of projected contour during triggered imaging improved with smaller CT slice thickness. Contouring vertebra superior and inferior to the treated site was necessary to detect clinically relevant phantom rotation. Clinical implementation verified robustness of patient immobilization. Based on visual inspection of projected IGRT contours on planar kV images, appreciable intrafraction motion was detected in only one fraction (1.3%). **Conclusion:** Feasibility of triggered imaging for spine SRS intrafraction motion management has been demonstrated in phantom experiments and implementation for patient treatments. This technique allows efficient, non-invasive monitoring of patient position using the TrueBeam OBI and patient anatomy as a direct visual guide.

Respiration-Induced Target Motion Prediction from a Surrogate Signal in Radiotherapy : A Bayesian Framework

C Remy^{1,2}, D Ahumada^{1,2}, A Labine^{1,2}, J Côté³, M Lachaine⁴, H Bouchard^{1,2,3}, (1) Université de Montréal, Montréal, QC, CA, (2) Centre de recherche du Centre hospitalier de l'université de Montréal, Montréal, QC, CA, (3) Centre hospitalier de l'université de Montréal, Montréal, QC, CA, (4) Elekta Ltd., Montreal, QC, CA

Purpose: To account for respiration-induced motion during lung radiotherapy, indirect tracking requires surrogate-based correlations and system latency compensation. The present study proposes a unified Bayesian framework addressing both issues. Its potential to predict both future target motion from a surrogate signal and the related uncertainty is investigated. **Methods:** The proposed framework is based on a Kalman filter theory specifically adapted for surrogate measurements. Since the quality of the surrogate motion affects the accuracy of the method, two external surrogates (abdominal and thoracic markers) and an internal surrogate (liver structure) are examined. Their motions and simultaneous lung target motion are collected for 9 volunteers during 4 minutes each, including drastic breathing changes to assess the robustness of the method. A comparison with an artificial non-linear neural network (NN) is performed. The first 15 seconds of each volunteer's sequence are used to train both methods, while testing is conducted under two scenarios: a worst-case scenario and a simplified one. **Results:** Latencies ranging from 200 to 800 ms are tested. Surrogate predictability and target-surrogate correlation are also independently assessed to provide interpretable insights into the accuracy of the method. While the prediction errors from the thoracic surrogate are reduced with the NN in some cases, the proposed framework outperforms the NN in most cases when using the liver and the abdomen surrogates. The Bayesian method is found more robust to increasing latencies and to breathing variations. The thoracic marker is found to be less reliable than the other surrogates to predict the target position, whereas the liver appears as a better surrogate. **Conclusion:** The proposed framework predicts both expected target positions and their associated confidence intervals. This study opens the way for real-time uncertainty prediction to further assist motion management decisions. Future work will investigate an adaptive version of the proposed framework.

This research was supported by Elekta, Medteq and NSERC (Collaborative Grant no. CRDPJ/502332-2016) and in part by the Fonds québécois de la recherche sur la nature et les technologies (FRQNT scholarship no. 271036).

Verification of a System for Real-Time EPID Based Breath Hold Monitoring During DIBH Tangential Breast Cancer Radiotherapy

E Vasina¹, P Greer², D Thwaites³, J Lehmann^{4*}, (1) University of Newcastle, AU, (2) Calvary Mater Newcastle, Newcastle, AU, (3) University of Sydney, Camperdown, Sydney, AU, (4) Newcastle Mater Hospital, Newcastle, AU

Purpose: In breast cancer radiotherapy, the deep inspiration breath hold (DIBH) technique helps sparing heart, lungs, and liver from unintended radiation. The quality of DIBH is typically assessed via surrogates with varying degree of correlation with the patient's anatomy. This work reports on the accuracy validation of an anatomy based system for assessment of the quality of DIBH using live MV images collected with the electronic portal imaging device (EPID). **Methods:** The system consists of: (i) an image grabber application which acquires and saves MV EPID frames as TIFF files and (ii) image-processing software which analyses the files to assess the quality of the breath hold in real time. Measures used in the assessment are the lung depth (LD) and the distance from the breast surface to the posterior field edge (skin distance, SD) at user-defined locations. The system has been developed using 1000+ patient images. To assess the accuracy of the system, images of radiotherapy phantoms placed on and moved by a precision motion platform were analysed and the observed LD and SD were compared to those expected from the applied motion. A clinical surface imaging system was employed to confirm the phantom motions. **Results:** The accuracy of LD and SD measurements for a PMMA CTDI phantom were 0.31(1.09) mm (mean (standard deviation)) and -0.10(0.14) mm, respectively. The accuracy of LD and SD measurements on an E2E SBRT phantom were 0.01(0.18) mm and 0.05(0.08) mm, respectively. The latency of the system is <350 ms: the sum of the time delays of the image grabber (100ms) and the image processing (<250ms) applications. **Conclusion:** The system is able to assess the quality of DIBH breath hold via LD and SD with sub-millimetre accuracy. Processing times are short enough for real time clinical use. Clinical measurements with patients have begun.

This work is supported by National Health and Medical Research Council (NHMRC) grant 1147533 of the Australian Government.

Inter-Fraction Motion Assessment and Accumulated Dose Quantification of Upper GI Organs During MR-Guided Ablative SBRT Treatment

S Alam^{1*}, H Veeraraghavan¹, K Tringale¹, E Amoateng², C Crane¹, N Tyagi¹, (1) Memorial Sloan Kettering Cancer Center, New York, NY, (2) City University of New York, New York, NY

Purpose: To quantify inter-fraction deformations and dose accumulation of upper GI organs using T2w MRI in locally advanced pancreatic cancer (LAPC) patients undergoing MR-guided ablative SBRT on Elekta Unity MR-linac. **Methods:** Five LAPC patients underwent 5 fraction SBRT treatment using daily online plan adaptation to 50Gy. A pneumatic compression belt was used for all treatments to minimize GTV motion within 5mm. Between each consecutive fraction, pre-treatment MRI was deformably registered to next fraction using in-house Large Deformation Diffeomorphic Metric Mapping (LDDMM) deformable image registration (DIR) method and the total dose delivered to the duodenum-stomach, small and large bowels were accumulated. Inter-fraction deformations were quantified for all three directions using gradient magnitude of the Deformation Vector Fields (DVF). The DVFs were fit to a B-spline to provide elasticity to the converging/diverging vectors resulting from large organ deformations. Registrations were assessed using Dice and Hausdorff distance (HD) calculated between the deformed and physician's contours. DIR accumulated dose metrics (Dmax, D0.035cc, D2cc and D5cc) were compared against rigidly accumulated doses. **Results:** A total of 25 MRIs were analyzed. Average Dice and 95th percentile HD were: Stomach (0.93, 1.2mm), Small bowel (0.84, 4.4mm), and Large bowel (0.88, 3.2mm). Small bowels showed the largest motion with maximum (mean±SD) inter-fraction deformation of 21.9mm (9.1±2.5mm) compared to stomach: 15.8mm (6.8±2.8mm) and large bowels: 20.9mm (8.8±3.6mm). Mean difference between rigid and DIR accumulated dose for D0.035cc and D5cc was 1.52±0.59, 1.29±0.96 and 1.56±0.9 Gy and 0.36±0.26, 0.53±0.4 and 1.43±0.44 Gy for stomach, small bowel and large bowel respectively for all the fractions. **Conclusion:** LDDMM registration was able to account for large deformations of upper GI organs greater than 2cm. Rigidly accumulated doses to all organs at risk were significantly larger compared to DIR, suggesting use of deformable dose accumulation to spare major mobile structures for LAPC patients.

Tumor Motion Tracking in a KV Scattered X-Ray Imaging System for Lung Cancer Radiotherapy

Y Zhong^{1*}, T Chiu¹, Y Huang¹, Y Shao¹, C Shen¹, K Yang², X Jia¹, (1) UT Southwestern Medical Center, Dallas, TX, (2) Harvard Medical School, Massachusetts General Hospital, Boston, MA

Purpose: Tumor motion tracking is a critical component of lung radiotherapy. We previously proposed a new scheme of using kV scattered x-ray photons for markerless tumor tracking and presented the imaging capability of using photon-counting detection. This study investigates suitability of this technique for tumor motion tracking accuracy via experiments and Monte Carlo (MC) simulations. **Methods:** A CIRS lung phantom was used in the measurements and modeled in the simulation. The targeted tumor with a diameter of 2 cm was aligned to the iso-center. The collimated primary X-rays from the on-board kV X-ray tube illuminated the tumor from 45° gantry direction. The scattered X-rays were detected using a photon-counting detector (XC_THOR, DirectConversion, Sweden) with a parallel multi-hole collimator. The kV x-ray technique was 120 kVp and 10 mAs (200 mA, 50 ms). Exposure time of 50ms was selected to achieve a 10 Hz imaging speed. An MV beam (6 MV, 600 MU/min, 2x2 cm²) was used to study the performance during treatment delivery. To investigate the tumor-tracking accuracy, we moved the couch in 1 mm steps in the superior-inferior (SI) direction in experiments. In MC simulation, the tumor was moved with a speed of 1 cm/s in the SI direction and along the kV beam direction. We tracked the tumor position in the scattering images using template-matching and compared with the ground truth. **Results:** The tumor can be visually identified clearly on the measured and the simulated kV scattered X-ray images. The measured tumor positions agreed well with the ground truth positions in the experiments and the simulation study, with the mean error of 0.65 mm and 1.0 mm for the experiments and simulation respectively. **Conclusion:** The experiments and simulations demonstrated sufficient motion tracking accuracy of real-time tumor tracking using the proposed technique.

TH-IePD-TRACK 3-07

Motion-Robust Free-Breathing Abdominal MR Fingerprinting (MRF) Using Radial Acquisition and Temporal Compressed Sensing Reconstruction: Initial Results

E Subashi^{1*}, V Yu², C Wu³, P Koken⁴, M Doneva⁵, R Otazo⁶, O Cohen⁷, (1) Memorial Sloan Kettering Cancer Center, New York, NY, (2) Memorial Sloan Kettering Cancer Center, New York, NY, (3) Memorial Sloan Kettering Cancer Center, New York, NY, (4) Philips Medical Systems, (5) Philips Medical Systems, (6) Memorial Sloan Kettering Cancer Center, New York, NY, (7) Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: Quantitative relaxometry in the abdomen is challenging due to respiratory, pulsative, and peristaltic motion. We present an implementation of free-breathing MR-fingerprinting and study improvements in image quality as a function of reconstruction. **Methods:** The acquisition method relies on golden-angle radial sampling combined with a varying flip-angle (FA), gradient-spoiled, SSFP MRF sequence. The imaging sequence consists of an inversion pulse followed by the varying FA train and a delay time (Td) to allow for relaxation to thermal equilibrium. The exam parameters were: TR/TE/TI=8/4/15 ms, FOV=25x25cm², matrix=224x224, and slice thickness=5mm. Two FA schedules were studied. The number of spokes/dynamic was varied in the range [1 2 3 4 5 10] while Td was varied in the range [0.1 1 10] seconds. Golden-angle radial sparse parallel (GRASP) reconstruction was implemented with total variation (tTV) or principal-component analysis (tPCA) as regularization functions in the temporal domain. Template matching was used for T1/T2 calculations. The quantitative maps derived from tTV-GRASP, tPCA-GRASP, and conventional gridding were compared using a NIST phantom with known T1/T2 values. Image quality was also compared in a healthy volunteer during a free-breathing (FB) and (BH) acquisition. **Results:** The bias for T1 and T2 was comparable in parameters calculated with gridding and tTV-GRASP, and larger for tPCA-GRASP reconstructions. For T1, we find an approximately two-fold decrease in the standard deviation of maps calculated with tTV-GRASP compared to gridding and tPCA-GRASP. For T2, tTV-GRASP and tPCA-GRASP generated maps with comparable uncertainty but improved when compared to gridding. The improvements were dependent on the number of spokes/dynamic, Td, and FA schedule. **Conclusion:** GRASP provides a feasible method for free-breathing MR-fingerprinting with improved image quality and reduced sensitivity to artifacts from physiologic motion.

Evaluation of a Novel Film Dosimetry System: Orthochromic OC-1 Film

S Lim*, G Tang, Memorial Sloan-Kettering Cancer Center, New York, NY

Purpose: A new radiochromic film dosimetry system consists of the new OrthoChromicTM OC-1 film and a novel calibration procedure was evaluated. **Methods:** The novel calibration procedure involved both intensity-to-dose conversion and scanner spatial correction using OrthoChromic-Pro software. Two films, C1 and C2, were exposed simultaneously using the 6xFFF beam with a step-wedge pattern of five 15x3 cm² steps ranging from 590 to 3000 cGy. The films were placed in solid water at 5.0 cm depth and SAD 100 cm. C1 was used for calibration and C2 was used to validate the calibration curves. Another set of films were irradiated to characterize the film system. A film was exposed with an open 20x20 cm² field at SSD 100 cm and 5 cm depth. The beam profile measured with the film was compared to that measured with an IBA cc04 ion chamber in water. To assess the scatter response, the St were generated by exposing films with 1x1 to 10x10 cm² at SSD 100 cm and 10 cm depth. The film St were compared with the stereotactic diode, SD, and cc04 daisy-chained measurements in water. All films were scanned with the Epson 12000XL scanner with 150 dpi and analyzed using an in-house program. **Results:** The new calibration procedure was validated with an average dose difference of 1.6% between C1 and C2 and a $\gamma(2\%,2\text{mm})$ passing rate of 100%. For profile, the average absolute difference between cc04 and film within ~80% of field was 0.4% (i.e. profiles were not normalized to each other). The St between films and SD/cc04 were within -0.7% difference on average (range: 0.1% to -1.9%). **Conclusion:** Preliminary data has shown that the new film dosimetry system with OC-1 film can achieve highly accurate results. Further studies on energy and intensity modulated fields responses are in progress.

This work was partially supported by the MSK Cancer Center Support Grant/Core Grant (P30 CA008748).

Temporal Growth of the Polymerization in Irradiated EBT3 and EBT-XD Radiochromic Films

Y Hao*, S Momin, J Williamson, H Li, R Khan, A Darafsheh, Washington University School of Medicine, St. Louis, MO

Purpose: EBT-XD is the latest GafchromicTM film model designed to cover up to 40Gy dose level. Characterizing the temporal structure of its response to radiation is an important step toward better understanding its use and handling. The purpose of this work is to investigate the development of the response of EBT-XD and EBT3 films from several minutes up to 2 months after irradiation. **Methods:** Film samples (5x5cm² pieces) were placed between solid water phantoms and irradiated with a 6 MV beam. Two film samples for each model were irradiated in dose range 2 to 40 Gy for EBT-XD and 1 to 10 Gy for EBT3. The net optical density (OD) was measured using a flatbed scanner post-irradiation, every 5 to 10 min during the first 6 hours, every 20 to 40 min from 6-12 h, and every 24 hours for the first 5 days, and every 10 days beyond that until 2 months post-irradiation. **Results:** The largest growth rate in the net OD of the film was observed during the first 3 hours after irradiation, whose variation depended on the dose delivered and color channel used for analysis (e.g. ~3.3%/h in the 15-Gy-irradiated EBT-XD film). In the time interval of 3-12 hours, the increase in the film response was much slower (~0.7%/h). From 12-24 hours, the response continues to develop at a slower pace (~0.4%/h). From 24-120 hours a small change (~0.1%/h) was noted. Beyond the 5th day, ~0.02%/h in OD was observed. **Conclusion:** The polymerization of both film models was observed to be continuously developing post-irradiation manifested as an increase in the net OD. A two-exponential model could fit the net OD up to 5 days, beyond that a three-exponential model provided a better fit to the net OD.

Uncertainty in OSLD Dose Reading Due to CBCT-Based IGRT

S Charyyev*, J Harms, Z Diamond, E Elder, B Ghavidel, M Axente, Emory University, Atlanta, GA

Purpose: Optically stimulated luminescence dosimeters (OSLDs) are commonly used for in-vivo dosimetry for in- and out-of-field applications. When kV-CBCT is part of IGRT, it is recommended to place OSLDs after imaging to avoid the dosimeter over-response to diagnostic x-rays. However, entering the treatment room between imaging and treatment is disruptive to IGRT clinical workflows. We quantify herein the OSLD dose reading overestimation due to kV-CBCT so that imaging and therapeutic doses can be separated. **Methods:** A thorax CBCT protocol (125kV, 270mAs) was utilized as the diagnostic beam quality. The OSLD kV dose linearity with number of scans was confirmed (predictive model). Standard and patient-specific setups were considered. For the standard setup (100cm SSD, 10x10cm² field size, d=1.5cm), in-field OSLDs were placed at the central axis, and out-of-field OSLDs were placed 10cm off-axis; outside the primary photon field but within the imaging field. Three irradiations were delivered with individual OSLD sets per irradiation: 200MU 6MV only, kV-CBCT only (12 scans), 200MU 6MV combined with kV-CBCT. For the patient-specific setup, a patient's head-and-neck VMAT plan was recalculated on a solid-water phantom with the OSLD placed under 1cm of bolus. The same three irradiation scenarios listed above were delivered for the patient plan, placing in-field OSLDs only. Only screened OSLDs were used and read according to manufacturer recommendations utilizing a 6MV calibration curve. **Results:** Per scan, and relative to MV only measurement, doses were overestimated on average by $1.9 \pm 0.02\%$ (in-field) and $60 \pm 0.3\%$ (out-of-field) when using the standard setup, and $4.6 \pm 0.05\%$ for the patient-specific setup. The added uncertainty was consistent with the prediction model. **Conclusion:** We quantified the OSLD readout uncertainty associated with the effect of kV-CBCT-based IGRT on MV readings. With overresponses as high as 60% for out-of-field applications, it is recommended to place OSLDs after IGRT or to create appropriate correction factors.

Design Considerations for CdTe-Based Radiation Detector for Correction-Less Dosimetry

F Akbari*, D Shvydka, E Parsai, University of Toledo Medical Center, Toledo, OH

Purpose: An ideal dosimeter for radiation therapy applications is typically described as water-equivalent to eliminate inhomogeneity-related perturbations and simplify interpretation of measurements. In practice corrections are required, especially in small-field dosimetry where both field-size and detector-specific corrections are employed. Water-equivalency becomes even more challenging for solid state detectors, restricting choices to Si or diamond. We explore an alternative approach of purposely modifying electron spectra reaching the sensitive volume, studying high-efficiency Cadmium Telluride (CdTe) detector as a practical example. **Methods:** Since the stopping-power ratios are not affected by the field-size-dependency changes in photon fluence, modifying electron spectra within detector sensitive volume becomes feasible. MCNP5 package was used to model dosimeter designs combining a semiconductor layer with a metal back reflector. CdTe of 30 and 300 μ m thickness was simulated in combination with copper (Cu) and lead (Pb) of varying thickness, with surrounding PMMA layer. The absorbed dose was calculated based on electron fluences and stopping power. **Results:** Based on the electron spectrum generated at the surface of CdTe under 6MV photon beam representative of Varian TrueBeam linac, we were able to acquire fluences due to electrons backscattered in CdTe from the interface with a metal layer, thus adjusting the final dose in CdTe. Varying thickness of Cu and Pb and thus changing electron backscattered fluence and spectra from the interface we can adjust dose ratio of CdTe to water in a controlled manner. Further design modifications can be done using electron backscatter coefficients for the corresponding interfaces. **Conclusion:** Cadmium Telluride (CdTe) detectors offer high sensitivity, limited dark current, and mature manufacturing technology. High sensitivity of solid-state detectors is an attractive attribute for radiation dosimetry applications. Our approach of modifying electron spectra through addition of a back-reflector metal to CdTe detector opens a venue for design of a new class of correction-less dosimeters.

TH-IePD-TRACK 5-05

Validation of a Full Monte-Carlo Beam Source On the Varian TrueBeam for Primary Standards Establishment in Dose Area Product (DAP)

J JURCZAK*, B Rapp, J Gouriou, Universite Paris-Saclay, CEA, List, Laboratoire National Henri Becquerel (LNE-LNHB), F-91120 Palaiseau, France

Purpose: To implement a full Monte-Carlo beam source of the Varian TrueBeam head for primary standards establishment in terms of Dose Area Product (DAP) for 6 MV FFF small field sizes. **Methods:** In Monte-Carlo dosimetry, multiple phase-spaces files from different Monte Carlo codes are available and free access. However, for small fields, the lack of detailed information and the reported limited accuracy are even more critical. As part of the establishment of the primary standards for small fields in DAP at the Laboratoire National Henri Becquerel (LNHB), the French Primary Standards Dosimetry Laboratory, and in order to overcome limits of Varian phase-space files, a full 6 MV FFF TrueBeam head has been modelled as a beam simulation source with the EGSnrc code with data provided by the manufacturer. A substantiated set of 11 configurations with specifically designed circular collimators of 5, 7.5, 10, 13 and 15 mm diameter and jaws of 5, 7, 10, 13, 15 and 20 mm side were investigated with respectively DOSXYZnrc and DOSRZnrc user codes. All the measurements were performed with a PTW 60019 Microdiamond and the validation was carried out with a strict gamma-index criteria of 0.5%/0.5mm, in accordance with metrological expectations. **Results:** Experimental and Monte-Carlo calculations are found to be in excellent agreement. Commissioned Monte Carlo models reproduce the dose distributions of radiation field sizes from 5 mm to 20 mm with an average of 89 % and 98% of points passing the gamma-index criteria for respectively inline/crossline jaws profiles and percentage depth doses (PDD). For circular collimators, these values are 91 % and 96% for respectively radial profiles and PDD. **Conclusion:** This robust validation of the 6 MV FFF source parameters allows a more confident use in the calculation of the graphite to water conversion factor, and possibly other correction factors.

Dosimetric Effect of Tumor Treating Field Electrodes for Pediatric Infratentorial IMRT

J Faught¹*, W Myers¹, E Bowers², M Gargone¹, L Zhao¹, T Merchant¹, C Tinkle¹, (1) St. Jude Children's Research Hospital, Memphis, TN, (2) Northwestern Medicine Lake Forest Hospital, Lake Forest, IL

Purpose: The addition of tumor treating fields (TTF) designed to target the infratentorial brain to radiotherapy for diffuse intrinsic pontine glioma (DIPG) will be explored in a phase II clinical trial. This study explored the dosimetric effect of concurrent TTF on target and structures-at-risk in pediatric patients with newly diagnosed DIPG undergoing IMRT. **Methods:** Scalp dose with and without TTF electrodes was measured using a parallel-plate ion chamber in solid water for a 10x10 cm² open field. Buildup thicknesses varying from surface to 2 mm simulated different depths in the skin. Beam incident angles varied from 0-90 degrees. Maximum dose increase at 1 mm depth was measured for three six-field IMRT patient plans. A treatment planning study was conducted by transferring clinical targets from ten patients ages 2-14 years onto age-appropriate ATOM phantom reference CTs with no TTF electrodes present. IMRT plans were generated with Eclipse AAA. TTF electrodes were contoured on CTs of the phantom with electrodes reconstructed with a metal artifact reduction algorithm. These contours were transferred to the reference CT and changes in target coverage and scalp dose (5 mm from skin surface) due to TTF electrodes were evaluated. **Results:** Open field measurements demonstrated an increased sensitivity to electrode presence for shallower depths. The dose increase ranged from 150% at 2 mm to almost five-fold at the surface. Increases were greatest for enface beams. Maximum IMRT dose increase at 1 mm depth due to TTF electrode presence was approximately 150%. The treatment planning study showed minimal PTV coverage differences ($\Delta V_{95\%} < 1\%$) and slight volumetric scalp dose increase ($D_{1cc} + 2\%$) with TTF electrodes present. Surface point doses calculated agreed with measurement results. **Conclusion:** Presence of TTF electrodes during pediatric infratentorial IMRT delivery modestly increased the local scalp dose but had a minimal impact on volumetric dose metrics.

Monte Carlo Calculations of Photon Shielding Properties for Commercial Blocks

M Kaluarachchi*, E Klein, M Rivard, Rhode Island Hospital / Warren Alpert Medical School Brown University, Providence, RI

Purpose: A commercial shielding company (Veritas Medical Solutions) provides shielding options for radiotherapy treatment rooms using modular, high-iron content interlinked blocks (VeriShield™). Monte Carlo simulations were used to calculate shielding properties and compare against density-scaled shielding parameters from the NCRP151 report. **Methods:** The simulation model utilized the Tool for Particle Simulation (TOPAS) code for radiation transport calculations where the realistic in-air model consisted of a photon source, concrete wall with varying thickness, and a detector. Vendor-provided (Varian Medical Systems) phase-space files for TrueBeam™ 6X, 6FFF, 10X, 10FFF, and 15X beams were used as sources for deriving primary tenth-value layer (TVL) values for ordinary concrete (V150) as well as concretes having higher iron content (V250 and V300). The concrete wall thickness varied between 0-100cm, with the source and wall exterior distance generally being 600cm. Circular-shaped detectors with 3cm radial bins and 0.05MeV-energy binning were placed 30cm from the wall exterior to score photon fluence. Subsequently, collisional kerma and primary shielding TVL values (1st TVL_i and equilibrium TVL_e) were calculated with consideration for detector volume-averaging. **Results:** Reproducing the NCRP151 geometry verified the primary TVL values for 6X in conventional concrete within 2%. Using the 6X phase-space files, TVL values of concrete were reduced by 2cm with (TVL_i, TVL_e) values in V150, V250, and V300 being (33.4cm, 31.2cm), (21.0cm, 19.4cm), and (16.7cm, 16.0cm) respectively. The 6FFF TVL values were (30.4cm, 30.4cm), (19.2cm, 18.9cm), and (15.3cm, 14.6cm) respectively. Similar trends were observed for 10X, 10FFF, and 15X beams. Sensitivity to angular volume-averaging was assessed towards providing reference values. Statistical uncertainties for TVL_e were typically < 1%. **Conclusion:** Radiological simulations to derive shielding parameters for VeriShield™ modular blocks indicated substantial differences between density-scaled results towards providing improved accuracy for vault shielding. Comprehensive simulations for remaining shielding parameters such as leakage and scatter are underway.

Audience Q&A

Do you ever feel inundated from surveys, be it professional, political, or product-specific? Requests arrive via email, social media, and text message, and they're waiting for you in your break room and mailbox. Surveys are an established way to learn about others' feelings, perceptions, and preferences in addition to fact-finding. Medical physicists can use survey tools to identify and learn more about issues or trends in our working environment that we are responsible to resolve.

How can you prevent your survey from getting crushed by a respondent's survey fatigue, or simply forgotten about? What are the optimal guidelines for crafting thoughtful queries that get specific answers your team needs? How do you move forward with data analysis once the responses are back? This session shares best practices in survey usage, design, implementation, and analysis. Topics include: how should questions be crafted; how many questions is the right number; how do we deploy surveys internally within departments or externally to larger groups; what is an expected response rate; what do we do with the data once we have it?

We will share concrete examples of researchers who have written their own surveys, adapted outside surveys for their own use, and deployed large-scale surveys. We will help the audience to understand what works well and what is unexpectedly challenging when physicists seek to ask questions of other physicists. Who can use the data, who can see the data, what identifying information is present, and other subtle but important aspects will be included.

Learning Objectives:

1. Share best practices for creating your own survey questions, methodologies, and workflows
2. Offer a framework for attendees to approach the task of translating established and validated survey questions to their own site, department, team, hierarchy, infrastructure, IRB, etc.
3. Provide guidance to those hoping to send a survey outside of their own institution by describing the process of large-scale survey design

Audience Q & A

There have been recent changes and developments in ideas about Effective dose (E) that could lead to an expanded use of the quantity in coming years. Medical physicists should be aware of the expanding definition and potential future developments of E. Despite various limitations of the E which was originally developed by the International Commission on Radiological Protection (ICRP) for occupational radiation protection, E has remained a universally-accepted quantity. Recently, ICRP has allowed the use of E to represent patient dose with the ICRP reference phantoms. Consideration is now being given to encourage the development of patient specific dose. Some medical physicists have been apprehensive about the use of E for individual patients. The current position of ICRP has been clarified in an upcoming report, ICRP Publication 147, and recent journal publications have acknowledged the substantial progress in assessing patient-specific doses computed based on libraries of phantoms that allow matching of anatomy to individual patients. Organ and tissue doses derived from MC calculations can be combined with the ICRP tissue weighting factors to calculate a value for the patient specific effective dose, in which the organ doses represent estimates of those for the individual, rather than a reference phantom. This session details the justification and processes of these developments, and further puts the estimation of individual radiation exposure in terms of E in the context of the broader objective of assessing and ensuring the safety of radiation in medicine.

Learning Objectives:

1. To understand what effective dose means and what it does not.
2. To become familiar with the new developments in ICRP on effective dose.
3. To understand the difference between E as a radiation protection dose quantity and patient or size-specific effective dose relating to individual patients.
4. To understand the relationship between varying metrics of dose and methods to assess patient specific dose

BEST IN PHYSICS (IMAGING): Parallel Imaging Stream for Multi-Purpose Real-Time Adaptive MRI-Guided Prostate Radiotherapy

T Bruijnen^{1,2*}, P Borman¹, T Schakel¹, B Raaymakers¹, (1) Department of Radiotherapy, University Medical Center Utrecht, Utrecht, UT, NL, (2) Computational Imaging Group for MRI diagnostics and therapy, Centre for Image Sciences, University Medical Center Utrecht, Utrecht, UT, NL

Purpose: To develop a multiple-purpose 3D parallel imaging stream for real-time adaptive MRI-guided prostate radiotherapy. Here, we propose to modify the clinical 3D CINE to increase the temporal resolution, decrease the reconstruction latency and to include multiple image streams for improved motion detection. The CINE is modified in two ways: 1) the k-space data is sampled using a novel dual density Cartesian Acquisition with SPiral profile ordering (dd-CASPR), which enables viewsharing and multi-resolution image reconstruction; 2) the k-space data is rerouted and processed outside of the vendors software using an in-house built reconstruction framework (ReconSocket) to produce multiple image streams with low reconstruction latency. **Methods:** The dd-CASPR CINE was implemented on a 1.5T MR-linac system (Elekta Unity, Elekta AB, Stockholm, Sweden) and connected to the ReconSocket to generate the three image streams: 1) Real-time high frequency 1D navigators (projection) to detect extreme bulk motion at 3Hz, 2) Real-time low-resolution (10mm²) imaging to detect large target motion (e.g. gas bubbles) at 0.5Hz, 3) Real-time or retrospective high-resolution (2mm²) imaging for online replanning or dose accumulation at 0.15Hz. Images were reconstructed with parallel imaging using the BART toolbox on a GPU. The dd-CASPR CINE was evaluated using the Quasar motion phantom (Modus Medical Devices Inc., Canada) in which motion traces were compared. In addition, dd-CASPR was qualitatively evaluated in a volunteer scan, with deliberate onset of bulk motion. **Results:** The k-space data was streamed in real-time using the ReconSocket (latency=17ms, maximum jitter<10ms). The phantom experiments showed a high correlation between the input trajectory and the three different image streams. The in-vivo scans showed high quality images with reconstruction times 25ms, 0.8s and 7s for image streams 1-3, respectively. **Conclusion:** The proposed 3D dd-CASPR CINE produces multiple image streams with low reconstruction latency. Future work will focus on the integration of the multiple-image stream to facilitate start-and-stop real-time adaptive prostate radiotherapy.

