic university, Hong Kong, HK, (2) Tsinghua University Affiliated Beijing Tsinghua Changgung Hospital, Beijing, China (3) Hong Kong Polytechnic University, Hong Kong

Purpose: Transrectal ultrasound (TRUS) is routinely used in ultrasound-guided brachytherapy of prostate cancer for treatment planning and verification. Manual delineation of the prostate volume is tedious, time-consuming, and subjective. The purpose of this work is to develop a prostate segmentation hybrid method using an improved redefined closed k-segment principal curve and improved differential evolution-based artificial neural network. **Methods:** TRUS scans of 55 brachytherapy patients obtained from the Vinno 70 Lab system were analyzed. We developed a novel method for TRUS prostate segmentation, using only a small number ($< 15\%$) of manually delineated points as the approximate initialization. This method contains three subnetworks: the first one uses an improved principal curve-based method to obtain the data sequences consisting of data points and projection indexes; the second one is using improved Memory-based and Cuckoo Search-based Differential Evolution (MCSDE) method for preliminarily searching for the optimal model of the machine learning method; lastly, we proposed a smooth mathematical model of prostate contour, which was denoted by the parameters of machine learning method. **Results:** Preliminary results show that the average Dice Similarity Coefficient (DSC), Jaccard Similarity Coefficient (Ω), and Accuracy (ACC) is 95.8%, 94.3%, and 95.4% on the testing dataset (15 patients). Meanwhile, the DSC, Ω , and ACC of the proposed method are as high as 93.3%, 91.9%, and 93%, respectively, at the influence of Gaussian noise (standard deviation of Gaussian function $\sigma=50$). Although σ increases from 10 to 50, the DSC, Ω , and ACC fluctuate about 2.5% at most, demonstrating the good robustness of our method. Compared with the competing models, our method has the best performance. **Conclusion:** Both qualitative and quantitative experimental results demonstrate that our hybrid method of prostate segmentation achieved superior performance compared with several state-of-the-art methods. Meanwhile, our method has good robustness to deal with the noise data effectively.

Automatic Spatial Registration System for Whole-Breast Three-Dimensional Ultrasound

C Park^{1,2*}, S Papernick^{1,2}, N Orlando^{1,2}, M Jonnalagadda¹, J Bax², L Gardi², K Barker², D Tessier², A Fenster^{1,2}, (1) Western University, London, ON, Canada (2) Roberts Research Institute, London, ON, CA

Purpose: Mammography remains the standard in breast cancer screening, but challenges still exist in the 40-50% of women with radiographically dense breasts. Automated breast ultrasound (US) has enabled whole-breast imaging, improving reproducibility and reducing operator-dependence when compared to handheld US. However, these systems still require extensive user training and are costly. We propose an alternative spatially tracked system for automatic registration of three-dimensional (3D) US volumes for whole-breast imaging. This paper describes the system development and feasibility for accurate whole-breast 3DUS image reconstruction. **Methods:** The system is composed of an in-house 3DUS imaging subsystem, which can be adapted to any US transducer, and clinician-operated multi-jointed arm and counterbalanced stabilizer, which enables motion in six degrees-of-freedom. The system contains electromagnetic encoders in each of the six joints, which were integrated with custom software modules to track the 3D spatial coordinates of the 3DUS scanner and its image. Tracking accuracy was assessed for each joint independently by comparing the spatially-tracked position of a custom stylus to its optically-tracked position. Automatic spatial registration and 3DUS fusion was tested using string and breast phantoms. **Results:** The mean absolute tracking error (SD) was 0.87 ± 0.52 mm, 0.70 ± 0.46 mm, 0.53 ± 0.48 mm, 0.34 ± 0.32 mm, 0.43 ± 0.28 mm, and 0.78 ± 0.54 mm for joints 1-6 respectively. Quadratic-based lookup table corrections optimized the spatial tracking accuracy in translational joints 1-2 and rotational roll-joint. Compound motions utilizing all joints resulted in an absolute error of 1.08 ± 0.88 mm ($N=20$) within the intended clinical workspace for breast imaging. 3DUS images of the string and breast phantoms with simulated lesions demonstrated the utility for automatic registration and fusion of multiple 3DUS images using their spatially tracked positions. **Conclusion:** We demonstrated an accurate spatially tracked system for whole-breast 3DUS imaging. The system

shows potential as an alternative, cost-effective US-based approach with the capability for whole-breast imaging in women with radiographically dense breasts.

Enhancement of Gene Therapy with MR-Guided Focused Ultrasound for Prostate Cancer

L Chen^{1*}, X Chen², D Cvetkovic³, C Ma⁴, (1) Fox Chase Cancer Center, Philadelphia, PA

Purpose: The purpose of this study was to investigate the effect of MR guided focused ultrasound (MRgFU) and AS-MDM treatment on investigate the inhibition of in vivo LNCaP tumor growth. **Methods:** LNCaP-orthotopic prostate tumor-bearing nude mice were divided into 3 groups (n=7/per group): group 1, MRgFU + AS-MDM2; group 2, AS-MDM2 only; and group 3, sham MRgFU. For group 1, tumors were allowed to grow to the size of 60 mm³ as determined by MRI and then treated with MRgFU for 6 treatments over three weeks (2 treatments per week). Each treatment was followed by an i.p. injection of AS-MDM (25 mg/kg) immediately after the MRgFU treatment. For group 2, only AS-MDM2 (25 mg/kg) was administered for 6 treatments (2 treatments per week). Group 3 received sham MRgFU treatment. Tumor growth was determined by measuring the tumor volume using weekly MRI. Mice were sacrificed when tumor reached about 600 mm³ or 7 weeks after treatment whichever occurred first. **Results:** Due to the limitation of the small animal model (25 g weight) 6 times of general anesthesia performed over three weeks caused high mortality (about 50%). Based on the 10 surviving animals that completed the treatment there were insignificant differences in tumor growth delay between the MRgFU+AS-MDM2 group and the AS-MDM2 only group. **Conclusion:** Possible reasons for the insignificant results of this study include (1) large variations in tumor growth due to limited number of mice, (2) insufficient tumor penetration of AS-MDM to enhance tumor growth inhibition, and (3) suboptimal conditions for AS-MDM2 as the greatest effect of AS-MDM2 was observed with androgen deprivation and/or RT. Further experiments are warranted to test MRgFU+AS-MDM2 under these other conditions.

WE-lePD-TRACK 1-04

Feasibility of An Automated Quality Assurance Tool for Ultrasound Shear Wave Elastography Images

D Gomez-Cardona^{1*}, SF Stekel², DJ Tradup², NJ Hangiandreou², Z Long², (1) Gundersen Health System, WI;(2) Mayo Clinic, Rochester, MN

Purpose: Ultrasound shear wave elastography (SWE) can estimate tissue Young's modulus in selected regions of interest (ROI). It relies on careful acquisition and measurement by the operator. This study aims to develop an automated quality assurance (QA) tool for clinical liver SWE images on GE LOGIQ E9 scanners, which do not have an onboard quality indicator. **Methods:** Settings on LOGIQ E9 scanners which could affect SWE quality and quantitative measurement were investigated. A suite of custom MATLAB programs was built to check these settings and institutional protocol details, which were designed to increase the frame rate on this scanner model and minimize motion artifacts as reported before, from liver SWE DICOM images. Specifically, settings such as transducer model (C1-6D), acquisition parameters such as elastography gain, width of the SWE acquisition box, distance between the liver capsule and the SWE acquisition box, push and track beam output, percentage of color filling of the acquisition box, and diameter of the measurement ROI. The distance from rib shadowing artifact, if any, to the SWE box at transducer face level was also checked. Color-coded QA outputs were overlaid on the original SWE images off the scanners. Suggestions for optimization strategies were provided when certain conditions were met. **Results:** The QA tool has been established and retrospectively processed 1455 images acquired since 2018 by clinical sonographers. 1.1% of all parameters and settings was incorrect or could have been improved. The default elastography gain was found to be modified in 36 earlier images. This gain relates to cross correlation threshold for selecting pixels to be included in the quantitative measurement and therefore should be unchanged. **Conclusion:** Feasibility of an automated QA tool for liver SWE images that could provide users near real-time QA results and feedback was demonstrated. Artifact recognition will be included in the future.

MR to Ultrasound Image Registration with Segmentation-Based Learning for HDR Prostate Brachytherapy

Y Chen*, L Xing, L Yu, W Liu, B Fahimian, T Niedermayr, H Bagshaw, M Buyyounouski, B Han, Stanford University, Palo Alto, CA

Purpose: To aid the organ contouring in high dose rate (HDR) prostate brachytherapy, a deep learning approach was first developed for automatic registration of magnetic resonance (MR) images to treatment planning ultrasound (US) images with severe needle artifacts. **Methods:** A new segmentation-based registration framework was proposed for this multi-modality image registration based on a weakly-supervised strategy, to address the problem of lacking training labels and difficulty of accurate registration from inferior image quality. Specifically, two prostate segmentation networks were trained to generate the weak supervision labels from the MR and US images automatically for the registration network training. To improve the registration accuracy, not only the image pair, but also the corresponding prostate probability maps from the segmentation were further fed to the registration network to predict the deformation matrix. A random augmentation method was designed to alleviate the map overfitting problem during the network training. MR data from 184 patient cases and US data from 167 cases were collected from our institution for the MR and US image segmentation networks, and the registration network learning. **Results:** The mean DSC, center-of-mass (COM) distance, Hausdorff distance (HD) and averaged symmetric surface distance (ASSD) results for the registration of prostate contours were 0.87±0.05, 1.70±0.89 mm, 7.21±2.07 mm, 1.61±0.64 mm, respectively. By providing the prostate probability map from the segmentation to the registration network, as well as applying the map augmentation method, the evaluation results of the four metrics were all improved, such as an increase of DSC from 0.83±0.08 to 0.86±0.06 and from 0.86±0.06 to 0.87±0.05, respectively. **Conclusion:** A novel segmentation-based registration framework was proposed to automatically register prostate MR images to treatment planning US images. It is potential to be applied in current HDR brachytherapy procedures to improve the treatment efficiency and quality.

This research was supported by a grant from Varian Medical Systems (Palo Alto, CA).

Quantitative Dimension Estimation and Clinical Utility of Three-Dimensional Ultrasound in Oral Cavity Tumors

C Park^{1,2*}, J Wihlidal^{3,4}, A Mendez^{3,4}, A Fenster^{1,2}, (1) Western University, London, ON, CA, (2) Robarts Research Institute, London, ON, CA, (3) Schulich School of Medicine and Dentistry, Western University, London, ON, CA (3) London Health Sciences Centre, London, ON, CA

Purpose: Oral squamous cell carcinoma (OSCC) is the most common oral malignancy, representing approximately 90% of all oral cavity cancers. In consideration of the complexity of the oral cavity, imaging is integral to the classification of the primary tumor and disease extent. We propose the use of three-dimensional ultrasound (3DUS) as a point-of-care imaging modality for bedside oral cancer identification and tumor volume quantification. This work presents the clinical utility of 3DUS in a clinical case study of OSCC compared to healthy control. **Methods:** We developed a motorized handheld 3DUS device housing custom-printed 14L5 (10MHz) and 11L3 (7MHz) linear transducer-holders. Trans-submandibular 3DUS acquisition protocol involved 5.0cm linear translation at 4.0cm depth-of-field by a trained observer. 3DUS images of the patient and healthy control were acquired and anatomical structures were identified. In the pathological case, the maximum tumor dimensions in anteroposterior (AP) and craniocaudal (CC) planes and depth-of-invasion (DOI) were calculated and compared with preoperative CT and MRI measurements by quantifying the error in tumor volume estimation. **Results:** Bilateral visualization was attained of the oral floor anatomy with 10 MHz and 7 MHz transducers in both healthy and pathological cases. Preoperative CT and MRI images indicated tumor dimensions: 1.60x1.12mm (AP/CC) and 0.44cm DOI, and

1.45x1.90 cm (AP/CC) and 0.66cm DOI. 3DUS with the 10MHz transducer allowed for the approximation of tumor measurements at 1.44x1.37cm (AP/CC) with a 0.49cm DOI. The error in dimension estimation was 6%, 9%, and 11% for AP, CC, and DOI between the 3DUS and mean preoperative dimensions between CT and MRI images. **Conclusion:** We demonstrated clinical utility of 3DUS in OSCC in the oral floor. 3DUS acquisition enabled the complete visualization of the oral cavity anatomy, which supplants the demand for preoperative bedside imaging of the primary site and tumor dimension estimation.

Imaging: Dose and Image Quality in CT and X-ray Imaging

WE-lePD-TRACK 2-01

Evaluation of the Feasibility of Universal Daily CT QC Protocols and Limits Across Different Manufacturers and Models

T Lin*, K Hamacher, Columbia University Irving Medical Center, New York, NY

Purpose: NYC requires daily CT QC to follow the requirements of the facility's accreditation body while NYS requires water CT #, noise, and uniformity to be performed using a common technique setting. With the goal to meet regulatory requirements, almost identical daily QC protocols were set up on all CT scanners at our institution. Initial limits were established by the QMP based on available data and ACR recommendations. This study retrospectively evaluates the feasibility of the approach and appropriateness of these limits. **Methods:** Manufacturers' CT phantoms were scanned axially and helically on 13 CT scanners (GE, Philips, Siemens, Toshiba). Center CT #, noise, and uniformity were recorded for both scan modes. According to the ACR, center CT # of water should be 0 ± 3 HU and must be 0 ± 5 HU; uniformity should be 0 ± 5 HU and must be 0 ± 7 HU, whereas limits for noise should be locally established by the QMP. Based on review of past daily CT QC, our institution established a universal limit of 0 ± 5 HU for center CT # and uniformity and 7HU for noise. **Results:** Center CT #, noise, and uniformity were analyzed for a median of 245 (183 – 360) days for each unit and mode. For all scanners and modes, the average values were -0.11 ± 1.02 HU, 1.02 ± 0.72 HU, and 4.56 ± 0.78 HU for center CT #, uniformity, and noise, respectively. Excluding the axial uniformity of the Philips unit, the difference between average and limit exceeded at least three standard deviations regardless of manufacturer, model, or scan mode. **Conclusion:** Universal daily CT QC is feasible on multiple makes and models. As part of quality improvement, decreasing the limits to 0 ± 3 HU for both center CT # and uniformity (excluding the Philips unit), and 6.5 for noise, is possible.

Local Diagnostic Reference Levels and Size-Specific Patient Dose in Computed Tomography at a Greek Hospital

D Stasinou^{1*}, V Zoiopoulou¹, J Antonakos¹, S Argentos², E Efstathopoulos¹, (1) Medical Physics Unit, 2nd Department of Radiology, National and Kapodistrian University of Athens, Greece (2) Computed Tomography Unit, "Attikon" University Hospital, Athens, Greece

Purpose: Diagnostic Reference Levels (DRLs) are a useful tool for patient dose optimization, however, they do not consider patient size as the concept of the size-specific dose estimate (SSDE) introduced by AAPM. The aim of this study is to extract local DRLs for computed tomography (CT) exams at a Greek University Hospital in terms of volumetric CT Dose Index (CTDIvol) and dose-length product (DLP), as well as to evaluate the impact of patient size in patients' dose through SSDE. **Methods:** The retrospective data from a total of 164 CT studies of Abdomen-Pelvis (A-P), Brain, Chest-Abdomen-Pelvis (C-A-P), Pulmonary Angiography (CTPA) and Heart were extracted from a 16-slice and a 64-slice CT scanner and were utilized to extract DLP and CTDI values. This study estimated the effective dose (ED) from DLP measurements using the appropriate k-factors. SSDE was calculated from the product of CTDIvol with the appropriate conversion factor, based on the sum of the lateral and anteroposterior diameters. Results are compared with international DRL data. **Results:** Compared to national DRLs, the local DRLs regarding the CTDIvol values were lower by 14% for Abdomen-Pelvis, 43% for Brain and 25% for Chest-Abdomen-Pelvis exams. For CTPA and heart exams national DRLs were not suggested. In comparison to international DRLs, the picture of our results is mixed, having both higher and lower DRLs than other countries. However, for the CTPA exams, the local DRLs were higher by a range of 13%-30%. SSDE mean values were higher than CTDIvol mean values by a range of 19%-24%, nonetheless for the brain exams their mean values were the same. **Conclusion:** The metrics of CTDIvol, DLP and ED were useful to evaluate our institution's radiology practice regarding the radiation exposure. Since SSDE is a more accurate patient dose indicator, it would be advantageous to be established as a DRL.

WE-lePD-TRACK 2-03

Local Noise and Size of Region of Interest in CT Images

G Li^{1*}, Y Liang², (1) University of Maryland, Baltimore, Baltimore, MD, (2)

Purpose: This study aims to investigate the correlation between the automated local image noise estimates with the manual noise estimates and effects of the size of region of interest (ROI) on the correlation. **Methods:** 76 clinical non-enhanced axial abdominal scans are randomly selected among the exams performed using the same protocol on the same scanner in the same quarter. One slice of each of 76 scans locating middle liver is used for comparison. For manual method, the standard deviation (SD) Hounsfield Unit (HU) within a 35-pixel radius circular ROI placed in a relatively uniformed area in the liver in ImageJ is used as the noise estimation. For local noise analysis, the SD HU of the $n \times n$ ROI ($n=3, 7, \dots, 67$) centering each body pixel is used as the noise estimate around that center pixel (Fig. 1). The local noise of each and every body pixel is calculated. This approach is automated in Matlab. The noise of the automated method is then compared with that of the manual method using linear regression approach. **Results:** The lower 25-percentile noise of all body pixel in general represents more uniform area shown in (Fig 2). Although the noises of the manual and automated method are well correlated, the slope and variance of residuals (Fig 3) increase with the square ROI size, suggesting that selecting the same smaller ROI for noise comparison across patients and scanners is required. **Conclusion:** The noise in clinic images estimated by a manual ROI is linearly correlated with the mean of lower 25 percentile of local noise obtained by an automatic method and a fixed small ROI is critical for intra- and inter-patient and scanner noise performance comparisons.