Correcting Image Distortion for Brain Tumor Treatments on an MRI-Linac

S Shan^{1,2*}, D Waddington^{1,2}, P Liu^{1,2}, B Dong², J Buckley^{2,3}, D Elwadia⁴, T Pham⁴, G Liney^{2,3,4}, P Keall^{1,2}, (1) ACRF Image X Institute, University of Sydney School of Health Sciences, Sydney, NSW, Australia (2) Ingham Institute for Applied Medical Research, Liverpool, NSW, 2170, Australia (3) Centre for Medical Radiation Physics, University of Wollongong, Wollongong, New South Wales, Australia (4) Liverpool and Macarthur Cancer Therapy Centres, Liverpool, New South Wales, Australia

Purpose: MRI-Linac systems have been developed to enable real-time image guidance and adaptive tumor tracking during radiotherapy treatments. However, MR gradient design constraints in these hybrid systems can lead to geometric distortions and inaccurate tumor shapes and positions, risking unnecessary radiation dose to surrounding healthy tissues. Here, we quantitatively analyze and correct geometric distortions on a 1.0 T inline MRI-Linac to facilitate accurate brain tumor treatments. **Methods:** A grid phantom with 3718 markers was used to measure distortion on an MRI-Linac in a 20cm×20cm×30cm volume. Based on measured distorted and undistorted marker positions, a spherical harmonic (SH) model was established to characterize and to correct the geometric distortion. A head phantom was then scanned in an MRI-Linac and a CT system to provide test MR images and CT (undistorted) reference images. The contours of head phantom MR images before and after correction were compared with CT reference images. **Results:** The magnitude of geometric distortion in the MRI-Linac increased with distance from the isocenter. The maximum displacement within the head phantom volume (15cm×15cm×15cm) was 5.0±1.8 mm before correction. The slices containing the orbits, a key organ at risk, had maximum displacement 3.6±1.8 mm. Applying the SH correction model reduced distortion by a factor of 3. **Conclusion:** Geometric distortion on brain images was quantitatively analyzed and the SH method was used to effectively reduce image distortion. This work will improve the accuracy of brain tumor treatments on MRI-Linacs.

Comparing Estimated Liver Elasticity Based on the Finite Element Method to MR-Elastography for Distribution of Liver Fibrosis

K Fujimoto*, T Shiinoki, Y Yuasa, Y Kawazoe, M Yamane, T Sera, H Tanaka, Yamaguchi University

Purpose: Finite element method (FEM) is a promising method to calculate the biomechanical parameters of human liver by performing the stress analysis. However, its performance to evaluate the distribution of liver fibrosis has not been demonstrated. In this study, to assess the performance to evaluate the distribution of liver fibrosis, the liver elasticity map estimated by using FEM (Elasticity-map) and the MRE were compared. **Methods:** Twelve patients who underwent magnetic resonance imaging (MRI) and MRE were enrolled in this study. The axial T1-weighted MR images were acquired at shallow inspiration and shallow expiration breath-hold. The displacement vector field (DVF) between T1-weighted MR images at the inspiration and expiration were calculated using deformable image registration. Elasticity-maps were calculated by using FEM and DVF. MRE images were acquired at shallow expiration breath-hold. The grade of liver fibrosis in all patients were determined by radiologist based on liver elasticity measured by MRE. The whole and regional liver (right lobe and left lobe of liver) elasticity estimated via Elasticity-map were evaluated for correlations with the elasticity obtained via MRE. **Results:** The whole liver elasticity estimated via Elasticity-map was significantly correlated with the elasticity measured via MRE ($r = 0.950$, $p < 0.001$) and the liver fibrosis grade ($r = 0.915$, $p < 0.001$). Furthermore, for the regional liver elasticity, the correlation coefficient between the Elasticity-map and MRE was 0.910 ($p < 0.001$) for right lobe of liver and 0.905 ($p < 0.001$) for left lobe of liver. **Conclusion:** The elasticity for whole liver, right lobe and left lobe of liver estimated via Elasticity-map were strongly correlated with the elasticity measured via MRE. Therefore, the Elasticity-map has a potential to be a feasible imaging biomarker to evaluate the distribution of liver fibrosis using only T1-weighted images without additional inspection and costs for special equipment for elastography.

Visual Network in Primary Open Angle Glaucoma: A Functional Connectivity Analysis Based On Group Parcellation From Resting fMRI

H Qu¹, W Lu¹, L Shi¹, J Qiu¹, W Lu^{1*}, (1) Shandong First Medical University & Shandong Academy Of Medical Sciences, Tai'an, Shandong, CN

Purpose: Network analysis was an effective way to assess brain function. The atlases used in network analysis were generated from healthy population, which may fail to reflect functional characteristic of the diseased brain. The aim of this study was to carry out functional connectivity (FC) analysis on primary open-angle glaucoma (POAG) patients using a data-driven parcellation atlas generated from the exactly same cohort. **Methods:** Thirty-six POAG patients and 20 healthy controls underwent fMRI scans. K-means algorithm was used to generate a group-averaged parcellation atlas of visual cortices with 20 subregions using the FC profile from the 36 POAG patients. FC was then performed between POAG patients and healthy controls using this atlas among the 20 subregions in the visual cortices, and between the 20 subregions and the rest of the brain. **Results:** A visual atlas with 20 subregions was generated. FC analysis via this atlas revealed that several functional connections in POAG patients were significantly decreased compared with healthy controls, while some functional connections were significantly increased compared with healthy controls. The decreased FCs in POAG patients were mainly between the visual cortices and the right hemisphere, and the increased FCs were mainly located between the visual cortices and left hemisphere. Significant correlations between decreased FCs and increased FCs were found in POAG group. In addition, we found clinical measures such as the elevated intraocular pressure had negative correlations with the decreased FCs. **Conclusion:** POAG may lead to impaired visual networks and lateralization of functional changes in the brain. Functional compensation and inhibition loss mechanisms may occur in POAG brain. Furthermore, elevated intraocular pressure may decrease function connections between visual cortices and rest of the brain in POAG patients.

Novel Sampling Strategy for Improved Reproducibility in Quantitative T1rho Mapping

C Wu^{1*}, Q Peng², (1) Department of Medical Physics, Memorial Sloan Kettering Cancer Center, New York, NY, USA (2) Department of Radiology, Albert Einstein College of Medicine and Montefiore Medical Center, Bronx, NY, USA

Purpose: T1rho (T1ρ) mapping emerges as a promising MRI tool for quantitative evaluation of low-frequency biochemical changes. However, the accuracy and reproducibility of T1ρ quantification can be compromised by B0 and B1 field inhomogeneities. The purpose of this study was to develop a novel sampling strategy of spin-locking time (TSL) for improved reproducibility in quantitative T1ρ mapping. **Methods:** Two TSL sampling strategies were compared in simulation and phantom experiments. The first one was the standard sampling strategy where TSLs were sampled in a linearly spaced fashion (TSL-LS). The second one was a novel TSL sampling strategy called precision- and reproducibility-guided TSL sampling (TSL-PRG) where all TSLs, except TSL=0 ms, were sampled near the expected T1ρ value of interest at a constant interval defined by the Mz oscillation frequency. Simulation was repeated 100 times with field offsets of B0 (±600 Hz) and B1 (±50%) in a 50×50 grid where the percentage of T1ρ errors < 5% (T1ρ_Error_5pt) and the coefficients of variation < 5% (T1ρ_CV_5pt) were compared. For phantom experiment, T1ρ standard deviations in the three tubes at 150 Hz B0 off-resonance were compared. **Results:** Simulation showed that TSL-PRG had slightly better T1ρ quantification accuracy within the range of B0 and B1 offsets (T1ρ_Error_5pt: 30.4% versus 32.8% for TSL-LS and TSL-PRG, respectively). Moreover, T1ρ variation was substantially reduced for TSL-PRG (T1ρ_CV_5pt: 44.3% versus 67.0% for TSL-LS and TSL-PRG, respectively). In the phantom experiment, standard deviation of T1ρ values at about 150 Hz B0 off-resonance was significantly reduced for TSL-PRG compared to TSL-LS in all three tubes (average of 5.40±0.75 ms versus 8.70±2.25 ms, $P < 0.001$). **Conclusion:** This study demonstrated that the proposed TSL-PRG sampling strategy produced more reproducible T1ρ quantification compared to standard linearly spaced TSL sampling (TSL-LS), suggesting the importance of TSL selection in quantitative T1ρ mapping.

TH-C-TRACK 3-06

A Simulated Comparison of Local SAR Near Orthopedic Implants at 7T Relative to Lower Field Strengths

P Jacobs*, A Fagan, Mayo Clinic, Rochester, MN

Purpose: Electromagnetic (EM) simulations were used to investigate the maximum local 1g-average SAR induced in tissue adjacent to orthopedic screws of varying lengths and field strengths. **Methods:** EM simulations were performed within a finite-difference time-domain solver package (Sim4Life, ZMT, Switzerland). Orthopedic screw models, ranging in length from 18-183mm, were placed within a tissue region assigned to dielectric properties of bone. A dipole antenna, rather than a birdcage-type RF coil model, was used to create uniform background electric fields in the vicinity of the implant for each field strength ranging from 3T to 7T. Simulations were performed using a dedicated GPU (Tesla V100, NVIDIA, USA), each taking approximately 4 hours to run. Two normalization methods were implemented on simulation input power. The first accounted for reflection losses and ensured identical transmit power (1W) into the tissue volume. The second ensured a uniform B1+ magnitude (0.45μT) was achieved at the implant location. Simulations were also performed on tissue with dielectric properties of muscle and white matter brain tissue at 7T. **Results:** After normalizing to a constant B1+ field, maximum 1g-average SAR as a function of screw length showed a peak near 4T; the value at 7T was 36% lower than the peak. The implant length at which the maximum SAR was measured for all field strengths occurred at approximately one-third of the wavelength at each field strength, as expected. The maximum SAR shifted to longer implant lengths in bone compared to muscle and white matter, reflecting the lower permittivity and conductivity in bone. **Conclusion:** For the specific set-up investigated, a low maximum SAR value was determined at 7T

compared to lower field strengths when normalized to the B1+ field. These results indicate RF-induced tissue may not necessarily be significantly higher at 7T compared to lower fields, as conventionally assumed.

Reproducibility of Functional Modes Identified by Non-Negative Matrix Factorization of fMRI Depends On Pre-Processing Strategy

Z Ahmed*, D Kang, N Meyer, M In, Y Shu, Mayo Clinic, Rochester, MN

Purpose: Blind source separation algorithms such as independent component analysis (ICA) and non-negative matrix factorization (NMF) can identify functional modes from fMRI scans. Results from NMF are easier to interpret than ICA, but NMF assumes that input is non-negative whereas fMRI pre-processing typically produces values with zero-mean and unit-variance to identify functional signal change. Different studies have employed various strategies for dealing with these negative values. The goal of this work was to evaluate the impact of four strategies in a test-retest fMRI dataset. **Methods:** A public dataset was downloaded from openneuro.org/datasets/ds000114. It consisted of 10 subjects scanned twice, spaced 2-3 days apart, while performing five behavioral tasks. All images were spatially aligned and then temporally concatenated for each session and task, resulting in 10 pre-processed series (2 sessions x 5 tasks). The fMRI data was standardized to zero-mean and unit-variance for ICA while four strategies were applied to remove negativity for NMF by: (1) setting negatives to zero, (2) taking absolute value, (3) using spectra magnitude after Fourier Transform, or (4) using signal magnitude without any standardization. Sixteen spatial components were computed for each task using ICA and NMF and the agreement between the two scanning sessions was evaluated using the dice coefficient. **Results:** Among the 80 computed components (16 components x 5 tasks), the number of NMF components with a dice coefficient above 0.5 was 39 if the data was zeroed, 27 if absolute values were used, 11 if the spectra magnitude were used, and 29 if the signal magnitude was used. For ICA, 28 components had a dice score above 0.5. **Conclusion:** The strategy for removing negativity has substantial impact on NMF performance on fMRI detection. This study showed that the best approach was to set negative values to zero after data standardization.

Q&A

Cone-beam computed tomography (CBCT) offers an imaging platform suitable for design of highly adaptable, compact, and portable systems that can be tailored to specific applications. These unique characteristics resulted in increased presence of CBCT as an on-board imaging tool (for image-guided radiotherapy, interventional radiology, and surgery) and as a diagnostic imaging tool in specific applications (e.g., breast or extremities imaging). The intrinsic advantages of CBCT are however accompanied by a number of image-quality degradation factors that include non-idealities of the imaging chain, increased scatter, and long acquisition time that results in patient motion. Those limitations have conventionally deemed CBCT as a modality suitable only to imaging of high-contrast features within a static setting. Novel developments in algorithmic approaches for CBCT acquisition, reconstruction and image processing are closing the gap, pushing CBCT towards image quality compatible with applications involving visualization of low-contrast structures in dynamic environments.

This symposium will illustrate novel developments for enhancement of CBCT image quality via data-driven methods for image reconstruction and artifact correction, new technologies for dual energy CBCT, and image-based methods for compensation of deformable motion. Finally, the symposium will cover translation of novel algorithmic approaches to clinical environments, with example application in adaptive radiotherapy.

Data-driven methods for image reconstruction and artifact correction:

Various data-driven solutions for CBCT image reconstruction and artifact reduction have been proposed. For example, methods for sparse image reconstructions, methods to reduce noise, approaches to reduce artifacts such as ring artifacts or metal artifacts, algorithms to estimate scatter in real time, or methods that estimate and compensate for patient motion. The lecture will highlight such approaches and indicate how they compare with classical algorithms.

New Technologies for Dual Energy CBCT:

Dual energy CT has become an important tool for diagnostic CT. This talk will discuss applications, approaches, and challenges for dual energy CBCT. Applications include material-specific, quantitative imaging and improved image quality; approaches include kV switching, dual layer detectors, photon counting detectors, and filters; and challenges include patient scatter and system design to optimize dual energy acquisitions.

Image-Domain Deformable Motion Compensation in CBCT:

The moderately slow acquisition time of CBCT systems often results in artifacts from involuntary patient motion. Motion in CBCT ranges from rigid displacement of bony structures to complex deformation of soft-tissues, hampering methods for tracking motion with external markers that would, furthermore, fit poorly into the workflow of image-guided procedures. This lecture will present image-based approaches to motion compensation via combination of autofocus techniques with learning-based methods.

Translating Recent Advances in CBCT to Clinical Practice:

CBCT is the most common and readily available onboard imaging system for patient positioning, target localization, inter-fractional monitoring, and even adaptive radiotherapy (ART). It has been a challenge using CBCT for ART, especially for online ART, due to inferior image quality compared to CT. Previous studies have proved that CBCT is helpful in ART for reducing the volume of irradiated healthy tissue and the dose delivered to OAR, if image quality can be improved through various post-processing algorithms or with the help of image registration algorithms. This presentation focuses on the recent advancement in CBCT image quality improvement or co-registration methods with the planning CT, for clinical application towards offline and online ART.

Learning Objectives:

1. Learn about challenges to image quality in state-of-the-art CBCT systems.
2. Understand approaches for image quality improvement via novel algorithms for multi-energy CBCT image processing, data-driven image reconstruction and artifacts correction, and image-based motion compensation.
3. Learn the potential for clinical application of novel approaches to high-quality CBCT.

A Novel 4D Dose Accumulation Algorithm for Predicting Dose to Organs at Risk During Motion Synchronized Treatments On Radixact

W Ferris*, W Culberson, J Bayouth, L DeWerd, University of Wisconsin, Madison, WI

Purpose: The Radixact is a helical tomotherapy device capable of delivering treatments with intrafraction target tracking, called Synchrony. The system dynamically collimates the radiation to follow target motion during treatment, addressing the effects of the motion by maintaining target dose. However, the radiation is directed without considering location changes of organs at risk (OARs). This study computed the dose to OARs from these motion-synchronized treatments. **Methods:** We developed a calculation algorithm that uses the patient's 4DCT scan as input and accounts for tissue deformations. The patient's respiratory amplitude throughout treatment was simulated by extracting the amplitude data from the 4DCT scan or assuming a generalized motion pattern (e.g. $\sin^2$). Based on the amplitude at each projection in the helical treatment, MLC leaf shifts and jaw corrections were applied, mimicking the corrections Synchrony applies during treatment. The helical treatment was broken up into 153 sub-projections per gantry rotation, which were each assigned to a corresponding discrete phase of the 4DCT. Dose was calculated on each phase separately and accumulated using a 4D deformable registration algorithm. **Results:** The algorithm has been used to predict dose for 4 lung SBRT treatments (10 Gy x 5 fx). Target motion ranged from 14 to 30 mm and PTV volume ranges from 12 to 130 cc. Dose to OARs was observed to deviate by up to 4 Gy between the planned dose and the synchrony-accumulated dose. In future work, the number of cases will be expanded, including upper abdominal cases. **Conclusion:** An algorithm for calculating dose from motion-synchronized treatments on Radixact has been developed and demonstrated. The algorithm can be used to predict dose to OARs and identify plans likely to deviate from planned dose when target tracking is activated.

A Trajectory Optimization Method for Non-Coplanar Volumetric Modulated Arc Therapy of Locally Advanced Unresectable Pancreatic Cancer

G Wang*, R Yang, Peking University Third Hospital, Beijing, CN

Purpose: To develop a trajectory optimization algorithm for non-coplanar volumetric modulated radiation therapy and investigate the potential of organ at risk sparing in locally advanced pancreatic cancer patients using non-coplanar VMAT. **Methods:** A cost map which represents the ray-OARs voxel intersections at each source position was generated using ray-tracing algorithm. A graph search algorithm was used to determine the least-cost path from the cost map. Lastly, full arcs or partial arcs were selected based on the least-cost path to generate the non-coplanar VMAT (ncVMAT) trajectories. Clinical coplanar VMAT (coVMAT) plans for 11 patients diagnosed with locally advanced unresectable pancreatic cancer (LAPC) were replanned using non-coplanar VMAT trajectories. The conformity index (CI), homogeneity index (HI), PTV coverage and dose to the organ at risk (OARs) were compared. **Results:** With ncVMAT, the mean coverage of PTV50Gy, PTV54Gy, PTV60Gy, and PTV70Gy increased significantly. The mean conformity index of PTV45Gy, PTV54Gy, and PTV70Gy was also improved in the ncVMAT plans. Compared with coVMAT plans, the ncVMAT plans resulted in significantly lower doses to the spinal cord, bilateral kidneys, stomach, and duodenum. The maximum dose to the spinal cord decreased by 6.11%. The mean dose to the left and right kidney decreased by an average of 5.52% and 11.71%. The Dmax, Dmean, and D15% of the stomach reduced by an average of 7.45%, 15.82%, and 16.79%, separately. The D15% and Dmean of duodenum decreased by 6.38% and 5.64%, respectively. **Conclusion:** A trajectory optimization algorithm was developed for non-coplanar VMAT. Compared with conventional coplanar VMAT, non-coplanar VMAT resulted in improved coverage and conformity to the targets. The sparing of OARs was significantly improved in non-coplanar VMAT compared with coVMAT plans for locally advanced pancreatic cancer.

Influence of the Freedom in Table Rotation on Plan Quality, Deliverability, Delivery Time and Robustness of Dynamic Trajectory Treatment Plans

H A Loebner^{1*}, S Mueller¹, W Volken¹, G Guyer¹, P Wallimann¹, D M Aebersold¹, M F M Stamparoni², M K Fix¹, P Manser¹, (1) Division of Medical Radiation Physics and Department of Radiation Oncology, Inselspital, Bern University Hospital, and University of Bern, Bern, Switzerland CH, (2) Institute for Biomedical Engineering, ETH Zuerich and PSI, Villigen, Switzerland CH

Purpose: To investigate the influence of freedom in dynamic table rotation on treatment plan quality, deliverability, delivery time and robustness against systematic machine position errors for dynamic trajectory radiotherapy (DTRT). DTRT extends VMAT by dynamic table and collimator rotation during beam-on, described by gantry-table and gantry-collimator paths. **Methods:** The gantry-table path is determined by minimizing overlap of OARs with PTV under following restrictions in freedom for table rotation: Maximum gradient of the path (G) between two adjacent control points ($\Delta\text{table-angle} / \Delta\text{gantry-angle}$) and maximum change of G (ΔG). A VMAT plan and 4 DTRT plans are created for different table rotation constraints $G \& \Delta G = 0.5 \& 0.125$ (DTRT1), $1 \& 0.125$ (DTRT2), $3 \& 0.125$ (DTRT3), $3 \& 3$ (DTRT4), including 2-4 arcs/trajectories, for a nasopharynx, a glioblastoma and a bilateral oropharynx case. For all plans, plan quality is evaluated by target coverage and OAR sparing, delivery time is estimated and dosimetric robustness against systematic errors between $\pm 1^\circ$ in gantry, table, collimator rotation and combination thereof is evaluated. Delivery accuracy is verified with film measurements on a TrueBeam for the nasopharynx plans. All dose calculations are Monte Carlo based. **Results:** With increasing $G \& \Delta G$, slight (oropharynx) and substantial (nasopharynx, glioblastoma) improvements in OAR sparing are observed compared to VMAT, while maintaining similar target coverage. However, delivery time was prolonged by up to 5 min. The VMAT (oropharynx), DTRT2 (nasopharynx) and DTRT1 (glioblastoma) plan revealed the best dosimetric robustness. Film measurements agreed by $>98\%$ (2%/2 mm Gamma-passing-rate) with the dose calculation for VMAT and DTRT1&2. DTRT3&4 resulted in interlocks due to gantry exceeding its tolerance limits. **Conclusion:** With increasing freedom in table rotation, plan quality can be improved for DTRT on cost of increased delivery time for the investigated cases. No clear dependency of dosimetric robustness on table rotation constraints was visible. This work was partially supported by Varian Medical Systems.

Management of Larger Number of Multiple Brain Metastases Patients Via Restricted Single Isocenter Stereotactic Radiosurgery (RESIST) Method

A Palmiero*, W St Clair, M Randall, D Pokhrel, University of Kentucky, Lexington, KY

Purpose: SRS of multiple brain metastases (m-bm) via single-isocenter/multi-target (SIMT) VMAT can improve treatment efficiency and patient comfort. Due to setup uncertainty, aligning m-bm on a single CBCT is nearly impossible and has shown clinically unacceptable loss of target coverage. Moreover, due to island-blocking, m-bm sharing the same MLC pair, low and intermediate dose spill causes an increase in normal tissue dose. This study proposes RESIST method to improve plan quality by reducing normal brain dose from island-blocking. **Methods:** Six patients with 6-16 tumors were selected for this study with an average PTV size of 10.8 ± 2.1 cc (8.2-13.4cc). Patients were planned with SIMT-VMAT using 10MV-FFF beam with a 20Gy prescription to each lesion. Isocenter was placed at the geometric center of targets. Patients were replanned using RESIST, utilizing a single isocenter with lesions treated in two groups based on brain hemisphere location with corresponding non-coplanar partial-arc geometry. This technique uses DCA-based dose and aperture shape controller before VMAT optimization. It allows for two separate plans to be created for each group while sharing the same isocenter and all tumors to be treated in same session. **Results:** Compared to SIMT-VMAT, RESIST plans provide slightly better coverage and conformity with less low and intermediate dose spread. RESIST showed reductions in normal brain V8Gy and mean brain dose by an average of 64cc and 1Gy with slight increase in V12Gy by 3cc. Overall monitor units decreased by 2278MU and decrease modulation factor by 1.1, on average. Slight decreases in beam on time were evident; however, treatment time would increase with an additional CBCT and couch-kicks. **Conclusion:** For superior target coverage and reduced dose to normal brain, RESIST planning for m-bm is a simplified approach that provides patient comfort and compliance for those complex patients who may not tolerate traditional longer treatment times with multiple isocenters.

Treatment of Gynecological Cancer Patients with Extended Fields (EF) Via Dual-Isocenter Volumetric Modulated Arc Therapy (VMAT) Using 6MV-FFF O-Ring Halcyon Linac

D Pokhrel*, M Randall, D Fabian, University of Kentucky, Lexington, KY

Purpose: A 28 cm² field size at isocenter is a limitation of the ring-mounted Halcyon V2.0 linac. Field size is extendable up to 36 cm utilizing dual-isocenter and junctional auto-feathering option during VMAT optimization. We report initial clinical experience using Halcyon dual-isocenter VMAT, enabling EF treatment for complex gynecological cancers. **Methods:** Five complex gynecologic cancer patients received EF irradiation with dual-isocenter VMAT, delivering 45 Gy in 25 fractions incorporating a 55 Gy simultaneous integrated boost (SIB) to PET-avid lymph nodes (LNs) on Halcyon. Two plans were generated with 4 full arcs (2 per isocenter) and three plans with 8 full arcs (4 per isocenter); different collimator settings were used for auto-feathering. Dual-isocenters were separated by 8 cm in the craniocaudal (CC) direction and the daily CBCT imaging isocenter was placed between them. We report plan quality, quality assurance results, treatment delivery accuracy and efficiency. **Results:** Mean EF size in CC direction was 32.1 ± 2.3 cm (29.2–34.3 cm). Mean target conformity and heterogeneity indexes were 1.05 ± 0.08 (1.01–1.09) and 0.15 ± 0.09 (0.06–0.25) respectively. 95% of the PTV45Gy and PTV55Gy received 46.8 ± 2.2 Gy (45.2–51.3 Gy) and 56.8 ± 2.3 Gy (55.6–60.2 Gy), respectively. Plans were evaluated per RTOG-0418 and all OAR were within protocol compliance. Pre-treatment portal dosimetry QA result was 99.7%, on average for 3%/3mm gamma passing criteria. The 3D radial couch correction and repositioning from daily CBCT imaging was 0.84 ± 0.57 cm (0.41–1.93 cm). Mean beam-on time was 2.6 ± 0.2 min (2.4–2.9 min). Mean patient couch time including CBCT was 9.5 ± 0.3 min (9.2–9.9 min). **Conclusion:** Treating extended fields in complex gynecologic cancers patients on Halcyon utilizing dual-isocenter VMAT auto-feathering is safe, feasible and efficient. Rapid treatment delivery on Halcyon may increase patient comfort, reduce intrafraction motion errors, and improve clinic efficiency and patient throughput. Follow up for disease-control and toxicity in a larger patient cohort is warranted.

BEST IN PHYSICS (THERAPY): Color Imaging of Cherenkov Emission in Vivo During Radiotherapy Exhibits Correlation with Superficial Tissue Composition and Blood Oxygenation Changes

P Bruza^{1,2*}, D Alexander¹, A Nomezine¹, E Aulwes¹, L Jarvis^{3,4}, D Gladstone^{1,3,4}, B Pogue^{1,2,3,4}, (1) Thayer School of Engineering, Dartmouth College, Hanover, NH, (2) DoseOptics LLC, Lebanon, NH, (3) Geisel School of Medicine, Dartmouth College, Hanover, NH, (4) Norris Cotton Cancer Center, Dartmouth-Hitchcock Medical Center, Lebanon, NH

Purpose: Cherenkov imaging has demonstrated its usefulness for real-time beam monitoring and incident detection during X-ray and electron radiotherapy, as well as for remote in vivo surface dosimetry. In the latter case, sub-surface tissue composition introduces approximately 30% error in Cherenkov-dose accuracy. Here we introduce the concept of in vivo color Cherenkov imaging and investigate the potential for correcting these tissue composition factors, and explore novel application of seamless intra-fraction tissue oxygenation monitoring. **Methods:** A three-channel intensified CMOS camera was developed using a relay lens system and a pair of dichroic beamsplitters, which split the incoming image onto three separate intensifiers. The intensified RGB channels were read by three CMOS sensors and combined into 24-bit color image following spatial and color calibration. Tissue-mimicking phantoms containing water, 1% intralipid and blood were imaged during 6MV beam irradiation to study the effects of tissue composition (0-3.5% blood) and blood oxygenation (adjusted by glucose oxidase-catalase assay) on the color of Cherenkov emission. Lastly, in vivo color Cherenkov images of three right-sided breast patients were acquired for one treatment fraction each. **Results:** Oxygenated blood in tissue phantom images produced a visibly redder hue compared with deoxygenated blood due to decreased attenuation of red wavelengths by oxyhemoglobin. Variation in blood concentration produced a blue-red linear correlation ($R^2=0.96$) between blood concentration and the derived luminance parameter x in the CIE xyY color space. Cherenkov emission from patients exhibited pink color, and the luminance parameter was found to be in correlation with fibroglandular vs. fat tissue composition. **Conclusion:** This first investigation of color Cherenkov imaging has uncovered the natural relationship between tissue composition and the color of emitted Cherenkov light. The correlation between blood content and color will be translated into future work for in vivo sensing of variations in fat and fibroglandular content in irradiated tissues.

Hardware and software support for this project was provided by DoseOptics LLC, a company manufacturing Cherenkov imaging cameras. B. Pogue is the President and P. Bruza is an employee of DoseOptics LLC. D. Alexander reports receiving consulting fees from DoseOptics LLC. Intellectual Property application is pending.

Commissioning of a Novel Compensator-Based IMRT System for Low- and Middle-Income Countries

K Oh*/The University of Washington and The University of Texas MD Anderson Cancer Center, B Sengupta/The University of Washington, A Olanrewaju/The University of Texas MD Anderson Cancer Center, R Douglas/The University of Texas MD Anderson Cancer Center, K Roach/The University of Texas MD Anderson Cancer Center, C Cardenas/The University of Texas MD Anderson Cancer Center, L Court/The University of Texas MD Anderson Cancer Center, E Ford/The University of Washington

Purpose: In support of a novel compensator-based IMRT system for low- and middle-income countries, here we demonstrate commissioning in Eclipse. This allows for high-quality treatment plans created locally and integration into the Radiation Planning Assistant, a web-based automatic planning system being developed

specifically for resource-limited clinics. **Methods:** The treatment device consists of a cobalt-60 unit and nine field compensator arrays. Each compensator has a 3D-printed plastic mold filled with reusable 2mm tungsten beads and is mounted around the patient. We commissioned it in Eclipse (v15.6). Validation tests described in MPPG 5.a were performed using Monte Carlo (MC) data calculated by GATE. Dose distributions and penumbra were evaluated for basic dose validation using a gamma index for the compensator-based IMRT dose validation. Compensator-based IMRT plans with the cobalt-60 unit were generated for five head-and-neck cancer cases, and PTV coverage and OAR sparing were compared to linac-based plans reviewed by physicians. **Results:** The PDDs and profiles of the Eclipse deviated from the MC simulation by $0.65 \pm 0.41\%$ (Range: 0.1-2.1) and $1.02 \pm 0.99\%$ (Range: 0.1-3.6) and are within 2% tolerance. The 80%-20% penumbra deviation is $0.5 \pm 0.3\text{mm}$ and is within 3mm tolerance. The gamma passing rate with criteria of 2%/2mm was 92.6%. Cobalt-60 compensator IMRT plans were found to deliver comparable quality treatment plans with standard linac-based VMAT plans based on DVHs. PTV D95% and D5% were within 1% for both plans evaluated. Each PTV received a conformal dose based on homogeneity index (0.04 vs. 0.05 for linac-based VMAT plan and compensator-based IMRT plan). Doses for critical structures were slightly higher in the cobalt-60 compensator plans but within clinical tolerances. **Conclusion:** The compensator-based cobalt-60 device can generate highly conformal IMRT plans on par with clinical linac-based technologies at a reduced cost. We are developing a test device with clinical partners in low- and middle-income countries.