WE-lePD-TRACK 2-04

Global Noise Analysis of Single and Dual Source CT for Obese Patients

MA Thomas*, M Ahmad, MC Jacobsen, N Wagner-Bartak, C Jensen, RR Layman, UT MD Anderson Cancer Center, Houston, TX

Purpose: CT imaging of obese patients is limited by tradeoffs between image quality and radiation output (dose). For demanding clinical situations like abdominal imaging, sacrificing image quality may be required due to scanner output limits. In this study, we compared acquisition parameters and global noise (GN) between a standard, single-source (SS) CT protocol and a new dual-source (DS) protocol with enhanced radiation output capacity. **Methods:** A total of 97 matched SS and DS scans from 49 patients were compared. Matched pairs were included if the tube voltage, reconstruction kernel, and scanner platform were consistent between scans from each protocol, and changes in patient weight and water equivalent diameter were $<5\%$. GN was determined with a previously reported algorithm and its uncertainty within each protocol was established at the 95% prediction interval (PI, $\pm 1.96\sigma$). Prediction models were developed to estimate GN based on protocol type, CTDIvol, reconstruction kernel, and patient size parameters. **Results:** The median $\pm 1\sigma$ increase in CTDIvol for DS scans from the matched pairs was $52 \pm 32\%$

(21±11 mGy). The 95% PI for the uncertainty in GN was ±1.1 HU. GN in DS scans was reduced by more than 1.1 HU in 87% of matched pairs (Δ GN median±1 σ : -2.5±1.7 HU). The prediction models could estimate GN with RMS error of 0.9 and 0.6 HU, respectively, for SS and DS scans. Model predictions for three example patient sizes showed that DS scans provide the same GN at a lower dose under nearly all achievable scanning conditions when compared to SS scans. **Conclusion:** A DS protocol for obese patient CT imaging provides enhanced dose capabilities and reduces noise relative to our standard SS protocol which is limited in radiation output. The noise reduction benefits of the DS protocol improve with increasing patient size.

WE-lePD-TRACK 2-05

Deep Learning Vs. Iterative Reconstruction in CT Dose Reduction and Image Texture Preservation: A Live Animal Study

J Zhang¹, F Raslau², H Ganesh³, E Escott⁴, J Zhang^{5*}, (1) Math Science Technology Center (mstc), Paul Laurence Dunbar High School, (2) University of Kentucky, Lexington, KY, (3) University of Kentucky, (4) (5) University of Kentucky, Lexington, KY

Purpose: This study is to investigate the potential of deep learning (DL) in CT dose reduction while preserving image texture when compared to iterative reconstruction (IR) alone. **Methods:** The upper abdomen of a live 4-year-old sheep was scanned under anesthesia on a Siemens Force CT scanner at different exposures (120 kV, mA from 25 to 250). Images were reconstructed using both Filtered Back Projection (FBP) and Advanced Modeled Iterative Reconstruction (ADMIRE) at each exposure with various strengths (1-5). A recently-developed modularized deep neural network (MAP-NN) with 5 modules was used for CT imaging at each exposure level via progressive denoising. Region of Interest (ROI) were manually delineated over the liver for all image sets. Radiomic features were retrospectively extracted from the ROI with IBEX. The concordance correlation coefficient (CCC) was applied to quantify the agreement between any two sets of radiomic features. The structural similarity index measure (SSIM) was used to measure the similarity between any two images. **Results:** A total of 113 features are extracted. For FBP, the CCC shows consistent decrease with lower exposure. Both IR and DL have the potential to increase CCC of radiomic features with desired features (e.g., features at standard exposure with FBP), depending on DL/IR strength. DL has higher potential than IR to improve radiomic features at extremely lower exposure level. The relationship between exposure and IR/DL strength for dose reduction while preserving image quality is nonlinear. SSIM decreases with progressive increases of DL or IR strength. DL has higher potential than IR to preserve image structure at higher strength, independent of exposure. **Conclusion:** Using a multi-exposure experiment in a live animal model, deep learning shows better potential than iterative reconstruction to further reduce radiation dose while preserving structural similarity and feature correlation.

WE-lePD-TRACK 2-06

Radiation Dose Estimation for Small Animal Pencil Beam X-Ray Luminescence Computed Tomography Imaging

IO Romero, C Li*, University of California, Merced, Merced, CA

Purpose: X-ray luminescence computed tomography (XLCT) is an emerging x-ray molecular imaging modality. Pencil beam XLCT imaging provides superior spatial resolution than other imaging geometries like sheet beam and cone beam geometries. However, the pencil beam XLCT suffers from long scan times resulting in concerns over dose, which discourages the use of pencil beam x-ray sources in XLCT imaging. **Methods:** To investigate the dose deposited by pencil beam x-ray in XLCT imaging, we used the Monte Carlo simulation platform, GATE (Geant4 Application for Tomographic Emission) to estimate the dose of one angular projection scan with three different x-ray sources. Furthermore, to investigate the dose deposited in a typical small animal XLCT imaging scan, dose estimations from six angular projections by the three different x-ray source energies were performed on a mouse trunk model composed of muscle, spine bone, and a tumor. **Results:** With the Sigray source from Sigray Inc, the bone marrow in the mouse leg model was estimated to have a radiation dose of 43 mGy for typical XLCT imaging with six angular projections, 100 micrometer scan step size, and 106 x-ray photons per linear scan. The spine bone, muscle tissues, and tumor structures of the mouse trunk model received a radiation dose of 38.49 mGy, 15.07 mGy, and 16.87 mGy respectively after six angular projections with 100 micrometer scan step size, and 106 x-ray photons per linear scan. **Conclusion:** A typical pencil beam based XLCT imaging has an acceptable dose deposited in small animals when six projections of measurements are used.

WE-lePD-TRACK 2-07

Assessing the Viability of Establishing Patient Dose Tables in Pediatric Radiography by Mining Quality Control Data

D Beaulieu*, D Kim, D Zhang, Boston Children's Hospital, Boston, MA

Purpose: To determine the feasibility of establishing patient radiation dose look-up tables for pediatric X-ray exams by assessing the consistency of performance of 24 radiography X-ray tubes over a period of 5 years. **Methods:** Annual quality control testing records were collected over a period of 5 years between 2016 and 2020 for 24 Philips X-ray rooms. The data includes information about each tube's measured kVp, output/dose, and beam quality (HVL in mm Al). Measurements were taken using either a Raysafe X2 or RTI Piranha solid-state detector under narrow-beam in-air conditions at a source-to-detector distance of 58.5 cm. **Results:** The mean measured kVp had an average error of 0.52% over 5 years ranging from -3.8% to 2.48% deviation from the nominal. The mean kVp had an average percent standard deviation of 0.77% between machines over the same time period, where the largest percent standard deviation was 1.25% at 50 kVp in 2016 and 2018. The measured HVL averaged over 5 years was 2.38 mm Al at 60 kVp and 3.11 mm Al at 80 kVp with average percent standard deviations of 2.82% and 2.52% respectively. The maximum percent standard deviation was 3.32% at 60 kVp and occurred in 2016. The measured tube output in mR/mAs had an average percent standard deviation of 6.44% with a maximum deviation of 8.23% at 50 kVp in 2019. The mean standard deviation in average mR/mAs year-to-year was 1.18% with the maximum of 1.25% occurring at 50 kVp. Example look-up tables for pediatric chest and abdomen exams were generated based on average equipment performance data from the previous 5 years. **Conclusion:** Machine performance was found to be consistent between machines as well as year-to-year, suggesting that the creation of exam dose look-up tables is feasible.

Multi-Disciplinary: Novel and Emerging Imaging Technologies in Radiation Therapy

WE-lePD-TRACK 3-01

An AI-Based Watchdog Application to Screen Out COVID-19 Patients in Radiation Therapy

J Tan*, D Nguyen, J Wu, P Iyengar, F Kay, Y Yan, S Jiang, UT Southwestern Medical Center, Dallas, TX

Purpose: To mitigate the risk of spreading COVID-19, it is crucial to detect people with the disease as early as possible. As Artificial intelligence (AI) assisted film reading technology is being increasingly adopted in radiology clinics, we developed a fully automated AI-based system to specifically screen out COVID-19 patients using routine CT simulation images. The tool will report the probability of a patient having contracted COVID-19. Particularly, it is not a diagnostic tool. **Methods:** The tool, which we call it AI-watchdog, consists of four components: monitoring of new CT simulation, prescreening of CT for the presence of lungs, detection of COVID-19 traits on CT images, and notification of positive patients to care team. As soon as a CT scan is found to be completed, it is copied to the AI-watchdog server. If lung is found on a CT scan, the AI component predicts the probability of COVID-19. The prediction is implemented using deep learning model convolutional neural network (CNN). It was trained and tested on three external datasets, and one internal dataset. To test generalizability, the model was tested on a cancer patient,

who had scans both before and after contraction of COVID-19. **Results:** The CT monitoring detects and make copies of new CT scans at a frequency of every 10 seconds. There is no discernable effect on the current clinic workflow. The prescreening takes 2 seconds. The prediction takes about 35 seconds, with accuracy of 96.7% and false positive 4.4%. The notification to care team includes 3 probabilities for COVID-19, common pneumonia, and normal. The model correctly identified all of the cancer patient scans. **Conclusion:** An AI-based watchdog application offers extra layer of barrier to prevent spreading of COVID-19 in clinics of radiation therapy. It has proven to be effective and practical.

WE-lePD-TRACK 3-02

Cherenkov Imaging of TSE Patients Using Cameras from Multiple Angles

T Zhu*¹, Y Ong¹, W Zhong¹, H Sun¹, P Bruza², T Miao³, A Dimofte¹, A Maity¹, J Plastaras¹, I Payder¹, L Dong¹, B Pogue², 1Radiation Oncology, University of Pennsylvania, Philadelphia, PA; 2Thayer School of Engineering, Dartmouth College, Hanover, NH 3 Radiology, Yale University, New Haven, CT

Purpose: Cherenkov signals generated in patients treated with TSET can be recorded in-real time to monitor the dose distribution on patient body surface during the treatment. However, the front facing camera alone cannot predict dose accurately near periphery areas (e.g. Vertex) of the patient due to large angle emission of Cherenkov light. **Methods:** The TSE patients were treated in Stanford technique at 500 cm source to patient midplane distance using dual-field 6-MeV electron beams at gantry angles 74° and 106° at 6 postures with HDTSE mode delivered by Varian Truebeam. Three ceiling mount time-gated intensified cameras were used to capture the Cherenkov signal generated from patient's skin surface. Scintillator luminescent detectors (SLD) and optically stimulated luminescent dosimeters (OSLDs) were taped to patient's chest, umbilicus, and side to record and verify the dose delivered to those locations. Prospective (geometrical) calibration was performed in 2-dimensions to correct the camera vignetting effect, lens correction and different pixel response. Dose was reconstructed from the Cherenkov imaging by normalizing intensity to the OSLD measurements at the same location. **Results:** Perspective calibration was studied in 2D for Cherenkov imaging for all cameras and applied to acquired patient data. The corrected Cherenkov intensity can be converted to dose by normalizing to OSLD or SLD measurements at one location. Using additional Cherenkov cameras improved agreement in vertex from 40-50% low to within 5% for most of the patients compared to the in vivo dose measurements. **Conclusion:** Cherenkov imaging provides valuable information about the dose distribution for TSET. Geometrical correction was established in 2D for Cherenkov imaging and dose distribution can be reconstructed from the Cherenkov imaging.

WE-lePD-TRACK 3-03

Developing Internal Liver Vascular Models for Radiation Therapy Assessment of Dose to Circulating Lymphocytes

C Correa Alfonso^{1*}, J Withrow¹, S Domal¹, C Grassberger^{2,3}, S Xing^{2,3}, J Shin^{2,3}, H Paganetti^{2,3}, W Bolch¹ (1) University of Florida, Gainesville, Florida, (2) Massachusetts General Hospital, Boston, MA, (3) Harvard Medical School, Boston, MA

Purpose: Lymphopenia is a side effect of radiation therapy that correlates with treatment outcome. The purpose of this work was the development of a model of the internal vasculature of the liver for the adult female and male (AF/AM) in order to calculate dose to the blood. Computational phantoms currently have no intra-organ vasculature that allows the calculation of dosimetric quantities in the blood. **Methods:** Computer models of arterial, portal and hepatic vein trees were generated from optimization and physical principles using the Constrained-Constructive-Optimization (CCO) method. As liver has independent vasculature for each of the eight segments (following the Couinaud classification), AF/AM reference livers were divided into segments by matching the percentage of total liver volume to reported values of human liver. Next, the vessel generation algorithm was utilized to create independent vascular trees for all inflows (arterial and portal) and outflow (hepatic veins). Hemodynamic and geometric parameters of the main vessels were used as inputs. During the algorithm, pressure, blood flow, and radius of vessels in the tree are updated each time a new vessel is created and connected to the optimal bifurcation site. **Results:** A closed vascular tree of approximately 6000 straight cylindrical non-intersecting pipes representing the hepatic artery, portal and hepatic veins was created independently for the AF/AM reference liver. While a straightforward comparison is difficult because of the variation in vascular structures, the morphology of our models shows similar trends to those observed in actual human liver vasculature. **Conclusion:** We have developed computational models of human liver vasculature by implementing a vessel generation algorithm that creates binary trees representing realistic liver vasculature. Although the present model does not include the precapillary and capillary vasculature, or blood sinusoids, our model will be a useful tool to perform more realistic dose-calculations to circulating blood cells during radiation therapy.

This research is supported by NCI Grant R01 CA248901

WE-lePD-TRACK 3-04

Preclinical Application of a Cross-Voxel Exchange Model for the Estimation of Tracer Transport and Drug Accumulation

N Sinno^{1*}, T Hompland², E Taylor¹, M Milosevic¹, D Jaffray³, C Coolens¹, (1) Princess Margaret Cancer Centre, University Health Network, Toronto, ON, (2) Oslo University Hospital, Oslo, (3) The University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: Transport models, when paired with non-invasive imaging techniques, aim to predict drug accumulation in tumor tissue, greatly advantageous for tumor diagnosis and treatment outcome assessment. A Cross-Voxel Exchange Model (CVXM) describes the change in tracer concentration as the exchange of tracer between blood and tissue, in addition to the transport of tracer through the interstitium (diffusion and convection). At the level of a voxel, CVXM considers intra- and inter-voxel exchange of tracer. The goal is to derive kinetic properties of tumor tissue from DCE-MRI to predict drug perfusion and accumulation. **Methods:** Twenty TS-415 human cervical carcinoma xenografts were established inside the gastrocnemius muscle of adult female BALB/c nu/nu mice. The mice were subjected to DCE-MRI for a period of 15 minutes using a 1.5-T whole body scanner (Signa, General Electric) at a spatial resolution of 0.23x0.23x2.0mm³ and a time resolution of 14 seconds. The tracer injected was Gd-DTPA. Regions of interests were selected radially from the tumor center outwards. CVXM was fitted to the data to generate spatial maps for fluid flow velocities v , diffusion coefficients D and extravasation parameters Kext and v_e . **Results:** The fitting results allowed distinguishing higher velocity measures at the periphery averaging to 14.37±3.65µm/s. The other resulting parameters are D (mean 253.98±85.37µm²/sec), Kext (mean 0.02±0.01min⁻¹) and v_e (mean 0.09±0.02). These kinetic properties are in line with the observations in the MRI scans: strong contrast enhancements at the periphery (convection) and slower concentration uptakes towards the center of the tumor (slower acting diffusion). **Conclusion:** CVXM fittings show a heterogeneous distribution of transport parameters suggesting an uneven accumulation of drug in the tumor microenvironment. The results support the need to investigate CVXM as a non-invasive technique to determine kinetic properties of the tumor tissue leading to better predictions of tumor aggressiveness and more informed treatment decisions.

WE-lePD-TRACK 3-05

Understanding the Effect of CPAP On Respiration for Thoracic Radiation

S Hegarty^{1*}, N Hardcastle², J Booth³, A Briggs³, V Cailliet⁴, B Harris⁵, R Franich¹, (1) RMIT University, Melbourne, Victoria, AU, (2) Peter MacCallum Cancer Centre, Melbourne, VIC, AU, (3) Royal North Shore Hospital, Sydney, NSW, AU, (4) The University Of Sydney, Sydney, NSW, AU, (5) Dept Respiratory and Sleep Medicine, Royal North Shore Hospital, St Leonards, NSW, AU

Purpose: To use implanted electromagnetic beacons to understand the effect of Continuous Positive Airway Pressure (CPAP) on the regularity and amplitude of respiration when undergoing thoracic radiation therapy. **Methods:** This was an exploratory objective of an MLC tracking trial in patients receiving stereotactic ablative body radiotherapy for lung tumours. Electromagnetic beacons (Calypso, Varian Medical Systems) were endobronchially inserted in the lungs of eight patients receiving stereotactic ablative body radiotherapy for lung tumours. Beacon motion traces were acquired for four treatment fractions per patient under regular

respiration (during radiation therapy). Subsequent to each fraction, CPAP was applied and the pressure was increased over 5-minutes from 5 cmH₂O to 15 cmH₂O, after which beacon motion traces were recorded for 3 to 8 minutes. 3D motion vectors were assessed; the difference in mean respiratory period and motion amplitude were compared between regular respiration and CPAP traces. **Results:** CPAP reduced the amplitude by (mean $\pm$ st.dev.) 1.0 $\pm$ 4.4 mm (range -4.6 to 11.5 mm); greater amplitude reduction was observed for larger breathing motions (Spearman rank ρ = 0.67). CPAP increased motion however in eighteen fractions in seven out of eight patients, although the increase in five of the fractions was under 1 mm. The mean respiratory period increased by 1.4 $\pm$ 2.1 seconds (range -6.7 to 2.3 seconds) when using CPAP. Five out of the eight patients had fewer breaths statistically considered outliers with the use of CPAP than with regular respiration, implying less erratic breathing. **Conclusion:** While on average CPAP reduced respiratory motion most patients experienced an amplitude increase in at least one fraction. Motion reduction was maximised for patients with larger respiratory motion, indicating a subset who may benefit from CPAP for motion margin reduction. CPAP resulted in an increase in respiratory period and a decrease in erratic breaths.

Uptake and Retention of Radiosensitizing Nanoparticles in Key Cells of a Pancreatic Tumor Microenvironment

A Alhussan^{1*}, D Chithrani¹, W Beckham², K Bromma¹, (1) University of Victoria, Victoria, BC, CA, (2) BC Cancer Agency- Vancouver Island Centre, Victoria, BC, CA

Purpose: Pancreatic cancer is one of the deadliest types of cancer with a 5-year survival rate of only 10%. Nanotechnology offers a novel perspective to treat such deadly cancers through their incorporation into radiotherapy and chemotherapy. However, the interaction of nanoparticles (NPs) with cancer cells and with other major cell types within the pancreatic tumor microenvironment (TME) is yet to be understood. Therefore, our goal is to shed the light on the dynamics of NPs within a TME of pancreatic origin. **Methods:** In addition to cancer cells, normal fibroblasts (NFs) and cancer associated fibroblasts (CAFs) were examined in this experiment due to their important yet opposite roles of suppressing tumor growth and promoting tumor growth, respectively. We used gold nanoparticles as the model NP system due to their biocompatibility and physical & chemical proprieties, and their dynamics were studied both quantitatively and qualitatively in vitro and in vivo. **Results:** The in vitro studies revealed that both cancer cells and CAFs take up 50% more NPs compared to NFs. Most importantly, they all managed to retain 70-80% of NPs over a 24-hour time period. Uptake and retention of NPs within an in vivo environment was also consistent with in vitro results. **Conclusion:** The experiment concludes that NP-based targeting of both tumor cells and CAFs could be used as a smart novel strategy towards improving current anti-cancer therapies.

WE-lePD-TRACK 3-07

Enabling Upright Radiotherapy Through the Deformation of Horizontally Acquired Images

P Liu^{1,2*}, D Waddington^{1,2}, S Shan^{1,2}, B Dong², P Keall^{1,2}, (1) ACRF Image X Institute, University of Sydney School of Health Sciences, Sydney, NSW, AU, (2) Department of Medical Physics, Ingham Institute for Applied Medical Research, Liverpool, NSW, AU

Purpose: Upright radiotherapy can lead to improved treatments for lung cancer and more widespread adoption of proton therapy. However, as CT/MRI scanners are orientated horizontally, treatment planning for upright radiotherapy relies on bespoke vertical imaging systems. The purpose of this work was to enable upright radiotherapy by mathematically deforming horizontally acquired images to represent upright anatomy. **Methods:** Horizontal (supine) and upright (seated) volunteer lung images were acquired on a 1T prototype open-bore MRI-Linac. Free-breathing MR slices were acquired with using gradient echo sequences (TE/TR=10/124 ms) in the coronal plane. Both volumes were corrected for gradient non-linearity distortion and rigidly aligned. MIM was then used to contour and register the horizontal images to the upright images using the contour-based hybrid deformable image registration (DIR) algorithm. From the DIR output, a novel deformation algorithm was applied to the horizontal images to generate new images that represented upright anatomy. The horizontal to upright transformation was quantified by (1) magnitude of deformation, (2) the structural similarity index measure (SSIM) and (3) the Dice similarity coefficient (DSC) of lung volumes. **Results:** The average deformation from horizontal to upright anatomy for lung voxels was 1.0 $\pm$ 6.2mm, 4.4 $\pm$ 9.9mm and -3.9 $\pm$ 7.2mm in the LR, SI and AP directions, respectively. Compared to acquired upright images, the generated upright images had a SSIM=0.36, while a repeated upright acquisition had a SSIM=0.46 and a horizontal acquisition had a SSIM=0.30. Lung volumes on the generated upright images had a DSC=0.86 with lung volumes on acquired upright images. This compared to a DSC=0.90 for repeated upright acquisitions and a DSC=0.76 with horizontal images. **Conclusion:** This work is the first to demonstrate the feasibility of using DIR to represent upright anatomy from horizontal images. This technique could be used to create upright treatment plans from horizontal CT/MR images and enable upright radiotherapy treatments.

Therapy: SBRT/SRS Treatment Planning

WE-lePD-TRACK 5-01

Impact of Machine Uncertainties on Dosimetric Robustness of Modern-Day Stereotactic Radiosurgery Techniques

T Cui^{1*}, I Vergalasova¹, H Liu², M Alonso-Basanta³, L Dong³, J Li², K Nie¹, W Shi², B Teo³, Y Yu², N Yue¹, J Zou³, T Li³, (1) Department of Radiation Oncology, Rutgers Cancer Institute of New Jersey, Rutgers University, New Brunswick, NJ (2) Department of Radiation Oncology, Thomas Jefferson University Kimmel Cancer Center, Philadelphia, PA (3) Department of Radiation Oncology, University of Pennsylvania Abramson Cancer Center, Philadelphia, PA

Purpose: Multiple techniques are available for stereotactic radiosurgery (SRS) treatment of brain metastases on either a linac or Gamma Knife (GK) machine. Aside from the dosimetric differences, these techniques differ from each other in the magnitude of machine uncertainties inherently present and subsequently in the errors those uncertainties may cause. This study was designed to compare the dosimetric robustness of frameless GK, Elements, HyperArc and VMAT techniques as a function of various machine uncertainties. **Methods:** 16 patients previously treated for multiple brain metastases were retrospectively identified. 5 SRS plans were generated per patient: frameless GK, Elements, HyperArc, and two VMAT plans by independent planners. All plans met clinical planning standards. PTVs were defined as 1mm isotropic expansion of GTVs. We simulated dosimetric perturbations caused by machine uncertainties by applying a range of translational/rotational displacements to PTVs, up to maximum magnitudes of 0.1 mm/0.3 deg and 2 mm/0.5 deg for frameless GK and linac-based plans, respectively. The impact on V100% (V100), normalized D99% (nD99), and the Paddick Conformity Index (PCI) were assessed and compared for PTVs among plans. The one-way ANOVA and Tukey tests were performed for statistical analysis with a significance level of $p < 0.05$. **Results:** The mean V100, nD99, and PCI accounting for machine uncertainties were all significantly different ($p < 0.001$) among the plans. Overall, the GK Frameless plans demonstrated the best robustness across the metrics

(V100=0.877; nD99=1.180; PCI=0.962), which could be explained by the much tighter machine tolerance for GK. Among the Linac-based plans, Elements (V100=0.840; nD99=1.120; PCI=0.740) was more robust against machine uncertainties than the HyperArc/VMAT plans. Smaller variances were also observed within the other VMAT plans. **Conclusion:** Our results indicate that GK and Elements are more robust against machine uncertainties than the other common linac-based SRS treatment techniques.

Dosimetric Impact of Dose Calculation Algorithms on Lung SBRT Plan for COPD Patients

S Jang*, S Lee, X Zhang, K Mak, A Hirsch, M Truong, Boston Medical Center and Boston University School of Medicine, Boston, MA

Purpose: We evaluated the AAA and AcurosXB (AXB) algorithms for varying Hounsfield-Units (HUs) in lung SBRT patients to investigate the dosimetric impact of an extremely low-HU caused by Chronic Obstructive Pulmonary Disease (COPD) on target coverage and Organs-at-Risk. **Methods:** SBRT lung plans were generated using a Quasar Lung Phantom with a prescription of 12Gy $\times$ 5 to the PTVs located centrally and peripherally. The lung average-HU was varied from -990 to 650 to simulate the low-HU region caused by COPD. The AAA plans were calculated with varying HUs in lung using the Eclipse 15.6-AAA and normalized to cover 95% of the PTV with the prescription dose. With the same HU and monitor-unit, the AXB plans were generated. The dose-to-medium in AXB plans was compared with the dose-to-water in AAA plans with the dosimetric indices including D99% for GTV/PTV, maximum dose of spinal-cord and rib, and lung V20. PTV coverage in AAA plans was analyzed for varying HUs caused by COPD, and evaluated with respect to the PTV coverage in AXB plans. **Results:** The AAA overestimated the PTV coverage of > 10% for both targets in the HUs below -900. The central target was less impacted by varying HUs compared to the peripheral target. For an extremely low-HU of -990, the AAA overestimated the PTV D99% up to 45% compared to the AXB. However, the two dose algorithms were comparable in the normal lung HU range from -750 to -650. Spinal-cord and rib doses were relatively insensitive to the variation of HU for both targets. As the HU decreased below -900, the AAA overestimated the lung V20 and skin dose, and lung V20 was strongly dependent on varying HUs. **Conclusion:** For COPD SBRT cases, the AAA overestimates the PTV coverage over 10% in the HUs below -900 and the AXB is more accurate than the AAA.

Robust Optimization with Multiple-CT Sets to Account for Deep Inspiration Breath Hold Variation in Pancreatic Stereotactic Body Radiotherapy

D Miles*, C Hill, A Narang, H Li, S Han-Oh, Johns Hopkins Medicine, Baltimore, MD

Purpose: Internal margin expansion on the gross tumor volume (GTV) is widely used to account for deep inspiration inter-breath hold (DIBH) variation in tumor positioning in pancreatic stereotactic body radiation (SBRT). This margin expansion promotes better target coverage potentially at the cost of increased dose to the gastrointestinal organs. We investigated whether robust optimization with multiple breath-hold CT sets can account for inter-breath hold variation with organ-at-risk (OAR) sparing in comparison with the margin-based compensation. **Methods:** Ten DIBH SBRT pancreatic cancer patients were selected for this retrospective study. At simulation, four DIBH CT sets were acquired. Conventional margin-based plans were generated using volumetric modulated arc therapy (PTV-VMAT), where planning tumor volume (PTV) definition included breath hold variation and a 2-mm setup margin. GTV-based plans (GTV-RO-VMAT) were generated using robust optimization (RO). OAR positioning uncertainties were considered using physician-approved contours on all DIBH CT sets with a 2-mm isotropic setup uncertainty. PTV-VMAT and GTV-RO-VMAT plans were considered matched when GTV coverage was equal at D99%. Target coverage and OAR doses were compared for both approaches. The metrics used for the dosimetric comparison were D99% and V130% for the GTV, and V20Gy and Dmax for duodenum, stomach and bowel. **Results:** RO reduced OAR V20Gy by an average of 10%, 20%, and 40% for duodenum, stomach, and bowel, respectively, at the cost of slightly increased Dmax (2-3%). Due to plan matching conditions, GTV D99% was consistent between plans. The V130% increased from an average of 0.4 to 6.4 cc in RO plans, however, these hot spots were well-contained within the GTV. **Conclusion:** We have demonstrated that RO techniques can be applied to pancreatic SBRT planning with DIBH to significantly reduce OAR dose while maintaining GTV coverage. RO tools are clinically available and may be applied to enhance the efficacy of photon-based SBRT planning.

Feasibility of Using RayStationTM TPS MonteCarlo Algorithm for Evaluating Ocular Dose Delivered Via Dedicated Proton Eyeline

M Mamalui*, M Rutenberg, R Dagan, University of Florida/Radiation Oncology, Jacksonville, FL

Purpose: Treatment of Ocular melanoma with protons, delivered via a dedicated fixed gantry beamline (aka Eyeline) has a long history and excellent clinical outcomes. However, creating a TPS that satisfies the requirements of modern multi-professional ocular treatment team, has been largely a matter of in-house program development at a few institutions. As new commercial treatment planning systems coming on the market, some of which are offering highly accurate computational methods, such as MonteCarlo, it stands to reason to attempt adapting such an algorithm to the purpose of calculating the dose for Eyeline treatment of Ocular Melanoma. **Methods:** A spectrum of PDDs and lateral profiles, corresponding to the options available in Eyeline was recreated in RaystationTM treatment planning system, using clinically commissioned pencil beam scanning option and MonteCarlo calculation algorithm. Semi-automated inverse optimization routine was constructed in RaystationTM optimization module to ensure target coverage. The size of the target was determined by the Range and Modulation of the option under investigation. 11 beams were inverse-optimized in this manner. In addition, a brass aperture was defined as an automatically created structure in Raystation. Block margins were kept to 2.5 mm as used clinically. **Results:** Distal and lateral dose fall-off distances were compared to the counterparts from eyeline measured PDD and profiles. It is shown that, given appropriate parameters of the optimization, layer-to-layer and spot-to-spot distance and appropriate overrides (brass block, air, negligible air gap between range shifter and the external planning structure), Distal Fall-off and Lateral 80-20% penumbra can be easily recreated in the vicinity (i.e., within 0.5mm on average, maximum deviation was 0.9mm for lateral penumbra) of the true measured clinical beam values: i.e., 3mm distal fall-off and 1.1-1.7 mm penumbra, respectively. **Conclusion:** It appears quite feasible to use Raystation MonteCarlo algorithm for Eyeline dose calculation and evaluation.

WE-lePD-TRACK 5-05

Uncertainties in the Lung Heterogeneity Correction and Local Control for Lung SBRT

B Erickson*, B Ackerson, C Kelsey, F Yin, W Giles, J Adamson, Duke University, Durham, NC

Purpose: In this study, local control for 93 prior lung SBRT patients was evaluated in regard to dosimetric uncertainties related to the lung heterogeneity correction. **Methods:** Under a retrospective IRB protocol, 93 patients who received SBRT for non-small-cell lung cancer from 2007-2014 with treatment plans originally calculated with AAA (n=86) or PBC (n=7) were retrospectively recalculated using Acuros. A subset (n=22) was also recalculated with Monte Carlo for comparison. Dosimetric uncertainty was quantified for PTV mean dose, D95%[Gy], D1%[Gy], mean lung dose, lung V12Gy[cc], biologically effective dose (BED), and tumor control probability (TCP). Correlation with local control was analyzed. **Results:** 8 of 93 patients experienced local failures within four years. For local failures and controls, BED from Acuros was 107.2 $\pm$ 14.8Gy and 127.7 $\pm$ 27.0Gy, respectively, for PTV mean dose (p=0.03) and 119.2 $\pm$ 10.8Gy and 151.8 $\pm$ 31.5Gy, respectively, for D1%[Gy] (p=0.005). After recalculation with Acuros, the original BED and TCP decreased by 5.2 $\pm$ 6.2% and 4.2 $\pm$ 4.9%, respectively, with 10% of all plans having their PTV mean dose decreasing by >12.2% and D95%[Gy] by >26.7%. For one particular failure, BED decreased from 109.9Gy to 72.5Gy and TCP from 0.55 to 0.26. Plan parameters that were correlated with dosimetric uncertainties in a multivariate analysis included beam energy (Δ D95%[Gy] of -5.8%, -7.2%, and -11.5% for 6X, 10X, and 15X, respectively), lung volume (Δ D95%[Gy] = -2.9% per 1000cc), PTV mean density (Δ D95%[Gy] = 1.9% per 100HU), and PTV size (Δ D95%[Gy] = -0.82% per 25cc). Consistent with previous studies, Acuros had better agreement with Monte Carlo (Δ D95%[Gy] = -1.7% $\pm$ 1.4%) than did AAA

($\Delta D95\%[Gy] = -9.7\% \pm 7.8\%$). **Conclusion:** For lung SBRT, dosimetric uncertainty from the heterogeneity correction can have a substantial effect on BED, potentially leading to increased probability of local failure. Future work will include expanding the patient cohort for further statistical analysis of local control.

This work was partially funded by a grant from Radialogica. Dr. Justus Adamson reports ownership of Clearsight RT LLC, which is unrelated to this study.

Feasibility of Using 6MV-FFF Halcyon RDS for Single-Isocenter/Two-Lesion Lung SBRT

A Webster*, J Visak, M Bernard, R McGarry, M Kudrimoti, D Pokhrel, University of Kentucky, Lexington, KY

Purpose: To demonstrate the plan quality and delivery efficiency of volumetric modulated arc therapy (VMAT) with Halcyon ring delivery system (RDS) in the treatment of single-isocenter/two lesion lung stereotactic body radiation therapy (SBRT). **Methods:** Fourteen patients with two lung lesions previously treated with 6MV-FFF VMAT lung SBRT using a single-isocenter on C-arm TrueBeam Linac were selected. The mean isocenter to lesion distance was 6.0 ± 2.4 cm and combined target volume was 56.8 ± 37.4 cc. Prescribed dose was 50 Gy to each lesion in five fractions, treated every other day with 2-4 non-coplanar partial/full arcs using 6MV-FFF beam and AcurosXB dose calculation engine for tissue heterogeneity corrections. For comparison, TrueBeam single-isocenter plans were re-optimized for Halcyon RDS coplanar geometry. TrueBeam and Halcyon plans were normalized for identical combined target coverage. High and intermediate-dose spillage were compared. Normal lung metrics and dose to organs at risk (OARs) were evaluated. Plan complexity was assessed via total monitor units, beam-on time and modulation factor. **Results:** Halcyon plans were statistically similar to clinically delivered TrueBeam plans. No statistical differences in target conformity, dose heterogeneity and intermediate-dose spillage were observed (all, $p > 0.05$). Halcyon plans on average demonstrated statistically insignificant reduced maximum dose to most adjacent OAR. However, Halcyon yielded statistically significant lower maximal dose to the ribs ($p = 0.02$) and normal lung V10Gy ($p = 0.04$). Plan complexity slightly increased as seen in the average increase of monitor units, modulation factor and beam-on time by 533, 0.5 and 2.8 min, respectively. However, the estimated overall treatment time was reduced by 2.4 min. **Conclusion:** SBRT treatment of synchronous lung lesions via single-isocenter VMAT on Halcyon RDS is feasible and dosimetrically equivalent to clinically delivered TrueBeam plans. Halcyon provides excellent plan quality and shorter overall treatment time that may improve patient compliance, reduce intra-fraction movement and improve clinic efficiency.