A Deconvolution-Based Image Fusion Technique for Heterogenous Multi-Layer Portal Imagers

I Valencia Lozano^{1*}, M Jacobson¹, M Myronakis¹, T Harris¹, M Lehmann², P Huber², R Fueglistaller², D Morf², R Berbeco¹, C Williams¹, (1) Brigham and Women's Hospital, Dana Farber Cancer Institute & Harvard Medical School, Boston, MA, (2) Varian Medical Systems, Baden-Dattwil, Switzerland

Purpose: Multi-layer (ML) portal imagers contain multiple imaging layers whose signals are combined to increase detector performance. For heterogeneous configurations with different properties in each layer, the overall performance depends on the different layer responses and how the signals are combined. This work introduces a joint Richardson-Lucy (RL) deconvolution to fuse the sub-images from the layers. **Methods:** Synthetic images of a bar-pattern and the Shepp-Logan phantom were generated for a ML detector containing one GOS layer and one with a high-efficiency plastic scintillator. The individual images are obtained by convolving the phantom geometry with Monte Carlo estimated point spread functions of each layer, scaling according to the quantum efficiency and applying Poisson noise. The final image was obtained by using a joint RL deconvolution of the two sub-images, both with and without a regularization based on total variation (TV). The spatial resolution, contrast-to-noise ratio (CNR) and signal-to-noise ratio (SNR) of the images were evaluated and compared with a simple summation of the signals. **Results:** The MTF evaluation of the bar-pattern showed an enhanced 10%-contrast level (f_{10}) for the fusion image ($f_{10}=0.9\text{ lp/mm}$) compared to the summation image ($f_{10}=0.7\text{ lp/mm}$). In this case, the TV regularization suppressed the noise, however slightly reduced the gain in spatial resolution. For the central high-density region of the head phantom, the fusion resulted in 2.7 times higher CNR if regularization is used. Similar improvements were observed for the SNR. **Conclusion:** A novel method for image fusion of ML detectors was presented that improves the performance of heterogeneous ML imagers compared to conventional image summation. Future work will investigate the optimal regularization and deconvolution parameters.

This work was partially supported by award number R01CA188446 from the National Institute of Health.

Exploiting Pair Production for Nanoparticle Imaging and for In-Vivo Beam Monitoring in Megavoltage Radiotherapy

D Brivio^{1*}, E Sajo², P Zygmanski¹, (1) Brigham and Women's Hospital, Boston, MA, (2) University of Massachusetts Lowell, Lowell, MA

Purpose: We propose a new imaging technique for detection of high-Z nanoparticles and for in-vivo beam monitoring in megavoltage X-ray beams by means of coincidence counting of annihilation photons following pair-production in nanoparticles and/or in tissue. **Methods:** The proposed megavoltage X-ray induced positron emission (MVIPE) imaging technique is studied by radiation transport computations using MCNP6/CEPXS-ONEDANT for two water phantoms: 35cm slab and similarly sized cylinder with 5cm gold nanoparticle (AuNP)-filled region in the center. MVIPE is compared to standard X-ray fluorescence computed tomography (XFCT). MVIPE adopts megavoltage X-ray sources and relies on the detection of 511keV annihilation photon pairs. XFCT uses kilovoltage sources and imaging is characterized by analysis of $K\alpha_{12}$ Au-characteristic lines. Four levels of AuNP concentration were studied: 0%, 0.1%, 1% and 10% by-weight. **Results:** Annihilation photons in the MVIPE technique originate along the X-ray beam path in the AuNP-loaded region and in water. Their flux is proportional to the MV source energy and linearly increases with AuNP concentration, while XFCT signal reaches saturation due to self-absorption within AuNP. The MVIPE technique using 15MV pencil beam and 10wt% AuNP detects about 4.5×10^3 511keV-photons/cm² at 90° w/r to the incident beam per 10° source-photons/cm²; 0.5×10^3 of these come from AuNP, while the rest come from water/tissue. The latter alone can be utilized for monitoring MV beams in tissue. In contrast, the XFCT technique using 150kVp detects about 100 $K\alpha_1$ -photons/cm² per 10° source-photons/cm² without collimation. **Conclusion:** In MVIPE, the number of detected annihilation photons secondary to pair-production is significantly greater than the $K\alpha_1$ -photons from fluorescence. Furthermore, coincidence counting in MVIPE enables collimation-free imaging, while collimation is a major limiting factor in XFCT. Additionally, MVIPE offers the potential of direct visualization of the x-ray beam in tissues during radiotherapy treatment, which may pave the way for in-vivo beam and dose monitoring.

Hypersensitivity of Cancer Cells to Photon and Proton Radiation Caused by Disruption of Cell Cycle Arrest by An ATR Inhibitor

M Manandhar*, S Bright, B Turner, D Flint, M Ben Kacem, D Martinus, S Shaitelman, G Sawakuchi, University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: Under the presence of DNA damage, the DNA repair protein ATR has essential roles in arresting cells in the G2 phase of the cell cycle so that DNA repair can take place. ATR is also a key protein in homologous recombination double strand break repair. Here we investigate the consequences of disrupting cell cycle arrest at G2 through ATR inhibition on cancer cell lines irradiated with photons and protons. **Methods:** H1299 and PANC-1 cancer cell lines were treated with DMSO (control), or an ATR inhibitor (ATRi) (AZD6738, 0.1 or 1 μM) for 1 h prior to irradiation. Cells were exposed to 5 Gy of 6 MV x-rays or 9.9 keV/ μm protons (dose-weighted LET in water), and then fixed and stained for flow cytometry analysis to evaluate cell cycle distribution (propidium iodide), mitosis (phospho-histone 3) and DNA damage ($\gamma\text{-H2AX}$). Clonogenic cell survival assays were also performed. **Results:** The relative biological effectiveness (RBE) had a non-significant increase for protons+ATRi compared to protons alone. Irradiated cells showed a pronounced G2 arrest after both photons and protons. ATRi 1 μM was effective in abrogating G2 arrest in cells exposed to photons or protons. A higher amount of mitotic cells was observed with 1 μM ATRi+5 Gy compared to DMSO+5 Gy (P-value <0.01). This effect was higher for protons alone compared to photons alone (P-value <0.01). Persistent $\gamma\text{-H2AX}$ foci was higher for ATRi treated cells compared to DMSO indicating that ATRi also suppressed DNA double strand break repair. **Conclusion:** Both photons and protons induced robust cell cycle arrest at G2. Administration of ATRi disrupted the G2 arrest and increased the amount of cells in mitosis. Our results suggest that ATRi is effective at inducing sensitivity of

cancer cells to radiation in part because of the role of ATRi on cell cycling.

Plastic and Lead-Doped Scintillators for Ultrahigh Dose-Rate Irradiations Delivered with An X-Ray Tube

D Cecchi^{1*}, C Gigeure², F Larose², F Theriault-Proulx³, L Beaulieu², M Bazalova-Carter¹, (1) University of Victoria, Victoria, BC, CA, (2) CHU de Quebec - Universite Laval, Quebec, QC, (3) MedScint, Quebec, QC, CA

Purpose: To examine the capabilities of plastic scintillators of different compositions to accurately measure dose in high dose-rate dose irradiations delivered with an x-ray tube. **Methods:** The output of five 1-mm in diameter and 3-mm long scintillators of varying materials was measured in short sub-second irradiation intervals using a traditional x-ray tube equipped with an in-house rotating shutter-wheel system. The shutter system was developed to limit exposure time to the scintillator by a continuous x-ray beam. Two plastic scintillator dosimeters made of polystyrene (BCF-10 and BCF-60) and three lead-loaded scintillators (0.5%, 1.4%, and 5% concentrations) were used. Scintillator output was normalized with respect to TOPAS Monte Carlo (MC) dose calculations using 100 and 200 ms exposures at a constant tube current of 25 mA and tube voltage of 80 kVp. Output linearity was measured for irradiation times between 10-100 ms. Dose-rate independence was tested with varying tube-current between 3-37.5 mA for the 80 kVp beam. Energy dependence was tested for all the probes at tube voltages ranging between 80-120 kVp. **Results:** All probes showed excellent agreement with MC for the 80 kVp beam and irradiation intervals of 100 and 200 ms. When irradiation time was varied between 10-100ms, scintillator output was shown to be linear with exposure time ($R^2 > 0.999$) for all probes. Scintillator output was also shown to be dose-rate independent ($R^2 > 0.999$) for all tested probes. At tube voltages higher than 80 kVp, it was shown that scintillators output exhibited some quenching, resulting in a maximum difference between experimental and MC data of 5.8% across the studied 80-120 kVp energy range for the 5% lead-loaded scintillator. **Conclusion:** Plastic scintillators of different compositions have the capability to accurately measure high dose-rate irradiations delivered in short ~10 ms intervals by a conventional x-ray tube.

The Feasibility of Measuring In Vivo Tumor Microenvironment pH During Radiotherapy Using a Novel Cerenkov Emission Multispectral Optical Probe Based On Silicon Photomultipliers

I Oraiqat^{1*}, M Konieczek^{2,4}, R Clarke^{3,4}, A Rehemtulla², I El Naqa¹, (1) H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, (2) University of Michigan - Radiation Oncology, Ann Arbor, MI, (3) University of Michigan - Physics Department, Ann Arbor, (4) Endectra, LLC, Ann Arbor

Purpose: Tumor pH has been suggested as an indicator of cancer aggressiveness. In this work, we explore the use of a novel Cerenkov Emission (CE) multispectral optical probe based on silicon photomultipliers (SiPM), known as CMSI, for interrogating tumor microenvironment pH in head and neck cancer tumors in a proof-of-principle in vivo demonstration consisting of two mice. **Methods:** One mouse was implanted, subcutaneously, on the flank, with the UMSCC47 cell line while the other with an artificial tumor consisting of Matrigel (buffered at a pH of 7.4). During CMSI measurements, the mice were injected with a pH contrast agent consisting of phenol red (PR) and irradiated with 9MV photons. The intensity of CE spectral components at 445nm and 560nm were measured using CMSI and a quantitative value for pH was obtained by taking the ratio of these value (known as the CMSI ratio) in conjunction with a calibration curve, which was prepared from a collection of buffered solutions with PR added at varying pH values (6.5 to 7.8). Calibration was further refined to take into account changes in the CMSI ratio through the mouse tissue by using the artificial tumor pH as a baseline (7.4). **Results:** The CMSI ratio measured for the UMSCC47 tumor on the mouse flank is 1.15 compared to the 1.66 measured on the mouse with the benign artificial tumor. By using the pH calibration curve, the corresponding pH value of the UMSCC47 tumor is 6.5 (compared to the baseline of 7.4 in the artificial tumor), showing the cancerous tumor having a more acidic microenvironment. **Conclusion:** This work shows the feasibility of using CMSI for CE spectroscopic interrogation for real-time in vivo pH measurements during radiotherapy by successfully demonstrating tumor pH measurements during a pilot mouse study.

Three-Dimensional Tumor Spheroid Model as a Tool to Optimize the Nano-Bio Interface

K Bromma^{1*}, W Beckham², D Chithrani^{1,2}, (1) University of Victoria, Victoria, BC, CA, (2) BC Cancer - Vancouver Island Centre, Victoria, BC, CA

Purpose: Radiotherapy and chemotherapy are the gold standard for treating patients with cancer in the clinic, which are limited by normal tissue toxicity. The use of nanomaterials, such as gold nanoparticles (GNPs), to improve radiosensitivity and act as drug delivery systems can mitigate toxicity while increasing deposited tumor dose. To expedite a quicker clinical translation, three-dimensional tumor spheroid models that can better approximate the tumor environment compared to a two-dimensional monolayer model have been used. **Methods:** We tested the uptake of 15 nm GNPs and 50 nm GNPs on a monolayer and on spheroids of two cancer cell lines, CAL-27 and HeLa, to evaluate the differences between a 2D and 3D model in similar conditions. The anticancer drug docetaxel, which can act as a radiosensitizer, was also utilized, informing future potential of gold nanoparticle-mediated combined therapeutics. The optimal treatment dose was elucidated using a resazurin-based proliferation assay. The uptake of GNPs into the cells was measured using inductively-coupled plasma mass spectrometry and imaged using darkfield microscopy. **Results:** In the 2D monolayer model, the addition of docetaxel induced a small, non-significant increase of uptake of gold nanoparticles of between 13% and 24%. In the 3D spheroid model, docetaxel increased uptake by between 47% and 186%, with CAL-27 having a larger increase relative to HeLa. Further, the depth of penetration of 15 nm gold nanoparticles over 50 nm gold nanoparticles increased by 33% for CAL-27 spheroids and 17% for HeLa spheroids. **Conclusion:** These results highlight the necessity to optimize gold nanoparticle treatment conditions in a more realistic tumor-life environment. A 3D spheroid model can capture important details, such as different packing densities from different cancer cell lines, which are absent from a simple 2D monolayer model. Inclusion of a more complex model into future lab experiments is imperative for future clinical translation.

Measurement of Secondary Neutron Spectrum with He4 Fast Neutron Detector

Y Liang¹, S Gokhale¹, J Nimmagadda¹, E Kryck², A Enqvist¹, S Samant^{3*}, (1) Nuclear Engineering Program, University of Florida, Gainesville (2) Nuclear Engineering Program, University of Florida, Gainesville (3) University of Florida, Dept of Radiation Oncology, Gainesville, FL

Purpose: He4 fast neutron scintillation detector can measure a wide range of neutron energies up to 10MeV with low gamma-sensitivity. This provides faster and wider spectral analysis than the standard Bonner spheres method, which needs measurements at different activation foil thicknesses and is mostly within thermal range. **Methods:** He4 fast neutron detector (Arktis Detection Systems, USA) was used to measure neutron spectrum from 18MV x-ray linac and IBA double-scattering proton gantry. Measurements were done with 20cm solid water (located at isocenter) irradiated with 18MV X-ray beam and 20x20 cm² collimation; and 180MeV proton beam with 15.1cm SOBP and 20cm² field size. A pulse-shape-discrimination algorithm was used to separate gamma-ray and neutron signals based on charge-integration method that calculates the integral of slow and fast components of each pulse; and spectrum unfolding algorithm, separately validated with a spectrum (up to 10MeV) using time-of-flight techniques calibrated by a deuteron-beryllium neutron source. Detector was placed near gantry room wall at 220cm from isocenter at distances of 30cm and 60cm lateral to edge of solid water. Measurements were done for 15cm, 20cm, 25cm, and 30cm water thicknesses. **Results:** Secondary neutrons are dominant in thermal range for the 18MV X-ray beam. He4 detector could not be used to measure neutron spectrum due to counting inefficiency. For <1MeV neutrons, other detectors (such as organic liquid scintillator EJ-309 and Cs₂LiYCl₆:Ce³⁺ (CLYC) scintillator) with higher detection efficiency were used. Neutron spectra at >1MeV were successfully measured with He4 for 180MeV proton beam. Differences in measured exiting neutron spectra from various solid water thicknesses (15cm, 20cm, 25cm, and 30cm) and detector-solid water distance (30cm versus 60cm) were observed. **Conclusion:** The secondary neutron spectrum and dose from 18MV x-rays and 180MeV protons were measured directly with He4 fast neutron detector. Measured results are comparable to simulations conducted by previous researchers.

Q&A

Functional radiosurgery procedures involve targeting morphologically normal brain anatomy with extremely high (80 Gy-160 Gy maximum) doses in order to lesion or selectively inhibit neurological activity to treat disorders such as trigeminal neuralgia, essential tremor, and obsessive-compulsive disorder. The techniques and acceptable procedural uncertainties for functional radiosurgery can differ substantially as compared to the more common radiosurgical indications for solid tumors and vascular malformations.

This session will introduce the clinical indications and rationale for functional radiosurgery, as well as the technical considerations for safely performing these radiosurgery procedures across different radiosurgery delivery platforms. In particular, speakers will provide a historical overview of functional radiosurgery; modern clinical indications; imaging, visualization, and treatment planning techniques; and quality assurance on various delivery platforms to ensure the required level of accuracy and precision. The session will highlight the differences between more common radiosurgical techniques used for tumors and vascular malformations and those required for functional radiosurgery.

Learning Objectives:

1. To enumerate the clinical indications treated with functional radiosurgery and published clinical outcomes.
2. To understand the significant differences between functional radiosurgery and radiosurgery as practiced for tumors/vascular malformations in terms of targeted tissue, dose, and acceptable uncertainties
3. To gain an understanding of how functional radiosurgery can be delivered on different SRS platforms, including imaging/visualization techniques, beam configurations, and quality assurance.

Q&A

A treatment plan captures a single moment in time and fails to account for changes in anatomy over the course of treatment. Changes in weight or variations in internal anatomy, for example, can result in displacement of the target volume and OAR's relative to the planned dose cloud. The process of adapting a plan can be labor intensive and time consuming for both physicians and staff. Artificial intelligence (AI) has the potential to improve the accuracy, precision, efficiency, and overall quality of radiation therapy for patients by automating adaptive radiotherapy workflows such as target segmentation, treatment planning and, in some cases, radiotherapy delivery. Vendors will present their AI adaptive solutions and describe how their products can improve the workflow and empower the clinician and staff to make informed decisions related to patient cancer treatments.

Learning Objectives:

1. Review the rationale behind adaptive planning.
2. Explore the different means of adapting a plan including off-line, on-line, and real-time adaptive planning.
3. Explain how AI can help streamline the adaptive treatment process.

Review of the Current State and Future Demand of Medical Physics Workforce

The medical physics profession is a recognized, established, and mature workforce that is undergoing growth and change driven by scientific, technical, and medical advances. In this session we will review the size and general characteristics of the medical physics profession related to the Diagnostic and Therapy Medical Physics workforce and the national radiation professional workforce. Presenting 2020 diagnostic and therapy workforce survey results and discuss the factors that are driving the current and future demands and supply issues in the supply pathways for Diagnostic and Therapy Physicists. Participants will understand the current state of knowledge of the medical physics workforce, including uncertainties and gaps in knowledge. Authors will discuss the key workforce-related challenges facing the medical physics profession in the next decade. Presentations will examine supply and demand of qualified medical physicists for Diagnostic and Therapy Physicists. Presenters will summarize major challenges and opportunities to meet the profession's future needs, strategies and tactics. This information may be used to maintain an adequate and well-trained Medical Physics Workforce.

Learning Objectives:

1. Describe the General Characteristics of the medical physics profession.
2. Understand current state of the Diagnostic and Therapy Physics Workforce
3. Review Current and Future Issues in the Supply Pathways for Diagnostic and Therapy Physicists.
4. Discuss Projections of Demand and Supply for Diagnostic and Therapy Physicists.
5. Summarize major challenges, opportunities, strategies and tactics to maintain an Adequate and Well-Trained Medical Physics Workforce.

CT Protocol Case Studies: Safety and Image Quality

TH-D-TRACK 2-04

Audience Q & A

CT protocol management is an essential element of a quality assurance (QA) program to ensure patient safety and acceptable image quality. Furthermore, the regulations for many states and accrediting bodies, such as the American College of Radiology (ACR) and the Joint Commission, require CT protocol review to be performed annually. One of the goals of CT protocol management and review is to ensure all the protocols are standardized across a fleet of CT systems at a facility. However, this task can be daunting when faced with CT systems of various models from different manufacturers with potentially different technologies. These differences can lead to inconsistent image quality and disparate radiation dose from opposing acquisition and reconstruction techniques. Additional nonuniformities can result in tissue and vascular enhancement due differences in scan delay timing for different phases, injection site, injection rates, contrast injector pressure limits, needle size, and iodine concentration during the injection of iodinated contrast agents. Finally, there are encounters of nonideal patients due to implanted devices, noncompliance leading to patient motion, and obesity where artifacts are induced and image quality compromised.

The overall objective of the presentation is to provide a better understanding and process for developing a robust CT protocol management program. There will be particular emphasis on CT acquisition and reconstruction standardization, optimization of CT injected contrast optimization, and strategies for CT imaging of the nonideal patient.

Learning Objectives:

1. Understand the need for routine CT protocol management and methods for protocol standardization
2. Understand the basics of intravenous contrast dynamics and corresponding tissue enhancement and the relationship to the CT system for optimization of the contrast protocol
3. Understand how to adjust protocols to account for common artifacts related to the patient condition such as metallic implants, motion, and obesity

An Effective Deep Learning Framework for Lung Tumor Segmentation in 4D-CT

S Momin*, Y Lei, Z Tian, T Wang, J Roper, A Kesarwala, K Higgins, J Bradley, T Liu, X Yang, Department of Radiation Oncology and Winship Cancer Institute, Emory University, Atlanta, GA

Purpose: To present a deep-learning-based framework for tumor auto-segmentation in 4D lung CT images. **Methods:** We proposed a motion convolutional neural network (CNN) to perform lung tumor segmentation in 4D CT images. The unique network design first extracts tumor motion information from with consecutive 4DCT phases for input into an integrated backbone network architecture. The extracted motion information is advanced into the subsequent global and local motion head network architectures, respectively, to estimate the corresponding deformation vector fields. A self-attention strategy was incorporated in the final mask head network to remove any noisy features that might degrade segmentation performance. The mask head architecture was supervised by segmentation loss, which considers both, dice loss and binary cross entropy loss. A 4D-CT dataset with 200 images from 20 lung cancer patients was used to evaluate our method using cross-validation and hold-out experiments. The accuracy of the auto-segmented contours were benchmarked against expert contours drawn by physicians using the center-of-mass-distance (CMD), Dice-similarity-coefficient (DSC), 95th percentile Hausdorff distance (HD95) and mean surface distance (MSD). The performance of our approach was statistically compared against the U-Net architecture via paired t-test. **Results:** For all patients, our method framework yielded good overall agreement with contours drawn by the physicians. Our method yielded a CMD, DSC, HD95, and MSD of $0.71 \pm 0.36\text{mm}$, 0.91 ± 0.07 , $1.82 \pm 0.47\text{mm}$, and $0.45 \pm 0.16\text{mm}$, respectively. Our method significantly outperformed the U-Net architecture in terms of segmentation accuracy for both cross-validation ($p < 0.05$) and hold-out ($p < 0.05$) experiments. **Conclusion:** We developed a novel motion CNN – based approach for fully automated 4D tumor delineation for lung cancer patients and demonstrated its feasibility and reliability. The promising results of this work provide impetus for its potential applications in both current clinical practice and for real-time, image-driven automatic contouring to advance adaptive lung radiotherapy.

Automated Tumor Localization and Segmentation Through Hybrid Neural Network in Head & Neck Cancer

A Qasem^{1*}, Z Zhou², (1) , Warrensburg, MO, (2) University of Central Missouri, Warrensburg, MO

Purpose: Accurate localizing and segmenting tumors is important for diagnosis and treatment in head & neck (H&N) cancer. We aim to develop a hybrid neural network (HNN) model, fully automatic tumor localization and segmentation through a combination of Faster-RCNN / U-Net in CT images. **Methods:** In this preliminary study, a total of 48 patients with PET and CT images in H&N obtained from The Cancer Imaging Archive are used. It consists of complete CT/PET and Gross Tumor Volume (GTV) contours, and 825 slices were selected for training, 176 for validation and 79 for testing. HNN consists of two phases in the training stage, they are Faster-RCNN for tumor localization and U-Net for tumor segmentation. Each phase is trained independently. Since PET can detect the tumor location very well and Faster-RCNN is an outstanding model for learning object localization PET is fed into Faster-RCNN to learn the tumor localization. Furthermore, since U-Net has been proved an excellent medical image segmentation model, it is used for tumor segmentation in CT images. The testing stage consists of two steps: (1) tumor localization and segmentation: the PET image is fed into the trained Faster-RCNN which produces a class label and bounding box coordinates, these coordinates are used to automatically crop the testing CT image to a fixed-sized window, which is then fed into the U-Net for segmentation; (2) OTSU threshold method is applied for post-processing. The segmentation results were evaluated using accuracy, sensitivity, and specificity. **Results:** The proposed model achieved the average values of 0.959, 0.930, and 0.962 for accuracy, sensitivity, and specificity respectively. **Conclusion:** In this preliminary study, a hybrid neural network (HNN) for tumor localization and segmentation was proposed in H&N cancer. The experimental results demonstrated that HNN can localize tumors very well and obtain promising segmentation performance as well.

Deep Siamese Network for False Positive Reduction in Brain Metastases Segmentation

Z Yang*, M Chen, R Timmerman, T Dan, Z Wardak, W Lu, X Gu, UT Southwestern Medical Center, Dallas, TX

Purpose: Stereotactic radiosurgery requires precise target delineation, which can be highly time-consuming especially in patients with multiple (>4) brain metastases (BMs). We have developed a CNN-based BMs segmentation platform (BM-Seg) for accurate and efficient BMs delineation, but it suffers from false-positives caused by varied levels of contrast in planning MRI acquisition. Built on BM-Seg, we developed false-positive reduction Siamese network (FPrSN) to improve BM-Seg performance. **Methods:** The proposed FPrSN consists of a parallel feature extractor and a following classifier. The feature extractor utilized a pair of truncated pre-trained ResNet50 with shared weights. In the training stage, paired BM candidate images are used as the input into the feature extractor to 1) increase the training set size by a factor of N/2 and 2) identify the inter-class difference. Then the classifier will randomly take the output from one branch of the feature extractors to classify the corresponding input as a false-positive segmentation or true BM. In the testing stage, only one branch of the feature extractor will be utilized with the classifier to classify a single candidate input as false-positive segmentation or true-positive segmentation. The performance of FPrSN and FPrSN-integrated BM-Seg are evaluated. **Results:** The performance of the FPrSN reaches accuracy of 0.94, area under the curve of 0.92, sensitivity of 0.88 and specificity of 0.97 in a testing dataset. The BM-Seg has initial sensitivity of 0.96 and specificity of 0.59 in BMs detection/segmentation, and get improved to 0.86 and 0.89 after integrating FPrSN, respectively. Due to the flexibility of FPrSN, sensitivity/specificity balance of the FPrSN-integrated BM-Seg can be further adjusted to satisfy clinic needs. **Conclusion:** This developed FPrSN can effectively reduce the false-positive rate of the BMs segmentation candidates. Integrating FPrSN in the BM-Seg can improve the performance, and this integrated platform could be a beneficial tool for clinical implementation.

Development of Artificial Intelligence (AI) Based Platform for Locally Advanced Rectal Cancer Prognosis

Y Zhang¹*, L Shi², X Sun², S Jabbar¹, N Yue¹, K Nie¹, (1) Rutgers Cancer Institute of New Jersey, New Brunswick, NJ, (2) Department of Radiation Oncology, Sir Run Run Shaw Hospital, Zhejiang Univ., Hangzhou, China

Purpose: To develop a deep learning based platform to explicitly quantify multi-regional phenotypes of local advanced rectal cancer (LARC) and assess the association with neoadjuvant chemoradiation (CRT) outcome. **Methods:** A total of 203 patients receiving neoadjuvant CRT followed by total mesorectal excision (TME) were enrolled. All underwent anatomical T1/T2, diffusion-weighted MRI (DWI) and dynamic contrast-enhanced (DCE) MRI before CRT. 133 cases were used for training with four-fold validation, while remaining 70 cases treated at a later time was used as a separate validation set. Pixel-based deep learning algorithm with convolutional neural network (CNN) was developed to automatically localize the rectum and further identify tumor based on all-frame DCE sequences. A radiomics sequencer was then constructed using deep-learning based approach to understand tumor phenotypes across multi-modality MRI images. The radiomics sequencer was further utilized to associate with treatment outcome as pathologic complete response (pCR), good response (GR), and T-downstaging. Results were evaluated using area under the receiver operating characteristics curves (AUC). **Results:** The segmentation result was evaluated by comparing with physicians' contours using Dice Similarity Coefficient (DSC) with a mean of DSC is 0.84 among all cases. A deep-learning based radiomics sequencer was built in predicting pCR, GR and T-downstaging, with AUCs of 0.82, 0.79, and 0.77 respectively. It is also found that DCE sequences especially the second phase of post-contrast T1 contributed the most predictive features followed by DWI sequence. **Conclusion:** Based on the radiomics features from multiparametric MR imaging, machine learning is a feasible way to localize and predict the pathological outcome. Especially, support vector machines can provide better performance than other simple models.

Unsupervised COVID-19 Pneumonia Lesion Segmentation in CT Scans Using Cycle Consistent Generative Adversarial Network

Y Liu*, C Fang*, J Wen, Y Yang, University of Science and Technology of China, Hefei, Anhui, P. R. China

* The authors contribute equally

Purpose: COVID-19 has become a global pandemic and is still posing severe health risk for publics. Accurate and efficient segmentation of pneumonia lesions in CT scans is vital for the disease diagnosis and treatment decision-making. To automatically segment the pneumonia lesion, we proposed a novel unsupervised approach using cycle-consistent generative adversarial network (cycle-GAN) which could liberate people from heavy burden of manual labeling and accelerate the diagnosis process. **Methods:** To restrain the CT volume of interest used for lesion segmentation, a previously proposed method was used to delineate the whole lung first. The cycle GAN was developed to generate synthetic healthy CT lung volume from infected patients. Then, the pneumonia lesions were extracted by subtracting the synthesis healthy CT from the infected CT one. Noise and isolated points were eliminated using maximum connected component, threshold segmentation and gaussian smoothing. **Results:** Two public datasets (Coronacases and Radiopedia) were used to evaluate our approach. The dice reached 0.709 on average in the Coronacases, and 0.653 in the Radiopedia. Both are comparable with existing supervised approaches and outperforms previous unsupervised methods. Meanwhile, our approach reaches a specificity of 0.682 and sensitivity of 0.811 in Coronacases, and 0.655 and 0.706 respectively, in Radiopedia. Comparing with existing label-free method, the proposed method outperforms in all index except specificity for Coronacases which varies due to lesion shape, size and position. **Conclusion:** The proposed unsupervised method could automatically delineate the pneumonia lesion in a highly efficient and accurate way. It can also be used as a baseline for further manual modification and a quality assurance tool in clinical diagnosis.