Impact of Deep Inspiration Breath-Hold Parameters and Gastrointestinal Gas Volume on Tumor Position Uncertainty in Stereotactic Body Radiation for Pancreatic Cancer

S Han-Oh^{1*}, L Hsu², C Hill¹, H Lin³, A Martin-Gomez^{3,4}, A Narang¹, (1) Department of Radiation Oncology and Molecular Radiation Sciences, Johns Hopkins University, Baltimore, MD, (2) Office of Capacity Management and Operations Integration, Johns Hopkins Health System, (3) Laboratory for Computer Aided Medical Procedures, Johns Hopkins University Whiting School Of Engineering, MD, (4) Chair for Computer Aided Medical Procedures and Augmented Reality, Department of Informatics, Technical University of Munich, Munich, Germany

Purpose: Deep-inspiration breath-hold (DIBH) is often employed to minimize respiratory-induced tumor motion in pancreatic stereotactic body radiotherapy (SBRT). Spirometer systems such as the Active Breathing Coordinator (ABC) assists patients during the DIBH process to promote reproducibility in tumor position, but how breath-hold parameters and daily variation in bowel gas patterns influence tumor position is unclear. We investigated the impact of these variables on tumor-position reproducibility (BH_Tumor_Var). **Methods:** Twenty pancreatic cancer patients who underwent DIBH SBRT were selected for the study. A total of 379 DIBH simulations and CBCT images and the corresponding ABC signals were analyzed. The tumor position was quantified as the centroid of three fiducial makers implanted into the tumor. The BH_Tumor_Var was defined as a relative shift of the centroid compared to that in the planning CT. The ABC signal of each image was characterized based on breath-hold duration (BH_Duration), percentage of inhaled volume relative to the total lung volume (Lung_Utilization), and rate of inhalation (Inhale_Rate). The total lung and gastrointestinal gas volumes (Lung_Volume and GI_Gas_Volume) were also quantified. Multivariate linear regression analysis was performed to understand a correlation between the five variables and BH_Tumor_Var. **Results:** The Inhale_Rate was the only statistically significant variable for BH_Tumor_Var in SI. As the Inhale_Rate increased, the tumor moved inferiorly. The BH_Duration, Lung_Utilization, and changes in GI_Gas_Volume were correlated with BH_Tumor_Var in AP. The tumor moved posteriorly when the BH_Duration, Lung_Utilization, and GI_Gas_Volume were shorter, higher, and increased, respectively. The BH_Tumor_Var in LR was correlated with all four variables except the GI_Gas_Volume. When the Inhale_Rate, Lung_Volume, and BH_Duration increased, the tumor moved to the left while higher Lung_Utilization caused the tumor motion to the right. **Conclusion:** Our study indicates that controlling DIBH parameters including visual-feedback of inhalation rate and minimizing variation of gastrointestinal gas volumes are important for reproducible tumor position.

The Role of Surface-Guided Radiation Therapy to Improve Patient Safety

N Viscariello^{1*}, H Al-Hallaq², V Batista³, M Kugele⁴, E Ford¹, J Meyer¹, (1) University of Washington, Seattle, WA (2) The University of Chicago, Chicago, IL, (3) Heidelberg University Hospital, Heidelberg, DE (4) Lund University Hospital, Lund, SE

Purpose: Surface-guided radiation therapy (SGRT), while most useful for patient positioning and motion management during radiotherapy, can also improve safety and quality by acting as an "independent observer" during treatment. This study uses multiple incident learning systems (ILS) to identify the types and frequency of errors that could potentially be avoided by implementing SGRT in the clinic. **Methods:** Three ILS were retrospectively mined to categorize and quantify errors that could have been prevented with SGRT. As the availability of technology and types of errors may vary across practices, the ILS represented international (SAFRON, IAEA), regional (AvIC, Sweden), and institutional (UW-ILS, USA) databases. General incident categories relevant for SGRT were identified and used to search events. Each event was reviewed individually and assigned to the relevant Incident categories if considered preventable with SGRT. The severity of SGRT-related events was investigated. **Results:** A total of 179 events were identified to be preventable with SGRT, representing 21% of reports at the verification/treatment stage. The most common events were wrong isocenter (43%) and wrong immobilization (34%). The distribution of event types was similar between the UW-ILS and SAFRON databases. AvIC had a smaller absolute number of events and immobilization-related events, which was attributed to the widespread use of SGRT in Sweden. Severity data indicated that SGRT-preventable events tend to have high severity scores. **Conclusion:** To our knowledge this is the first study of its type to study the value of SGRT in error prevention. Errors related to the wrong isocenter and immobilization are the most common pathways that could be detected with SGRT. By reducing misalignments and monitoring the entire treatment process, SGRT has the potential to be a valuable tool for increasing patient safety in radiotherapy.

Leveraging a Multi-Institutional Consortium to Understand Dose Accuracy in the Near-Surface Region for Whole Breast Irradiation

A Moncion^{1*}, M Wilson², R Ma³, R Marsh¹, J Burmeister⁴, D Dryden⁵, D Lack⁶, M Grubb¹, A Mayville⁷, P Jursinic⁸, K Dess⁴, J Kamp³, K Young⁵, J Dilworth⁶, R Jagsi¹, M Mietzel¹, F Vicini², L Pierce¹, J Moran¹, on behalf of the Michigan Radiation Oncology Quality Consortium (1) University of Michigan Medical Center, Department of Radiation Oncology, Ann Arbor, MI, (2) Michigan Health Professionals, Radiation Oncology Institute, Farmington Hills, MI, (3) Sparrow Health Systems, Department of Cancer Care and Oncology, Lansing, MI, (4) Wayne State University, Karmanos Cancer Center, Detroit, MI, (5) Covenant HealthCare, Covenant Radiation Center, Saginaw, MI, (6) Beaumont Health, Beaumont Cancer Center, Troy, MI, (7) Mercy Health, Lacks Cancer Center, Grand Rapids, MI, (8) West Michigan Cancer Center, Kalamazoo, MI

Purpose: To assess accuracy of dose calculations in the near-surface region for different treatment planning systems (TPSs), plan complexities, and energies to improve clinical decisions for patients receiving whole breast irradiation (WBI). This work is part of a multi-institutional effort investigating the correlation between mean dose calculated in the near-surface region and acute skin toxicities considering different WBI treatment techniques. **Methods:** A portable custom breast phantom was designed for measurements at eight institutions. Clinically-relevant treatment plans (open, field-in-field (FiF), FiF mixed-energy, and IMRT) were created in four TPSs on a patient dataset (50Gy/25fx) and peer reviewed by participants. After transfer to the phantom dataset, plans were re-calculated with fixed monitor units. For each irradiation, which included linear accelerators from different vendors, the phantom was aligned with predetermined moves or CBCT. Dose was measured with radiochromic film (1.5cmx13.0cm) placed at two depths (0.5 and 1.0cm) and three locations per depth within the phantom. Film was scanned (> 24h post-irradiation) and analyzed using FilmQA Pro. Dose differences were evaluated relative to the calculation. **Results:** Measured and calculated doses agreed well for all TPSs, complexities, and beam energies with 86.7%, 77.8%, 91.9%, and 80.6% of measurements within $\pm 5\%$ agreement for open field, FiF, FiF mixed-energy, and IMRT, respectively. Based on a Gaussian fit of the difference distribution, the mean percent difference was $-0.2 \pm 2.9\%$, with 95% of measurements within 6% agreement. Furthermore, Pearson correlation scores (# of measurements) of 0.8(60), 0.9(54), 0.7(36), and 0.8(72) showed good agreement for open fields, FiF, FiF mixed-energy, and IMRT, respectively. **Conclusion:** To the best of our knowledge, these results demonstrate that dose calculations from clinically relevant WBI plans for various complexities and beam energies are accurate in the near-surface region. This lays the foundation for future work to investigate the correlation between near-surface dose and patient skin toxicities.

Gradient-Dose Segmented Analysis (GDSA): An Improved Method for IMRT QA Analysis Compared to the Gamma Analysis

J Steers*, B Fraass, Cedars-Sinai Medical Center, Los Angeles, CA

Purpose: Presentation of a new method for IMRT QA comparisons that is more sensitive, more specific, and more clinically meaningful than gamma comparisons. **Methods:** Gradient-dose segmented analysis (GDSA) works by segmenting the dose map from calculations on an IMRT QA phantom into regions of high vs. low dose and dose gradient. The mean local dose difference in the high-dose low-gradient regions of the phantom comparison directly predicts the changes in the patient PTV mean dose using only information from the calculation on the detector array. GDSA is based on analysis of >180,000 comparisons in 40 IMRT and VMAT cases using various induced errors to determine appropriate dose/gradient thresholds and dose differences for phantom dose segmentation for GDSA. Here, GDSA is compared to five gamma criteria, using 3 different detector geometries (ArcCHECK, MapCHECK, Delta4), to evaluate the ability to predict $\pm 3\%$ changes in PTV mean dose (as a binary metric) using ROC analysis. An independent set of 25 clinical IMRT/VMAT cases were the validation dataset for evaluation of the GDSA dose/gradient thresholds and overall behavior. **Results:** ROC analyses comparing the sensitivity/specificity of GDSA to five different gamma criteria showed GDSA exhibited improved AUC compared to all five gamma criteria for all devices. AUC results from the validation dataset illustrate that sensitivity/specificity of GDSA is much improved compared to gamma with AUC values for GDSA vs gamma at 3%/3mm threshold 10%, global normalization were 0.893 vs. 0.79, 0.983 vs. 0.877, and 0.977 vs. 0.934 for ArcCHECK, MapCHECK, and Delta4, respectively. **Conclusion:** GDSA analysis of IMRT QA is capable of directly predicting changes in patient PTV mean dose using only information from the QA phantom measurement geometry, while also providing more clinically meaningful results and better identification of errors without any increases in clinical workload or effort.

Clinical Implementation of Deep Learning-Based VMAT Patient-Specific QA

X Yang^{*1,2}, L Wang³, D Li⁴, Y Guo⁵, Y Li⁶, Y Guan⁷, X Wu⁸, S Xu⁹, S Zhang¹⁰, M Chan¹¹, R Yang¹, L Geng², J Sui³ (1)Peking University Third Hospital, Beijing, CN, (2)Beihang university, Beijing, CN, (3)Institute of Automation, Chinese Academy of Sciences, Beijing, CN, (4)Henan Cancer Hospital, Zhengzhou, Henan, CN, (5)The First Affiliated Hospital of Zhengzhou University, Zhengzhou, Henan, CN, (6)The First Affiliated Hospital of Chongqing Medical University, Chongqing, CN, (7)Yantai Yuhuangding Hospital, Yantai, Shandong, CN, (8)Shanxi Provincial Cancer Hospital, Xi'an, Shanxi, CN, (9)General Hospital of People's Liberation Army, Beijing, CN, (10)Beijing Hospital, Beijing, CN, (11)Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: To commission and implement an Autoencoder based Classification-Regression (ACLR) model for VMAT patient-specific quality assurance (PSQA) in a multi-institution scenario. **Methods:** 1836 VMAT plans from seven institutions were collected for the ACLR model commissioning and multi-institutional validation. We established three scenarios to validate the gamma passing rates (GPRs) prediction and classification accuracy with the ACLR model for different delivery equipment, QA devices, and treatment planning systems (TPS). The prediction performance of the ACLR model was evaluated using mean absolute error (MAE) and root mean square error (RMSE). The classification performance was evaluated using sensitivity and specificity. An independent end-to-end test (E2E) and routine QA of the ACLR model were performed to validate the clinical use of the model. **Results:** For multi-institution validations, the MAEs were 1.30-2.80% and 2.42-4.60% at 3%/3mm and 3%/2mm, respectively, and RMSEs were 1.55-2.98% and 2.83-4.95% at 3%/3mm and 3%/2mm, respectively, with different delivery equipment, QA devices, and TPS, while the sensitivity was 90% and specificity was 70.1% at 3%/2mm. For the E2E, the deviations between the predicted and measured results were within 3%, and the model passed the consistency check for clinical implementation. And the predicted results of the model were the same in daily QA, while the deviations between the repeated monthly measured GPRs were all within 2%. **Conclusion:** The performance of the ACLR model in multi-institution scenarios was validated on a large scale. Routine QA of the ACLR model was established and the model could be used for VMAT PSQA clinically.

Treatment Delivery Errors as a Component of IROC Phantom Dose Deviations

S Edward*, S Kry, C Peterson, R Howell, P Balter, J Pollard-Larkin, UT MD Anderson Cancer Center, Houston, TX

Purpose: To investigate whether delivery log files predict dose deviations in IROC phantom irradiations **Methods:** Delivery log files were collected for IROC lung and head and neck (H&N) phantom irradiations from January 2019 to present. We evaluated these files in Mobius FX to determine the difference between the TPS-calculated and machine-delivered doses (as a perturbation of the TPS). We evaluated whether this perturbed dose more accurately predicted the actual delivered dose (as measured by the TLD). A total of 41 lung phantoms (82 TLDs) and 36 H&N phantoms (216 TLDs) were evaluated. The maximum RMS errors in the MLCs, jaws, collimators, and gantry angles during treatment delivery were also analyzed for correlations with delivered dose. **Results:** Compared to the average dose

deviation (TPS vs TLD) of 2.4% (max = 11.6%) for the H&N phantom, and 2.6% (max = 9.6%) for the lung phantom, the dose perturbations predicted by log files were relatively small. The delivery errors ranged between -0.73% to 1.20% for the H&N phantom. Delivery played an even smaller role for the lung, which had a dose difference range of -0.75% to 0.17%. Minimal correlation between dose deviation and delivery error was found: $r = 0.13$ ($p = 0.04$) for H&N, $r = 0.03$ ($p = 0.7$) for lung. Delivered dose was not strongly correlated with MLC, jaw, collimator, and gantry angle maximum RMS errors ($-0.2 < r < 0.2$). **Conclusion:** Analysis of IROC H&N and lung phantom delivery log files showed minimal contributions to the total TLD dose deviations seen among these phantoms. This indicates that few delivery errors are present, or that these errors are not properly captured within the delivery log files. Future work will investigate the ability of this delivery data to catch/identify irradiation errors in IROC phantoms.

Streamlining Complex Multi-Isocentric VMAT Based Treatment Delivery Using a Newly Developed Software Tool

J Teruel*, P Galavis, K Osterman, S Taneja, B Cooper, N Gerber, C Hitchen, D Barbee, NYU Langone Health, New York, NY

Purpose: Multi-isocentric treatment delivery for CSI and TBI poses specific challenges for treatment delivery. We have developed a software tool to streamline all aspects of delivery for therapists and physicists at the machine, as well as to inform attending physicians of setup variability and image residuals at different locations. **Methods:** Our institution delivers VMAT-based CSI and TBI with up to 3 and 7 isocenters, respectively. A software tool was developed to assist with treatment delivery including initial patient setup, patient imaging, automatic calculation of the optimal global shift based on each isocenter's ideal shift, and automatic calculation of each isocenter's couch coordinates. Initial treatment couch coordinates are queried via the Eclipse scripting API. The global shift was calculated prioritizing the head isocenter for CSI treatments and the chest isocenter for TBI treatments by first maximizing residual tolerance at any other location prior to accepting any residual deviation at these locations. Maximum residuals tolerance was determined based on target margins, plan uncertainty and as per physician instructions. Delivery parameters are reported to a document uploaded to ARIA via API. **Results:** The developed tool was employed for 11 cases. The software tool replaced the need for plan shift comments or instructions for therapists. In particular, its use eliminated the need to provide isocenter shifts to therapists by directly providing final couch parameters for treatment, greatly reducing the risk of delivery errors. The software effectively informed the therapists if any expected tolerance was surpassed, triggering a patient setup evaluation. **Conclusion:** The described software tool is a core component to our multi-isocenter treatment programs and has streamlined delivery of these complex techniques that would otherwise require complicated instructions, including multiple shifts and on-the-fly calculations of optimal image alignment based on multiple imaging locations. This has substantially reduced the possibility of delivery errors.

Double-Vertebral Segment SBRT Via Novel Ring-Mounted Halcyon Linac: Plan Quality, Delivery Efficiency and Accuracy

J Stephen*, A Webster, M Bernard, D Pokhrel, University of Kentucky, Lexington, KY

Purpose: Evaluate the plan quality, treatment efficiency and accuracy of single-isocenter volumetric modulated arc therapy (VMAT) of double-vertebral segment SBRT on Halcyon Linac. **Methods:** In-house multi-target end-to-end phantom tests and independent dose verification using MD Anderson's single-isocenter/multi-target thorax phantom (spine/lung targets) was completed. Six clinical patients with two-vertebral segments on thoracic and/or lumbar spine were replanned on Halcyon Linac with 6MV-FFF beam using a single-isocenter between vertebral segments. Three full arcs with 0° and ±10° collimator angles and advanced Acuros-based dose engine for heterogeneity corrections were used. Prescription was 35 Gy in 5 fractions to each vertebral-segment, synchronously. Halcyon VMAT-SBRT plans were retrospectively created on Truebeam Linac with a 6MV-FFF beam using identical planning geometry and optimization objectives. Plan quality metrics were evaluated per NRG-BR002 protocol. Treatment delivery parameters were recorded for both plans. **Results:** Phantom measurements showed acceptable spatial accuracy (<1mm within 5 cm from isocenter) of CBCT-guided Halcyon SBRT treatments. MD Anderson's phantom irradiation credentialing results met IROC requirements. Mean isocenter-to-tumor center distance was 3.3 ± 0.6 cm (range, 2.4–4.3 cm). Mean combined PTV was 57.3 ± 31.3 cc (range, 20.1–99.9 cc). Both Halcyon and Truebeam VMAT-SBRT plans met NRG-BR002 criteria and show similar CI, HI, GI, D2cm and maximal dose to adjacent OAR including dose to partial cord. Total monitor units, modulation, and overall treatment time were lower with Halcyon plans by 130 MU, 0.2, 3.8 min, on average, with similar beam-on time. Portal-dosimetry patient-specific QA on Halcyon showed a high pass rate of $99.6 \pm 0.3\%$ for 2%/2 mm clinical gamma passing criteria. **Conclusion:** SBRT treatment of double-vertebral segment via single-isocenter VMAT on Halcyon for select patients, is feasible and dosimetrically comparable to Truebeam Linac. Faster treatment delivery (≤ 10 min) of double-vertebral segment SBRT on Halcyon can improve patient tolerance due to back pains, potentially reduce intra-fraction motion errors, improve patient throughput and clinical efficiency.