BEST IN PHYSICS (IMAGING): Validation of a Deep-Learning Model Observer in a Realistic Lung-Nodule Detection Task with Convolutional Neural Network-Based CT Denoising

H Gong*, N Huber, C Koo, T Johnson, A Inuoe, J Marsh, J Thorne, S Leng, J Fletcher, C McCollough, L Yu, Mayo Clinic, Rochester, MN

Purpose: Deep convolutional neural network (CNN)-based denoising techniques have been used in clinical CT to improve image quality and reduce radiation dose. Objective assessment of its performance is desired but has been challenging due to its highly non-linear characteristics. We previously developed a deep-learning model-observer (DLMO) that can be directly applied to patient CT images. The purpose of this work is to validate the DLMO in a lung-nodule detection task in real patient images denoised by a CNN-based technique. **Methods:** Fifty nodule-free patient chest CT exams were retrospectively collected. Nodule-present cases at lower radiation dose levels were synthesized using clinically-validated projection-domain lesion- / noise-insertion tools: 10 experimental conditions involving two nodule types (ground-glass-nodule, partial-solid-nodule), three nodule sizes (3.4–7.4 mm) and four radiation dose levels (10%, 25%, 50%, and 100% of routine-dose, quality-reference-mAs 50). A ResNet-based CNN-denoising model was trained using only nodule-free training cases at 25% routine-dose, and deployed to independent testing cases across four dose levels. DLMO used sliding window to analyze local features and generate pixel-wise test-statistics, and used an internal-noise-component to calibrate the performance to human level. DLMO was established with two **Methods:** DLMO-1 (baseline method) – DLMOs were separately trained and deployed at each dose level; DLMO-2 (more computationally-efficient method) – one DLMO was trained at one dose level and deployed to other levels. Two fellowship-trained thoracic radiologists and one general radiologist interpreted the same DLMO test cases. Area-under-curve of localization-ROC was used as figure-of-merit. **Results:** In preliminary study, DLMO-1 and DLMO-2 performance yielded strong correlation with the averaged human performance (Pearson's

correlation coefficient: DLMO-1 – 0.995, P-value 0.0049; DLMO-2 – 0.996, P-value 0.004). Mean performance difference was small (DLMO-1 – 1.02%; DLMO-2 – 1.47%). **Conclusion:** DLMO demonstrated the potential for efficient and objective image quality assessment in realistic lung-nodule detection tasks with CNN-based CT denoising.

Towards Understandable AI in Lung Nodule Detection: Using the Genetic Algorithm for Interpretable, Human-Understandable Optimization of Nodule Candidate Generation in Lung CT Imaging

M Wahhi-Anwar*, N Emaminejad, G Kim, M Brown, M McNitt-Gray, David Geffen School of Medicine at UCLA, Los Angeles, CA

Purpose: Despite the recent growth in artificial intelligence (AI), the “black-box” nature brings a need for “explainable” AI (XAI) to better understand system performance and limitations. We apply this concept to an AI-based system for lung nodule detection in CT, which can be decomposed into steps of (1) candidate generation (CG), and (2) false positive reduction. The specific purpose of this work is to demonstrate the utility of a Genetic Algorithm (GA) in improving performance of CG in an explainable, understandable fashion. **Methods:** 1010 CT lung image cases from the Lung Image Data Consortium were used. Nodules ≥ 4 mm were identified based on markings from at least 3 radiologists. A previously validated SN CAD system was modified to enable tunable parameters for nodule CG, encoded as chromosomes in the GA. A training subset was used for progressive training, and a validation subset to select the optimal chromosome. Performance on the test set was measured for SNs: (a) hand-tuned, no GA, (b) GA, basic operations (GA-basic), or (c) GA, complex operations (GA-complex). GA-complex incorporated additional operations, to try to promote GA concepts of diversity (maintaining sufficient genetic heterogeneity in each generation) and elitism (propagation of the higher performing chromosomes). Performance was measured via sensitivity and false positive (FP) rate. Parameter importance was measured through random forest variable importance. **Results:** Trained from scratch, GA-complex-optimized CG matched hand-tuned model performance with 90.8% sensitivity with false positive rate greatly reduced to 498 FP/case. Tuning parameters “minimum x-y circularity”, “HU-range”, and “maximum x-y area” demonstrated the highest impact. **Conclusion:** GA-optimization permitted construction of a CG model from scratch that met hand-tuned performance. Further training could enable better performance than human-optimized model parameters. The GA allows examination and deconstruction of chromosomes in the optimization process, to easily follow and manage the evolution of parameters over time.

A Direct Machine-Specific Parameters Incorporated Spot-Scanning Proton Arc (SPArc) Algorithm

G Liu^{1,2*}, L Zhao¹, D Yan¹, X Li¹, X Ding¹, (1) Beaumont Health System, Royal Oak, MI, USA (2) Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Purpose: To address the challenges of generating a deliverable and efficient spot-scanning proton arc (SPArc) plan for a proton therapy system. We developed a novel SPArc optimization algorithm (SPArcDMSP) by directly incorporating machine-specific parameters such as mechanical constraints and delivery sequence. **Methods:** A SPArc delivery sequence model (DSMarc) was built based on the machine-specific parameters of the prototype arc delivery system, IBA ProteusONE®, including mechanical constraint (maximum gantry speed, acceleration, and deceleration speed) and delivery sequence (energy and spot delivery sequence and time). SPArcDMSP resamples and adjusts each control point's delivery speed based on the DSMarc calculation through the iterative approach (Figure 1). In SPArcDMSP, clinical users could set the expected arc delivery time and gantry max acceleration as a mechanical constraint during the plan optimization. Four representative cases (brain, head neck, liver, and lung cancer patients) were selected to test SPArcDMSP. Two kinds of SPArc plans were generated using the same planning objective functions: (1) SPArcDMSP plan meeting the maximum allowable gantry acceleration speed (0.6 deg/s²); (2) SPArcDMSP-user-speed plan with a user pre-defined delivery time and constraint the acceleration speed < 0.1 deg/s². Additionally, the arc delivery sequence was simulated based on the DSMarc and was compared. **Results:** With a similar objective value, number of energy layers and spots, both SPArcDMSP and SPArcDMSP-user-speed plans could be delivered continuously within the ± 1 degree tolerance window. The SPArcDMSP-user-speed plan could minimize the gantry momentum change based on clinical users' input compared to the SPArcDMSP, which could help relieve mechanical challenges to accelerate or decelerate the hundreds of tons of gantry (Figure 2&3). **Conclusion:** For the first time, clinical users not only could generate a SPArc plan meeting the mechanical constraint of their proton system but also directly controlled the arc treatment speed and momentum changes of the gantry during the plan optimization. This work paved the roadmap for the clinical implementation of proton arc therapy in the treatment planning system.

Comparison of Robust Optimization and PTV Margins for Mixed-Beam Radiotherapy

E Heath^{1*}, S Mueller², G Guyer², O Elicin², D Aebersold², M Fix², P Manser², (1) Carleton University, Ottawa, ON, CA, (2) Inselspital, Bern University Hospital and University Of Bern, Bern, BE, CH

Purpose: Mixed-beam radiotherapy (MBRT) using intensity modulated electron and photon beams collimated by the photon MLC has been shown to give superior plan quality in the treatment of tumours with a superficial component. Conventional PTV margins may not be effective at compensating for setup errors in MBRT. We previously developed and validated a framework for robust optimization of deliverable MBRT plans. The aim of the current work is to apply this framework to clinical patient cases and to compare with PTV-based plans. **Methods:** The framework uses a hybrid direct aperture optimization approach which combines simulated annealing and column generation algorithms. To make plans robust against setup errors, the optimization minimizes the expectation value of the objective function evaluated across all specified setup error scenarios under simultaneous consideration of both beam modalities. Robust-optimized and PTV-based MBRT plans were designed on three clinical cases consisting of two head and neck cases and one brain case. The PTV-based plans used a 5 mm isotropic PTV margin while the robust plans considered ± 5 mm systematic translational setup errors along the principal axes (SI, LR, AP). For each plan, dose distributions were calculated for 5 mm isocenter shifts along the principal axes and were compared in terms of target coverage and OAR sparing. **Results:** The robust optimized plans respected the institutional planning guidelines for all considered setup error scenarios while the PTV-based plans had clinically unacceptable hotspots in the CTV and exceeded

OAR tolerances for many of the scenarios. Robust optimized plans achieved an 18% increase in the CTV dose homogeneity for the head and neck cases and, on average, a 6% reduction in Dmean and 15% reduction in D2% for the OARs in all patient cases. **Conclusion:** Robust optimization is a promising alternative to conventional PTV margins to account for setup uncertainties in MBRT.

Development of An Irradiation System for MRI-Guided Proton Therapy

Y Fujii^{1,2*}, H Ueda¹, T Takayanagi², K Umegaki¹, T Matsuura¹, (1) Hokkaido University, Graduate School of Engineering, Sapporo, Hokkaido, Japan. (2) Hitachi Ltd., Research and Development Group, Hitachi-shi, Ibaraki-ken, Japan

Purpose: To investigate a proposed design for an MRI-guided proton therapy system that simultaneously achieves both the large field size (FS) for protons and large field of view (FOV) for MRI. The basic characteristics of the proton beam delivered in the proposed system were analyzed. **Methods:** An open MRI design with iron magnetic poles was adopted in order to achieve both the large FS for protons and FOV for MRI and reduce the MR fringe fields at the beam scanning magnets and spot position monitor. A hole was made in the center of the yoke to ensure an unobstructed proton beam path. The shape of the magnetic poles was optimized assuming axis symmetry to ensure the magnetic field was uniform. Then the magnetic field strength map was calculated considering the yoke with a hole. A helium chamber was installed between the spot position monitor and dose monitors to reduce the beam size. Geant4 simulation (ver. 10.05.p01) was used to model these configurations and analyze the beam size with and without the helium chamber. **Results:** The achieved uniformity of the magnetic field strength was less than 0.8 ppm on the FOV surface. The maximum magnetic field strength in the area upstream from the yoke was 2.8 mT. This indicated that the MR magnetic flux was successfully confined in the yoke and the fringe fields decayed rapidly. The beam sizes of a 70 MeV proton beam were 10.2 and 9.2 mm at the iso center without and with the helium chamber, respectively. **Conclusion:** The proposed design of the MRI-guided proton therapy system realized both the large FS for protons and FOV for MRI, while the magnetic fringe fields were sufficiently small and did not affect the beam monitoring. Beam size was shown to be small enough to be used in clinics.

Evaluation of GRID and Spatially Fractionated Radiation Therapy: Dosimetry and Preclinical Trial

T Johnson*, A Bassil, C Kent, N Williams, G Palmer, Y Mowery, M Oldham, Duke University Medical Center, Durham, NC

Purpose: To develop and implement novel methods of extreme spatially fractionated radiation therapy (including GRID therapy) and subsequent evaluation in pre-clinical mice trials investigating the potential of novel radiation treatments that more effectively promote anti-cancer immunogenic response. **Methods:** Spatially fractionated GRIDs were designed and precision-milled from 3mm thick lead sheets compatible with mounting on a 225 kVp small animal irradiator (X-Rad). Three pencil-beam GRIDs created arrays of 1mm diameter beams, and three "bar" GRIDs created 1x20mm rectangular fields. GRIDs projected 20x20mm fields at isocenter and beamlets were spaced at 1, 1.25, and 1.5mm, respectively. Output factors, peak-to-valley ratios, and dose distributions were determined with Gafchromic film. The bar GRID with 1mm beamlet spacing (50:50 open:closed ratio) was selected for the pre-clinical trial. Soft-tissue sarcoma (p53/MCA) was transplanted into C57BL/6 mice's flanks. Four treatment arms were compared: unirradiated control (n=14), conventional radiation therapy (n=8), GRID therapy (n=12), and hemi-irradiation (n=10) where one-half of the beam was blocked. All irradiated mice received a single fraction of 15 Gy to irradiated regions. **Results:** Very high peak-to-valley ratios were achieved (bar GRIDs: 11.9±0.9, 13.6±0.4, 13.7±0.5; pencil-beam GRIDs: 18.7±0.6, 26.3±1.5, 31.0±3.3). Pencil-beam GRIDs spared twice the number of intra-tumor immune cells as bar GRIDs but left more of the tumor untreated (2-3% vs 14-17% area receiving 95% prescription, respectively). Penumbra was halved when GRIDs were 50% closer to treatment isocenter. The GRID selected for mouse trials was capable of sparing approximately 30% of intra-tumor CD8+ and CD4+ T cells. Preliminary results indicate mean times to tumor quintupling were: 9, 12, 12, and 24 days for unirradiated, GRID, hemi-irradiated, and conventional treatment groups, respectively. **Conclusion:** Peak-to-valley ratios with kV grids were substantially superior to MV grids. In data collected to date, GRID did not control tumors as effectively as conventional treatment at the same dose level.

Experimental Study of An Innovative Thermo-Brachytherapy Seed for Simultaneous Delivery of Radiation and Hyperthermia

S Taghizadehghahremanloo*, E Parsai, D Shvydka, A Shan, University of Toledo Medical Center, Toledo, OH

Purpose: To experimentally characterize ferromagnetic materials for use in an innovative Thermo-brachytherapy (TB) seed, serving as a heat and radiation source for concurrent administration of radiation therapy and hyperthermia. The combination of two modalities has been confirmed very effective in the treatment of prostate cancer without an increase in complications. Measuring the quantity of relative permeability as a function of temperature will be utilized through the power-versus-temperature method for calculation of temperature distribution around the seed in a prototype treatment planning system. **Methods:** We measure μ_r of small (<1cm-long, ~1mm diameter) cylindrical TB seed samples with the same geometrical size and shape as the one used for prostate Brachytherapy seed implant. The nonlinear effects, demagnetization, and magnetic saturation effects in a finite-sized cylinder reduce the value of μ_r compared to those measured with a standard toroid sample (effective length of a toroid is infinite). The inductance, parasitic resistance, and relative permeability of the sample were derived from impedance measurements for a solenoid that was a custom-wound for the sample. The results are compared to the theoretical values and simulations from COMSOL Multiphysics for consistency. **Results:** We measured μ_r for ferrite and Ni-Cu samples. The Curie temperature for the ferrite and Ni-Cu cores are ~55 °C and ~45 °C correspondingly. Our values are closest to theoretical results for a long solenoid corrected for the circular wire shape, mutual inductance between the coil loops, wire self-inductance, the gradient resistance inside the wire, and diameter-to-length ratio. **Conclusion:** The ferrite core has a much steeper permeability fall-off with temperature. Rapid Curie transition, decoupling of the magnetic material properties from electrical properties of the coating, and higher value for permeability make ferrite samples much better candidates for the TB seed. These results can help us to identify a ferrite composition with ideal power generation.

Effect of Incoming Particle Energy and Ionization Cluster Size On the G-Value of Hydrated Electrons

A Bui^{*1}, L Childress², J Sankey², J Seuntjens^{1,3,4}, S A Enger^{1,3,4} (1) Medical Physics Unit, McGill University, Montreal, QC, CA, (2) Department of Physics, McGill University, Montreal, QC, CA (3) Research Institute of the McGill University Health Centre, Montreal, QC, CA, (4) Lady Davis Institute for Medical Research, Jewish General Hospital, Montreal, QC, CA

Purpose: To accurately calculate absorbed dose to water in hydrated electron ($e^-(aq)$) dosimetry, the radiation chemical yield (i.e. G-value) of hydrated electrons, $G(e^-(aq))$, must be precisely determined. The relationship between the G-value, linear energy transfer (LET), and ionization cluster size were also investigated for better understanding of factors affecting the G-value using Geant4-DNA. **Methods:** Different scenarios were investigated using Geant4-DNA track structure Monte Carlo toolkit. In scenario A, a 10 x 4 x 2 cm³ phantom of liquid water was placed at SSD 70 cm and irradiated with monoenergetic electron beams of different incoming energies from 1 keV to 1 MeV. $G(e^-(aq))$ and the G-value of all generated species with respect to incoming energy were scored. In scenario B, the relation

between $G(e^{-}(aq))$ and cluster size was investigated by irradiating a $0.1 \times 0.1 \times 0.1 \text{ cm}^3$ water phantom with electron point sources of energies from 0.01 keV to 1 MeV, starting at the center of the volume. **Results:** The time-evolution of the G-value showed good agreement with previous simulations and experiments. It was observed that as the incoming electron energy decreases (i.e. higher LET), $G(e^{-}(aq))$ generally decreases, and its rate of change over time becomes steeper. For 1 MeV electron beams, the initial $G(e^{-}(aq))$ at 1 picosecond was calculated to be 4.1 ± 0.1 . Moreover, we observed a negative correlation between $G(e^{-}(aq))$ and cluster size as a function of incoming electron energy. The results indicated that cluster size had a pattern similar to that of LET, which has been shown to remain relatively constant as the incoming electron energy increases. **Conclusion:** As the incoming electron energy increases to tens of MeV, $G(e^{-}(aq))$ will remain relatively constant, since it decreases with increasing cluster size and LET. This is beneficial, as Geant4-DNA can only simulate electron interactions up to 1 MeV.

Ionoacoustic Treatment Monitoring for Radiosensitizer-Enhanced Carbon Ion Therapy: A Feasibility Study

J Lascaud*, M Wuerl, P Dash, M Nitta, K Parodi, Department of Medical Physics, Ludwig-Maximilians-Universitat Munchen

Purpose: To evaluate the impact of radiosensitizers on ion-induced acoustic emissions (ionoacoustics) and assess the accuracy of ionoacoustic range verification for carbon ion therapy at clinical synchrotrons. **Methods:** Acoustic emission resulting from the absorption of optical photons produced from scintillation and absorbed in optical dyes or photosensitizers (similar to photodynamic therapy) were investigated. Alternatively, the local enhancement of the energy deposition in presence of gold nanoparticles (radiosensitizers) was also evaluated. FLUKA Monte Carlo simulations were performed to model a monoenergetic carbon ion beams (215 MeV/u) in water in presence of scintillation materials or gold nanoparticles. The resulting acoustic emission was simulated using k-Wave, considering the temporal microstructures of carbon ions delivered by synchrotrons. The interference pattern (beats) between the direct ionoacoustic signal from the Bragg peak (BP) and the pressure produced due to radiosensitizers at the location where the ion beam enters the targeted volume was analyzed in the frequency-domain. The BP position relative to the tumor entrance was estimated from the beat frequency accounting for the speed-of-sound in the target. **Results:** Assuming sufficiently high light yield in the typical range of scintillation decay time, the absorption of optical photons as used in photodynamic therapy can enhance the ionoacoustic emission, e.g., light emission at wavelength of 300 nm with a light yield of 10^3 photons/MeV increases the signal amplitude by 50%. Alternatively, low concentration (<1 wt.%) of high-density materials like gold nanoparticles significantly enhance the ionoacoustic emission (>100 % increase). The additional pressure generated at the entrance of the target in presence of radiosensitizers allows for accurate BP localization (<1% error relative to the 9.8 cm range) for ion beam at synchrotrons. **Conclusion:** This simulation study shows the potential benefit of radiosensitizers on ionoacoustics-based range verification to enable accurate BP localization for carbon ion beams delivered by synchrotron accelerators.

3D DenseNet for Improving Dose Prediction of Volumetric Modulated Arc Therapy in Prostate Cancer

J Fu^{1*}, K Singhrao¹, Z Wang¹, D Ruan¹, D Low¹, J Lewis², X Qi¹, (1) Department of Radiation Oncology, UCLA, Los Angeles, CA, (2) Department of Radiation Oncology, Cedars-Sinai Medical Center, Los Angeles, CA

Purpose: Accurate prediction of radiotherapy dose distributions could guide the treatment planning process to rapidly and consistently achieve high-quality plans. In this study, we proposed a novel 3D DenseNet for predicting dose distributions of volumetric modulated arc therapy (VMAT) for prostate cancer patients. **Methods:** 75 prostate cancer patients were included. Each patient was planned with a prescription dose of 40 Gy in 5 fractions using Eclipse. We built a 3D DenseNet to generate patient-specific dose distributions from the concatenation of the planning CT image, the contours of the external body, planning target volume (PTV), and organs-at-risk (OARs). The proposed DenseNet contains five dense blocks that could alleviate the vanishing gradient problem, encourage feature reuse, and reduce the number of model parameters. The patient cohort was randomly split into 53 patients for training, 11 patients for validation, and 11 patients for independent testing. A 3D U-Net was also trained for dose prediction and model comparison. The model performance was evaluated by comparing the predicted dose with the clinical dose using Dice similarity coefficients (DSCs) of isodose volumes and relevant dosimetric metrics. **Results:** The average DSCs of isodose volumes, between 0% and 100% (step size: 1%) of the prescription dose, achieved by the 3D U-Net and 3D DenseNet are 0.939 and 0.948, respectively. The average absolute differences in Dmean of the PTV and OARs are under 1.43 Gy (UNet) and 0.89 Gy (DenseNet). The average absolute difference in PTV V40Gy is under 2% for both models. **Conclusion:** The proposed 3D DenseNet could accurately predict the dose distribution of VMAT for a prostate cancer patient in about 8 seconds. It achieved more accurate dose prediction than the state-of-the-art 3D U-Net. The 3D DenseNet is a promising tool for fast dose prediction and guiding plan optimization in an online adaptive workflow.

A Deep Learning-Based Framework for Dose Prediction of Pancreatic Stereotactic Body Radiation Therapy

S Momin*, Y Lei, T Wang, J Zhang, J Roper, J Bradley, T Liu, P Patel, X Yang, Department of Radiation Oncology and Winship Cancer Institute, Emory University, Atlanta, GA

Purpose: Efficacy of deep learning (DL) methods in dose prediction of pancreatic cancer is still to be fully explored. This study aims to implement and demonstrate the feasibility of a dual pyramid networks (DPNs) integrated DL model for predicting dose distributions of pancreatic stereotactic body radiation therapy (SBRT). **Methods:** The proposed framework is composed of four parts: CT-only feature-pyramid-network (FPN), contour-only FPN, late-fusion-network (LFN) and an adversarial network. During each phase of the network, combination of mean absolute error, gradient difference error, histogram matching, and adversarial loss was used for supervision. The performance of proposed model was demonstrated for pancreatic cancer SBRT plans with doses prescribed between 33 and 50 Gy across as many as three planning target volumes (PTV) in five fractions. Five-fold cross validation was performed on 30 patients, and 20 patients were used as hold-out tests of trained model. Predicted plans were compared with clinical plans through clinically relevant dose-volume parameters and paired t-test. For the same cross validation and hold-out datasets, our results were compared with the ones predicted by traditional 3D U-Net network architecture. **Results:** The proposed framework was able to predict 87% and 91% of clinically relevant dose parameters for cross-validation sets and holdout sets, respectively, without any significant differences ($P > 0.05$). The proposed model was also able to predict the intentional hotspots as feature characteristics of SBRT plans. In comparison to 3D U-Net, proposed network architecture increased prediction accuracy of 21/26 and 14/22 dose volume parameters for cross-validation and hold-out test, respectively. **Conclusion:** We developed a new DPN-based method to predict dose distributions of pancreatic SBRT and demonstrated its feasibility of dose distribution prediction for both single and multiple PTVs. The predicted prior information could help save pancreatic SBRT planning times for multi-level experienced dosimetrists.

Attention-Gated U-Net Implementation in Total Marrow Irradiation Plan Dose Prediction

D Du*, K Qing, W Watkins, C Han, T Ketcherside, J Wong, T Williams, A Liu, City of Hope National Medical Center, Duarte, CA

Purpose: To implement an attention-gated deep convolutional neural network (cnn) to predict the optimal 3D dose distribution for Total marrow irradiation (TMI) plans. TMI using intensity modulated radiation therapy has many potential benefits compared to total body irradiation for patients receiving hematopoietic cell transplant. The iterative optimization process in TMI is challenging due to dose constraints on organ-at-risks (OARs) and multiple target volumes (PTVs). **Methods:** Twenty-Seven Tomotherapy TMI plans with 20Gy/10fx prescription doses were collected. We focused on the most difficult to be optimized: the thoracic region where lung limits must be met. In this area, there are 6 PTV structures and 3 OARs. We incorporated an attention mechanism in an U-Net network to develop an Attention-Gated U-Net model for predicting 3D dose distributions. The model was trained on twenty randomly selected plans and was validated on the other 7 datasets. **Results:** The Attentional-gated U-Net model predicted the PTV and OAR doses accurately. The training time on was around 150 minutes (2500 epochs) on NVIDIA Quadro P6000 GPU. The average absolute difference ($|D_{\text{predict}} - D_{\text{true}}| / D_{\text{true}}$) of mean dose, max dose and D95 for (1) PTV_Ribs were $2.79\% \pm 1.86\%$, $3.24\% \pm 2.75\%$, $6.95\% \pm 5.18\%$. (2) PTV_Bone was $0.86\% \pm 0.71\%$, $5.09\% \pm 2.79\%$, $7.79\% \pm 5.05\%$. The average absolute difference of mean and max dose was $3.65\% \pm 2.64\%$, and $5.97\% \pm 4.01\%$ for lungs, $6.67\% \pm 5.1\%$, and $12.59\% \pm 11.45\%$ for heart. **Conclusion:** The Attention-Gated U-Net network models predicted the optimal dose distribution for complex multiple targets TMI plans. Our future work includes training and testing the model on a larger patient cohort with different prescription levels as input into plan optimization. We will also implement the model on other body regions and build a whole-body model for TMI planning.

Transfer Learning for Fluence Map Prediction in Adrenal Stereotactic Body Radiation Therapy

W Wang^{1,2*}, Y Sheng¹, M Palta¹, B Czito¹, C Willett¹, F Yin^{1,2}, Q Wu^{1,2}, Q J Wu^{1,2}, Y Ge³, (1) Duke University Medical Center, Durham, NC, (2) Medical Physics Graduate Program, Duke University, Durham, NC, (3) University of North Carolina at Charlotte, Charlotte, NC

Purpose: To predict fluence maps and automatically generate clinically acceptable plans for adrenal stereotactic body radiation therapy (SBRT) and to establish a deep learning framework that requires less demanding data volume using transfer learning (TL). **Methods:** Due to the small number of adrenal SBRT cases, we developed a TL framework that leverages the treatment planning knowledge from a pancreas SBRT model. This framework consists of two convolutional neural networks (CNN), which sequentially predict individual beam doses (BD-CNN) and fluence maps (FM-CNN) for 9-beam intensity modulated radiation therapy (IMRT) plans. One hundred pancreas and 45 adrenal plans were retrospectively included. The two types of plans had different dose prescriptions and beam settings. A base model (including two CNNs) was trained with all 100 pancreas cases. The adrenal plan cohort were first split into training/validation/test sets with the ratio of 20/10/15 without TL. The base BD-CNN was re-trained using 5, 10, 15, and 20 adrenal cases with TL to produce candidate adrenal BD-CNN TL models. The base FM-CNN was directly used for adrenal cases without TL. The resulting AI plans were evaluated by PTV and OAR dosimetric endpoints to produce a percentage score with the clinical plans as the benchmark. **Results:** Transfer learning significantly reduced the necessary training data size and training time. The TL models trained with 5/10/15/20 cases achieved the validation plan quality scores of 81.5/89.9/88.2/86.7, respectively. In contrast, a model using only adrenal training cases (maximum of 20) without TL only scored 78.2. For the test set, the 5/10/15/20-case TL models achieved the scores of 75.3/79.4/82.0/82.3. **Conclusion:** It is feasible to use transfer learning to train the proposed fluence prediction framework, therefore reducing the required data size, training time and effort. Further, this strategy is capable of accommodating different beam geometries and dose prescriptions.

How Fluence-Prediction Error Impact Final Plan Quality: Insights Into a Deep-Learning-Based (DL-Based) Head-And-Neck (H&N) IMRT Planning AI Agent

X Li*, QJ Wu¹, Q Wu¹, C Wang¹, Y Sheng¹, W Wang¹, H Stephens¹, F Yin¹, Y Ge², (1) Duke University Medical Center, Durham, NC, (2) University of North Carolina at Charlotte, Charlotte, NC

Purpose: To collect insights into dosimetric responses from fluence-map-prediction errors of a DL-based AI agent in H&N IMRT planning. **Methods:** A reported AI agent could automatically predict fluence maps and generate plans that are comparable to clinical plans for prostate IMRT. However, when trained for a more complex site, H&N, the AI agent tended to generate plans with higher quality variations. Most DL models are “black-boxes”, whose inner mechanism is not intuitive nor interpretable, and the relationship between fluence-map-prediction error and AI plan quality lacks thorough understanding and investigations. We designed five analytical protocols to collect insights on how the DL-based AI agent model performance affects the final plan quality. The DL model was trained with H&N 216 cases and tested with 15 additional cases. The fluence-map-prediction error (prediction minus ground truth) was analyzed for its dosimetric effects using five error-decomposition methods, including three spatial decompositions: ground-truth fluence-intensity thresholds, predicted fluence-intensity thresholds, and ground-truth fluence-gradient thresholds; and two frequency domain decompositions: Fourier-space frequency bands and Fourier-space truncated low-frequency disks. The decomposed error components were analyzed for their impact on resulting plans’ dosimetric metrics. The PTV dosimetric metrics included heterogeneity index, conformity index, whole-body maximum dose D_{2cc} , PTV $V_{105\%}$, $V_{110\%}$, and $V_{115\%}$. OAR dosimetric metrics included $D_{0.1cc}$ of brainstem and cord+5mm, D_{mean} of parotid left/right, oral cavity, larynx, and pharynx, and D_{2cc} of mandible. **Results:** Majority of PTV metrics were significantly correlated with various error components. Among different decompositions, the Fourier-space low-frequency disks could maximally extract error components that reveal plan quality impacts: error within ~20% area of Fourier space captures most of the dosimetric differences between prediction and ground truth. **Conclusion:** The fluence-map-prediction error in Fourier-space low-frequency region is critical to AI plans’ quality, especially for PTV-related metrics. This insight will help improving network architecture and loss function design.

Feasibility Study of Cross-Modality IMRT Auto-Planning Guided by a Deep Learning Model

G Szalkowski*, X Xu, S Das, P Yap, J Lian, University of North Carolina, Chapel Hill, NC

Purpose: To evaluate the ability of our machine learning model to predict 3D dose distributions that can be converted to deliverable plans using the same and alternate treatment techniques than the training set plans. **Methods:** We developed a triple-stage cascaded U-Net model for 3D dose prediction for head and neck treatments using the data provided for the 2020 AAPM OpenKBP planning challenge. These plans were created using nine field step-and-shoot IMRT, prescribed to deliver 70 Gy in 35 fractions to a high risk PTV, and potentially 63 Gy to an intermediate risk PTV and/or 56 Gy to a standard risk PTV. We used our model to predict dose for 11 patients and imported the data into Raystation. Using the fall-back planning function, we created two plans that attempted to mimic the predicted dose, one using the same 9 field IMRT beam arrangement as the training plans and one using VMAT with two full arcs, which is the standard at our institution. The plans were normalized to give 95% coverage at 70 Gy to the high risk PTV. These plans were compared against the predicted dose based on several main clinical objectives: coverage of the standard risk PTV, max dose to the cord, mean dose and D50 to the left and right parotids, and max dose in the plan. **Results:** There were no

statistically significant differences in the majority of the clinical goals ($p > 0.05$), with the exception of the max spinal cord (for IMRT and VMAT) and the max overall (IMRT) dose. Adding an optimization objective for these goals in addition to the mimic dose objective for select plans removed this difference. **Conclusion:** Our model generates 3D dose predictions that are clinically achievable both using the technique used in the training plans and an alternate technique.