SAM Professional Symposium**TRACK 1*****"Picture a Scientist": Toward Gender Equity*****TH-A-TRACK 1-00****"Picture a Scientist": Toward Gender Equity**

Moderator: Kristi Hendrickson, University of Washington, Seattle, WA

TH-A-TRACK 1-01**K. Paradis (Younge), University of Michigan:****"Picture a Scientist": Toward Gender Equity and a More Diverse Medical Physics Workforce**

The gender imbalance in the field of medical physics continues. While increasing numbers of women enter the trainee ranks, we do not see these increases propagating up the ranks of the medical physics profession. This is sometimes called the "leaky pipeline" as it indicates that women are both interested and capable of succeeding in medical physics, but are often leaving the field before advancing to senior levels. There are unique obstacles and challenges faced by women physicists including gender bias, discrimination, and harassment that differ from those experienced by male colleagues. This session incorporates a three-part interactive experience. First, anonymous, real-world examples of challenges occurring in medical physics workplaces are shared from descriptions provided by women medical physicists (collected from an IRB-approved, national qualitative interview study). An anonymous audience response system will be used for attendees to share their reactions to the examples, tactics to address these issues, and advice on how to be an effective ally for our women colleagues. Then, we will break out into small groups to examine the examples and consider ways to respond in similar situations. Finally, participants will share the results of their small group discussions with the full group.

*Picture a Scientist is a 2020 documentary film that chronicles and examines gender bias and sexual discrimination experienced by women scientists. This film has been available for screening and discussion by AAPM membership.

Learning Objectives:

1. Understand the unique challenges and obstacles to a medical physics career that women face
2. Share and implement strategies to address the challenges
3. Be an active ally to early career women in medical physics

SAM Imaging Educational Course**TRACK 2*****Breast Imaging 2: Possible Future Directions*****TH-AB-TRACK 2-00****Breast Imaging 2: Possible Future Directions**

Yang, Harvard Medical School, Massachusetts General Hospital:****Noise Power Spectrum Analysis of Breast Tissue Textures Presented in Mammographic Images****TH-AB-TRACK 2-05****Audience Q & A**

While mammography and tomosynthesis remain the mainstream for breast x-ray imaging, newer technologies are helping to fine-tune diagnosis and are playing an increasing role in follow-up studies and the early detection of cancer.

In this session, four speakers will describe and review recent technological advances in breast x-ray imaging, including dedicated breast CT, contrast enhanced spectral mammography, localization and biopsy via tomosynthesis/stereotactic guidance, and tissue texture analysis of breast x-ray images which showed correlation with breast density and cancer detection performance. The speakers will describe the clinical background, review the status quo and clinical adoption of current technologies, and report active investigations and ongoing/future directions of research in these topics.

Learning Objectives:

1. Understand the physics and principles behind contrast enhanced spectral mammography, stereotactic and tomosynthesis-based localization, breast CT, and tissue texture analysis.
2. Understand the clinical applications as well as current trend of investigations of the described emerging breast x-ray imaging technologies.

Q&A & Panel Discussion

Since their introduction in the late 1970's MRI systems have evolved inexorably towards higher field strengths due to the greater spin polarization, and ultimately image signal-to-noise ratio, that higher fields allow. Commensurate with the increasing field strength was the need to overcome the many technical challenges associated primarily with the higher Larmor frequencies involved, from SAR-related safety considerations and imaging sequence modifications to new radiofrequency coil design concepts. This push to higher fields led to the recent arrival of 7 Tesla MRI systems into the clinical domain. The benefits and challenges of imaging at 7 Tesla will be reviewed, both from a technical/physics perspective and that of developing clinical applications of this technology. Future prospects for this technology will be reviewed.

At the same time, advances in MR technology and imaging techniques are facilitating renewed interest in imaging at lower field strengths. The benefits that pertain to imaging at low field will be reviewed, from 0.55 Tesla all the way down into the low milliTesla regime. New applications of a 0.55 Tesla MRI system equipped with contemporary hardware and software for cardiac imaging, lung imaging and MRI-guided cardiac interventions will be discussed, together with the capabilities of this system for routine diagnostic imaging. A high performance MRI system which operates at 6.5 mT will be described, highlighting the technical innovations which facilitate diagnostic impact. The use of modern image acquisition and reconstruction methods that can be used to maintain SNR and image quality at lower fields will also be discussed.

Learning Objectives:

1. Understand the underlying physics concepts describing the benefits of MR imaging at 7 T
2. Be familiar with the technical challenges of 7 T MRI and techniques to mitigate image artifacts
3. Demonstrate a knowledge of the safety aspects of 7T MRI
4. Understand the breath and limitations of current clinical applications of 7 T MRI
5. Apply knowledge of how modern image acquisition and reconstruction methods can be used to maintain SNR and image quality at lower fields
6. Understand the benefits of imaging at lower magnetic fields
7. Understand the opportunities and limitations of potential clinical applications for low field MRI

The Role of Dose in Task-Based Assessment of Image Quality — Diagnostic Imaging and Radiation Therapy

TH-AB-TRACK 4-04

Q&A

Medical imaging systems and image processing operations are widely employed to support clinical practice.

In medical imaging, images are often acquired for specific purposes and the use of objective measures of image quality (IQ) has been widely advocated for assessing imaging systems and image processing algorithms. Task-based measures of IQ quantify the ability of an observer to perform specific tasks.

Advanced deep-learning (DL) methods are being rapidly developed for a large number of medical imaging applications. The optimization of medical imaging systems and algorithms is still mainly guided by traditional physical measures of IQ, and the objective evaluation of IQ of medical imaging and image processing methods remains largely lacking. Traditional IQ measures such as spatial resolution, contrast, dice coefficient, and noise levels are widely employed; however, it is well-known, but perhaps under-appreciated, that their clinical value is limited because they are not always sensitive to the intended use of the image.

This symposium will address recent developments in task-based IQ assessment in diagnostic imaging and radiation therapy, and its applications for the assessment

and optimization of advanced DL-based image processing algorithms. In addition, the challenges of using task-based IQ measures to guide the optimization and assessment of imaging system and image processing will be discussed as well.

Learning Objectives:

1. Understand basic principles of task-based image quality assessment and its applications in optimizing medical imaging systems.
2. Understand the difference and relationship between objective/task-based and traditional physical metrics-based image quality assessment.
3. Understand the difference and relationship between model observers and human observers, understand the challenges in using task-based image quality assessment theory to guide clinical applications and assess DL-based imaging operators such as image reconstruction, image denoising, super-resolution, and others.

I. El Naqa, Moffitt Cancer Center:

Automated Adaptive Decision Making with Deep Learning Neural Network (DLNN)

Adaptive radiation therapy (ART) aims to adjust the treatment plan based on anatomical and/or functional changes assessed based on frequent images acquired during the treatment course. Despite the appealing advantages, clinical implementations of ART, especially on-line ART, have been limited due to its complexity and lack of efficient and robust software tools in almost every step of the process. The rapid advances of artificial intelligence (AI) and AI-based technologies hold great promise for ART. This session will start with the current clinical ART workflows and its clinical challenges, then will discuss the latest AI-based development & clinical applications in each aspect of the ART workflow, including AI/deep learning (DL) based auto-segmentation; AI-based tools for auto-planning, secondary dose verification, plan check and patient-specific QA. Advanced development accounting for treatment response (as a feedback), including AI and data mining for outcome-driven radiation treatment planning; treatment response-based on delta radiomics for ART, and automated ART decision making frameworks built from deep learning neural networks will be also presented.

Learning Objectives:

1. Understand the current clinical practice and challenges of ART and the role of AI
2. Present the latest developments & clinical applications of AI-based automatic segmentation
3. Present AI-based tools for auto-planning, secondary dose verification, plan check and patient-specific QA
4. Learn AI and data mining for outcome-driven radiation treatment planning
5. Learn treatment response based on delta radiomics for ART
6. Present AI methods for automated ART decision making using deep learning neural networks for clinical implementation of ART

3D Isocenter Coincidence Measurement for MR-Linacs with Cherenkov Imaging

D Alexander^{1*}, R Zhang^{1,2,3}, P Bruza¹, A Rassias¹, J Andreozzi⁴, B Pogue^{1,2,3}, D Gladstone^{1,2,3}, (1) Thayer School of Engineering, Dartmouth College, Lebanon, NH, (2) Geisel School of Medicine, Dartmouth College, Lebanon, NH, (3) Norris Cotton Cancer Center, Dartmouth-Hitchcock Medical Center, Lebanon, NH, (4) Moffitt Cancer Center, Tampa, FL

Purpose: In this study, a novel Cherenkov imaging-based isocenter coincidence verification method is presented as a clinically deployable, integrated solution for MR-Linac daily quality assurance (QA). **Methods:** An acrylic water-filled cylindrical phantom was designed containing a custom-machined plastic conical structure fixed in place with 3D-printed spacers. Cherenkov emission from the cone was highly scattered, providing optical contrast from the surrounding water. The plastic is also visible with high contrast on low-field MR imaging, and the conical structure was etched with fiducials, which were visible on Cherenkov images. The phantom was aligned using co-registration of MR the images to baseline. A star shot plan was developed and delivered to the phantom to provide x-z isocenter localization

relative fiducials on the phantom, while a four-field thin sheet plan yielding a ring-shaped Cherenkov emission distribution, which encodes isocenter localization along the y-axis. A custom analysis program with a graphical user interface was developed in MATLAB to analyze results in near-real-time. **Results:** Strong linearity was observed ($R^2 > 0.99$) between longitudinal position and optical ring diameter using calibration data, and error was low (RMSE = 0.184 mm). A minimum circle radius of 0.34 mm was measured during the star shot analysis. Initial isocenter coincidence measurements in the lateral, longitudinal, and vertical directions were -0.61 mm, 0.55 mm, and -0.14 mm respectively, yielding a 3D coincidence of 0.83 mm, below the 2 mm tolerance defined in TG-142. Longitudinal analysis showed an average coincidence of $1.5 \text{ mm} \pm 0.4 \text{ mm}$ over 8 weeks of daily use. **Conclusion:** This method represents a robust and efficient method for MR-Linac isocenter coincidence verification which can be realistically deployed in the clinic for daily measurement. Longitudinal use data from our clinic suggests this method is a viable alternative to measurements which use reduced datasets or heavy time resources.

An Evaluation of the Use of EBT-XD Film for SRS/SBRT Commissioning of Unity MR-Linac System

S Lim*, N Tyagi, E Subashi, J Liang, M Chan, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: The magnetic field (1.5-Tesla) of Unity MR-Linac (MRL) creates a high-intensity force on ferrous materials rendering many conventional QA detectors inoperable and poses significant challenges for clinical physicists. In this work, we evaluated using the Gafchromic EBT-XD film for the commissioning of SRS/SBRT in MRL. **Methods:** Unity MRL is a combined 1.5T MR scanner and 7X-FFF Linac. The output factors (St), for 1x1, 2x2, 3x3cm², were measured with film in solid water at d=5cm, SAD=143.5cm. The results were compared with (1) the measurements by a PTW CV diamond detector (CVD) in 3D water phantom; (2) the calculation by Monaco TPS (MTPS) in water using 1.0mm dose-grid and 0.5% statistical uncertainty. The inline and crossline profiles, measured by films and the CVD, were also compared. An SRS plan with three targets (1-3cm) was created in MTPS and was measured with EBT-XD film in a StereoPhan® phantom. The 3x3cm² field size was used for film calibration with doses ranging from 0 to 28.21Gy. Water was added to the phantom-film-phantom interface to reduce the electron-return-effect (ERE). Films were scanned on an Epson scanner following the One-scan dosimetry protocol. **Results:** The measured St between films and CVD were within 0.5% and 1.9% for 1x1 and 2x2cm² respectively. Compared with MTPS, films were within 1.5% and 2.4%. At the central B-field induced asymmetric region, films were within 0.6% on average from the CVD and the MTPS. 5-8% differences were observed between films and CVD in the 40%-5% gradient region in crossline profiles due to different magnitude of ERE. The differences in localization and dose were found to be 0.6mm and 3.3%. The $\gamma(3\%, 2\text{mm})$ and $\gamma(5\%, 2\text{mm})$ within 50% target dose region were 94.4% and 99.3%. **Conclusion:** EBT-XD film agreed well with the diamond detector and is a valuable QA tool for SRS/SBRT commissioning in MRL.

One of the authors has a research grant from Ashland. This research was funded in part through the NIH/NCI Cancer Center Support Grant No. P30 CA008748.

TH-A-TRACK 6-03

Experimental Validation of a Prototype Ion Chamber for Accurate Magnetic Resonance Image Guided Radiation Therapy (MRgRT) Output Measurements in Solid Phantoms

B Muir*, H Nusrat*, A Sarfehnia*, J Renaud*, (1) National Research Council, Ottawa, ON, (2) Sunnybrook Health Sciences Center, Toronto, ON

Purpose: Previous studies demonstrate large (up to 4 %) variations in response using commercial ionization chambers in solid phantoms. This work investigates an optimized chamber design for accurate output measurements in solid phantoms in MRgRT radiotherapy beams with a set-up most commonly used in conventional clinical workflow. **Methods:** We previously demonstrated an optimized chamber design that uses a thick (1.1 mm) brass wall to eliminate variations in response due to air gaps between the chamber and the solid phantom used for output measurements. Here, we construct and test a prototype chamber in a 7 MV Elekta Unity MR-linac with a 1.5 T magnetic field. The radiation field is collimated to 10x10 cm² at the surface of a plastic phantom with the chamber at a depth of 10 cm. The chamber is rotated about its axis through 360 degrees in the phantom with measurements made at each cardinal angle. This reveals any variation in chamber response by varying the thickness of the air gap between the chamber and the phantom. The chamber axis is perpendicular to the linac beam and tested both parallel and perpendicular to the magnetic field. **Results:** The prototype chamber exhibits less than 0.3 % variation in response when rotated about its axis in the plastic phantom, independent of whether its axis is parallel or perpendicular to the magnetic field. This is much smaller than the previously reported variations for thin-walled commercial Farmer-type chambers of similar designs. **Conclusion:** A prototype chamber has been constructed and validated for accurate output checks in a beam from an MR-linac. The chamber design enables the use of conventional equipment and procedures in MRgRT systems, minimizing disruption to current clinical workflow and allowing the use of solid phantoms unlike all other non-conventional solutions.

TH-A-TRACK 6-04

Assessment of the Dependence of the Field Shape On Calibration Coefficients in Dose Area Product (DAP) for Small Field Sizes

J JURCZAK*, B Rapp*, S Dufrenco*, F Delaunay*, J Gouriou*, J-M Bordy*, (1) Université Paris-Saclay, CEA, List, Laboratoire National Henri Becquerel (LNE-LNHB), F-91120 Palaiseau, France, (2) Institut de Cancerologie de l'Ouest - Site Paul Papin (ICO Angers) - Département de physique médicale - 15 rue Boquel, 49055 Angers Cedex 02, France

Purpose: To assess the influence of the field shape on detectors calibrated in terms of Dose Area Product (DAP) for small field sizes. **Methods:** So far, primary references in radiotherapy are established in a 10x10cm² field in terms of absorbed dose to water at a point, in accordance with the recommendations of international protocols for more than two decades, despite the evolution of treatment modalities. The Laboratoire National Henri Becquerel (LNHB), the French Primary Standards Dosimetry Laboratory, proposed to use an innovative approach to obviate the difficulties of traceability for point measured quantities. Instead of considering a point measurement, an integrated measurement over an area larger than the irradiation field is adopted through another quantity: the Dose Area Product (DAP). To do so, a 30 mm core diameter graphite calorimeter and three plane-parallel ionization chambers of the same sensitive surface were built at LNHB. These chambers were calibrated in a 6 MV FFF field, at the maximum dose rate of 1400 UM/min with specifically designed circular collimators of 5, 7.5, 10, 13 and 15 mm diameter and jaws of 5, 7, 10, 13 and 15 mm side on the Varian TrueBeam accelerator of LNHB. **Results:** Preliminary results show the same behaviour for the three calibrated chambers with both circular collimators and jaws. All calibration coefficients are compatible with each other at a coverage factor of k=1, considering the same nominal field size. **Conclusion:** For small fields from 5 mm to 15 mm, calibration coefficients appear to be independent of the beam shape, allowing the primary standards carried out at the LNHB in DAP to be used independently by stereotactic cones or MLC/jaws. These promising results open the door of a paradigm shift in small field dosimetry.

TH-A-TRACK 6-05

Development of a Comprehensive Framework for the Validation of a Respiratory Gating System

M Stock*, C Chu*, K Matthews*, J Fontenot*, (1) Louisiana State University, Baton Rouge, LA, (2) Mary Bird Perkins Cancer Center, Baton Rouge, LA, (3) Louisiana State University, Baton Rouge, LA, (4) Mary Bird Perkins Cancer Center, Baton Rouge, LA

Purpose: To develop a framework to evaluate dosimetric and temporal characteristics of a respiratory gating system. **Methods:** We characterized the gating system dosimetrically and temporally using two distinct approaches. The gating system was composed of an automatic gating interface (Elekta Response™) and an in-house respiratory monitoring system featuring an optically tracked surface marker. Central-axis output and energy constancy were evaluated across 8 linear accelerators. Additionally, a representative set of 5 treatment plans were delivered both non-gated and gated on each accelerator to a 2D diode array (MapCHECK™). The surface marker was attached to a dynamic phantom (QUASAR™) which was programmed to replicate a typical DIBH breathing waveform. The passing rates between these modes of operation were evaluated using gamma analysis and a percent dose difference comparison. Modular and end-to-end approaches were used to quantify system latencies. The modular components studied included the optical tracking camera, sampling rate of the tracking software, signal travel time, and latency of the linear accelerator. The end-to-end approach involved measuring the displacement of a target moving at known velocities during the gating process. **Results:** Output and energy constancy were both within $\pm 0.5\%$ across each accelerator studied. The average difference in passing rates between non-gated and gated treatment deliveries were within $\pm 0.4\%$ using gamma analysis (2%, 1mm). Average passing rates were greater than 99% using a percent dose difference comparison (1%). No significant difference was observed $t(14)=0.21$, $p=.83$, between the modular ($M=1.55$ seconds, $SD=0.25$) and end-to-end ($M=1.49$ seconds, $SD=0.03$) approaches used to quantify beam-on latency. **Conclusion:** The proposed framework can be used to validate the operating characteristics of a respiratory gating system. The modular approach provides a convenient method to analyze the component latencies contributing to the end-to-end total.