A Deep-Learning-Enabled Remote Teaching Platform for Pancreas SBRT Treatment Planning: A Pilot Study in Pandemic Era

Y Xie^{1*}, W Wang², Y Chang², X Li², K Lu², R Li², H Stephens², F Yin¹, Q Wu¹, Y Ge³, Q Wu¹, Y Sheng¹, (1) Duke University Medical Center, Durham, NC, (2) Duke University, Durham, NC, (3) University of North Carolina at Charlotte, Charlotte, NC

Purpose: Covid-19 pandemic calls for more effective remote teaching method necessary for social distancing, while remaining equal quality of teaching. This study innovatively developed a tutoring program to help physics residents to learn pancreas stereotactic body radiation therapy (SBRT) treatment planning. **Methods:** The pilot tutoring program is a compact front-end visualization platform composed of three modules: 1) teaching case module, 2) interactive knowledge module (IKM) and 3) scoring module. The teaching case module included five teaching cases. The trainee began with the benchmark case independently to benchmark the baseline skill level, which was revisited after completion of training of the other four cases to evaluate clinical planning readiness. The IKM included a deep neural network based dose-volume prediction model previously developed for pancreas SBRT. The trainee can seek reference and guidance from the IKM during learning. The scoring module summarized the plan quality by weighing key dosimetric endpoints and their relative importance. Grade point average (GPA) was introduced to qualitatively appraise the plan quality into A, B and C (within 3%, 3-10% and >10% difference of clinical plan score, corresponding to 4, 3, 2 point respectively). Five trainees with minimum planning experience completed the teaching course. **Results:** Trainees achieved an average of 65.1% of total points (3.6 GPA) with 84 minutes planning time for the benchmark case pre-teaching, and improved to an average of 75.7% (4.2 GPA) using 48 minutes post-teaching. The clinical plan scored 72.7% of total points. All trainees improved their teaching plans' scores after taking the virtual tutoring program. Post-teaching, all trainees received the GPA of A (clinical quality level) on the benchmark case planning. **Conclusion:** The remote teaching program with knowledge modules provides encouraging learning outcomes in pancreas SBRT planning for less experienced planners. This deep-learning-enabled remote teaching platform could provide valuable addition to the traditional human resource heavy in-person teaching of SBRT planning.

Gamma Knife QA from TG 21 to TG-178

TH-D-TRACK 7-04

Q&A

This talk describes the report prepared by AAPM Task Group 178, beginning in 2008. The completed report will soon be published in Medical Physics. The scope of the investigation is the calibration and quality assurance of the Leksell Gamma Knife, in use worldwide since the original commercial unit was installed in 1987. The report adopts the formalism described by Alfonso et al (2008) for radiation therapy devices non-compliant with the AAPM Task Group 51 dose in water protocol, to extend its use to the Leksell Gamma Knife. Results of Monte Carlo calibration and subsequent verification by the manufacturer in 2010 provided the missing factors for use of 9 commonly used ionization chambers for three different phantoms. The round-robin measurement conducted by TG 178 in 2011 to 2012 are also reviewed. Quality Assurance recommendations for the latest Leksell Gamma Knife Perfexion and Icon will be presented.

This talk aims to present the results of the external audits offered by the IROC Houston QA office Gamma Knife. The program provides a verification of the output of unit and an end-to-end test with an anthropomorphic head phantom. Most of the institutions that use the service are NCI clinical trial's participants. The output verification requires the irradiation of TLD located in an insert that is compatible with the QA phantom used for ion chamber measurements (cassette for the Elekta ABS ball or insert for the solid water phantom). The SRS head phantom is a plastic shell with an insert that includes a centrally located target, TLD located in the target and gafchromic film. The information presented includes the distribution of the results of the dose comparison at the point of measurement as well as demographic information from these irradiations: models of the unit, calibration protocol use for determination of the output and reference medium.

This talk aims to give an example of the evolution of a Gamma Knife QA program, in particular in the context of the recent publication of TG-178 and the development of the Gamma Knife Icon. An extremely well developed for Gamma Knife QA program developed for the Gamma Knife Perfexion model. This system was based on Tg-21 calibration in the Elekta ABS ball. Then in November 2017 we received the Gamma Knife Icon. With the publication of TG-178 (released for public comment in 2018) and IAEA TRS 483 in November 2017, was a great catalyst for the revamping of our QA program. We reviewed every section of our qa program, safety, mechanical, calibration, relative dosimetry, imaging, intrafraction motion management, end to end testing, and secondary dose calculation. Most of the changes there are two common trends, 1) the need to address new technology, and 2) the desire to simplify and improve consistency. This talk discusses some lessons learned during this process.

Learning Objectives:

1. Understand the reasoning behind the creation of TG-178 and the recommendations made within the task group.
2. Understand the importance of external dosimetry audits for Gamma Knife and a review of results seen by IROC
3. See a realworld example of how to adopt some of the changes mentioned in TG-178

A Method to Estimate the Half-Value Layer in CT from Two Exposure Measurements

R Al-Senan*, K Brown, S King, Penn State University, Hershey, PA

Purpose: Among other factors, dose to a CTDI phantom depends on the beam quality. If contributions from scatter to exposure to center-hole is excluded one can, in theory, estimate the central beam half-value layer (HVL). The proposed study investigates the validity of this concept. **Methods:** Transmission factors (TFs) through 15.4-cm PMMA were determined using a spectrum generator of beams whose qualities were modified by adding various aluminum filter thicknesses. The resulted HVLs and TFs from the simulations, at four tube-potentials, were fitted together using a second-order polynomial. To find the HVL from CTDI measurements, scatter-to-primary ratio (SPR) at each kV was determined. This was achieved through measurements in phantom (with 32-cm CTDI phantom, center-hole) and in-air on five scanners with HVLs manually-measured with Al filters. SPR was estimated as: $[\text{Center hole exposure} / \text{Primary exposure} - 1]$, where primary was calculated as: $\text{TF} \times \text{in-air exposure}$, where TF was determined using the polynomial relationship. Finally, by estimating the TF from the mean SPR at each kV, HVL was calculated for every scanner and kV combinations and compared to those manually-measured. Also, manually-measured HVLs were compared to values measured automatically by a calibrated multi-sensor. **Results:** SPR per kV did not vary significantly among different scanners/bowtie filters with different HVLs. Collimation showed no effect on SPR. Average SPRs were: 8.1, 7.6, 7.1 and 6.9 for 80, 100, 120 and 140 kV, respectively. Error of calculated vs. manually-measured HVLs was, on average, 4.7% (± 0.34 mm) over all four kV stations. Measured HVLs from the multi-sensor were found to result in an average error of 10.8% (0.75 mm). **Conclusion:** The method of estimating the HVL from in-air and in-phantom measurements was found to be reasonably accurate and practical. It can be used during the periodic CT testing. Furthermore, it showed higher accuracy than using the multi-sensor.

TH-IePD-TRACK 1-02

Half-Value Layer at Different Positions in Wide-Beam CT Scanners

N Correa*, I Barreto, M Arreola, University of Florida, Gainesville, FL

Purpose: To demonstrate how Half-Value Layer (HVL) and Effective Energy (E_{eff}) are spatially-dependent in the x-y plane and the z axes of wide CT beams. **Methods:** HVL in the x-y plane and z-axis, bowtie profiles in the x-y plane, and dose profiles along the z-axis were measured for all tube voltages (80-135 kVp) and bowtie filters in two 320-slice Canon CT scanners. All measurements were conducted in service engineer mode with the X-ray tube parked at the 12 o'clock position in the gantry. For HVL and bowtie profile measurements, 6-cm³ and 0.6-cm³ ion chambers were used, respectively. The dose profile along the z-axis was measured using OSL dosimeters and corrected for energy dependence by using calculated correction factors. Using HVL measurements, the effective energies for both scanners were estimated using SpekCalc, an x-ray spectrum generator. **Results:** Along the x-y plane, Scanner 2 had higher HVLs (4.27-11.3 mm-Al) and E_{eff} (39-71.2 keV) than Scanner 1 (4.10-8.40 mm-Al, 38.4-63.7 keV). Along the z-axis, the anode side had a higher HVL (5.17-11.2 mm-Al) and lower dose (5.63 mGy, which was the minimum dose at 80 kVp) than the cathode side of the x-ray tube (3.92-10.2 mm-Al, 57.8 mGy, which represented the peak dose at 135 kVp). The bow-tie profile showed a symmetrical curve for all energies for both scanners. **Conclusion:** Differences were observed for HVL and effective energy as a function of position within wide X-ray beams. Furthermore, Scanner 2 had a harder beam spectrum than Scanner 1. These findings imply differences in image quality and dosimetry in wide CT beams scanned with a single volumetric rotation. Individuals assessing image contrast, CT number accuracy, OSL dosimetry, or Monte Carlo simulations must consider the spatial dependence of HVL and effective energy within X-Ray beams.

TH-IePD-TRACK 1-03

Spatial Resolution of Extremity CTA On a Wide Coverage Diagnostic CT Scanner: Effects of Focal Spot Size and Reconstruction Algorithm

Z Qi*, (1) Henry Ford Health System, Troy, MI

Purpose: To study the effects of focal spot size and reconstruction algorithm on the spatial resolution performance of a wide coverage CT scanner (GE Revolution Apex) in the context of upper/lower extremity CTA imaging. **Methods:** A GE QA phantom for CT was used and the MTF was measured by analyzing the HU profile across a 0.05 mm diameter tungsten wire. A clinical extremity CTA protocol was modified for the use of different focal spot sizes and reconstruction settings. Four reconstructions settings are included: standard kernel with ASIR-V 50%, detail kernel with ASIR-V 50%, detail kernel with ASIR-V 30%, and detail kernel with ASIR-V 0%. For each reconstruction setting, three focal spot sizes, XL, L and S, were used by varying tube current while CTDIvol stayed constant. 10% MTF spatial frequency was used to quantify spatial resolution performance. The partial volume effect was also evaluated based on the relative change in the peak HU. **Results:** The change of reconstruction kernel from standard to detail, when focal spot size L and ASIR-V 50% were used, resulted in an increase in 10% MTF frequency from 6.35 lp/cm to 7.47 lp/cm. The change of focal spot size resulted in a maximum of 0.15 lp/cm difference when the standard kernel was used, and a maximum of 0.5 lp/cm difference when the detail kernel was used. The change of ASIR-V percentage resulted in minimal difference when the detail kernel was used. For partial-volume effect, the increase in focal spot size from S to XL resulted in a maximum of 14% decrease in 10% MTF frequency. **Conclusion:** Our results indicate more pronounced effect of reconstruction kernel on spatial resolution compared to both focal spot size and ASIR-V percentage. MTF measurements with varying signal contrast are desired for more comprehensive characterization of spatial resolution performance of the system.

Optimal Tube Voltage Selection in Coronary Artery Angiogram with Dual-Source CT

Y Zhou*, Y Zhou, D Zhang, A Scott, Cedars-Sinai Medical Center, Los Angeles, CA

Purpose: As we experienced in clinical practice, the default automatic tube voltage selection may not be optimal in coronary artery CT angiogram (CCTA). This study was designed to find alternative tube voltages that are optimal in CCTA with dual-source CT. **Methods:** Iodine targets of different diameters and densities (3 -5mm and 0.5-10 mg/cc) were inserted on the coronary artery track of a medium size anthropomorphic heart phantom. Large and extra-large phantom sizes were made by adding additional fat layers. The heart module in the phantoms was set in 3-dimensional motion by an ECG signal of 60 beats-per-minute. A Siemens Force CT was used to acquire CCTA with prospective gating at 65-75% of R-to-R peaks. The vendor CarekV was used first (with a typical CNR strength 9 for CCTA). Additional kVp (+/- 10) were manually selected with the scanner's automatic mA compensation for CNR maintenance. Images were reconstructed to thickness of 0.5 mm (Bv40 and ADMIRE 3). Cylindrical voxels of interest were placed inside the targets of 5 mg/cc and 10 mg/cc and nearby blood pool to measure the contrast-to-noise ratio (CNR). The figure-of-merit (FOM) was defined by the CNR normalized to the square root of volume CT dose index to focus on the impact of kVp selection. **Results:** On average the FOM was found 12% higher when the kVp was lowered by one step (10 kVp) from the machine auto-selection for all three phantom sizes. Visual comparison of image quality of the coronary iodine targets at different kVp values was consistent with the FOM results. 150 kVp was not found optimal for the extra-large phantom. **Conclusion:** When the kVp was lowered by one step (10 kVp) from the machine auto-selection, the CCTA with dual-source CT delivers better performance.

TH-lePD-TRACK 1-05

A New Approach for Low Dose Low KVp Coronary Artery Calcium Scoring

D Zhang*, A Scott, C Lee, N Gellada, M Hyun, Y Zhou, Cedars-Sinai Medical Center, Los Angeles, CA

Purpose: Dose reduction using lower kVp in coronary artery calcium scoring (CACs) CT is appealing due to the population dose concern from the wide use. Previously we proposed a vendor-independent approach for low dose low kVp CACs without changing the Agatston thresholds. This study was to further validate the approach by incorporating a large phantom size. **Methods:** By applying consistent calcium contrast-to-noise ratio (CNR) to two anthropomorphic heart phantoms (medium and large) with 3-cm hydroxyapatite (HA) inserts, scanned using a dual-source CT, the relationship was derived between the volume CT dose index (CTDIvol) at lower tube voltages and the baseline CTDIvol at 120 kVp based on consistent CNR. The baseline CTDIvol was obtained using the specified noise thresholds from the images acquired at 120 kVp. To preserve the conventional Agatston thresholds, down-scaling with the found calcium HU enhancement factors was applied to images acquired at lower voltages with a dynamic heart module in 3D motion simulating heart movement at 60 beats per minute with 1.2-5 mm calcium inserts (50- 400 mg/cc) on the coronary tracks. Scores were evaluated on the scaled images by six readers and compared against the ground truth scores at high CTDIvol. **Results:** The CTDIvol at lower voltages was related to the baseline CTDIvol following a power form of the voltage (index 1.246), regardless of the phantom size. The baseline CTDIvol was found to be 1.5 and 4.5 mGy, for the medium and large phantoms, respectively. Correspondingly, the reduced CTDIvol at 100-70 kVp were 1.28-0.76 mGy, and 3.57-2.32 mGy. The downscaling factors were 0.88-0.63. The calcium scores at lower voltages were found within 12% of the ground-truths. **Conclusion:** A vendor- and patient size-independent approach was established to obtain the reduced dose and correct coronary calcium scores at lower tube voltages. Up to 50% dose reduction was achieved.

TH-lePD-TRACK 1-06

A Quantitative Approach to Patient Size Dependent Optimal Dose for Coronary Artery Calcium Scoring CT at the Standard KVp

Y Zhou*, Y Zhou, D Zhang, E Eastman, C Lee, A Scott, Cedars-Sinai Medical Center, Los Angeles, CA

Purpose: Coronary artery calcium scoring (CACs) CT is performed at 120-kVp in current practice. The dose becomes a concern because of CACs' screening nature. The dose delivery is empirical and may not be optimal. We aimed to find the optimal dose for different patient sizes. The result can also serve as the baseline for further dose reduction for CACs at lower kVp. **Methods:** A surrogate noise (SN) was constructed as a function of the patient effective diameter and the volume CT dose index (CTDIvol). For the specified threshold noises at two known patient sizes covering the concerned range, the corresponding CTDIvol values were experimentally determined. To derive the CTDIvol as a function of the patient size within the range, we assumed that the threshold noise, thus SN, varies linearly with the patient size. The experiment was conducted using two thoracic phantoms (medium and large) with a moving heart module. They were scanned at 120 kVp using a prospectively gated CACs with a Siemens Force CT at different CTDIvol (0.76 -6 mGy). Its motion was driven by an ECG of 60 beats-per-minute. Noise measurement were made in the heart blood pool. A constant noise threshold (20 HU) and the recommended variable noise thresholds (20 HU for medium and 23 HU for large subjects) from Society of Cardiovascular CT (SCCT) were applied separately. The results from the model were further compared retrospectively with 33 clinical cases using dose modulation with a reference effective mAs of 80. **Results:** According to the model, the doses to achieve the constant noise threshold (20 HU) were found more consistent with the observed patient doses, but switching to the SCCT variable thresholds resulted in a dose reduction of up to 25%. **Conclusion:** A quantitative model was established to obtain the patient-size dependent optimal dose for CACs scans.

TH-lePD-TRACK 1-07

Graph-Based Low Dose Computed Tomography

Z Zhang*, W Liu, L Xing, Stanford University, Stanford, CA

Purpose: Computed tomography (CT) has played a vital role in medical diagnosis, assessment, and therapy planning, etc. Concerns about the increase of X-ray radiation exposure attract more and more attention in clinical practice. To lower the X-ray radiation, low-dose CT (LDCT) has been widely adopted in certain scenarios, while it will induce the degradation of CT image quality. In this paper, we proposed a graph-based denoising neural network to reconstruct high-quality LDCT images. **Methods:** Inspired by the non-local mean method, although conventional convolutional neural network (CNN) has obtained outstanding success in LDCT, the convolutional operation only focuses on the local area of CT pixels, which is inefficient at processing structural information across large regions. Therefore, we introduce the graph convolutional network (GCN) and employ a well-designed spatial GCN module and a Channel GCN module. Given the dimension of the LDCT image is $M \times N$. First, we used six convolutional layers to obtain low-resolution features ($M/4 \times N/4$) piecewise in case of memory overflow. Then we fed these features into four spatial GCN modules to explore large-range dependencies. Finally, we employed skip connections to introduce those features with the same resolution from the first six convolutional layers into the piecewise reconstruction, like U-Net. We employ residual learning to ease the network training. We use mean square error (MSE) as the loss function to train the proposed graph-based neural network. **Results:** In this work, we evaluate our method on the dataset from the 2016 NIH-AAPM-Mayo Clinic Low-Dose CT Grand Challenge. We randomly select seven patients as the training dataset, one for validation and two for testing. For visual inspection, we can see that the proposed method can tell more fine structure. **Conclusion:** The experimental results demonstrate that the proposed method can improve the LDCT image quality and verify the significance of large-range dependencies on LDCT.

Comparative Analysis of T2W Contrast for Clinical Prostate Protocols Using a Dedicated MR System Phantom

K Hwang*, J Yung, A Venkatesan, R Stafford, UT MD Anderson Cancer Center, Houston, TX

Purpose: Sequence parameters for most clinical diagnostic imaging protocols have traditionally been designed based upon subjective image interpretive feedback by radiologists. Imaging parameters are typically selected based on compromises between contrast, resolution, scan time, SNR, and motion. While perceived differences in contrast exist for different sequences, the standardization and validation of intrinsic sequence contrast across scanner platforms and field strengths is not addressed by standard QA procedures. Hence longitudinal imaging on disparate scanners can be associated with observed contrast changes between timepoints, negating radiologists' diagnostic confidence. In this study, we used the ISMRM-NIST system phantom to evaluate contrast of a T2-weighted acquisition protocol used for prostate imaging across several scanners in our institution. **Methods:** The system phantom was scanned on three 1.5T and three 3T scanners with a thin slice T2-weighted Turbo Spin Echo PIRADS 2.1 compliant acquisition. Within field strengths, the scanners had identical hardware configurations and executed identical scan parameters. Since the phantom cannot be imaged with an endorectal coil, coronal slices were acquired using the body coil to maximize signal homogeneity. Signal intensity of the T2-sensitive compartments was measured for evaluation of relative contrast, as defined by change in signal intensity as a function of T2. Background water signal near the spheres was also recorded as a measure of overall B1- inhomogeneity, which was applied as a correction factor to minimize residual signal inhomogeneity in the image. **Results:** Contrast as defined by signal percent difference between two designated spheres averaged 28.0% at 1.5T and 45.0% at 3T. For T2 ranging from 46.42 to 581.3 msec, contrast curves varied within $\pm 1.3\%$ of average at 1.5T and $\pm 9.4\%$ at 3T. **Conclusion:** A standardized system phantom

and measurement protocol enables the measurement and validation of T2 contrast between scanners. Notable contrast deviations were detected at 3T, which warrant further investigation.

A Dynamic Susceptibility Contrast MRI Digital Reference Object for Testing Software with Leakage Correction

H Chen^{1*}, M Jen², P Hou¹, R Stafford¹, H Liu¹, (1) UT MD Anderson Cancer Center, Houston, TX, (2) University of Wisconsin-Madison, Madison, WI

Purpose: Relative cerebral blood volume (rCBV), derived from dynamic susceptibility contrast (DSC)-MRI, is a perfusion biomarker commonly used for evaluating brain tumors. To account for the extravasation of contrast agents, post-processing leakage correction is often applied to improve rCBV accuracy. Digital reference objects (DRO) are ideal for testing the post-processing software, because the DRO's biophysical model can be matched to the one implemented in the software. Our aim is to develop and test such DSC-DROs. **Methods:** Three DROs were generated using the Weisskoff model, each composed of nine foreground lesion objects with combinations of different levels of rCBV and contrast leakage effects. Three types of background were implemented for these DROs: 1) a multi-compartment brain-like background, 2) a sphere background with a constant signal time curve, and 3) a sphere background with signal time curve identical to that of the brain-like DRO's white matter (WM). The DROs were then analyzed with an FDA-cleared software with and without leakage correction. Leakage correction was tested with and without brain segmentation. **Results:** Accuracy of leakage correction was able to be verified using the brain-like phantom and the sphere phantom with WM background. The sphere with constant background did not perform well with leakage correction with or without brain segmentation. The DROs were able to verify that for the particular software tested, leakage correction with brain segmentation achieved the lowest error. **Conclusion:** DSC-MRI DROs with biophysical model matched to that of the post-processing software can be well used for the software's validation, provided that the background signals are also properly simulated for generating the reference time curve required by the model. Care needs to be taken to consider the interaction of the design of the DRO with the software's implementation of brain segmentation to extract the reference time curve.

Development of a Quality-Assurance Program for MR-Derived PDFF Measurements

S Fielden*, W Triffo, Geisinger Health System, Danville, PA

Purpose: MRI accreditation does not currently require inspection for quantitative MR measures such as proton density fat fraction (PDFF). Here we report on the initiation of such a program for MRI-derived PDFF measurements at a large, regional health system. A low-cost phantom composed of varying fat percentages was constructed and scanned repeatedly over the course of 1 year. Based on repeatability coefficients reported in the literature, we hypothesized that an action limit of 2% absolute would capture normal variation. **Methods:** Six fat/water vials were constructed with fat concentrations 0, 5, 10, 15, 22.5, 30% wt/wt. The phantom was scanned using the LiverLab product from Siemens Healthineers on five 1.5 T MRI systems. Software levels varied among systems: XA11 (1 system), VE11E (2 systems), and two systems were upgraded from VE11C to VE11E during the study period. The default CSE-PDFF protocol was used, with changes only to slice orientation to accommodate phantom geometry. **Results:** All slopes were not significantly different from one ($p > 0.10$ for all systems), albeit with wide confidence intervals (mean [CI]: 1.1 [0.9, 1.4]). Excellent agreement was found for repeated scans, with no repeated measures differing from baseline by more than 1.7% absolute. Small biases (maximum -0.2% absolute) and a maximum coefficient of repeatability of 1.8% were found, in good agreement with values from the literature. **Conclusion:** Given the excellent repeatability of CSE-PDFF measures, a quality assurance program that assessed longitudinal changes of a low-cost, home-made phantom with an action limit of 2% absolute change per vial found no changes over the course of one year.

Dependence of B₀ Homogeneity on Field Strength and Phantom Size When Measured with Four Common Methods

T Salzillo^{1*}, D Jordan², D Ragan³, M O'Shea⁴, T Andrews⁵, C Dillon⁶, S Fielden⁷, M Tressler⁸, J Saunders⁹, J Och¹⁰, C Brunnquell¹¹, (1) MD Anderson Cancer Center, Houston, TX, (2) University Hospitals Cleveland Medical Center, Cleveland, OH, (3) Medical College of Wisconsin, Milwaukee, WI, (4) University of Pennsylvania, Cherry Hill, NJ, (5) Washington University at St Louis, Saint Louis, MO, (6) Alliance Medical Physics, Alpharetta, GA, (7) Geisinger Health System, Danville, PA, (8) Alliance Medical Physics LLC, Canton, GA, (9) US Navy, San Diego, CA, (10) Geisinger Medical Center, Danville, PA, (11) University of Washington, Seattle, WA

Purpose: A uniform static magnetic field (B₀) is imperative in clinical MRI applications to minimize artifacts such as geometric distortion, signal loss, banding artifacts, and failures in frequency-selective techniques. Several methods to measure B₀ homogeneity (ΔB_0) have been developed. The purpose of this work is to assess the variability in measurements from different methods and potential contributing factors. **Methods:** ΔB_0 was measured by multiple users and scanner types. Four methods to measure ΔB_0 were analyzed: Spectral Peak (N=41), Bandwidth (N=45), Phase Difference Map (N=55), and Field Map (N=35). This dataset was retrospectively analyzed: average values of ΔB_0 and coefficients of variation (CV) were calculated for each method. These data were further grouped by field strength and phantom size and tested for significant differences to determine any contributing factors of ΔB_0 variability. **Results:** Average ΔB_0 in ppm and CV of the four methods were as follows: Spectral Peak (0.93, CV=0.68), Bandwidth (1.23, CV=0.82), Phase Difference Map (1.52, CV=0.43), Field Map (1.45, CV=0.43). Spectral peak was reported as root-mean-square, while the other methods were reported as peak-to-peak. The Bandwidth difference method had the highest CV while the two mapping methods had the lowest. Measurements for each method grouped by field strength did not differ significantly. ΔB_0 was significantly lower ($p=0.0464$) when measured in smaller phantoms (16-29 cm) compared with larger phantoms (30-45 cm) using the Spectral Peak method but did not differ significantly when measured with the other methods. **Conclusion:** This analysis of ΔB_0 measurements using four common methods serves as an initial reference for those conducting their own homogeneity tests. These initial data are highly variable, which may be explained by differences in scanner technology and reflect variability in methods across physicists. However, as more data points are added to the study, these reference values can be reported more precisely.

TH-lePD-TRACK 2-05

MRI Isocenter Consistency at Various Gantry Angles Using MODUS MRID3D Phantom

D Sievert¹, B Lewis¹, J Shin^{1,2}, E Barberi³, B Quinn³, J Kim², T Kim¹, (1) Washington University in St. Louis, St. Louis, MO, (2) Yonsei University College of Medicine, Seoul, KR, (3) Modusqa, London, ON, CA

Purpose: MRI isocenter consistency at all gantry angles is critical to ensuring accurate treatment delivery in MRgRT. Previous reports from our group showed an imaging isocenter shift of <1mm utilizing a rectangular phantom at multiple imaging locations with ViewRay's analysis software. In this study, we verified MRI isocenter fidelity using an independent 3rd party 3D geometric phantom and corresponding software. **Methods:** This experiment used a QUASAR™ MRID^{3D} phantom on a 0.35T ViewRay MRidian MR-linac alongside the QUASAR™ MRID^{3D} geometric distortion analysis system. Images were acquired at twelve gantry angles from 0–330° at 30° increments. Acquisitions utilized a 3D TRUF1 sequence with TR: 3ms, TE: 1ms, flip angle: 60°, FoV: 450x450x360mm³, imaging matrix: 300x300x240. Images were acquired with the onboard Siemens distortion correction function turned on and off to measure the ability of the system to correct geometric distortion. All images were imported into the distortion analysis software to quantify MRI isocenter shift and geometric distortion of the phantom per gantry angle. The baseline for all measurements is G300 for Gantry home position in RT. **Results:** The mean and standard deviation deformation vectors for Distortion

On were 0.28 ± 0.37 mm, 0.27 ± 0.32 mm, and 0.28 ± 0.33 mm in the AP, RL, and SI directions respectively, and 2.91 ± 4.44 mm, 3.15 ± 4.75 mm, and 1.82 ± 2.49 mm for Distortion Off. The mean isocenter shift was 0.62 mm with a range of 0.21 mm to 0.96 mm for Distortion On, and 0.65 mm ranged from 0.24 mm to 0.93 mm for Distortion Off. **Conclusion:** The magnitude of MRI isocenter shift from 3D MRID^{3D} phantom showed similar trends as previous work with a 2D slab phantom for all gantry angles. This study showed that the gantry position can impact the image isocenter yet can be corrected by applying a deformation vector field at all measured gantry angles using the QUASARTM MRID^{3D} phantom and software.

Need for a Saturation RF Band to Mitigate Flow Artifact in 3D-MPRAGE On a Compact 3T Scanner

M In*, N Campeau, J Huston, D Kang, L Bardwell Speltz, N Meyer, J Trzasko, Y Shu, M Bernstein, Mayo Clinic, Rochester, MN

Purpose: Due to the smaller dimensions (inner diameter 37 cm, length 40 cm) of the RF-transmit coil on compact 3T (C3T) scanner [1], the B1 field falls off rapidly outside the head. This offers great potential for safe brain imaging of patients with implanted devices without sacrificing any imaging capabilities [2]. For a whole-body scanner, during a fast gradient-echo scan, the arterial blood usually experiences repeated RF pulses before flowing into the brain, so the magnetization becomes saturated. However, because of the relatively shorter RF coverage of the C3T, inflowing blood saturates less than with a conventional, whole-body transmit RF coil does (Fig. 1). This results in strong hyperintense intravascular signal and intense flow-related ghost artifacts. In this study, we demonstrate that these specific 3D-MPRAGE flow artifacts can be mitigated by applying an additional inferior spatial pre-saturation. **Methods:** An RF spatially selective saturation band module was added to the standard 3D-MPRAGE sequence to saturate incoming arterial flow from the heart (Fig. 2) and consequently suppress the intensity of intracranial vasculature. 3D-MPRAGE imaging was performed on the C3T both without and with use of the inferior RF saturation band in two human subjects under an IRB-approved protocol. Image assessment was performed by two board-certified neuroradiologists. **Results:** With the additional saturation RF pulses, the acquisition time was increased 20 seconds compared to the standard acquisition (5:02 vs. 5:22). While prominent ghost artifacts were observed along the in-plane phase-encoding (i.e., inferior-to-posterior) direction in the standard sagittal scan, the pulsation effects were substantially reduced in the proposed scan due to RF pre-saturation of the incoming arterial signal (Fig. 3). **Conclusion:** 3D-MPRAGE imaging with an additional RF saturation band is an effective method to suppress vascular ghost artifacts caused by the arterial blood flow inherent to smaller bore MRI system such as C3T.

MRI Scanner 3D Field Homogeneity Evaluation for ACR Acceptance and Performance Testing

J.-X. Wang^{1*}, (1) University of Alabama at Birmingham, Birmingham, AL

Purpose: To quantify and to improve the measurement accuracy of the “MRI scanner field inhomogeneity evaluation” for the “ACR MRI system Acceptance Test” and the “ACR MRI System Annual Performance Test”. **Methods:** A spherical phantom of 25 cm diameter (which is MRI site facility dependent, normally larger) at the isocenter of the MRI scanner bore was scanned with a 3D dual gradient echo sequence with TE1=7 ms and TE2=21.7 ms (which are scanner field strength dependent). A slab of 25-slices (which is phantom size dependent) was scanned and a total of 2x25 amplitude plus 2x25 phase images were acquired. An appropriate 3D phase unwrapping method was developed and applied to the phase images. The field variation map was then generated according to the guidance in the “ACR 2015 Quality Control Manual Medical Physicist Section” (Chapter IV, Section A-4) and the “ACR Acceptance Testing and Quality Assurance Procedures for MRI Facilities” (Chapter III, Section E-1) based on these two unwrapped 3D-phase images. The field at the isocenter was set as the reference point. **Results:** The result shows that each 3D-phase image is unwrapped perfectly as one unit and the 3D-field map generated based on these 3D-phase images is smooth and intuitive. It can be viewed with any 3D viewing tools from any viewing angle. The result shows that for this particular scanner, up to a diameter of 25 cm, the crossing field variation is about 0.3 ppm in the transverse plane while the field variation reaches over 1.0 ppm in the longitudinal direction. **Conclusion:** A semi-automated tool to generate the MRI scanner field variation map (2D and 3D) is developed based on this method and it provides a convenient, efficient and accurate mean for physicists to perform the MRI scanner field inhomogeneity evaluation for the “ACR MRI system Acceptance Test” and the “MRI System Annual Performance Test”.