Geometric and Dosimetric Verification for a Novel Stereotactic Radiosurgery System: ZAP-X

Y Niu*, Y Yuan, A Rashid, D Pang, Department of Radiation Medicine, MedStar Georgetown University Hospital, Washington, DC

Purpose: The ZAP-X is a novel self-shielded radiosurgery system providing precise and highly conformal treatment to intracranial lesions. Here, we aimed to verify the delivery accuracy of ZAP-X and validate the dosimetric accuracy of its dedicated treatment planning system (TPS). **Methods:** ZAP-X is characterized by a 2.7-MV linac mounted on a gyroscope-like gantry rotating around isocenter. A tungsten wheel collimator provides circular collimation with diameters from 4 to 25 mm. A patient table enables translational head movement resulting in multi-iso treatment. Non-coplanar beams are optimized from the beam-geometry space with 2π steradians solid angles to achieve desired plan quality. Dose calculation uses ray-tracing algorithm with 0.5 or 1 mm grid sizes. Beam data were acquired using water tank, including the TPR converted from PDD, off-axis profiles and collimator output factors. For checking the iso-positioning accuracy, end-to-end test was performed using an anthropomorphic head phantom with skull structure. An integrated kV imaging system rotating around axial axis provides skull/phantom alignment. The head phantom accommodates the inserts holding thermo-/optically stimulated luminescence detectors (TLD/OSLD) and Gafchromic films to verify point absolute doses and relative dose profiles. Measurements of absolute dose profiles were performed using a polymethyl methacrylate cylindrical phantom with SRS MapCheck, i.e., a 2D diode array with 0.5 mm resolution. **Results:** Routinely performed end-to-end test for iso-positioning accuracy resulted in deviations of less than 0.7 mm. Absolute point dose measurements of TLD and OSLD agreed with TPS calculation within 3.5% with average difference $-1.9\pm1.8\%$ and $2.3\pm0.6\%$, respectively. Relative and absolute dose profiles measured by Gafchromic film and SRS MapCheck showed an average gamma pass rates of 98.06% and 98.93% when using 3%/1mm criteria. **Conclusion:** The positional and dosimetric accuracy of ZAP-X system were evaluated. The TPS and its commissioning beam data can be used to predict the delivered dose precisely and accurately.

TH-A-TRACK 6-07

Quality Assurance of CyberKnife Small Radiation Fields Using High-Resolution Scanning Diode Detector

K Yang^{1*}, S Sharma¹, A Ju¹, (1) East Carolina University, Greenville, NC

Purpose: The quality assurance of CyberKnife systems requires monthly beam profile measurement, to verify beam shape, symmetry, and field size. These QAs are typically performed using Gafchromic films due to their high spatial resolution. However, the film has drawbacks such as film polarization, nonuniformity, and relatively slow develop time. The objective of this study was to simplify these QA procedures and offer real-time reading using a custom-made 3D scanning tool. **Methods:** A diode was attached to an optical stage configured in linear XYZ translation, and stepper motor actuators with positioning accuracy $<5\mu\text{m}$ were mounted on all axis. The diode motion was programmed along crossline and inline directions in 0.2 mm step, in step-by-step scanning mode. The beam profiles were measured in air for diode and compared against films irradiated with no buildup material. All films were scanned in one image, and film-derived readings were corrected by a batch-specific calibration. **Results:** The beam profiles measured with diode showed less than 3% difference from the film references with a field size of 5 mm and 7.5 mm for fixed cone, and variable aperture Iris collimator. The dose map from film showed uniformity variations and noise, where diode profile showed fewer signal fluctuations. For diode, the FWHM calculated from the profile showed better agreement to nominal field size. In addition, the differences in FWHM between diode and film for the same field were typically within 0.2 mm range. **Conclusion:** We have designed a diode scanning tool with three-dimensional high-spatial resolution and accuracy, the program capability in acceleration/deceleration, and motion path. The scanning diode setup was shown to be within acceptable tolerance compared to film and enables potential monthly dosimetric verification for small radiation fields.

Hands On Session – Cases 3 & 4

Simulated error training is a method to practice error detection in situations where the occurrence of error is low. Such is the case for the physics plan review where a physicist may check several plans before encountering a significant problem. By simulating potentially hazardous errors, physicists can become familiar with how they manifest and learn from mistakes made during a simulated plan review. To this end, the WGPE has developed a series of mock treatment plans/charts which include a variety of errors based on the risk-assessment performed by TG-275. The mock datasets include documentation, screen shots, and digital content derived from common treatment planning and radiation oncology information systems. In this workshop, attendees are invited to review several mock datasets via remote interface. Moderators will guide a group discussion related to the types of errors encountered, the use of systematic search methods, and recommendations derived from TG-275's final report. The creation of the mock datasets will also be discussed along with personal experience implementing simulated error training as an educational tool for residents and trainees.

Learning Objectives:

1. Learn the rationale for simulated error training.
2. Learn how WGPE simulation data sets were created and their connection to TG-275 recommendations.
3. Learn how to implement the WGPE mock datasets as a training measure within a local setting.

This project is sponsored in part by an education grant provided by Elekta.

Audience Q&A

Despite the recent emphasis on and awareness of standardization and consolidation in health care, the complexity of radiation oncology processes poses a complex challenge and, potentially, a safety concern as it attempts to fully embrace this paradigm shift. Our leading professional bodies including the American Association of Physicists in Medicine (AAPM), the American College of Radiology (ACR), the American Society for Radiation Oncology (ASTRO), the National Comprehensive Cancer Network (NCCN), etc have outlined patterns of care and best practices reports, guidelines and recommendations. Nonetheless, departmental and institutional management and operations, including policies and standards for quality and patient safety, still may vary. This may be especially true in multi-center clinics where there is a likelihood of variation in personnel and physical resources, technology, workflow, and methodology. This session aims to discuss different experiences with standardization and consolidation with the understanding that there is currently not a prescription to achieving this end. Further, this session aims to look at the challenges that come with providing consistent high-level quality care when standardized and consolidation involves multiple sites. The session will conclude with a round table discussion to brainstorm for ideas and (new) approaches to facilitate the integration of clinics and their ultimate transition into one continuous program. The primary focus of the session discussions will be on technology integration and (physical and personnel) resource management and how they impact overall workflow.

Learning Objectives:

1. Highlight the benefits and challenges of standardization and consolidation across multi-site radiation oncology practices.
2. Learn about the impact of a teams-based enterprise-wide approach(es) to (treatment planning) workflow.
3. Communicate some best practices to staffing and standardization that are applicable to large satellite Radiation Oncology programs.

Decompose KV Projections Using Neural Network for Improved Motion Tracking in Paraspinal SBRT

X He*, W Cai, F Li, Q Fan, P Zhang, L Cervino, X Li, T Li, Memorial Sloan Kettering Cancer Institute, New York, NY

Purpose: On-treatment kV X-ray images have been used in tracking patient motion during spine SBRT. One major challenge is the reduced contrast due to the passing of the X-ray through a large portion of the patient's body from the lateral direction. Besides, the overlap of the spine with the moving soft tissues could lead to significant errors in auto-registration. Our goal in this work is to automatically extract the spine component from the conventional 2D X-ray images to facilitate more robust and accurate motion management. **Methods:** A ResNet generative adversarial network (ResNetGAN) consisting of one generator and one discriminator was developed to learn the conditional mapping between the 2D kV X-ray images and the spine-only DRR. The trained model took a kV X-ray image as input and learned to generate the spine component of the X-ray image. The training dataset included 699 x-ray images from 11 patients and the corresponding matched spine-only DRRs. Another 185 x-ray images from additional three patients were used for validation. The resulted spine-only X-ray images and the original X-ray images

were registered to the DRRs, to compare the spine tracking accuracy. **Results:** The decomposed spine-only X-ray images matched with the calculated DRRs with submillimeter accuracy (165 out of 185), indicating that the model retains accurate information of the spine structure from the original X-ray images. For cases with low contrast in the original X-ray image, the decomposed spine-only X-ray significantly reduced the mean matching errors (in mm) to 0.62 and 0.16 from 0.69 and 0.21, and the maximum errors to 3.6 and 0.4 from 7.2 and 1.4, in x- and y- directions, respectively. **Conclusion:** We have developed a deep learning-based approach to suppress soft tissues in a kV projection image, leading to more accurate markerless spine tracking in paraspinal SBRT.

Near Real-Time Intra-Fractional 6D Monitoring of Prostate Position Using a Scheme Based on the Skeletonization of Implanted Marker Images

H Kuo^{1,2*}, D Lovelock¹, C Della-Biancia¹, A Damato¹, L Happersett¹, S Lin², M Zelefsky¹, L Cervino¹, S Berry¹, (1) Memorial Sloan Kettering Cancer Center, New York, CT, (2) Norwalk Hospital, Norwalk, CT

Purpose: Apply skeletonization scheme to extract gold marker locations from 2D planar images and to construct a 3D marker model for automatic 6D registration of prostate SBRT. Further, to evaluate the angle dependency of intrabeam 3D motion monitoring using 2D monoscopic X-ray images. **Methods:** 2D paired-planar images of markers were masked and skeletonized to represent the markers as 2D lines and to construct a 3D motion model of the marker position in space. An iterative closest point (ICP) algorithm was utilized to calculate the 6D transformation. The skeletonization scheme was compared at different kV/MV energies and techniques and the 6D registration was validated using a prostate phantom. 36 projected images were acquired over a full gantry rotation and were used to evaluate the range of angle directions and separations that preserves the approximation that two adjacent images can accurately localize the marker in 3D space. **Results:** Applying the skeletonization technique, kV and 2.5MV/6MV/16MV images showed similar Skeleton coordinates (differences <0.45mm). Using CBCT registration as ground truth for the 6D iso-center movement, the 2D to 3D registration accuracy of 2D-paired images from 11 observations had medians of 0.1mm, -0.2mm, -0.2mm, 0.1°, 0.0°, 0.0° in vertical, longitudinal, lateral, yaw, pitch, roll directions, respectively. The mean accuracy of 3D motion estimated from two consecutive kV images were <0.3mm for angle separation of 10° to 160°. The standard deviations (SD) were less than 0.3mm for angle separations of 20° to 120°. SD could be greater than 0.5mm if angle separation were 10°, 160° or 170°. **Conclusion:** The skeletonization scheme is feasible and has an accuracy in 6D comparable to 3D match using CBCT. The 2D line projection from the skeletonized 3D model can be used to estimate the 3D motion during treatment from 2D projected images with an angle separation as small as 10°.

Prediction of Lung Tumor Position Using 0.35 T Cine MRgRT in Retrospective Study

J Shin^{1,2*}, Z Ji¹, Y Huang¹, B Lewis¹, A Guta¹, S Oh³, J Kim², T Kim¹, (1) Washington University in St. Louis, Saint Louis, MO, (2) Yonsei University College of Medicine, Seoul, KR, (3) Allegheny General Hospital, Wexford, PA

Purpose: Real-time tumor tracking is a key feature of MRgRT. However, uncertainty in real-time tumor contours from low-resolution MRI acquired on a 0.35T MR-Linac system can lead to inaccurate beam delivery. To assist tumor tracking capabilities, we developed intra- and inter-fractional models for tumor position prediction from anatomical surrogates on 0.35T cine MR images. **Methods:** Cine MR images were acquired for real-time tumor tracking in standard MRgRT clinical workflow. Images included the tumor contour produced by the MRgRT system. Surrogates were automatically contoured using in-house software. Models were developed using linear regression and principal component analysis (PCA) to predict tumor motion from diaphragm and abdominal contours. A total of 1,069,071 images from 53 fractions for 10 lung cancer patients were analyzed retrospectively. The model for intra-fractional prediction was trained and tested on each fraction. The inter-fractional prediction was tested on each fraction using the patient's remaining fractions for training. The mean square error (MSE) and mean absolute error (MAE) between predicted and true position of the tumor were used for evaluation. **Results:** The regression model predicted the superior-inferior and anterior-posterior position of the tumor center from the diaphragm contour and abdomen contour with an average MSE of 0.57 and 0.54 mm² and an average MAE of 0.54 and 0.81mm, respectively. The PCA model predicted the tumor center with an average MSE of 1.15 and 1.70 mm² and an average MAE 0.80 and 1.24 mm, respectively. These errors were within two pixels on sagittal images. **Conclusion:** We developed models to predict tumor motion from anatomical surrogates using sagittal cine MRI. In this study, the models can predict the tumor motion using a linear model within a couple of millimeters. This study is on-going to apply the models to other treatment sites and additional imaging modalities, for example, on-board x-ray imaging.

Experimental and Monte Carlo Simulation Characterization of a kV Scattered X-Ray Imaging System for Real-Time Lung Tumor Motion Tracking

Y Huang^{1*}, Y Zhong¹, T Chiu¹, C Shen¹, K Yang², X Jia¹, (1) UT Southwestern Medical Center, Dallas, TX, (2) Harvard Medical School, Massachusetts General Hospital, Boston, MA

Purpose: Motion management is a critical component of radiotherapy. We previously proposed a new scheme of using kV scattered x-ray photons for marker-less real-time tumor tracking in lung cancer radiotherapy. This study performs Monte Carlo (MC) studies and experimental validations to characterize its performance. **Methods:** A thin slice of x-ray beam (120kVp, 200mA, 50ms) was generated from the x-ray tube on a Varian TrueBeam linear accelerator and the slice was configured to pass the iso-center and the superior-inferior axis. The beam was directed to the moving target around the iso-center in a CIRS lung phantom. We measured the outgoing Compton-scattered photons using a photon-counting detector with a slat collimator. We set up a MC simulation system using an in-house developed GPU-based MC package for kV photon simulations and GATE/Geant4 for MV photon simulations modeling the image formation process. We also investigated effects of scattered photons from the therapeutic MV beam, the impact of scattered photons from bed and walls, and the imaging performance under several beam angles typically used in real treatments. We compared results in simulations and measurements. **Results:** The tumor can be clearly identified on the scattered images in both simulation and experimental results. MC simulations and experimental measurements agreed within 9 %. The scattered photons from the therapeutic MV beam generated a relatively uniform background signal without obvious anatomy structure; hence, they are expected not to affect tumor tracking. MC simulations showed that the amplitude of scattered photons from bed and walls was < 3% of the imaging signal of interest. The image quality does not significantly depend on kV beam angles. **Conclusion:** MC simulations and experimental measurements confirmed the feasibility of using scattered x-ray imaging as a method for real-time image lung tumor tracking.

Evaluation of Bronchoscopically Implanted Anchored Electromagnetic Transponders for Tumor Tracking and Monitoring During Deep Inspiration Breath Hold Lung Radiotherapy

W Harris^{*}, E Yorke, H Li, C Czmielowski, M Chawla, R Lee, A Hotca-Cho, D Mcknight, A Rimner, D Lovelock, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: To evaluate the efficacy of using implanted anchored electromagnetic transponders (EMTs) as surrogates for 1)tumor position and 2)repeatability of lung inflation during deep-inspiration breath-hold (DIBH) lung radiotherapy. **Methods:** 40 patients were treated with either SBRT or conventional lung radiotherapy on an IRB approved prospective protocol using coached DIBH. Three anchored EMTs were bronchoscopically implanted into small airways near or within the tumor.

DIBH treatment was gated with Calypso™ by tracking the EMT positions. Breath-hold cone-beam CTs (CBCTs) were acquired prior to every SBRT treatment or weekly for conventionally fractionated patients. Rigid registration between each CBCT and the patient's breath-hold planning-CT was performed to match to 1) spine 2) EMTs and 3) tumor. Differences in registration between EMT-centroid and spine were analyzed to determine surrogacy of EMTs for lung inflation. Differences in registration between EMT-centroid and tumor were analyzed to determine surrogacy of EMTs for tumor position. **Results:** 221 CBCTs were acquired and analyzed. The average differences between EMT-centroid and spine registration among all CBCTs were 0.05 ± 0.62 cm, -0.05 ± 0.41 cm, and 0.06 ± 0.23 cm in superior-inferior (SI), anterior-posterior (AP) and lateral directions, respectively. Only 58% of CBCTs had differences in registration <0.5 cm for EMT-centroid compared to spine, indicating that lung inflation is not reproducible from simulation to treatment. The average differences between the EMT-centroid and tumor registration among all CBCTs were 0.06 ± 0.18 cm, 0.06 ± 0.19 cm, and 0.02 ± 0.12 cm in SI, AP and lateral directions, respectively. 95% of CBCTs resulted in <0.5 cm change between EMT-centroid and tumor registration, indicating that EMT positions correspond well with tumor position during treatments. **Conclusion:** The implanted anchored EMTs are good surrogates for tumor position and are reliable for monitoring and maintaining tumor position during DIBH treatment when tracking with Calypso™. Large differences in registration between EMT-centroid and spine for most treatments suggest that the level of lung inflation achieved at simulation is often not reproduced.

The authors gratefully acknowledge the financial support of Varian Medical Systems, Palo Alto, CA. The anchored electromagnetic transponders were supplied by Varian Medical Systems, Palo Alto, CA.