The Segmentation of Main Intestinal Organs Based on CT Images With Deep Learning Method

w wu¹, R Lei¹, Z He^{2*}, K Niu³, R Yang⁴, (1) Beijing University of Posts and Telecommunications, Beijing, CN, (2) Peking University Third Hospital, Beijing, CN

Purpose: Fully analyze the features of three intestinal organs including colon, small intestine and duodenum in morphology, texture, and location distribution, and used some specific structures to capture these features, so as to achieve the simultaneous and high-precision segmentation of the three intestinal organs. **Methods:** Considering the changes in the shape and size of the intestinal organs, the model needs to adequately capture the information at different scales. HRNet can maintain high-resolution feature map throughout the whole network, and can fully integrate features of different scales, which is helpful for the segmentation of large-scale organs such as colon, small intestine and small-scale organs like duodenum. In addition, by introducing location information and reasonable data enhancement operations, we further improve the segmentation ability of the network for different organs and alleviate the problem of mutual interference between multiple organs. **Results:** Our data is collected from 80 patients with 3316 CT images which is divided into three parts: 2652 for training, 332 for validation and 332 for the final test. For the 332 test CT images, dice coefficients of colon, small intestine and duodenum were 0.8963, 0.8792 and 0.8510, respectively, which all achieved excellent results so far. In the duodenum, which is the most difficult to segment, our results were 5% higher than those of some previous networks. **Conclusion:** The rich multi-scale information provided by HRNet is very important for large morphological changes of intestinal organs. Meanwhile, the maintenance of high-resolution feature maps also provides detailed information for fine segmentation of small target regions, such as organ edges and duodenum. Location information is the key to further distinguish small intestine and duodenum. By simply introducing coordinate information, the segmentation accuracy of duodenum can be improved. Meanwhile, a reasonable data enhancement strategy is also conducive to alleviating the class imbalance problem.

Investigation of Clinical Target Volume Segmentation for Whole Breast Irradiation Using 3D Convolutional Neural Network and the Shape Regularization Model Without the Prior Information of the Target-Side Breast

M Oya^{1*}, S Sugimoto², (1) Juntendo University Graduate School of Medicine, Tokyo, JP, (2) Juntendo University, Tokyo, JP

Purpose: This study aims to implement three-dimensional convolutional neural networks (3D-CNN) for clinical target volume (CTV) segmentation for whole breast irradiation and investigate the performance with and without shape regularization model (SRM). **Methods:** The 3D-UNet CNN was adopted to conduct automatic segmentation of the CTV for breast cancer. The 3D-UNet was trained using the 192 patients' dataset which contains both left- and right-sided breast cancer patients.

SRM was introduced to the 3D-UNet model to improve the segmentation performance by modifying the segmentation shape. SRM was trained in advance using the dataset of the incomplete CTV shapes and the ground truth CTVs. In the 3D-UNet+SRM model, the customized loss function was employed. The segmentation accuracy was evaluated using the Dice similarity coefficient (DSC) and Hausdorff distance (HD). To compare the performance of the 3D-UNet alone and 3D-UNet+SRM, the Wilcoxon signed-rank test was applied to the DSC and HD scores of the test dataset. **Results:** For the 3D-UNet alone, the DSC and the HD for the test dataset were 0.852 and 57.80, respectively. The DSC and the HD for the 3D-UNet+SRM were 0.854 and 52.67. The Wilcoxon signed-rank test demonstrated that both DSC and HD of the 3D-UNet+SRM performed better than 3D-UNet alone. The incomplete structures like small holes, jagged edges, and imperfect shapes were eliminated or compensated with SRM. SRM also worked to modify the images which had islands predicted as part of the CTV on the opposite side of the breast. However, if the 3D-UNet predicted the opposite side of the breast as the target breast, the small island on the correct side was eliminated. **Conclusion:** SRM modified the incomplete CTV shapes during the training process of 3D-UNet segmentation. If we make the SRM more sophisticated with a larger dataset, 3D-UNet+SRM could be improved more.

Attention Guided Network for Vestibular Schwannoma Growth Prediction

K Wang*, L Chen, N George-Jones, J Hunter, J Wang, UT Southwestern Medical Center, Dallas, TX

Purpose: Knowledge of tumor growth behavior is key to clinical decision-making in the management of vestibular schwannoma (VS) patients. In clinical practice, a series of images acquired at a fixed interval are used to determine VS tumor growth, which may lead to delayed treatment for fast-growing tumors or over-imaging for slow-growing tumors. In this work, we aim to build an attention guided convolutional neural network to predict VS tumor growth with the initial diagnosis imaging to aid in personalized management of VS. **Methods:** Contrast-enhanced T1-weighted MR images of 103 VS patients were used in this study. Each patient has two MRI scans with median interval of 7.2 months. VS on these images were segmented by a neurologist. Sixty-two out of 103 patients experienced VS growth based on the volumetric measurements on two consecutive scans. Our attention guided model used an UNet segmentation module and an AlexNet-style classification module to exploit the tumor growth related structures for VS growth prediction. The segmentation module is used to identify tumor and its surrounding area relevant to tumor growth prediction and generate attention maps from different layers, while the classification module takes the MR image and attention maps as input and predicts tumor growth. These two modules are trained simultaneously through optimizing the combination of dice coefficient loss from the segmentation part and binary cross-entropy loss from the prediction part. **Results:** Eighty patients' data were used for model training, 10 for validation, and 13 for testing. The growth prediction accuracy and AUC of the proposed model on testing data are 0.85 and 0.82, which are higher than those from a separate classification network without the attention mechanism. **Conclusion:** We developed an attention guided network for VS tumor growth prediction using the initial diagnosis MR image. Comparison with separate modules demonstrated its efficiency and effectiveness.

TH-lePD-TRACK 3-04

Segmentation by Individualized Registration (SIR) for CBCT-Based Adaptive Radiation Therapy

X Liang^{1*}, J Chun², H Morgan¹, T Bai¹, D Nguyen¹, J Park¹, S Jiang¹, (1) Medical Artificial Intelligence and Automation (MAIA) Laboratory, Department of Radiation Oncology, University of Texas Southwestern Medical Center, Dallas, TX, (2) Department of Radiation Oncology, Yonsei University, Seoul, KR

Purpose: The purpose of this study is to develop a method that can automatically generate segmentations on cone-beam CTs (CBCT) for head and neck adaptive radiation therapy (ART). Due to the prevalence of artifacts and truncations on CBCTs, directly contouring on CBCTs is very challenging. Thus, we propose to utilize a learning based deformable image registration method and contour propagation to get updated contours on CBCTs, where expert-drawn contours on the planning CT (pCT) can serve as prior knowledge. **Methods:** Different from other deep learning based image registration methods which are generally trained on a large datasets and tested on separate data, our proposed method uses deep learning architectures as a function f taking only a pair of moving and fixed images (pCT and CBCT in our case) as input and yielding warped moving images as outputs. The function f is composed of two parts: deformation vector field (DVF) generation and spatial transformer. DVF generation can predict a DVF from a pair of pCT and CBCT, then spatial transformer can warp pCT to deformed pCT (dpCT) based on predicted DVF. The function f can be learned by minimizing the cost function of image similarity between fixed and warped images plus regularization terms. **Results:** When compared with manual segmentations by a radiation therapy expert, the average dice coefficients of organ-at-risks and target by Elastix, 3DSlicer B-spline deformable registration, 3DSlicer demon deformable registration, FAIM, Voxelmorph, 5-cascaded Voxelmorph, VTN, and 10-cascaded VTN are 0.84, 0.83, 0.80, 0.83, 0.80, 0.84, 0.81, and 0.84 respectively. However, the average dice coefficients of Voxelmorph, 5-cascaded Voxelmorph, VTN, and 10-cascaded VTN using our proposed training strategy can reach up to 0.83, 0.85, 0.85, and 0.86. **Conclusion:** Our proposed method outperforms both the state-of-the-art learning based and traditional based image registration methods.

This study is funded by Varian Medical Systems Inc.

Intentional Deep Overfit Learning (IDOL): An Application to CT Segmentation-Based Daily Adaptive Radiotherapy

Byongsu Choi^{1,4}, Inkyung Park^{1,5}, Jaehyeon Chun^{1,4}, Sven Olberg^{1,2,3}, Jinsung Kim⁴, Yang Kyun Park¹, Mu-han Lin¹, Bin Cai¹, Steve Jiang¹, Justin C. Park¹, (1) Department of Radiation Oncology, The University of Texas Southwestern Medical Center (2) Department of Radiation Oncology, Washington University in St. Louis, St Louis, MO (3) Department of Biomedical Engineering, Washington University in St. Louis, St Louis, MO (4) Department of Radiation Oncology, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea (5) Department of Integrative Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea

Purpose: Adaptive radiotherapy (ART) workflows have been increasingly adopted to achieve dose escalation and tissue sparing under shifting anatomic conditions, but the necessity of recontouring and the associated time burden hinders a real-time, online ART workflow. In response to this challenge, approaches to auto-segmentation involving deformable image registration, atlas-based segmentation, and deep learning-based segmentation (DLS) have been developed. Despite the particular promise shown by DLS methods, implementing these approaches in a clinical setting remains a challenge, namely due to the difficulty of curating a data set of sufficient size and quality so as to achieve generalizability in a trained model. In this study, we utilize a patient's prior information to leverage the behavior of an intentionally overfit model with the application of the Intentional Deep Overfit Learning (IDOL) framework to the auto-segmentation task. **Methods:** The intentionally overfit model is trained in two stages. In the first, a conventional, general model is trained with a diverse set of patient data ($n = 80$ patients) consisting of CT images and clinical contours. Following this, the same model is tuned with a data set consisting solely of deformations derived from data from the single patient of interest. The conventional model and proposed overfit models were evaluated using the Dice similarity coefficient computed for 2 structures in 20 test patients. **Results:** Adopting the IDOL framework improved segmentation performance for each patient. Dice scores improved from 0.85 with the conventional model to 0.92 with the patient-specific overfit model on average and by up to 14% in the best case. **Conclusion:** The IDOL framework applied to the auto-segmentation task achieves improved performance compared to the conventional DLS approach, demonstrating the promise of leveraging patient-specific prior information in a task central to online ART workflows.

Deep Learning Neural Network for Automatic Delineation of Para-Aortic Clinical Target Volume

W Lu*, P D Cunha, W Chi, M Chen, L Ma, M Kazemimoghdam, Z Yang, X Gu, K Albuquerque, University of Texas Southwestern Medical Center, Dallas, TX

Purpose: To develop and evaluate an artificial-intelligence-based approach that automatically delineates clinical target volume (CTV) of para-aortic lymph nodes (PAN) for locally advanced cervical cancer (LACC) treatment. **Methods:** We retrospectively collected 47 planning CTs of LACC patients. For each CT, the Aorta, Inferior Vena Cava (IVC) and PAN-CTV were manually delineated for the elective para-aortic region from the left renal vein to the aortic bifurcation. The PAN-CTV was prophylactically contoured (ignoring gross para-aortic nodes) according to the recent Small et al. (2020) consensus guidelines. For each CT set, the spine structures were automatically delineated using threshold- and morphology-based segmentation. Then, all CTs were registered to a common reference frame based on the delineated spine structures and cropped to dimensions of 15x15x20 cm³ centered along the spine. A U-Net-based segmentation network was developed and trained to automatically segment Spine, Aorta, IVC, and PAN-CTV in the registered and cropped region. The segmented structures were converted into DICOM RTStruct with the original CT association. **Results:** We used 32 CTs for training, 8 for validation, and 7 for testing. The Dice-coefficient (DSC), Hausdorff-distance (HD95), and average symmetric-surface-distance (ASD) were used as the evaluation metrics. For PAN-CTV segmentations, our model achieved mean (SD) values of 75.5 (7.3)%, 8.42 (4.52) mm, and 1.55 (0.61) mm for DSC, HD95, and ASD, respectively. All PAN-CTV segmentations were visually checked by an attending radiation oncologist specializing in gynecologic malignancies and deemed clinically acceptable. **Conclusion:** An Artificial Intelligence approach comprised of registration and DL network was developed and validated for automatic segmentation of Spine, Aorta, IVC, and PAN-CTV in LACC. Registration was used to improve the boundary definition of the virtual structure, PAN-CTV, for DL segmentation without human intervention. This approach could facilitate efficient workflow and allow for optimal dose delivery to the involved nodal basins in LACC.

Auto-Segmentation of Important Centers of Growth in the Pediatric Skeleton to Consider During Radiation Therapy Based on Deep Learning

W Qiu^{1*}, W Zhang², X Ma¹, Q Zhou², J Zhu¹, (1) Department of Radiation Oncology Physics and Technology, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Ji'nan, P.R. China, Jinan, Shandong province, CN, (2) Manteia Medical Technologies, Milwaukee.

Purpose: Routinely delineating important skeleton growth centers is imperative to track and reduce exposure dose for pediatric neoplasms population with radiotherapy. The goal of this study is to explore network structure dimension effect on the efficiency and accuracy of deep learning segmentation models for skeleton growth plates. We devised a novel deep learning network called 2.5D UNet, that extends the semantics of adjacent slices to automatically segment the important centers of growing skeleton. **Methods:** The craniofacial, shoulder and pelvis growth plates, with a total of 19 structures, were manually delineated by a radiation oncologist on axial, coronal, sagittal CT images from 75 child cancer patients. Based on the UNet network structure, three models of segmentation networks including 2D, 3D and proposed 2.5D are compared. 2.5D refers to the use of three consecutive image slices to predict the segmentation of the middle slice, which can increase the associated semantic information. Dice Similarity Coefficient (DSC) and Hausdorff Distance 95% (HD95) were used to evaluate the segmentation accuracy of each model, and time consumption was recorded respectively. **Results:** Comprehensive evaluation of the 19 ROIs output by the three models of 2D, 3D and proposed 2.5D, the average DSC is 0.7972, 0.7975, 0.7987, and the average HD95 is 4.25, 1.88, 1.90, respectively. The HD95 performance of the latter two is clearly better than the former, while the DSC performance is not significantly different. The efficiency of the 3D model (23.5 hours of training time, 180 seconds of average inference time per patient) is significantly lower than 2D (3.1 hours, 45 seconds) and 2.5D (3.3 hours, 48 seconds). **Conclusion:** The deep learning-based models to automatically delineate pediatric growth plates have a satisfactory segmentation performance. Considering segmentation accuracy and time efficiency, 2.5D is more appropriate for clinical application than 2D and 3D models.

Development and Deployment of a Real-Time Transit EPID Dose Verification System

JA Baeza^{1*}, C Cassell¹, D Lee¹, N Kong², P Greer^{1,2}, (1) School of Mathematical and Physical Science, The University of Newcastle, NSW, Australia, (2) Department of Radiation Oncology, Calvary Mater Hospital Newcastle, NSW, Australia

Purpose: We have previously demonstrated feasibility of real-time transit dosimetry using EPID image prediction. This work aims to develop and deploy a clinically-ready real-time transit EPID dose verification system for modern treatment platforms that enables verification per control point of the delivery. **Methods:** A real-time transit dose verification system based on EPID image frames was developed and deployed for TrueBeam Linear Accelerators and aS1200 detectors (Varian Medical Systems, USA). Predicted images are generated for every CP using the DICOM treatment plan file and CT dataset and a previously published dual-source fluence model. Measured EPID images are acquired and evaluated in real-time using C# and Matrox Imaging Library (MIL) X (Matrox, Canada). Online real-time processing incorporates: 1) integration of measured frames for the selected arc-segment and synchronization to predicted images; 2) gamma and signal evaluations between measured and predicted images, and 3) evaluation of machine treatment parameters including delivered monitor units, multileaf collimator positions, and gantry and collimator angles. Six VMAT and four SBRT treatment plans from several treatment sites were irradiated in air and on an anthropomorphic phantom (CIRS, USA) for model testing purposes. Arc-segment resolution was set to 3 CPs per evaluation. **Results:** Gamma evaluation (5%, 2mm) passing rates for test cases were 98.8% (6X) and 98.0% (6XFFF) for in-air measurements, and 99.0% (6X) and 99.1% (6XFFF) for transit measurements. Differences in dose delivered per arc-segment were comparable for all test cases and averaged less than 1%, with a few isolated instances with differences of up to 2.5%. CP processing times including gamma evaluation and properties comparison are below 100ms. Preliminary results of the ongoing patient study suggest strong inter-fraction consistency in signal per patient. **Conclusion:** A real-time transit dose verification system has proven to be sufficiently stable, efficient, and automated to be integrated in the clinical practice.

Evidence-Based Evaluation of Skin Flash for Prone Breast Treatments by Using Edge Detection on Daily Exit Dosimetry Images

W Gu*, S Yoon, E Hubley, A Haertter, G Freedman, N Taunk, J Zou, B Teo, C Kennedy, L Dong, T Li, University of Pennsylvania, Philadelphia, PA

Purpose: In breast radiotherapy, skin flash is important to account for setup uncertainties and intrafraction motion. On Halcyon linear accelerator, exit dosimetry images are automatically acquired at each fraction, providing a method to assess the breast position with respect to the radiation field borders. We developed a tool to analyze the interfractional skin flash and breast anatomy variation using breast edge detection technique based on the exit dosimetry images. **Methods:** 288 daily exit dosimetry images were acquired for 9 patients undergoing 16-fraction prone breast treatments, with two opposed fields. The field border and breast contour map were acquired for every portal image using Canny algorithm. Algorithm parameters were derived automatically from a gradient-based initial estimate, to eliminate manual tuning. Noise and couch edges were removed combining local information and pixel connectivity. The distance between field border and apex of breast edge was calculated as the flash amount per fraction, and compared with the value from plans. The breast shape and position variation were evaluated by the range of breast contour change in beam's-eye-view (BEV) at three positions, upper, middle and lower part of the breast. **Results:** The mean and standard deviation of difference between fractional flash and planned flash is -1.8 ± 3.8 mm (negative sign represents actual breast closer to field border than planned). The variation of breast contour during treatment course has a mean and std of 9.5 ± 2.8 mm. **Conclusion:** An edge detection tool was developed for breast radiotherapy based on Halcyon exit dosimetry images, which is used to investigate skin flash and breast position change with treatment progression. Breast contour in BEV for this patient cohort varies up to 17 mm through the treatment course. This tool could be useful to automate daily breast contour detection, and to facilitate ongoing physics chart check by alerting user in case of insufficient skin flash

A Cross Institution Study of Anatomy Changes in Head-And-Neck Cancer Patients Using In-Vivo Electronic Portal Imaging Device (EPID) Transit Images

C Trauernicht¹, J Steers², C Bojchko^{3*}, (1) Stellenbosch University, Cape Town, South Africa, (2) Cedars Sinai Medical Center, Los Angeles, CA, (3) University of California San Diego, La Jolla, CA

Purpose: To develop automated tools and perform a cross-institutional study to evaluate patient anatomy trends using in vivo EPID transit images collected after every fraction of treatment. The tools were designed to forego a complex commissioning process and were deployed at two cancer centers, that have disparities in access to cancer care, to analyze head-and-neck cancer patients. **Methods:** For 252 patients treated at academic institutions in South Africa (40 patients) and United States (212 patients), analysis of in vivo EPID images for head-and-neck patients was performed. Both centers treated patients on the Varian Halcyon which collects EPID images for every fraction of treatment. Deviations relative to the first fraction of treatment were assessed, for 5630 fractions, with a novel technique, Gradient-Dose Segmented Analysis (GDSA) which correlates with changes in the PTV mean dose. The change in PTV mean dose over a treatment course was compared between centers and individual patient trends were investigated. **Results:** The mean and variance of the change in PTV mean dose were statistically equivalent for the two centers, demonstrating comparable magnitude and frequency of anatomical changes. Both centers observed patient weight loss/tumor shrinkage in the later fractions of treatment. One center observed cyclic patterns in the patient's external body contour, for half of the patients analyzed. These trends were not observed at the other institution and may be driven by differences in the access to cancer care for the two centers. **Conclusion:** We have developed an automated framework that can measure in vivo patient anatomy trends and how they compare between different clinics. In aggregate, anatomy deviations of head-and-neck patients at two different centers analyzed were equivalent. Further study is required to understand the source of different anatomy change trends observed. This framework is portable and can be deployed to other centers to perform similar analyses.

Impact of Delivery and Measurement Uncertainties On the Calculation of Pixel Sensitivity Maps for MV Portal Imagers

M Ahmed^{1*}, H Nourzadeh², J Siebers³, (1) Vanderbilt University Medical Center, Nashville, TN, (2) Thomas Jefferson University, Philadelphia, PA, (3) University of Virginia Health System, Charlottesville, VA

Purpose: To describe possible error pathways during calculation of the Pixel Sensitivity Maps (PSMs) and to study the impact on the calculated PSMs with different approaches. **Methods:** PSMs are used to normalize EPID's diode-pixels response to the incident radiation. Multiple approaches were developed to calculate EPID-specific PSMs. A shifting-based method uses multiple laterally shifted measurements of same flood field signals to find pixel-gain through utilizing the relative gains of pixels irradiated identically. A shiftless-based method, uses regression surface models to capture low-frequency features of the incident fluence and ascertain the device PSM by removal of these features from signals superimposing high-frequency PSM features with low-frequency fluence features. Here, we use Monte-Carlo calculated EPID signals with introduced errors to study the impact on the reconstructed PSMs. Errors introduced include misalignment of signals used during the PSM calculation, change of output between irradiations and inconsistent background removal from signals used in PSM generation algorithms. **Results:** In an ideal setup the shifting-based and the shiftless methods reconstructed the original PSM with 99% and 95% accuracies, respectively. For the shifting method; a one pixel misalignment during the PSM calculation resulted in 90% and 100% of the pixels retained 99% and 90% of the original gain values, respectively. A 0.1% and 0.5% change in linac output between images resulted in 27% and 11% of the gains have 99% of the original values. A 0.1% and 0.5% pixel-to-pixel variance in the individual pixel response resulted in 1.7% and 32% of the pixel gains have 99% and 90% of the original values, respectively. Introduction of the aforementioned errors in the shiftless method worsen the agreement results by a max of ~4%. **Conclusion:** The simulation conducted here shows that both methods are accurate in impeccable clinical setups. The shiftless PSM method performs better in sub-standard calibration scenarios.

Evaluation of Dynamic Tumour Tracking (DTT) uncertainty for a Fiducial-Based Stereotactic Ablative Radiotherapy (SABR) Treatment of the Liver Using EPID Images

M Rostamzadeh*, A Bergman, K Luchka, BC Cancer, Vancouver, BC, CA

Purpose: To assess dynamic tumour tracking (DTT) uncertainty for fiducial-based stereotactic ablative radiotherapy (SABR) treatments of the liver using electronic portal imaging device (EPID) images. **Methods:** EPID images were acquired during 3D conformal radiotherapy (3DCRT) DTT using a Vero4DRT linac (Brainlab-Mitsubishi), equipped with an amorphous-silicon (aSi) EPID (maximum frame-rate: 2Hz). Images acquired in phantom and patients were pre-processed using a Laplacian-of-Gaussian (LoG) function. Three gold fiducials were inserted into an acrylic phantom. The phantom was placed on a 1D, moving Brainlab platform with sine-wave motion synchronized to a respiratory platform. EPID images were acquired for 3DCRT noncoplanar DTT beams. The EPID images of nine liver SABR patients treated with 3DCRT noncoplanar beams were also analyzed. All patients had 3-4 implanted fiducials. A chain-code algorithm was applied to the EPID images to detect field-edges of the MLC-defined apertures. Fiducials were detected using a connected-neighbor algorithm. For each beam, the centre-of-mass (COM) of the fiducials relative to the field-edge was reported (at isocentre plane). **Results:** Of the 123 EPID phantom images, 100% of the fiducials were located. The Standard-Deviation (SD) of the relative position between the fiducial COM and field-edge in the X(h) and Y(v) direction, for all fields, was 0.2 and 0.3 mm,

respectively. Of the 1418 EPID patient images acquired, 81% had detectable fiducials. Fiducials may not be detected if the images were noisy, or the location was occluded by the MLC. The SD of the relative position between the fiducial COM and field-edge in X and Y direction was between 0.27-0.82 mm and 0.53-1.61mm, respectively. Sources of uncertainty in the relative positions include field-edge localization, fiducial-localization, and physical tracking uncertainty during treatment. **Conclusion:** DTT uncertainty can be evaluated on a field-by-field basis using EPID images. The DTT uncertainty was <0.82 and 1.61mm in X and Y direction, respectively.

Theoretical Derivation and Experimental Verification of Beam and Tissue Factors Affecting the Reemitted Cherenkov Signal During External Beam Irradiation

S Decker^{1*}, D Alexander¹, R Hachadorian¹, R Zhang^{1,3,4}, D Gladstone^{1,3,4}, P Bruza^{1,2}, B Pogue^{1,2,4}, (1) Thayer School of Engineering, Dartmouth College, Hanover, NH, (2) DoseOptics LLC, Lebanon, NH, (3) Department of Medicine, Geisel School of Medicine, Dartmouth College, Hanover, NH, (4) Norris Cotton Cancer Center, Dartmouth-Hitchcock Medical Center, Lebanon, NH

Purpose: To explain why the Cherenkov intensity emitted from MV x-ray delivery in tissue does not appear to change with beam energy in radiotherapy. The study developed a quantitative theoretical understanding of the effects of beam and tissue properties on the reemitted light. **Methods:** The reemitted Cherenkov signal was theoretically derived with a diffusion theory solution and experimentally measured as a function of the dose build-up slope and tissue optical properties over a range of clinical x-ray energies. Diffuse liquid tissue phantoms of various scattering and absorption properties were irradiated with 6, 10, and 18 MV x-rays. Each phantom was imaged with an intensified camera, and irradiated top-down for entrance surface imaging, as well as from underneath for exit surface imaging. Phantoms were built with the thickness of the depth of d(max) per energy. The reemitted Cherenkov intensity was calculated as the mean pixel intensity of a ROI at each phantom's surface. **Results:** At low energy, a higher surface dose and steeper build-up slope result in a greater reemitted Cherenkov signal per unit dose, a ~46% increase at 6 versus 18 MV. However, at high energy, more Cherenkov photons are generated per unit dose, resulting in a ~44% increase in the reemitted signal at 18 versus 6 MV. These competing effects yield an approximately constant reemitted Cherenkov signal from the surface of the phantoms at different energies. With increasing scattering and absorption properties of the phantoms, the reemitted Cherenkov signal increased ~10% and decreased ~20%, respectively. **Conclusion:** The results of this study explain why the reemitted Cherenkov signal during radiotherapy is not strongly dependent on beam energy, despite greater Cherenkov photon generation at higher energies. Quantifying the effects of beam and tissue properties is a progressive step towards verifying surface dose delivery with Cherenkov imaging during radiotherapy treatments in real-time.

In Situ Radiochromic Film Dosimetry Using Portable Spectrophotometer

S Jung*, J Cho, J Han, J Kim, J Park, C Choi, J Son, J Kim

Purpose: This study aims to report the performance of using a portable spectrophotometer as a reader for radiochromic film dosimetry. The study compares net optical density (net OD) of the EBT3 film between a typical flatbed scanner and a portable spectrophotometer. **Methods:** The EBT3 films were irradiated by using 6 MV photon beam with 0 to 3 Gy. The films were read by the flatbed scanner (EPSON 10000XL) and the portable spectrophotometer (YS-3020, 3nh, China) at 10 min, 1 hour, 3 hours, 6 hours, and 24 hours after the irradiation. The net OD in red channel was acquired for each scanner. EBT3 films with 0.7 Gy and 1.8 Gy irradiation were read by the scanners and the measured doses were compared with the delivered doses. **Results:** During 10 min to 6 hours, the curves from the portable spectrophotometer showed larger fluctuations in net OD than those from the flatbed scanner. Calibration curves at 6 hours and 24 hours after the irradiation were acquired. Dose responses of the portable spectrophotometer were 28.2% to 51.7% higher than those of the flatbed scanner. The EBT3 film with 0.7 Gy irradiation read by the portable scanner at 6 hours after the irradiation showed large discrepancy (17.7%) comparing with the actual delivered dose. The discrepancies were reduced to 6.6% at 24 hours after the irradiation. For the same delivered dose read by flatbed scanner, the difference between the actual and estimated were 5.8% and 4.5% for 6 hours and 24 hours, respectively. **Conclusion:** The portable spectrophotometer has advantages over the flatbed scanner that it is much lighter, easier to use than the flatbed scanner. However, the portable spectrophotometer limits the film dosimetry to the point measurement and the impact of post-irradiation was more significant in the portable spectrophotometer.

Audience Q&A

There have been many professional sessions at previous Annual and Spring Clinical meetings related to finding a job. One topic that has not been previously covered in depth is the important job-related topic of professional letters of reference. The PROFS Committee aims to host a session covering a broad range of topics relating to letters of reference. This will be coupled with an AAPM Newsletter Series of articles.

A letter of reference or recommendation letter is used to provide information about the candidate from an outside source, providing details about skills and

qualifications, sometimes giving a personal perspective of the candidate, and listing achievements. As Medical Physicists, we find ourselves needing letters of reference for new jobs, promotions, and awards but also needing to write them for colleagues, students, and residents. The goal of this session is to detail the differences and similarities in types of professional letters, because whether you are asking someone to write a letter of reference for you or writing a letter for someone else, it can be helpful to understand the difference types and perspectives of professional reference letters.

Learning Objectives:

1. Define and describe the different types of reference letters
2. Understand how to develop professional references and ask for letters of reference
3. Understand how to write different letters of reference

Panel Discussion

In this invited scientific session, current extramurally funded Principal Investigators (PIs) from different areas of Medical Physics will shed light on the high impact scientific research being conducted by AAPM members. During each session, PIs will briefly describe their unique funding mechanisms and pathway to funding to highlight the depth and breadth of funding opportunities available to Medical Physics researchers. AAPM members who are single PIs and those participating as the primary PI in a multiple PI grant will be highlighted. For each grant, the PI will describe the clinical motivation and scientific underpinnings of the work. Specific aims and key initial scientific results will be highlighted along with a look toward future research directions. Finally, each PI will conclude with brief parting comments regarding grant funding to share their perspective and words of wisdom with the AAPM audience.

Learning Objectives:

1. To understand the different grant mechanisms currently funding AAPM members.
2. To learn about the scientific initiatives that have extramural funding.
3. To learn about the grant development process including developing preliminary data and specific aims.