Markerless Tracking of Lung Tumor Motion Using Simulated Coded Aperture Scatter Imaging

A Mahl*, B Miller, C Altunbas, B Kavanagh, M Miften, B Jones, University of Colorado Anschutz Medical Campus, Aurora, CO

Purpose: Scattered treatment photons contain information about patient anatomy, yet the extremely low SNR makes scatter imaging challenging. A coded aperture is a device that encodes spatial information into the scatter image to boost the SNR and enable tracking of tumor motion without adding imaging dose to the patient. The purpose of this study was to explore the feasibility of Coded Aperture Scatter Imaging (CASI) for markerless tracking of lung tumors. **Methods:** 4DCT data of 10 lung cancer patients were imported into an MCNP6.2 radiotherapy model that included an MV treatment beam and an orthogonal kV on-board imager (kV-OBI). A MURA Coded Aperture was modeled between the patient and kV-OBI, and simulated scatter images were generated for different respiratory phases. These data were decoded, and the signals originating from the patients' tumors were analyzed. The tumor position was measured throughout the breathing cycle by a template matching algorithm and compared to the reference position. **Results:** Using the CASI method, tumor motion could be detected and tracked within the ITV throughout the patients' respiratory cycle, without adjusting the relative aperture position. Calculated deviations of the template correlation for large, mobile tumor positions were quantified with RMSE values in a range of [0.188-0.302] indicating the capability for accurate identification. Other anatomical features such as the diaphragm, chest wall, and ribs were visualized, along with their motion within the visible field edges. **Conclusion:** CASI is a novel markerless imaging technique which allows for visualizing tumor location and motion during radiation treatment. Results show that the CASI method is effective in visualizing a variety of tumor sizes' and different patient specific respiratory motion. Real-time, markerless tracking of lung tumor motion using scattered treatment photons during radiotherapy delivery might enable more accurate dose delivery while avoiding the risk of invasive fiducial marker placement.

Markerless Motion Tracking with Simultaneous MV/kV Imaging in Spine SBRT Treatment

W Cai*, F Li, X He, P Zhang, L Cervino, X Li, T Li, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: Motion tracking with simultaneous MV/kV imaging has the distinct advantage over single kV imaging system in detecting patient motions in three dimensions in real time. This is the first report evaluating the feasibility and accuracy of the technique in markerless motion tracking for spine SBRT treatments. **Methods:** First, a phantom study was carried out with clinical plans using 6FFF beam and 9 field-sliding window IMRT technique. Simultaneous MV/kV image pairs were acquired on a TrueBeam machine during beam delivery. High quality DRRs were generated using high-resolution CBCT (voxel size of 0.25mm) as the reference for matching. The MV images were taken continuously at 11.6 fps and kV images were acquired every 200MU, leading to 3~7 kV images per beam usually. Due to the limited size of the field aperture in each MV frame, an enhanced synthetic MV (ESMV) image were generated by combining multiple frames of MV images after corrections for scatters and frame intensity fluctuation. 3D translational shifts were then calculated by matching the ESMV/kV image pair to the reference DRRs based on mutual information. The motion tracking accuracy was evaluated by comparing the calculated shifts with the ground truth in the phantom study. Furthermore, the MV/kV motion tracking method was applied to two patient cases to investigate its feasibility in clinic (IRB approved). **Results:** The phantom study showed maximum error of 0.4mm in three directions for all beam angles for the proposed method. For the patient cases, the image acquisitions were seamless with no impact on the normal treatment workflow. The two patient data were retrospectively analyzed and revealed a motion up to 1.1mm and 0.6mm, respectively. **Conclusion:** The proposed simultaneous MV/KV markerless motion tracking technique is feasible of providing high quality orthogonal image pairs and sub-millimeter tracking accuracy in spine SBRT treatments.

The present study is partially supported by a research agreement with Varian Medical Systems.

Estimation of Effective Atomic Number and Relative Electron Density Maps From Single-Energy CT Using Deep Learning

B Kim*, H Kim², S Jung¹, J Son¹, C Choi¹, J Kim¹, J Park¹, (1) Seoul National University Hospital, Seoul, KR, (2) Genai Lab, Seoul, KR

Purpose: In general, parametric maps are derived from dual-energy (DE) computed tomography (CT) which has potential to differentiate materials. This study aims to develop deep generative models for parametric maps from single-energy (SE) CT with clinically used dual-layered DE-CT spectral results. **Methods:** Pix2Pix conditional generative adversarial network (cGAN) and U-net were used for generating parametric maps from conventional polychromatic CT data. For this purpose, effective atomic number (EAN) and 120 kVp CT data of 63 patients were collected from Philips iQon spectral results including: head & neck, chest and abdomen & pelvic images. For training the relationship between parametric maps and CT values, total sets of images were processed with cGAN and U-net, then U-net was applied to head & neck and chest images respectively. This study was implemented under IRB approval. The generated parametric maps were compared to the ones from the original spectral results. Image profiles of the input and output data were obtained and compared. The model performance was then assessed with R-square and pixel similarity values. **Results:** The preliminary results illustrated that U-net model outperformed the cGAN model. Compared to original parametric maps, the image profiles generated from U-net presented more smoothed lines. For head & neck and chest EAN maps, the R-square values were 0.9836 and 0.9793 and the pixel similarity values were 0.9010 and 0.8748, respectively. **Conclusion:** We developed deep learning model for generating parametric maps from conventional CT images and the accuracy of the model was evaluated. Further study consists of generating relative electron density with the commercial DE-CT spectral results and in-house calculated parametric maps.

Are Spectral Modulator and Flying Focal Spot Beneficial for Fast-KV Switching Dual-Energy Cone-Beam CT ?

Hao Zhou, Yifan Deng, Hewei Gao*, Tsinghua University, Beijing, CN

Purpose: This work presents the first attempt to explore the potential of the combination of the spectral modulator and flying focal spot technology for material decomposition and scatter estimation in fast-kV switching cone-beam CT(CBCT)system. **Methods:** A preliminary simulation experiment was performed to investigate how the spectral modulator and flying focal spot affected the energy separation in fast-kV switching CBCT. Three sets of experimental configuration were used for kV switching: 80/140kV, 80/140kV+spectral modulator and 80/140kV+spectral modulator+flying focal spot. The Molybdenum and Copper are selected as the materials of the spectral modulator, and the thickness is set to 0.1mm and 0.4mm respectively taking the similar level of dose into consideration. The material decomposition simulation study was conducted in the three sets cases. The water phantom that we used has a size of 24 cm in diameter in which there are four rods of iodine solutions with concentrations at 5, 10, 15, 20 mg/cc. **Results:** In the simulation case with only spectral modulator applied, the energy separation can be improved from 23 keV to [23,27.5] keV for fast-kV switching CBCT system. In the other case combined with the flying focal spot technology, the spectral modulator can change the energy separation from [23,24] keV to [18,32] keV, while the energy separation of 24% pixels gets worse due to the flying focal spot. In material decomposition study, the CNR of water and iodine was improved in the case of using spectral modulator and flying focal spot. **Conclusion:** The preliminary simulation experiment shows that the spectral modulator and flying focal spot can improve energy separation for the most pixels, which is beneficial for material decomposition. In the future, the algorithms of material decomposition and scatter estimation will be developed for the fast-kV CBCT system combined with spectral modulator and flying focal spot.

Assessment of Cardiac Gout Identification Using Dual EnergyCT and a Dynamic Phantom

A Scott*, Y Zhou, D Zhang, Cedars-Sinai Medical Center, Los Angeles, CA

Purpose: There has been recent clinical interest in identifying gout (monosodium urate – MSU) vs. calcium deposits in the pericardium using dual energy CT (DECT). The unique challenge arises from the small size of the lesion in the fast-moving heart. This study was designed using a dynamic heart phantom and DECT with gated cardiac acquisition to evaluate identification of pericardial MSU in the presence of calcium lesions. **Methods:** The phantom was designed using two batches of kidney stones returned from clinical pathology; one was 80% MSU and 20% calcium oxalate (CaOx), while the other was 100% CaOx. The stones of size 1 - 4mm were loaded into separate 5mm polypropylene tubes, which were also filled with water and sealed. The tubes were inserted into a dynamic cardiac phantom with fillable epicardial coronary artery tracks. The phantom was controlled to execute the manufacturer's cardiac motion pattern at 60 bpm and 90 bpm. It was also kept stationary in combination with synthetic ECG. Imaging was performed on a Siemens Force CT using a DECT retrospectively-gated cardiac protocol at 70% R-to-R peak. For temporal and spatial resolution, the pitch defaulted to 0.19, the rotation time was 0.25 sec, and the tube voltages were 90 and 150(Sn) kVp. Images were reconstructed to thickness of 0.5 mm (Bv36) and processed on dual-energy software to distinguish calcium and MSU. The material decomposition parameters were chosen to maximize MSU identification without false positives from CaOx. **Results:** An average MSU volume (cc) of 0.18 and 0.17 was determined for the stationary and 60 bpm images, respectively. The MSU volume averaged 0.12 for 90 bpm images. The software correctly identified all MSU stones. **Conclusion:** This study shows potential for differentiating pericardial MSU and calcium in vivo, although our findings suggest that quantifying cardiac MSU is affected by lesion motion.

Dose Savings and Image Quality in Dual-Energy Non-Contrast CT Scans

G Anthony*, Y Liang, Indiana University, Indianapolis, IN

Purpose: To assess the benefit of dual-energy (DE) over single-energy (SE) CT and determine optimal tube potential settings across a range of phantom sizes in routine non-contrast abdominal scans. **Methods:** Images of the Catphan 500 phantom low-contrast module were acquired and reconstructed using standard clinical abdominal protocols on a dual-source (Siemens SOMATOM Force, Erlangen, Germany) CT scanner. Phantom scans were repeated with 30- and 35-cm rings added to evaluate SE and DE dose modulation. Six reference dose levels (0.75–24 mGy CTDIvol 32cm) were tested at four SE kVp settings (80, 100, 120, 140) and five DE kVp settings (70/Sn150, 80/140, 80/Sn150, 90/Sn150, 100/Sn150). Dose modulation (CAREDose4D) was enabled to adjust tube current based on phantom attenuation. The water-equivalent diameter (WED) of each phantom was determined. For each WED, size-specific dose estimates (SSDE) and image contrast-to-noise ratios (CNR) were computed. **Results:** Tube current modulation behaved similarly in SE and DE scans. SSDE was consistent across SE and DE kV settings for a given CTDIvol and WED. DE acquisitions (mixing ratio 0.6) consistently produced greater CNR than SE acquisitions. Dose efficiency (CNR per mGy SSDE) was consistently greater for DE acquisitions by 46–89%. Dose efficiency was also greater for lower kV settings when imaging smaller phantom diameters with either SE or paired DE acquisitions. As phantom diameter increased, low-kV settings became less dose-efficient and produced artifacts. **Conclusion:** For equivalent image CNR, non-contrast DE scans can reduce CT dose by approximately 40% over SE scans. For smaller patients, reduced kV settings should also be considered for greater dose efficiency and improved tissue contrast. These results indicate a dose-saving benefit to routine DE abdominal scanning. Contrast performance in vivo may differ from the low-contrast phantom data reported here. Additional benefits of low-contrast detectability in virtual monoenergetic images are being evaluated.

Evaluation of Intra-Manufacturer Dual-Energy CT Iodine Quantification Accuracy: Phantom Studies

A Zhao^{1*}, A Borhani¹, R Catania², (1) Northwestern Medicine, Chicago, IL, (2) Northwestern University, Chicago, IL

Purpose: To evaluate the accuracy of dual-energy CT iodine quantification comparing three different CT models from the a manufacturer, with two phantoms. **Methods:** Two phantoms (one with two setups to evaluate the effect of body habitus) with various nominal known iodine concentration inserts (0.5 to 15 mg/ml, and 2, 4 mg/ml mixed with blood mimicking materials) and other tissue/organ mimicking inserts were scanned with three Siemens CT scanners (Drive, X.cite and Force) that have two different dual-energy mechanisms, using clinically used abdomen/pelvis dual-energy scanning protocols, with different kilovolt peak or energy spectral separation settings and with automatic tube current modulation employed. Scans were performed with different insert locations in one phantom. Iodine concentration measurements were made on the images generated on Siemens Syngo.via. Linearity of measured iodine concentrations with nominal known insert concentrations were assessed. The absolute iodine concentration difference between aforementioned two were also analyzed. **Results:** Measured iodine concentrations from all three scanners are linear with nominal known iodine concentrations, with R^2 values between 0.9935 and 1. Among three scanners, absolute difference on iodine concentrations measured from two phantoms ranged from -1.8 to 0.7 mg/ml and from -1.5 to 1.6 mg/ml, respectively, with one scanner outperformed the other two on one phantom. Accuracy of iodine quantification was degraded prominently at 10 and 15 mg/ml on two scanners, especially when these inserts were placed in the periphery of the phantom that mimics large body habitus. One scanner showed notable degradation on contrast-enhance blood iodine concentration, while one scanner showed slight improvement, when those inserts were placed in the large-sized phantom. **Conclusion:** There's general agreement on iodine quantification accuracy with notable variations among three scanners from the same manufacturer. Locations of the iodine inserts and size of the phantom resulted in different accuracy of iodine quantification.

TH-IePD-TRACK 1-06

The Impact of Dual Energy CT (DECT) Protocol Settings on Image Quality

R Nosrati^{1,2*}, M Palmer³, O Brook³, D Zhang^{1,2}, (1) Harvard Medical School, Boston, MA, (2) Children's Hospital, Boston, MA, (3) Beth Israel Deaconess Medical Center, Boston, MA

Purpose: To explore the acquisition parameter space in dual source DECT by analyzing the impact of kVp, Quality Reference mAs ratio (QRM=QRM(A):QRM(B)), and pitch on image quality. **Methods:** A custom anthropomorphic phantom (25Hx32Wx25Lcm) was constructed with soft tissue-mimicking material and organ-mimicking inserts simulating liver, pancreas, kidney, aorta, bone, and water, with realistic organ-specific HU values, size and relative positions. Each organ contained a cylindrical insert that simulates iodinated organ tissue. The phantom was scanned on a Siemens dual-source scanner with single-energy (SE) and DECT. A standard DECT protocol (90/Sn150kVp, QRM=1.6, pitch=0.6) was considered as baseline and subsequent DECT scans were performed by individually varying pitch (0.9,1.2), QRM (1.2,2,4), and kVp (70/Sn150, 80/Sn150 and 100/Sn150). QRM(A) and QRM(B) were adjusted to maintain CTDIvol of 7.5mGy. CNR,SNR, and noise were calculated and compared using ANOVA for all organs on SECT and mixture DECT images. **Results:** Pitch of 0.6 on average improved the CNR by $11\pm4.2\%$ ($p<0.05$) compared to other investigated pitch values while changing pitch from 0.6 to 1.2 had no significant impact on the noise or organ HU ($p>0.7$). Among the four tested kVp pairs, although 70/Sn150kVp resulted in the highest average noise level ($p<0.05$), it improved the CNR by an average of $14.1\pm8.2\%$ ($p<0.05$) in iodinated tissues with no significant impact on CNR of non-iodinated organs. The changes in QRM from 1.2 to 4 did not introduce any visible artifacts or changes in noise performance ($p>0.5$). **Conclusion:** Increasing pitch from the vendor-recommended value (0.6) to higher ones did not significantly impact CT number accuracy and noise performance in mixture images, implying the possibility of using faster scans to mitigate motion artifacts. With similar CTDIv, CNR was higher in all DECT contrast-enhanced images compared to SECT, indicating the feasibility of reducing patient exposure with an optimized DECT protocol while maintaining/improving CNR.

TH-IePD-TRACK 1-07

Spectrally Neutral CT Calibration

R Jennings*, Retired, Olney, MD

Purpose: To describe a computational approach to the design of spectrum-independent CT calibration materials and describe preliminary experimental verification. **Methods:** : The basis material paradigm asserts that the linear attenuation coefficient of an arbitrary material can be accurately represented by a combination of the linear attenuation coefficients of two dissimilar materials. The combined thicknesses, relative to the material being studied, of the basis materials do not, in general, equal unity. Adding a third material resolves that issue. Although the desired result is that the combined relative thicknesses of the three materials be equal to 1.0, volume changes when components are mixed may occur. Replacing the thickness condition of 1.0 with a constant, call it k, close to 1.0 allows for an iterative procedure that results in the desired match. If the constant is allowed to have values significantly greater or less than 1.0, and the material being characterized is water, the result is a mixture that has a constant ratio in attenuation coefficient relative to water, i.e., its CT number is independent of energy and is determined by the value of k. **Results:** Mixtures with nominal HU values greater than 0 were calculated using glycerol, water, and salt. Mixtures for negative CT numbers were calculated using isopropanol, water, and potassium nitrate. CT numbers up to 248 and down to -183 could be reached with the components studied. CT scans on a SIEMENS SOMATOM Force dual source CT scanner with samples calculated to produce HU values of 100 after correction for volume change were within 1 HU of the target value at kVs from 80 to 140. **Conclusion:** The method described produces material formulations that give CT numbers that are independent of x-ray spectrum. These formulations may be useful for the calibration of CT systems, especially in facilities with multiple scanners.

Comparison of Single Breathhold MDixon-Quant and Multi-Echo GRE Methods to Spin Echo Method for Estimating Liver Iron Concentration

J Zhang^{1*}, D Akselrod¹, J Gonyea², S Hipko^{1,2}, J Tam¹, M Bazylewicz¹, (1) University of Vermont Medical Center, Burlington, VT, (2) University of Vermont, Burlington, VT

Purpose: Ferriscan is FDA approved to determine liver iron concentration (LIC). It is a spin echo (SE) free breathing technique which is time consuming and motion degraded. We evaluated two single breath-hold **Methods:** 3D mDixon-quant (mDixon) and multi-echo gradient echo (GRE). LIC from these breath-hold techniques were compared to LIC from Ferriscan. **Methods:** Patient population: 12 subjects (age 8-80 years; 8 males), referred to MRI to estimate LIC, were scanned on a 1.5T magnet. The data was retrospectively analyzed. Institutional review board approved waiver of individual consent. MRI parameters:GRE: 16 echoes were acquired at TE1/ΔTE 1.08ms/0.8ms, TR/14ms, Flip angle(FA)/20°, time of acquisition (TA) per breath-hold: 10.7sec. mDixon: 6 echoes were acquired at TE1/ΔTE 0.92ms/0.7ms, TR/5.3ms, FA/5°. TA per breath-hold: 11.6sec. Ferriscan: multi-acquisition to acquire 5 echoes (6ms, 9ms, 12ms, 15ms, and 18ms) for R₂ calculation, TR/1000ms, FA/90°. Each TA: 117sec. Data analysis: The GRE data was fitted to an exponential decay to yield T2* maps. mDixon T2* maps were derived from a six-point method. LIC(GRE) and LIC(mDixon) were calculated using the equation: $LIC[mg/g\ dry]=0.0254x(1000/T2^*[ms])+0.202$. Resonance Health calculated the Ferriscan LIC(SE). The agreement between LIC(SE) vs LIC(mDixon) and LIC(GRE) was determined using Bland-Altman analysis. **Results:** Ferriscan images from all subjects had significant motion, limiting the area of liver available for LIC evaluation. mDixon and GRE images had little motion. There was strong agreement (bias ± 2SD): $0.50 \pm 1.04\ mg/g\ dry$, $0.79 \pm 1.06\ mg/g\ dry$ and $0.29 \pm 0.48\ mg/g$ when comparing LIC(GRE) vs LIC(SE), LIC(mDixon) vs LIC(SE), and LIC(mDixon) vs LIC(GRE) respectively. **Conclusion:** LIC values from the mDixon and GRE techniques are consistent with the Ferriscan LIC. These results require validation in a larger cohort of patients. An advantage of mDixon, the entire liver is imaged, is the ability to provide both LIC and fat fraction.

Analysis of Diffusion and Microstructure Properties in Brain Tumors Using a Random Walk with Barriers Model

Y Li^{1*}, M Kim², T Lawrence³, T Feiweier⁴, Y Cao⁵, (1) University of Michigan, Ann Arbor, MI (2) University Of Michigan, Ann Arbor, MI (3) University of Michigan, Ann Arbor, MI (4) Siemens Healthineers (5) The University of Michigan, Ann Arbor, MI

Purpose: Restricted water diffusion in microstructural tissue depends upon measurement (diffusion) time. A random walk with barriers model (RWBM) could analyze these effects on diffusion to reveal microstructural properties from macroscopic imaging characteristics within heterogeneous brain tumors. Gross tumor volume in gadolinium enhanced T1-weighted images (GTV-Gd) usually contains tumor mixtures, which is difficult to be analyzed by a single diffusion measurement. This research aims to combine clustering analysis with the RWBM to demonstrate microstructural diffusion properties in brain tumors. **Methods:** Ten patients with brain tumors (eight with brain metastases, two with glioblastoma) had diffusion weighted (DW) images with three different diffusion times using pulsed diffusion gradients (PG) and sine-modulated oscillating gradients at $f=30\text{Hz}$ (OG30) and $f=50\text{Hz}$ (OG50) of a prototype sequence on a 3T scanner (MAGNETOM Skyra, Siemens Healthcare). DW images were acquired in 6 diffusion directions with 8 b-values (0 to 2600 s/mm²) for PG, 6 b-values (0 to 1300 s/mm²) for OG30, and 5 b-values (0 to 500 s/mm²) for OG50. The delineated GTV-Gd of each tumor, if $> 1\text{ cm}^3$, was classified to smaller volumes using DW image intensities and fuzzy c-means. The RWBM that characterizes time-dependent diffusion was applied to DW images in the GTV-Gd to yield five parameters: cell diameter, unrestricted diffusion coefficient (D_0) at a short time limit, bulk diffusion coefficient ($D(\infty)$) at a long time limit, membrane permeability and effective restriction. **Results:** Of 23 brain tumors, the mean tumor cell diameter of GTV-Gds was $(16.5 \pm 4.20)\text{ }\mu\text{m}$. D_0 was $(2.20 \pm 0.70)\text{ }\mu\text{m}^2/\text{ms}$. $D(\infty)$ decreased to $(0.60 \pm 0.14)\text{ }\mu\text{m}^2/\text{ms}$ due to microstructure restrictions with the mean effective restriction of 2.8 ± 1.2 and the mean membrane permeability of $(0.053 \pm 0.009)\text{ }\mu\text{m}/\text{ms}$. **Conclusion:** The RWBM yields parameters beyond analyzing DW images with a single diffusion time, and has potential to reveal microstructure of brain tumors with further investigation.

Leveraging Prior Knowledge to Reconstruct Quantitative MR Relaxation Maps to Investigate Glioma Tumor Heterogeneity

X Zhao^{1*}, D Parsons², Z Iqbal¹, (1) University of Alabama - Birmingham, Birmingham, AL, (2) UT Southwestern Medical Center, Dallas, TX

Purpose: The purpose of this study is to generate relaxation maps from clinical MRI scans by leveraging prior knowledge. Furthermore, we analyze joint histograms of these maps (T1 pre contrast, T1 post contrast, and T2 relaxation maps) to investigate glioma tumor heterogeneity. **Methods:** This study uses 50 patients from the multi-modal brain tumor image segmentation benchmark (BRATS) dataset, which contains four tumor sub-type volumes (necrotic core, edema, non-enhancing and enhancing tumor), T1-weighted (T1-w), T2-weighted (T2-w), and T1-weighted post contrast (T1c-w) MR images. By employing a novel method, we generate relaxation maps (T1, T2, and T1c maps) by leveraging relaxation values of white matter (WM) and cerebral spinal fluid (CSF) from the literature and calibrating the clinical MRIs based on these values. After the calibration process, the gray matter (GM) T1 and T1c relaxation values are automatically assessed for quality control purposes. 3D joint histograms (JH) were then created using all voxels within the tumor and each tumor sub-type. We calculated the JH center of masses, which are defined in the T1-T2-T1c relaxation coordinate system, for each sub-type, and quantitatively evaluated the relationship of these center of masses using a correlation matrix across all patients. **Results:** Relaxation maps for 6 patients were deemed unacceptable for further analysis using the developed GM quality control metric. Multiple subtypes' center of mass correlations across the remaining 44 patients showed correlation values of $r > 0.5$, corresponding to $p < 0.0005$. The highest correlation is 0.894 between the non-enhancing T1 and the non-enhancing T1c, meaning that the relationship between these relaxation values is most consistent across all patients. **Conclusion:** We present a novel method capable of estimating relaxation maps for any set of T1-w, T2-w, and T1c-w clinical MRIs, and believe these maps can be valuable tools capable of characterizing changes in tumor heterogeneity over time.

Obtaining New Contrasts From a Single T1-Weighted Image

Y Wu¹, Y Ma², N Kovalchuk¹, J Du², L Xing^{1*}, (1) Stanford University, Palo Alto, CA, (2) University of California San Diego, San Diego, CA

Purpose: While MRI contrast is predetermined by imaging protocol, it can be retrospectively tuned, which is potentially useful for normalizing MRI data for radiomics. In this study, we present a new paradigm to obtain various contrasts from a single T1-weighted image. **Methods:** We propose a contrast tuning framework that combines deep learning-based quantitative MRI with Bloch equations. Using deep neural networks, quantitative tissue relaxation parametric maps (T1 map, proton density map) and field map (B1 map) are predicted from a single T1 weighted image. Here, ground truth T1 map was obtained from four variable-flip-angle T1-weighted images and a B1 map (measured using the actual flip angle method); proton density map was calculated from T1-weighted image and T1 map. In these tasks, self-attention convolutional neural network is employed with unique shortcuts equipped and attention mechanism integrated. A total of 1,344 knee images from 56 subjects are utilized for training and testing in six-fold cross validation. Given estimated parametric maps, MR images with different contrasts are generated with the application of Bloch equations. While a wide spectrum of contrasts can be obtained with various imaging parameter values, the result is only validated at certain contrasts (corresponding to variable flip angles). **Results:** High accuracy has been achieved in quantitative parametric maps and qualitative images. From a T1-weighted image, quantitative T1 map, proton density map and B1 map are predicted with an averaged correlation coefficient of 0.95~0.99 and L1 error of 0.02~0.09; and T1-weighted images corresponding to alternative flip angles are obtained with an averaged correlation coefficient of 0.97~0.99 and L1 error of 0.04~0.09. **Conclusion:** A new data-driven strategy is proposed for retrospective MRI contrast tuning from a single T1-weighted image, which requires no additional data acquisition.

Deep Learning Based T2* Mapping From MRI Images with Different Types of Weighting

Y Wu¹, Y Ma², N Kovalchuk¹, J Du², L Xing^{1*}, (1) Stanford University, Palo Alto, CA, (2) University of California San Diego, San Diego, CA

Purpose: Quantitative T2* mapping is important for the diagnosis and management of knee diseases. However, derivation of T2* maps typically requires acquisition of multi-echo images, which is time consuming. In this study, we present a new paradigm to predict T2* map from two conventional images obtainable in a standard clinical MRI examination, thus eliminating additional data acquisition for quantitative MRI. **Methods:** A deep learning framework is proposed to predict T2* map from a T1-weighted image and a T2*-weighted image. The principle is validated on knee MRI. 1344 T2* maps from 56 subjects are retrospectively collected. Every T2* map was extracted from six T2*-weighted images acquired with different echo time (of 0.032, 4.4, 8.8, 13.2, 17.6, and 22ms); in addition, a T1-weighted image was acquired. To derive T2* map from two input images, a self-attention convolutional neural network is employed. Here, a hierarchical network architecture is adopted; global and local shortcuts are equipped to facilitate residual learning; and attention mechanism is integrated to make efficient use of non-local information. Separate deep neural networks are trained, each accepting T2*-weighted image obtained with a specific TE. In training, a mixed function of l1 loss and SSIM loss is employed, and network parameters are updated using the Adam algorithm. All 1344 images are utilized for training and testing in a six-fold cross-validation strategy. The prediction result is quantitatively evaluated within the region of interest (i.e. cartilage manually segmented). **Results:** Using well-trained models, T2* maps are predicted from single T2*-weighted images (acquired using TE of 4.4, 8.8, 13.2, or 17.6ms) along with corresponding T1-weighted image. High accuracy has been achieved. The averaged L1 error with ROI is 0.13. **Conclusion:** A data-driven strategy is proposed for T2* mapping from two conventional MR images, which has a potential to eliminate additional data acquisition for quantitative MRI.

Quantitative Inter-Vendor Evaluation of PDFF and R2* Mapping Accuracy for 3T MRI Scanners

J Yu*, A Panda, Mayo Clinic, Arizona, Scottsdale, AZ

Purpose: To evaluate the relative accuracy of proton density fat fraction (PDFF) and R2* mapping sequences at 3T from different MRI scanner manufacturers and pulse sequence types using standardized quantitative MRI phantoms. **Methods:** PDFF and R2* phantoms manufactured by Calimetrix were scanned twice on GE PETMR, GE 750W, Siemens Vida, and Siemens Skyra platforms using the body coil and the two measurements averaged. For GE, IDEAL-IQ sequences were used to generate the fat fraction and R2* maps. For Siemens, product q-Dixon sequences were used, as well as a work-in-progress (WIP) q-Dixon sequence on the Skyra. MR parameters were kept at manufacturer's defaults. Data was processed by drawing a 1.6cm diameter circular ROI over the phantom vials DICOM images and recording the mean ROI value. **Results:** IDEAL-IQ sequences had lower overall average percent error for PDFF calculation, with 750W and PETMR measuring 2.6% and 7.1% error respectively. Skyra WIP q-Dixon had 4.8% error for PDFF; Vida product q-Dixon had 16.1% error. Siemens scanners were more accurate than GE for R2* measurements: Skyra WIP q-Dixon measured 7.1% error, and Vida product q-Dixon measured 7.8% error. In contrast, 750W and PETMR measured 14.6% and 17.7% error, respectively. Data from the Skyra product q-Dixon sequence was not accurate for both PDFF and R2* calculations, with an average error of 72% and 59%, respectively. Greater inaccuracy was observed at the high and low ends of the phantom's PDFF and R2* scale for both vendors, suggesting that extreme values are more challenging to reconstruct accurately. **Conclusion:** We observe modest accuracy for PDFF and R2* mapping sequences on both GE and Siemens MRI scanners, suggesting further refinement of reconstruction algorithms is possible. These results also highlight the importance of validation of quantitative results before integration into clinical workflows.

Automatic Stratification of Prostate Cancer Patients into Low- and High-Grade Groups Using a Support Vector Machine Model with Multiparametric Magnetic Resonance Image Features

A Urakami^{1*}, H Arimura², Y Takayama¹, F Kinoshita¹, K Ninomiya¹, K Imada³, S Watanabe², A Nishie¹, Y Oda³, K Ishigami¹, (1) Kyushu University Graduate School of Medical Sciences, Fukuoka, JP, (2) Kyushu University Faculty of Medical Sciences, Fukuoka, JP, (3) Kyushu University Hospital, Fukuoka, JP

Purpose: To explore the potential of automatic stratification of prostate cancer patients into low- and high-grade groups using a support vector machine (SVM) model with multiparametric magnetic resonance (MR) image features. **Methods:** MR images [T1- and T2-weighted, diffusion weighted b=0, b=1,000, b=2,000, and apparent diffusion coefficient (ADC) images] of 101 cancer regions corresponding to histopathological images of prostate cancer were selected and divided into a training (n=72) and test datasets (n=29). Each dataset was divided into two groups, low-grade tumors [$\leq$ International Society of Urological Pathology (ISUP) Grade Group (GG) 2] and high-grade tumors (ISUP GG3 $\leq$). 1,620 MR image features were derived from original images and two-dimensional wavelet filtered images for the six types of images. Seven significant features were chosen by using a least absolute shrinkage and selection operator (LASSO) algorithm to build a SVM model. Parameters of the SVM model were optimized based on a leave-one-out cross validation test so that areas under receiver operating characteristic curves (AUCs) can be maximized. **Results:** The most significant feature was one of wavelet features from ADC images. The AUCs based on the SVM model of the automatic stratification of prostate cancer patients into two groups were 0.977 in the training dataset and 0.910 in the test dataset. **Conclusion:** This study suggested the potential of automatic stratification of prostate cancer patients into low- and high-grade groups using the SVM model with multiparametric MR image features.

Benchmark of 4DCT Derived Motion Models with a Biomechanical Lung Model for Tumor Position Estimation

P Sabouri^{1*}, M Ranjbar², S Mossahebi³, A Sawant³, P Mohindra³, G Lasio³, L Topoleski², (1) Miami Cancer Institute, Miami, FL, (2) University of Maryland, Baltimore County, MD, (3) University of Maryland, School of Medicine, Baltimore, MD

Purpose: Several CT-based surrogate motion models (SMM) have been proposed to simulate the complexities of respiratory motion and cycle-to-cycle variations in the thoracic anatomy. However, the lack of high-contrast internal imaging on most linear accelerators limits evaluating the model's intra- and inter-fractional reproducibility and validity. Biomechanical models can serve as a reference for SMM verification because they are able to capture the underlying biophysical principles of lung-tumor motion. We used a hybrid finite-element (FE) lung-tumor motion model to benchmark the accuracy of two SMMs for tumor position estimation. **Methods:** 4DCT, VisionRT surfaces (VRT), and ~30s lateral and anterior-posterior fluoroscopic images (FLs) were collected from five lung-SBRT patients and used to construct two previously published CT-based volumetric SMMs: SMM-1 used a correspondence between 4DCT and phase-averaged VRT surfaces to estimate deformation vector fields for new VRT surfaces. SMM-2 integrated lung-surface motion observed in a few FLs to update the external-internal correlation. A FE biomechanical lung-tumor model was constructed and used as reference to verify SMM estimated tumor position. Prior validation of our FE model for 4DCT found an accuracy of 3 mm for centroid position estimation. **Results:** Changes in the external-internal correlation were frequently encountered and degraded SMM-1 performance. The correlation between internal lung-surface and tumor centroid motion was more stable, and SMM-2 fidelity was preserved with updates. Model updates significantly improved agreement with the biomechanical model: the 99th percentile absolute difference in tumor SI/AP centroid motion was reduced from 7/5.2 mm (SMM-1) to 3.4/2.6 mm (SMM-2). Differences between the SMM-2 and biomechanical model were most notable for tumor positions beyond the original training data set (4DCT), where SMM-2 resorted to extrapolation. **Conclusion:** Biomechanical models offer a robust mechanism for verifying SMM-estimated internal lung-tumor motion. Updating the external-internal correlation preserves SMM fidelity and significantly improves agreements with the FE model.

Feasibility of Intrafraction Motion Management Using Triggered KV Imaging During Spine Stereotactic Radiosurgery

J Koo^{1*}, L Nardella¹, M Degnan², J Andreozzi¹, H Yu¹, J Penagaricano¹, P Johnstone¹, D Oliver¹, K Ahmed¹, S Rosenburg¹, E Wuthrick¹, R Diaz¹, V Feygelman¹, E Moros¹, G Redler¹ (1) H Lee Moffitt Cancer Center and Research Institute, Tampa, FL, (2) The Ohio University, Columbus, OH

Purpose: Precision is vital in spine stereotactic radiosurgery (SRS) due to highly-conformal dose distributions and ~1mm margins. However, most image-guided radiotherapy (IGRT) techniques only monitor interfraction motion or require specialized devices to monitor intrafraction motion. Feasibility of utilizing triggered kV imaging with the TrueBeam advanced imaging package to capture intrafraction motion during the treatment of spine SRS patients is investigated. **Methods:** Triggered kV imaging for intrafraction motion management was tested with an anthropomorphic phantom and simulated spine SRS treatments to the thoracic and lumbar spine. Various shifts/rotations were introduced in x, y, z, pitch, and yaw. Gantry-angle-based triggering was set to acquire kV images every 45s to investigate how well various shifts could be visualized. The anterior portion of the vertebra (to spinal canal) and spinous process were contoured as IGRT structures. Upon each triggered kV image acquisition, a 2D projection of the IGRT structures was automatically calculated and updated at arbitrary angles for display onto kV images (qualitative visual guide for patient alignment during treatment delivery). This method was implemented clinically for treatment of 32 patients (75 fractions). During treatment, patient positions were monitored with kV images triggered every 15 seconds. **Results:** Phantom images revealed that IGRT structure accuracy and therefore utility