Dual Energy and Spectral CT and CBCT

TH-E-TRACK 3-01

Characterization and Optimization of Quantitative Greyscale Images from Photon Counting CT

D Byrd¹*, M Wu², P Edic², P Kinahan¹, (1) University of Washington, Seattle, WA, (2) GE Research, Niskayuna NY

Purpose: Radiologists don't like to review extra images. Leveraging the abilities of photon-counting CT (PCCT) by using energy weighting to form a single set of quantitative greyscale images leverages the unique advantages of PCCT while still providing familiar content and workflow for radiologists, i.e. not requiring them to read additional spectral or material-basis images. We evaluated methods to generate such quantitative greyscale CT images. **Methods:** We used CatSim-based simulations of a 120 kVp polychromatic x-ray tube with varying dose coupled with a model of an 8 energy bin PCCT detector within a standard CT gantry. An elliptical water phantom contained inserts (5 cm in diameter) of liver, intestine, and adipose tissue, along with a blood/iodine mixture. The long axis of the phantom was varied from 30 to 50 cm in 2 mm steps. CT acquisitions of the 100 phantoms with independent noise realizations were simulated, and images reconstructed with FBP after applying energy-bin-specific beam-hardening corrections. The 8 energy-bin images were combined using several approaches: uniform, spectral, inverse-spectral, and RMS-optimized weightings. For each case, bias, noise, and RMS error (RMSE) were measured and compared to equivalent results for a standard energy-integrating CT (EICT). **Results:** For the EICT images the Hounsfield Unit (HU) values for the 4 inserts varied as phantom size increased – liver: 52 to 38 HU, intestine: 22 to 12 HU, adipose: -244 to -240 HU, and blood/iodine: 260 to 200 HU. However, for the PCCT greyscale images, HU values for all inserts were essentially constant as a function of phantom size for all energy-weighting schemes. PCCT images had generally higher noise but lower RMSE compared to EICT. **Conclusion:** PCCT can be used to form quantitative greyscale CT images that are invariant to object size and with lower RMSE relative to EICT.

TH-E-TRACK 3-02

Development of a Prototype C-Arm Photon Counting Detector CT System for Interventional Imaging: First in Vivo Animal Results

X Ji, S Periyasamy, M Feng, G Chen, P Laeseke, K Li*, University of Wisconsin, Madison, WI

Purpose: This work aimed at bringing the energy-discriminating solid-state photon counting detector (PCD) technology to C-arm interventional systems to enable intraoperative PCD-CT imaging with superior low-contrast detectability and material differentiation capability. This abstract reports the hardware development of a rotating-gantry C-arm PCD-CT system and results from preliminary in-vivo porcine studies. **Methods:** The prototype system was constructed with minimal modification to an existing interventional system using a custom-made mounting device. A CdTe-based PCD strip (51cm×0.6cm; 100μm pixels) equipped with 2 energy thresholds and state-of-the-art anti-charge sharing technology was installed and can be translated in/out of the beam for switching between flat panel detector (FPD)-based imaging mode and PCD-CT mode. Artifacts due to gantry wobbling was corrected using an in-house geometric calibration phantom; the inter-CdTe panel response nonuniformity was corrected by imaging materials of known radiological pathlengths. Low-contrast detectability, image uniformity, and artifact level were characterized using physical phantoms. To explore the potential benefits of C-arm PCD-CT, four swine were imaged by both PCD-CT and FPD-based CBCT at clinical dose (35 mGy) and reduced-dose (7.1 mGy) levels with 7s gantry rotation time. **Results:** Phantom studies demonstrated, at matched collimation (2.5 cm), spatial resolution (8 lp/mm), slice thickness (4.2 mm), and dose level, PCD-CT resolved the 0.3% (3HU) 3mm inserts in Catphan and demonstrated excellent uniformity without any perceivable geometric distortion or ring artifacts. For the in vivo studies, interventional radiologists indicated that porcine abdominal PCD-CT showed a much better delineation of visceral detail and improved soft tissue contrast compared with FPD-CBCT acquired at matched dose levels; the reduced-dose PCD-CT porcine chest images closely matched the quality of the full-dose CBCT images. **Conclusion:** A prototype PCD-CT system was developed to generate high-quality and artifact-free images. In-vivo porcine studies demonstrated potential benefits in soft tissue imaging and radiation dose efficiency when compared to FPD-CBCT.

TH-E-TRACK 3-03

Dual Energy CT Using Flying Focal Spot and An Anti-Scatter Grid as a Filter

S Hsieh¹*, N Bennett², A Wang², (1) Mayo Clinic, Rochester, MN, (2) Stanford University, Stanford, CA

Purpose: Spectral CT is not available on all diagnostic systems because of its hardware requirements. A recent proposal is to achieve spectral CT by combining flying focal spot (FFS) with a fixed grating acting as a filter. We demonstrate that standard anti-scatter grid fabrication technologies can be used for this task, and we estimate the spectral separation that could be achieved. **Methods:** We envision an anti-scatter grid placed 100 mm from the source and focused at a first FFS focal spot. With a 10:1 grid ratio, the second FFS focal spot should be displaced 10 mm from the first spot to maximize spectral separation. We estimated spectral separation assuming 20 cm of water object filtration, 1.5 mm grid thickness, 0.036 mm lamellae at 60 lp/cm, 120 kVp, and several candidate materials. We provide an experimental tabletop system demonstration. A short focal distance grid was not easily available, so the concept was emulated by placing the grid at focus 105 cm from the source and acquiring two sequential scans with a 9.2 cm shift in source position. **Results:** Our experimental demonstration showed separation of multiple materials in a dual energy phantom, including adipose tissue and bone. We estimate 13 keV, 6 keV, and 2 keV spectral separation using a grid with tin, lead, or tungsten lamellae, respectively, with differences due to material K-edge. For comparison, a dual source CT system operating at 100 and 140 kVp provides a spectral separation of 12 keV. **Conclusion:** Anti-scatter grids could be combined with FFS for spectral imaging. The grid would need to be modified to have a short focal distance. A respectable spectral separation can be achieved using tin lamellae.

TH-E-TRACK 3-04

Quantitative Dual-Energy Imaging of Bone Composition on Multisource Cone-Beam CT with Model-Based Artifact Corrections

S Liu*, G Shi, G Osgood, J Siewerdsen, J Stayman, W Zbijewski, Johns Hopkins University, Baltimore, MD

Purpose: The recently introduced extremity Cone-Beam CT (CBCT) with a three-source x-ray unit enables single-rotation dual energy (DE) imaging by operating the x-ray tubes at different potential. We investigate the application of this novel DE acquisition mode for Bone Mineral Density (BMD) measurements in extremities with and without metal implants. **Methods:** The extremity CBCT implements three x-ray tubes arranged longitudinally (parallel to the long axis of the extremity). For DE imaging, the peripheral sources were operated at 70 kVp (low energy, LE) and the central source was operated at 100 kVp (high-energy, HE) in an alternating sequence. This yielded 105 views for each of the peripheral LE sources and 210 views for the central HE source; the total CTDI scan dose was ~10 mGy. Experimental studies involved a 16 cm water cylinder with BMD inserts (50 mg/mL, 100 mg/mL, 200 mg/mL) surrounding a Titanium tibial nail. Image domain DE decomposition was applied to estimate BMD (Calcium concentration). LE reconstruction for the decomposition was generated by weighted Filtered-Backprojection of the two peripheral source datasets. Scatter was estimated using accelerated Monte Carlo simulations (107 photons/view+denoising) from preliminary HE and LE reconstructions. To mitigate metal artifacts, constrained three-material decomposition (Ca, Ti and water) was first performed to obtain a model of the implant. The model was used to interpolate projection values behind the metal. Standard two-material DE decomposition was then applied to estimate BMD. **Results:** With the

proposed artifact correction framework, the BMD estimation errors were comparable for phantoms with and without metal: ~30% for the 50 mg/mL insert, ~16% for the 100 mg/mL insert, and ~12% for the 200 mg/mL insert. **Conclusion:** Single-scan DE imaging has been implemented on the multisource extremity CBCT. Model-based artifact corrections enabled accurate BMD estimation even in the presence of metal hardware.

Spectrum Optimization for Photon-Counting CT with a Silicon Detector

T Schmidt^{1*}, F Gronberg², J Fan², (1) Marquette University, Milwaukee, Wisconsin, (2) GE Healthcare, Waukesha, WI

Purpose: This study investigated improvement in material decomposition noise and iodine CNR by optimizing the tube voltage and filtration for photon-counting CT with a silicon detector. Silicon photon-counting detectors, which have demonstrated feasibility for human scanning, have unique spectral properties that may benefit from new tube potential and filtration approaches. **Methods:** A simulation study was performed across a range of conditions to identify promising filter and tube voltage combinations. The simulations modeled x-ray transmission through a 20, 30, or 40 cm water background and 1-cm iodine task with concentration varied from 1 to 20 mg/ml. Tube voltages of 80, 100, and 120 kV were modeled. Copper, tin, cerium, dysprosium, ytterbium, and tungsten filters of varying thicknesses were modeled in addition to inherent tube filtration. All spectra were modeled with skin exposure matched to the 120 kV beam without additional filtration. A silicon detector with eight energy bins was modeled assuming realistic detection efficiency and Compton scatter effects. The energy-bin thresholds were previously optimized for each tube voltage assuming no additional filtration. The Cramer-Rao-Lower-Bound material decomposition noise variance was calculated for each case and used to estimate the CNR of the resulting optimal virtual monoenergetic images. Promising filter and tube voltage combinations, considering realistic tube power constraints, were further investigated through photon-counting CT simulations. **Results:** Filters of 0.1-mm copper, 0.065-mm ytterbium, and 0.02-mm tungsten were identified as promising candidates. The study also demonstrated the improved noise and CNR when using 80 or 100 kV compared to 120 kV. For example, 100 kV spectra with 0.1-mm copper filtration demonstrated 12% CNR improvement and ~8% basis material noise reduction for the 20-cm phantom, and 22% CNR improvement for the 40-cm phantom. **Conclusion:** Photon-counting CT with silicon detectors may benefit from lower tube-voltage selection and additional filtration, for example 0.1-mm copper.

Characterization of a Bench-Top Photon-Counting CT System

D Richtsmeier^{1*}, J O'Connell¹, A Hart¹, P Rodesch¹, T Calheiros², A Frencken², K Iniewski³, M Bazalova-Carter¹, (1) Department of Physics and Astronomy, University of Victoria, Victoria, BC, CA, (2) Department of Chemistry, University of Victoria, Victoria, BC, CA, (3) Redlen Technologies, Saanichton, BC, CA

Purpose: To characterize a photon-counting CT (PCCT) bench-top system with a high-flux photon-counting cadmium zinc telluride (CZT) detector with 6 energy bins to determine the limiting spatial resolution and the smallest detectable concentration of multiple high-Z contrast agents imaged simultaneously. **Methods:** Spatial resolution in 2D-radiographic images was determined by imaging a QC3 phantom, a QCkV-1 phantom, a custom CT resolution phantom, and a 0.33 mm thick sheet of Cu to obtain a straight edge. For the phantom data, the modular transfer function (MTF) was determined using the Droege and Morin method (1982). For the Cu edge, an oversampled edge spread function was obtained and the MTF calculated. In CT images, limiting spatial resolution was determined using the custom resolution phantom to obtain an MTF. The smallest detectable concentrations of the contrast agents were imaged in 0.2 ml vials placed in a 10-cm cylindrical polyethylene phantom at 120 kVp and 2mA with 2 mm of Al filtration. K-edge images were obtained using K-edge subtraction to separate the contrast agents. The contrast-to-noise ratio was measured in CT images to determine the lowest discernible concentration, which was determined when the CNR fell below 4. **Results:** The limiting spatial frequency in radiographic images was 2.02 lp/mm, determined at 20% of the MTF of the Cu edge. The MTF data from the three phantoms supported this finding. The limiting spatial frequency was found to be 1.31 lp/mm in CT images. The two contrast agents were well separated using K-edge subtraction and the limiting concentrations discernible in CT images were 1.47 mg/ml for gold and 1.62 mg/ml for gadolinium. **Conclusion:** The presented bench-top PCCT system with a spatial resolution of 1.31 lp/mm and the capability to separate multiple contrast agents distinguishable at low concentrations in a single image is a promising tool for future clinical applications.

Iodine Quantification in a Full Field-Of-View Photon-Counting-Detector CT

K Rajendran^{1*}, J Marsh¹, J Thorne¹, E Shanblatt², J Fletcher¹, C McCollough¹, S Leng¹, (1) Mayo Clinic, Rochester, MN, (2) Siemens Medical Solutions USA, Inc, Malvern, PA

Purpose: To assess the multi-energy performance of a full field-of-view (FOV) photon-counting-detector (PCD) CT system in terms of iodine quantification accuracy. **Methods:** Five water phantoms of lateral size 25, 30, 35, 40 and 45 cm mimicking small to large adult body sizes were scanned on a full-FOV PCD-CT system (SOMATOM Count Plus, Siemens Healthcare GmbH) using a multi-energy abdomen protocol (144 x 0.4 mm collimation, 120kV, 0.6 pitch, 0.5s rotation and CAREdose4D with 150 quality reference mAs). The CTDIvol was matched to that of a routine abdomen protocol used in our clinical practice. Vials with iodine solutions at concentrations of 2, 5, 10, 15 and 20 mg/mL were placed inside the water phantoms and scanned. Threshold images at 20-120 keV and 65-120 keV were reconstructed using filtered back projection with a Qr40 kernel at 3 mm slice thickness and 250 mm FOV. Iodine contrast-to-noise ratio (CNR) was measured from the low threshold images for all concentrations and phantom sizes. Iodine and water maps were generated using a prior knowledge aware material decomposition technique. The quantitative accuracy of iodine maps was calculated using root-mean-squared-error (RMSE) for each phantom size. **Results:** Material decomposition enabled successful delineation of iodine inserts from the background (water) in the five phantom sizes. The 25 cm phantom exhibited the highest iodine CNR (average CNR = 33.4), and the CNR reduced by 2.6%, 21.5%, 38.1%, 48.9% for 30, 35, 40 and 45 cm, respectively. The iodine RMSE were 0.19, 0.25, 0.6, 1.12 and 0.99 mg/mL for 25, 30, 35, 40 and 45 cm phantoms, respectively. The average percent error for measured concentrations (against reference values) was 7.04% for all phantom sizes. **Conclusion:** We evaluated the iodine quantification accuracy in a full-FOV PCD-CT system. Accurate iodine quantification was achieved using a material decomposition technique with built-in noise reduction.

Few Shot Meta Learner for Post-Operative Prostate CTV Style Adaptation

A Balagopal*, D Nguyen, T Bai, H Morgan, M Dohopolski, N Desai, A Garant, R Hannan, S Jiang, University of Texas Southwestern Medical Center, Dallas, TX

Purpose: Clinical target volumes (CTV) are contoured for postoperative prostate radiotherapy to treat microscopic disease with the aid of consensus guidelines. Adjustments are made in accordance with a physician's preference/clinical judgement, resulting in large observer-variations (segmentation-styles) that are distinguishable. Although autosegmentation models can be adapted to specific physician styles, this would require sufficient data from each physician for their styles to be learnable. To address this limited sample size issue, we propose a deep learning (DL)-based few-shot meta-learning architecture for CTV style adaptation. **Methods:** We used existing prior information for a specific CTV contouring style in the form of previously segmented patients as support dataset. To train the meta-learning architecture, we simulated 6 different CTV styles (4-training, 2-testing) by varying the inclusion of bladder/rectum/seminal-vesicles. Initial CTV segmentations were performed via an in-house DL model. Then, our adaptive learning architecture was tasked to learn the changes required for new CTV styles. Three-hundred and seventy-three patients treated at a single institution were used. The network consisted of four parts: a shared encoder, style block, averaging layer, and decoder. The encoder extracted features from prior patients and the new patient, the style block evaluated the difference between the DL model CTV and the provided support style, and the average layer averaged features across all prior patients. These were concatenated with the new patient features and decoded to obtain the adapted CTV. **Results:** The performance of the in-house CTV segmentation model on the two unexposed styles for 50 independent test patients were 71.9% and 63.0% dice score coefficient (DSC). With just three prior patients as input to the few-shot network, the mean DSC across test patients' increased to 77.8% and 73.0% for each style, respectively. **Conclusion:** The trained few-shot meta-learner can effectively adapt to new CTV styles.

Multi-Year Clinical Experience with In-House Developed AI Auto-Segmentation for Radiotherapy Planning

S Elguindi^{1*}, J Jiang¹, A Apte¹, A Iyer¹, E LoCastro¹, Y Hu¹, E Cha², E Gillespie², I Onochie², D Gorovets², M Zelefsky², S Berry¹, M Thor¹, J Deasy¹, L Cervino¹, H Veeraraghavan¹, (1) Department of Medical Physics, Memorial Sloan Kettering Cancer Center, New York, NY, (2) Department of Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: To report on the clinical utility of in-house developed deep learning auto-segmentation (DLA) in radiotherapy at our institution. **Methods:** Two DLAs were developed to segment OAR and target volumes in routine prostate and head and neck (HN) radiation therapy. Output contours included bladder, rectum, prostate and seminal vesicles, penile bulb, left/right parotid (LP, RP), left/right submandibular glands (LS, RS), brainstem, and mandible. Both use different network architectures, a DeepLabV3+ pre-trained on ImageNet for prostate, and a Nested-Block Self-Attention method for HN. Training data consisted of 50 and 48 internally curated datasets for prostate and HN respectively. Each DLA is auto-triggered through our software pipeline, Ensemble of Voxel-wise Attributers (EVA), which manages DICOM transfers to our clinically approved high-performance computing cluster, input pre-processing, and RTSTRUCT generation. Clinical utility was gauged retrospectively through periodic random audits of comparison between the DLA output and final contours using published metrics Added Path Length (APL) and Surface DSC (SDSC). **Results:** To date our DLA have segmented 1277 prostate patients (314/25% audited) since June 2019 and 337 HN patients (79/23% audited) since May 2020. Mean APL (cm) and SDSC for each structure were bladder [107.9cm, 0.96], rectum [51.2cm, 0.92], prostate and seminal vesicles [129.1cm, 0.82], penile bulb [7.1cm, 0.94], LP [39.4cm, 0.86], RP [42.9cm, 0.85], LS [22.1cm, 0.82], RS [20.2cm, 0.83], brainstem [28.1cm, 0.88], and mandible [25.1cm, 0.94]. Average total manual contouring for all structures was reduced from 2586 cm to 473 cm, representing an average reduction of 82% across both DLAs. **Conclusion:** We successfully integrated two unique DLAs into routine clinical practice. This resulted in >80% reduction in APL, which has been shown to correlate with time savings. High contour surface similarity (>0.80) was achieved in all structures. This supports potential for artificial intelligence to improve the clinical workflow for segmentation in radiotherapy.

Physician Evaluation of Deep Learning-Based Dose Predictions for Head and Neck Radiotherapy

M Gronberg^{1,2*}, S Gay², B Beadle³, A Olanrewaju², C Cardenas^{1,2}, R Howell^{1,2}, C Peterson^{1,2}, C Fuller^{1,2}, A Jhingran², T Netherton^{1,2}, D Rhee^{1,2}, L Court^{1,2}, (1) The University of Texas MD Anderson Cancer Center UTHealth Graduate School of Biomedical Sciences, Houston, TX, (2) The University of Texas MD Anderson Cancer Center, Houston, TX, (3) Stanford University, Stanford, CA

Purpose: To predict high-quality, realistic dose distributions for head and neck (HN) VMAT plans that can be used as comparative dose distributions for automated peer review of plan quality. **Methods:** We trained a 3D dilated dense-UNet to predict 3D dose distributions for HN patients. The architecture takes a 24-channel input including CT images, target prescriptions, and normal tissue and target contours. 118 VMAT HN plans with 2-3 dose levels were split into train, cross-validation, and test datasets (3:1:1 respectively). The model was trained on random patches using a custom weighted mean squared error loss function, which assigns a customized weight to each contour. The predicted dose distributions were assessed by a HN radiation oncologist using a 5-point scale (1:No edits needed, 2:Minor edits optional, 3:Minor edits needed, 4:Major edits needed, 5:Fails to meet clinical criteria). A score of 1-3 indicates clinical acceptability. **Results:** The model predicted dose distributions of comparable plan quality to the clinical plans. The mean dose difference between the predicted and clinical dose distributions of the testing dataset was -0.42 ± 0.28 Gy. On average, the predicted target DVH metrics of D1, D95, and D99 normalized to the prescription were within $-1.94 \pm 1.35\%$, $-0.12 \pm 3.55\%$, and $0.64 \pm 6.23\%$ of the clinical plans, respectively. The predicted organ at risk metrics of mean and max doses were within -0.35 ± 1.41 Gy and -0.83 ± 1.85 Gy of the clinical plans, respectively. The predicted dose distributions on the test set were scored as clinically acceptable for 18/21 patients (score 1:5 patients, score 2:9 patients, score 3:4 patients). The other 3 patients received a score of 4 for poor target coverage and target dose fall-off. **Conclusion:** The 3D dilated dense-UNet can predict high-quality, realistic dose distributions for HN VMAT plans. Physician assessment indicates that greater than 85% of predictions are clinically acceptable, supporting the use of dose prediction to QA plan quality.

Scale-Adaptive Convolutional Neural Network for Deformable Image Registration of Lung 4DCT

Y Sang*, D Ruan, Department of Radiation Oncology and Department of Bioengineering, University of California, Los Angeles, CA

Purpose: Deformable image registration between phases in lung 4DCT is essential for understanding respiratory motion pattern and facilitates temporally conformal radiotherapy delivery. Multi-resolution hierarchical strategy is typically used in conventional optimization-based registration to capture varying magnitudes of

motions while avoiding undesirable local minima. A rough concept of the scale is captured in deep networks by the reception field of kernels, and it has been realized to be both desirable and challenging to capture convolutions of different scales simultaneously in registration networks. In this study, we propose a registration network that is conscious of and self-adaptive to motions of various scales to improve registration performance. **Methods:** Dilated inception modules (DIMs) are proposed to incorporate receptive fields of different sizes in a computationally efficient way. Scale adaptive modules (SAMs) are proposed to guide and adjust shallow features using convolutional kernels with spatially adaptive dilation rate learned from deep features. DIMs and SAMs are integrated into a registration network which takes a U-net structure. The network was trained in an unsupervised setting with 15 4DCT scans and then tested using 10 scans in the DIR-Lab dataset, each with 300 annotated landmark pairs. **Results:** The method achieved a (2.52 ± 2.96) mm target registration error on the anatomical landmarks, better than a conventional B-spline method in SimpleElastix and networks without DIM or SAM, with statistical significance. The adaptive dilation rate in SAM corresponded well to the spatially and temporally varying motion scale. The average registration time was 0.42 s for images with size $256 \times 256 \times 96$. **Conclusion:** The introduction and integration of DIMs and SAMs address the spatio-temporal scale heterogeneity problem in an efficient and self-adaptive way and can be an efficacious alternative to the conventional multi-resolution strategy.

Small Convolutional Neural Networks for Efficient 3D Medical Image Segmentation

A Celaya¹, J Actor^{1,2}, R Muthusivarajan¹, E Gates^{1*}, C Chung¹, D Schellingerhout¹, B Riviere², D Fuentes¹, (1) University of Texas Md Anderson Cancer Center, Houston, TX, (2) Rice University, Houston, TX

Purpose: To substantially reduce the computational overhead of convolutional neural networks (CNNs) to allow broader applicability in resource-constrained environments while maintaining the performance of full-sized networks. **Methods:** We propose a novel architecture modification that keeps the number of feature maps constant at each level of a CNN. Usually, the number of feature maps doubles at each layer of downsampling. This network design strategy is motivated by the similarity between CNNs and multigrid methods for solving partial differential equations. We call a network that uses this proposed design strategy a “pocket network,” or PocketNet for short. We apply our PocketNet strategy to three popular segmentation architectures (U-Net, ResNet, and DenseNet) and compare each of the modified network's performance to its unmodified counterpart on the publicly available Neurofeedback Skull-stripped (NFBS) repository. The dataset consists of isotropic 3D T1-weighted MR images and ground-truth brain masks (i.e., segmentation) from 125 subjects. We used a five-fold cross-validation scheme to train and evaluate each architecture. Predictions for full-sized and pocket-sized networks are evaluated using the Sorensen-Dice Similarity Coefficient (Dice) and the Hausdorff distance. **Results:** The pocket networks averaged a 97% reduction in the number of parameters and achieve segmentation accuracy comparable to the full architectures. The difference in Dice accuracy between the pocket and full architectures for NFBS segmentations is less than 0.003 for U-Net, ResNet, and DenseNet. The mean and maximum Hausdorff distances between the pocket and full architectures differed by less than 0.004 mm and 1.070 mm, respectively. Brain segmentations were visually indistinguishable. **Conclusion:** PocketNets demonstrated faster training and inference times and lower memory requirements while retaining segmentation performance. These savings in time and memory provided by PocketNet can make powerful segmentation architectures more accessible in resource-constrained environments that do not have access to specialized computing hardware.

CBCT-Based Prostate and Organs-At-Risk Segmentation Using Deep Attention Network

Y Fu*, Y Lei, T Wang, S Tian, J Roper, P Patel, A Jani, J Bradley, T Liu, X Yang, Emory University, Atlanta, GA

Purpose: To propose a deep attention network for cone beam CT (CBCT)-based multi-organ segmentation for facilitating CBCT-guided adaptive radiotherapy. **Methods:** Both the CBCT and synthetic MRI (sMRI) were used for the segmentation of soft tissue including the prostate, bladder, rectum, and the bones including left femoral head (LFH) and right femoral head (RFH). The synthetic MRI was generated using trained CycleGAN networks. The CBCT and sMRI were separately processed using two U-Nets for feature extraction. The CBCT has better ability in bony structure segmentation while the sMRI has better ability for soft tissue discrimination. It is important to effectively combine the feature maps learnt from both the CBCT and sMRI. To achieve this, a novel deep attention strategy was proposed to integrate the CBCT feature maps with the sMRI feature maps prior to final segmentation by a convolutional neural network (CNN). The deep attention strategy enables the network to focus on salient features that highlight the target organs. The network was trained and tested using 50 patients' datasets using five-fold cross validation. For evaluation, the dice similarity coefficient (DSC) and mean surface distances (MSD) were calculated for the target organs. **Results:** Our results show that the proposed method was able to segment all five organs simultaneously with a high accuracy. The DSCs and MSDs are 0.90 ± 0.06 and 0.94 ± 0.91 mm, 0.94 ± 0.04 and 0.87 ± 0.76 mm, 0.90 ± 0.03 and 0.88 ± 0.73 mm, 0.96 ± 0.04 and 1.16 ± 1.34 mm, as well as 0.95 ± 0.03 and 1.28 ± 1.43 mm for prostate, bladder, rectum, LFH and RFH, respectively. This proposed sMRI-aided CBCT segmentation outperforms CBCT-only based segmentations with better agreement with physicians' manual contours. **Conclusion:** We have developed a CNN network with deep attention strategy to segment prostate and multiple OARs on CBCT images. The accurate sMRI-aided organ delineation warrants further development of a CBCT-guided adaptive radiotherapy workflow for prostate cancer.

Automatic CT-Only Multi-Organ Segmentation for CT-On-Rails-Based Prostate Adaptive Radiotherapy

Y Liu*, Y Lei, T Wang, Y Fu, P Patel, A Jani, J Bradley, T Liu, X Yang, Emory University, Atlanta, GA

Purpose: Fast and accurate segmentation of target and organs-at-risk (OARs) is a key requirement in adaptive radiotherapy (ART). In the scenario of CT-on-rails-based ART, the absence of MRI may lead to inaccurate prostate delineation. We propose to develop a CT-only, synthetic MRI (sMRI)-aided dual networks for rapid and accurate multi-organ segmentation for prostate ART. **Methods:** We propose a dual network method that combines the bony structure information provided by CT and superior soft-tissue information provided by sMRI for effective pelvic multi-organ segmentation. Cycle-consistent adversarial networks (CycleGAN) were used to generate CT-based sMRI. Independent features are extracted from CT and sMRI via the dual networks separately: the first network is used to extract features from CT that represent bony structures, and the second network is used to explore features from sMRI that represent the soft tissues. Deep supervision is used to force the extracted CT and sMRI feature maps from hidden layers of each pyramid level to be semantically discriminative. Then, the comprehensive feature maps from corresponding pyramid levels of the first and second pyramid networks are combined and processed via several deconvolution layers and attention gates. The attention gates further highlighted the informative elements of combined feature maps to well differentiate different organ tissues. The proposed method was trained and evaluated using a cohort of 140 prostate patients. **Results:** The Dice similarity coefficients and mean surface distances between our results and ground truth were 0.95 ± 0.05 , 1.16 ± 0.70 mm; 0.88 ± 0.08 , 1.64 ± 1.26 mm; 0.90 ± 0.04 , 1.27 ± 0.48 mm; 0.95 ± 0.04 , 1.08 ± 1.29 mm; and 0.95 ± 0.04 , 1.11 ± 1.49 mm for bladder, prostate, rectum, left and right femoral heads, respectively. The mean center of mass distances was within 3 mm for all organs. **Conclusion:** We demonstrated the feasibility of sMRI-aided dual networks for multi-organ segmentation on pelvic CT images. This method could reduce clinical workload and facilitate the development of CT-on-rail-based adaptive radiotherapy.

A Feasibility Study for Deep Learning-Based Efficient Monte Carlo Dose Calculation Method in Radiotherapy

X Lu^{1*}, Y Li², Q Mengke¹, L Zhou¹, T Song¹, (1)Department of Biomedical Engineering, Southern Medical University, Guangzhou, Guangdong, CN, (2) Department of Radiation Oncology, Sun Yat-sen University Cancer Center, Guangzhou, Guangdong, CN

Purpose: We have proposed a Deep Learning-based Monte Carlo (MC) dose denoising framework, which innovatively uses MC statistical uncertainty (SU) distribution in combination with patient CT images for denoising to obtain accurate dose maps. **Methods:** First, we generate a database of MC dose maps and corresponding SU distributions for low- to high-histories using MC calculation engine. Then train the model to map the low-histories dose to high-histories dose maps. At the core of this framework is a multi-channel denoising network, which has multi-channel inputs with CT images and low-histories MC dose and its corresponding SU distributions, and outputs a denoised dose map. Finally, we evaluated the feasibility of the model to obtain high precision dose map through evaluation metrics MAE, ME, GPR, DVH, and dose maps. **Results:** The dose maps show the denoised dose is more consistent with the structural distribution shown in CT images, especially in the high-dose non-uniform areas. DVH curves provide more accurate target coverage and OARs distribution information. The predicted results effectively eliminate singularities in the input dose, and match better with the ground truth in both OARs and PTVs areas. The global prediction performance is also confirmed in the gamma maps. In the quantitative comparison results, the predicted dose demonstrated substantially improved match to the ground truth, with average GPR 99.38%±3.9%, the global ME and MAE were -0.25%±0.12% and 0.83%±0.33% respectively. The accuracy improvement between the input dose and the predicted dose can be up to tenfold. **Conclusion:** By using the SU distribution with dose difference information and CT images with electron density and anatomical structure information, the model better learned the potential inaccuracies in the input, further improving the accuracy of dose denoising. Our framework more efficiently obtain accurate dose distribution, to help physicists make more informed decisions when planning and evaluating treatment plans.

A Generative Adversarial Network (GAN) Based Monte Carlo Model for a Biology-Guided Radiation Therapy Machine

M Shi^{1*}, S Cui¹, D Zaks², B Han³, (1) Stanford University, Palo Alto, CA, (2) RefleXion Medical, Hayward, (3) Stanford University School of Medicine, Stanford, CA

Purpose: Phase space (PHSP) is commonly used as a source model in Monte Carlo (MC) simulation. It is cumbersome and inconvenient to use despite the outstanding simulation accuracy. This study aims to model a biology-guided radiotherapy (BGRT) machine by a convenient and storage-saving technique using: generative adversarial networks (GAN). **Methods:** The BGRT machine is a novel radiotherapy machine that irradiates target using a 64-leaf binary MLC system. Each leaf projects a 0.625 cm opening along the x direction at 85 cm SAD. Two pairs of Y jaws move simultaneously to open 1 cm or 2 cm at isocenter. A series of PHSP sources below the collimation system were generated using BEAMnrc at field sizes from 0.625 x 2 cm² to 10 x 2 cm². For each field size, a GAN model was trained from the collimated PHSP using a python tool, GAGA-PHSP, which implemented a Wasserstein GAN with three hidden layers in the generator and discriminator. The training PHSP was 0.5 GB – 9 GB in size, depending on the field size. To validate the model, dose distributions in water were simulated with PHSP and GAN sources and compared in terms of percentage depth dose (PDD) and relative planar dose. **Results:** The difference of %dd(10) simulated with PHSP and GAN sources is 0.42%±0.4%. The passing rate of 1%/1mm gamma analysis of the relative dose distribution in transverse, sagittal, and coronal planes are 92.9%±4%, 96.9%±3%, and 96.2%±3.7%, respectively. The GAN-based model can generate unlimited particles and is only 40 MB in size, saving file storage by a factor up to 200. The average training time is 5 hours. **Conclusion:** The GAN-based MC model can simulate the BGRT Linac accurately. The high adaptivity, storage-saving, and time-saving features make this model potentially useful in the simulation of a new Linac instead of PHSP.

TH-E-TRACK 5-03

Development of a Virtual Source Model for Monte Carlo Based Independent Dose Calculation for Varian Linac

J Castle^{1*}, X Feng¹, Q Chen², (1) Carina Medical LLC, Lexington, KY, (2) University of Kentucky, Lexington, KY

Purpose: Monte Carlo (MC) simulation is often based on phase-space files (PSF), as they are able to accurately represent particle characteristics. However, the large-sized PSF creates a bottleneck for speeding up calculations, as the reading of the PSF takes appreciable time. In addition, the number of independent particles is limited by the PSF, preventing further reduction of statistical uncertainty. The purpose of this study is to develop and validate a virtual source model (VSM) to address these limitations. **Methods:** Particles from existing phase space files for Varian 6X, 6FFF, 10X, and 10FFF beams were tallied and analyzed. The particle density distribution, energy spectrum, particle direction, and the correlations between characteristics were computed. Virtual phase space models were created for these energies. The VSM approach was validated with water tank simulations as well as clinical cases against the original PSF. Computation time and gamma index passing rate were recorded for each case. **Results:** The new VSM only takes 2MB of disk space for each beam energy, compared to 50GB for PSF. The VSM approach reduces the calculation time by 10 mins on our server. At 5% MC uncertainty, the VSM approach was 45% faster in water tank simulations and reduces the calculation time for most clinical cases from ~15 mins to ~1.5 mins. Gamma index passing rates remain high at 5% statistical uncertainty for both approaches, with 98.5% ± 1.0% for VSM and 99.1% ± 0.9% for PSF. **Conclusion:** We have created VSM model for Varian Linacs. The VSM approach significantly saves computation time without sacrificing accuracy for second dose calculation.

Microdosimetry of Radionuclides Using Geant4 Simulation Considering the Auger Electron Contribution

O Kwon*, D Adam, B Bednarz, University of Wisconsin, Madison, WI

Purpose: The recent surge in the interest and development of radiopharmaceutical therapy (RPT) agents requires the investigation of microdosimetry due to the short range of emissions and heterogeneous activity distributions. Monte Carlo microdosimetric simulations can accurately account for the heterogeneous activity distributions that can be present at the cellular level and will aid in the development of RPT treatment planning by accounting for the tumor microenvironment. This study created a model of an idealized tumor microenvironment using the Monte Carlo code, Geant4. **Methods:** Geant4 simulations were compared cellular S-values of I-131, Lu-177, Y-90, and Br-77 to MIRD by modeling the tumor environment as an agglomeration of spherical cells. The tumor microenvironment was simulated as a cluster of liquid spherical 5 µm radius cells in both hexagonal and lattice configurations. Both source and target cellular S-values were calculated using Geant4

and validated using MIRDcell. Because the radionuclides investigated have different decay characteristics, physics lists, decay relative functions, and electron scattering cross-sections were analyzed using Geant4. **Results:** The differences between Geant4 and MIRD were under 10% for I-131, Lu-177, and Y-90 and 15% for Br-77. The ARMflag function was required for accurately model Auger electron emissions. Appropriate physics lists were required for different radionuclides to account for the different emitting radiation energy ranges and interactions based on each decay scheme. Accordingly, Livermore physics was applied to Y-90, DNA_option8 was applied to I-131 and Lu-177, and DNA_option7 was applied to Br-77. Lastly, the electron scattering cross-sections, de-excitation, and fluorescence process were also considered. **Conclusion:** A Geant4 microdosimetric tumor model was validated by a standard MIRD configuration. This tumor model is flexible and extendible to more realistic tumor cell and source activity configurations. Appropriate microenvironment modeling and radionuclide physics considerations can provide more optimal RPT treatment plans and account for more realistic dosimetric phenomenon.

BB is a co-founder of Voximetry, Inc., a nuclear medicine dosimetry company in Madison, WI.

Clinical Transition from AAA to Acuro XB: A Comprehensive and Treatment Site-Specific Report for Dose Comparison, Plan Analysis and Strategic Deployment

X Zhong*, Y Park, Y Zhang, Z Trivedi, J Wu, L Chen, S Kazemifar, A Godley, S Jiang, M Lin, UT Southwestern Medical Center, Dallas, TX

Purpose: Accurate dose calculation algorithms, such as AcurosXB (AXB) and Monte Carlo (MC), have become the only dose calculation engine available for some new adaptive therapy systems and accelerated the need to transition to AXB/MC. In this work, we describe the approach to transition from AAA to AXB in a large institution. **Methods:** Phase I implementation is in physics side, a large scale AAA plan recalculation and reoptimization study was performed with AXB for total of 205 cases covering seven disease sites. Gamma analysis of 1%/1mm, 2%/2mm and 3%/3mm and dose-volume-histogram (DVH) metric comparisons were performed to quantify the systematic dosimetric impact for the individual disease sites and develop the proposal to handle the dosimetric impacts. In phase 2 implementation, the representative cases in each disease site were replanned with AXB. The treated AAA plan recalculated with AXB, representing prior practice in AXB-scale; the AXB plan recalculated with AAA, representing the future practice in AAA-scale; along with the statistics from phase 1 were presented to the physicians, planners, and therapists of each disease-oriented team (DOT). New guidelines and workflows were developed based on the feedback obtained. **Results:** Breast plans demonstrated the lowest gamma passing rate followed by bone and lung. Gamma failure was observed in lung, cortical bone, and heterogeneity interfaces. In the DVH and replan studies, higher D_{0.03cc} and heterogeneity on PTV was found for all sites, and no significant impact was found in OAR doses. Planning timeline was adjusted for case suffering from AXB planning such as larynx and lung SBRT. Metal object handling starts from the physician consulting phase and added into the physician consultation questionnaire to allow time to obtain the material information. **Conclusion:** Transition of dose calculation engine requires team effort. The site specific findings and the implementation process presented in this work can be used as reference for other institution.

Dosimetric Comparison of HDR Surface Applicator Brachytherapy Between TG-43 and TG-186 for Angiosarcoma of the Scalp and Face

TC Harris*, D O'Farrell, MB Lam, EH Baldini, PM Devlin, I Buzurovic, Department of Radiation Oncology, Brigham and Women's Hospital, Dana Farber Cancer Institute and Harvard Medical School, Boston, MA

Purpose: Cutaneous angiosarcoma is a rare cancer that forms in the blood and lymph vessels, occurring most often in the scalp and face -- regions involving complex topography. Surface applicator brachytherapy (SABT) may be effective in conformally treating such lesions while minimizing dose to organs at risk (OARs). TG-186 presents a model-based calculation method accounting for tissue heterogeneities. This study compares the TG-43 and TG-186 methodologies, assessing the dosimetric impact of different density materials on dose to angiosarcoma targets and OARs. **Methods:** 12 previously treated angiosarcoma plans were evaluated. Radio-opaque wires marked the tumor volume as well as a 5cm clinical margin expansion at CT simulation. Treatment planning was performed using Oncentra Brachy 4.5.3. 100% isodose was prescribed to 3mm depth in the marked target, allowing up to 8mm depth locally where visible evidence of disease on the CT. Contoured OARs include brain as well as bilateral orbits, lenses, lacrimal glands, cochlea, and parotids. The 100% TG-43 isodose volume was designated as the planning target volume (PTV) for comparison. The plans were recalculated using Oncentra's Advanced Collapsed-cone Engine (ACE) algorithm based on TG-186's recommendations. HU-based densities were applied with unchanged dwell times. A paired Wilcoxon signed-rank test was utilized to compare dose differences between the two calculations. **Results:** Using ACE compared to TG-43, the PTV median V_{100%} decreased 19.8% (p=0.001) and the D_{90%} decreased 7.1% (p=0.001). All OARs except for the parotids also showed decreases in median dose (p<0.05): Brain D_{max} 5.8%, V_{80%} 91.3%, V_{50%} 22.3%; mean orbit 9.5%, lens 11.0%, lacrimal gland 9.4%, and cochlea 7.4%. **Conclusion:** 12 scalp angiosarcoma SABT plans were recalculated using TG-186 formalism. Calculations using the TG-43 model are shown to underestimate doses for targets and OARs for superficial targets. Future studies will be required to evaluate any clinical impact of transitioning to TG-186 calculations.

Generation of 3D Dosimetric Reference Datasets Using Model-Based Dose Calculations for COMS Eye Plaque Brachytherapy

E Fletcher¹*, F Ballester², L Beaulieu³, Y Ma³, H Morrison⁴, M Rivard⁵, R Sloboda⁶, J Vijande², R Thomson¹, (1) Carleton University, Ottawa, ON, CA, (2) University of Valencia (UV-IFIC-IRIMED), Burjassot, ES, (3) CHU de Quebec - Universite Laval, Quebec, QC, CA, (4) Tom Baker Cancer Centre, Calgary, AB, CA, (5) Rhode Island Hospital / Brown University, Providence, RI, USA, (6) Cross Cancer Institute, Edmonton, AB

Purpose: To evaluate the dosimetry of brachytherapy treatments for intraocular tumours by comparing results from several Monte Carlo (MC) systems and one commercial model-based dose calculation algorithm (MBDCA). This work is done in order to develop test cases for adopters of MBDCA. The scenario investigated here is the treatment of ocular melanoma using a Collaborative Ocular Melanoma Study (COMS) 16 mm eye plaque loaded with 13 model 6711 ¹²⁵I seeds. **Methods:** The levels of agreement among four MC codes (EGSnrc_eyes_brachy, Geant4 ALGEBRA, Penelope2014, and MCNP6) were evaluated by comparing the results from various test cases. Some comparisons were also done using a research version of the OncentraBrachy/ACE commercial TPS. The test cases included: i) modelling the 13 seeds individually, ii) combined in water positioned within the plaque, iii) the full COMS plaque in a water phantom, and iv) the full plaque in a realistic eye phantom. Local and global dose comparisons were made. **Results:** For all test cases, local agreement of ALGEBRA, MCNP, and Penelope with eyes_brachy was within 2% and global agreement was within 1%. These values are consistent with the typical uncertainties expected in the low energy photon domain. The presence of the fully modelled plaque (including metal backing and plastic insert as opposed to just the seeds) increased variations between the codes. TPS doses show larger disagreements, with local dose differing by 2% on average and by as much as 8% at some points. **Conclusion:** This work indicates that these MC codes exhibited excellent agreement for these test cases both in water and within an eye phantom, justifying their use as a benchmark. Further work will investigate discrepancies between the TPS and MC calculations, towards clinical applications of advanced dose evaluations.

Cardiac Radio-Ablation Target Delineation On 3D Electro-Anatomical Maps

M Boeck^{1,2*}, C Wei², R Mak^{1,2}, U Tedrow^{1,2}, P Zei^{1,2}, H Cochet³, M Juhoor³, S Friesen¹, F Hacker¹, J Bredfeldt^{1,2}, (1) Brigham and Women's Hospital, Boston, MA, USA (2) Harvard Medical School, Boston, MA, (3) Department of Radiology And Division Of Cardiology, University Of Bordeaux, France

Purpose: Cardiac radio-ablation (CRA) target delineation and planning process evaluation using a novel multimodal 3D cardiac segmentation software. **Methods:** In this 3D-EAM-based workflow, the EP delineates the target on the epicardial surface of the left ventricle in the treatment planning interface of the proprietary software MUSIC (Liryc, Bordeaux, Fr). To guide the EP in the delineation process, the electroanatomic mapping (EAM) and cardiac- and fibrosis-segmented contrast-enhanced cardiac CT are in the same frame-of-reference. The resulting target is transmurally expanded and exported as a Dicom RT structure set in registry with the cardiac CT. In the subsequent planning process, the cardiac CT is registered with the planning CT to guide the ITV- and PTV delineation followed by treatment plan optimization. This 3D-EAM-based target delineation workflow replaces the axial-view-based targeting approach for CRA which relies on target delineation on CT scans without EAM data and fibrosis data being in registry. To quantify the time- and cost savings of our 3D-EAM-based workflow, we compared it to a previously performed time-driven activity-based costing (TD-ABC) analysis of the axial-view-based workflow. **Results:** The 3D-based targeting approach takes advantage of the EP's expertise and knowledge of the VT site. It removes the need for (i) the mental abstraction of the target from 3D to 2D, (ii) the use of external software to manually transfer EAM mapping and fibrosis segmentation to the treatment planning system (TPS), (iii) numerous follow-up consultations (further reducing total coordination efforts). Thus, the targeting process is more time-efficient and subject to less variability. TD-ABC demonstrates saving in overall procedural costs of 10.62% (\$1234.07), 7.25% (\$767.96) and, 8.80% (\$909.45) for the so far evaluated cases. **Conclusion:** The proposed workflow improves the time-efficiency and reliability of the targeting and planning process, leading to a much more streamlined workflow for CRA.

Dose Kernel Decomposition for GammaKnife and GammaPod Treatment Planning

M Chen*, Z Yang, Z Wardak, X Gu, W Lu, UT Southwestern Medical Center, Dallas, TX

Purpose: Pre-calculation of accurate dose deposition kernels for GammaKnife (GK) and GammaPod (GP) treatment planning can be very time consuming with an enormous number of candidate shots. To address this issue, we propose a novel decomposition model of dose deposition kernels for GK and GP treatment planning. **Methods:** The dose deposition kernel for an arbitrary shot position is modeled as the product of a shift-invariant kernel and spatially variant scale factor. The shift-invariant kernels, one for each collimator, are pre-calculated on the commissioning phantom using the Monte Carlo (MC) method. The spatially variant scale factor is defined as the ratio of the mean tissue maximum ratio (TMR) at the candidate shot to that at the commissioning shot. The scale factors or normalized mean TMRs can be calculated on the whole treatment volume through parallel-beam ray tracing followed by averaging over all source directions. The proposed dose calculation was compared with the MC calculation for various shot locations and spot sizes on the phantom and twelve clinical plans. **Results:** The kernel decomposition (KD) model achieved similar doses to those calculated by the MC method. The Gamma index passing rates in 2%, 2 mm criteria were greater than 99% for the phantom study and clinical plans. The calculation time of the KD approach was within sub-seconds, which was several orders of magnitude faster than the MC method. **Conclusion:** The scale factors can be calculated very efficiently when implemented in GPU and only needs to be calculated once before treatment planning. The proposed dose calculation can provide accurate dose and is very fast with kernel shifting and scaling. In addition, both dose and derivatives can be calculated in real-time without pre-calculating the dose deposition kernels, which is critical to efficient search of optimal plans for GK and GP.

Evaluation of Dose Calculation Accuracy of Intermediate-To-Low Dose Spillage in Single-Isocenter Multitarget Radiosurgery Using 3D Dosimetry

Y Wang^{1*}, P Fan², A Xu³, J Choi⁴, T Wang⁵, J Adamovics⁶, C Wu⁷, (1) New York Presbyterian/Columbia University Irving Medical Center, New York, NY, (2) New York Presbyterian/Columbia University Irving Medical Center, Bronxville, NY, (3) New York Presbyterian/Columbia University Irving Medical Center, New York, NY, (4) New York Presbyterian/Columbia University Irving Medical Center, (5) New York Presbyterian/Columbia University Irving Medical Center, New York, NY, (6) HEURIS, INC., Skillman, NJ, (7) New York Presbyterian/Columbia University Irving Medical Center, New York, NY

Purpose: Single-isocenter multitarget (SIMT) stereotactic radiosurgery using volumetric modulated arc therapy provides rapid delivery of high dose radiation to multiple brain metastases. However, the intermediate-to-low dose spillage to normal brain is unclear. Dosimetric accuracy of the dose spillage calculation in treatment planning system involves modeling of out-of-field doses, and multileaf collimator characteristics, which is challenging to be evaluated using 1D/2D dosimeters. This study presents a comprehensive 3D dose comparison between calculated and measured dose distribution with various treatment geometries. **Methods:** Ten SIMT plans for treating multiple brain lesions with different sizes and target separations were created using HyperArc treatment planning system (Varian Medical System). Hybrid plan verification of each plan was generated on computed tomography images of the 3D dosimeters, PRESAGE (Heuris Inc.). Hybrid plans were then delivered to the dosimeters using a TrueBeam (Varian Medical System) linear accelerator. Using fiducial registration, target and normal tissue structures were registered to the measured dose image. A comprehensive comparison of the 3D dose distribution between measurement and calculation was performed. **Results:** Most of the gamma failing points are at the intermediate dose regions (50-70%). Measured 3D dose distribution presents higher dose spillage to normal tissue up to 5-10% in regions connecting the two close targets. In addition, dose discrepancies were observed in off-axis low dose regions where out-of-field dose is underestimated by the treatment planning system. Using convectional portal dosimetry, observed errors in 3D measurement were washed out due to dose summation. **Conclusion:** A comprehensive view of the dose discrepancies between calculated and measured inter-target dose spillage in different SIMT treatment geometries was presented. The results provide insights into the planning strategy of SIMT treatments and lay the path for future comparison of Gamma Knife to linear accelerator radiosurgery using 3D dosimetry.

The dosimeters were provided by Heuris Inc. free of charge.

Which Metric Quantifies Dose Fall-Off for SRS Treatments of Brain Lesions?

T Nano^{1*}, D Capaldi², C Chuang², L Wang², S Soltys², L Boreta¹, S Braunstein¹, L Ma¹, (1) University of California, San Francisco, San Francisco, CA, (2) Stanford University, Stanford, CA

Purpose: Dose fall-off guidelines for stereotactic radiosurgery (SRS) are critical for ensuring normal brain sparing. Two well-known but distinctive metrics are (1) dose gradient index (DGI) and (2) Paddick gradient index (PGI). We investigated the intrinsic correlations and the pros and cons of these two indices for SRS

treatment of brain lesions. **Methods:** Two cohorts of patient cases with multiple brain lesions from two institutions were treated with CyberKnife (n=72, 202 lesions, volume $2.94 \pm 6.99 \text{ mL}$ [range: 0.01–41.0]) and GammaKnife (n=435, 1983 lesions, volume $1.23 \pm 2.77 \text{ mL}$ [range: 0.01–28.89]). Dose metrics were extracted to compute DGI, where 100 is considered “ideal” and decreases with worst dose fall-off, and PGI, which increases with worst dose fall-off. Simple linear regression of DGI and PGI was compared for both CyberKnife and GammaKnife cases, and Fisher Z-transformation was used to compare the correlation coefficients. **Results:** For CyberKnife cases, targets smaller than 1 mL have DGI and PGI values of 89.96 ± 17.67 and 8.51 ± 4.14 respectively, and targets larger than 1 mL have values of 58.18 ± 19.59 and 4.26 ± 2.41 respectively. GammaKnife cases, targets smaller than 1 mL have a DGI and PGI value of 108.61 ± 8.94 and 4.03 ± 2.50 respectively and targets larger than 1 mL have values of 78.73 ± 18.40 and 3.08 ± 0.85 respectively. DGI was found to positively correlated with PGI (slope=0.2626, $R^2=0.002$, $p=0.7039$) for CyberKnife cases and negatively correlated with PGI for GammaKnife cases (slope=-0.9163, $R^2=0.009$, $p<0.0001$). CyberKnife and GammaKnife plan relationship between DGI and PGI were found to be different ($p=0.0139$) indicating the DGI is flawed in quantifying dose fall-off. **Conclusion:** PGI was found to best describes dose fall-off, whereas, DGI was found to be only weakly correlated with PGI and indicates that it is not a direct measure of dose fall-off. Guidelines for dose fall-off in SRS treatments of multiple brain lesions should be provided exclusively using PGI, with special consideration for small lesions and complex targets.

TH-E-TRACK 6-05

Demonstrating the Practical Limitation of a Previously Validated Knowledge-Based Planning Model for SIB Lung SBRT of Large (> 5 Cm) Tumors

J Visak*, A Webster, M Kudrimoti, R McGarry, M Randall, D Pokhrel, University of Kentucky, Lexington, KY

Purpose: An in-house lung SBRT knowledge-based planning (KBP) model was previously validated and deployed on a limited basis to support non-coplanar VMAT treatments for centrally-located NSCLC tumors. Increasingly at our institution, lung SBRT is delivered via a simultaneous integrated boost (SIB) approach to escalate dose to hypoxic tumor cores in tumors >5cm. This study demonstrates a practical limitation of a robust KBP model via SIB-SBRT of large tumors. **Methods:** Clinically deployed KBP model trained with 86 patients was adapted by reconfiguring DVH-estimate objectives. Five complex validation cases (average tumor volume, 189.7cc) were selected and reoptimized with risk-adapted KBP model. Patients received 40-50Gy to PTV in 5 fractions using 3-6 non-coplanar 6X-FFF beams. An inner GTV (1.0 cm interior to ITV) was escalated to 60Gy for a larger hotspot. Plans were reoptimized with KBP and renormalized for identical PTV coverage including escalated GTV dose. Plans were compared relative to RTOG-0813 criteria including target metrics, OAR dosing and optimization time. **Results:** KBPs were statistically similar and RTOG-0813 compliant, but clinically inferior to clinical plans due to lessened DVH-estimation capability with larger PTVs. KBPs were produced on average in 1.8 ± 0.8 hours and 2.4 optimizations with minimal planner burden and modest manual intervention. For similar conformity and intermediate dose-spillage, KBPs demonstrated mean GTV dose escalation of 1.7Gy ($p=0.08$). OAR dosing differences were statistically insignificant with minimal plan complexity costs. KBPs on average spared maximum bronchial tree dose 0.04Gy ($p=0.87$) but increased maximum heart dose by 1.0Gy ($p=0.42$). **Conclusion:** KBP is a powerful tool that can assist with planning in lung SBRT. Complex cases with tumors >5 cm may not be ideal for using KBP model despite potential RTOG compliance. For non-urgent scenarios, use of the KBP model should be limited in complex cases. Further development of sub-model may support complex SIB-SBRT with larger tumors.

Radiobiological Analysis of Isotoxic SBRT Simultaneous Integrated Boost of Multi-Parametric MR Defined Dominant Intraprostatic Lesions

M Dumas^{1*}, M Leney², J Kim¹, E Mohamed¹, N Wen¹ (1) Henry Ford Health System, Detroit, MI (2) Northern Light Health, Brewer, ME

Purpose: To assess the utility of isotoxically boosting dominant intraprostatic lesions (DIL) by analyzing TCP and rectal NTCP with and without a DIL simultaneous integrated boost (SIB) using an MR-only workflow. **Methods:** A dosimetric study was performed on 10 patients with biopsy-proven prostate cancer who underwent T2, mDixon, and diffusion-weighted imaging on a 3T MRI. A physician contoured the DIL based on T2 and apparent diffusion coefficient (ADC) images. For planning, synthetic CT images were generated from fat and water mDixon sequences using a k-means segmentation-based method for assigning HU values to predefined tissue types. SIB and non-boosted plans were created for each patient. The entire prostate (PTVprostate) was prescribed 36.25Gy in 5 fractions. The PTVDIL was isotoxically boosted to the maximum dose allowed while maintaining the non-boosted rectal NTCP. Prescribed dose and rectum constraints were based on the hypo-FLAME and 50-Gy SBRT DIL boost clinical trials. The linear-Poisson tumor control probability (TCP) radiobiological model and Lyman-Kutcher-Burman (LKB) model for normal-tissue complication probability (NTCP) were employed. Radiobiological calculations were done with BioSuite software (Uzan et al 2011) to determine individualized TCPs based on each patient's ADC map and clonogen density. **Results:** Clonogen density in the DIL ranged from $4.4\text{E}08$ – $1.2\text{E}09$ clonogens/cc. Mean dose and D95 to the SIBs were 54.5 ± 1.9 Gy and 49.4 ± 2.7 Gy. The average TCP was $99.6 \pm 0.6\%$ with the SIB compared to $96.0 \pm 0.9\%$ without the boost. The average NTCP for incidence of late rectal toxicity grade ≥ 2 was $4.4 \pm 2.9\%$ (1.0–9.2%). Rectal doses to 1cc were within the protocol guidelines: 36.3 ± 0.7 Gy and 36.6 ± 0.9 Gy between the standard and SIB plans respectively. **Conclusion:** We demonstrated the viability of MR-only SBRT treatment planning for prostate cancer with an isotoxically boosted DIL. DIL dose was escalated to an average D95 of 49.4Gy, while maintaining rectal toxicity limits and improving overall TCP by 4%.

Using Deep Learning Framework (pytorch) for Circular Cone Treatment Planning of CyberKnife System

B Liang^{1*}, R Wei¹, Y Li², B Liu^{3,4}, S Xu⁵, F Zhou^{3,sup>}, <sup>4, Q Wu⁶, J Dai¹, (1) National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, Beijing, CN, (2) Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Guangdong Key Laboratory of Nasopharyngeal Carcinoma Diagnosis and Therapy, Guangzhou, Guangdong, CN, (3) Image Processing Center, Beihang University, Beijing, CN, (4) Beijing Advanced Innovation Center for Biomedical Engineering, Beihang University, Beijing, CN, (5) Chinese PLA General Hospital, Beijing, Beijing, CN, (6) Duke University Medical Center, Durham, NC

Purpose: With robot-controlled linac positioning, the CyberKnife system significantly increases the freedom in radiation beam placement, but also imposes more challenges on treatment plan optimization. This study proposed to use the deep learning framework (pytorch) for circular cone treatment planning of CyberKnife system. **Methods:** The candidate beams were initialized by simulating the process of covering the entire target volume with equivalent beam taper. For each voxel, the total dose was the weighted summation of the dose contributed by all beams. This dose summation was topologized into a simple feed-forward neural network, and the optimization was converted into network training. The pytorch framework, capable of automatic differentiation and dynamic adjustment, was utilized to train the network. The least absolute shrinkage and selection operator (lasso) and group lasso regularization terms were utilized to reduce the number of beams and nodes, respectively. **Results:** This method was validated and further compared with commercially available MultiPlan system on one typical lung case. This method protected the organs at risk (OARs) more effectively: the generated plan was of lower maximum dose within OARs. The homogeneity index (ratio of maximum dose to prescription dose, Dp) was reduced from 1.15 to 1.10. The volume covered by 50% (100%) Dp (V50 and V100) was reduced from 78.3cc to 59.3cc (14.6cc to 13.2cc), indicating more rapid dose fall-off. The number of nodes (beams) was reduced from 69 to 46 (146 to 93). In addition, the optimization time was shortened from around 30min to 52.3s. **Conclusion:** In conclusion, the generated treatment plan achieved more satisfactory dose distribution with fewer nodes and beams. Besides, the optimization was 1–2 orders of magnitude faster than the MultiPlan system. Using the deep learning framework for treatment planning optimization has the potential to be used clinically.

Risk Based Assessment for Tomotherapy Delivery (FMEA Analysis)

Since the publication of Task Group 148 in 2010, the TomoTherapy platform has undergone substantial development involving treatment delivery, image guidance, motion management, and treatment planning systems (TPS). New hardware and software capabilities have dramatically changed its delivery and planning characteristics. Task Group 306 was formed to provide guidance on the implementation, management, and quality assurance for these technological advances. In this session, the work of Task Group 306 will be presented. We will start by summarizing changes to the TomoTherapy platform since 2010. The impact on clinical delivery and QA practices, including QA tests and tolerance limits will then be presented. Finally, results of an FMEA analysis performed by the task group members on the TomoTherapy treatment planning and delivery processes will be presented.

Learning Objectives:

1. Review updates/changes to tomotherapy delivery and planning since TG 148.
2. Present updated tolerance limits, frequencies and QA tests for tomotherapy and Radixact delivery systems
3. Present updated imaging, treatment planning and patient specific QA
4. Learn about a performing risk bases assessment for tomotherapy (FMEA analysis) based on clinical practice.

Q&A

In the last a few years, diagnostic medical imaging has emerged as one of the most promising areas of healthcare innovation that artificial intelligence (AI) has clinical applications, including image processing and interpretation. AI is in general a technology involving computer science application in creating systems for tasks typically require human intelligence, and the term AI is also used when a technology simulates cognitive functions such as learning and problem solving. Machine learning (ML) is a subfield of AI involving all approaches that allow computers to learn from data without explicit programming, it utilizes computational models and algorithms mimicking the architecture of biological neural network in brain, which is defined as artificial neural network (ANN). When ML is used in medical imaging, it is narrowed to recognize patterns in imaging by using many example images to find the pattern with computer algorithms. On the other hand, deep learning (DL) is part of ML representing a branch of existing AI techniques. DL uses neural networks with many layers, and convolutional neural networks (CNNs) are common DL architectures for images, especially for image classification tasks.

Current and potential AI applications in diagnostic radiology may include improving image quality, reducing radiation dose, decreasing MRI imaging time, enhancing technical protocols, faster and standardized detection and characterization of image findings, and workflow improvement. With an ever increasing amount of data

and the potential use of AI, higher efficiency in diagnostic radiology will be available in the near future.

Learning Objectives:

1. Understand the basics concepts of Artificial Intelligence (AI) and its relation with Machine Learning (ML) and Deep Learning (DL).
2. Understand primary components of DL architectures and neural network.
3. Understand selected AI applications in diagnostic radiology.

Audience Q&A

Patients routinely view diagnostic imaging studies and radiation therapy as complicated medical procedures. Misconceptions about radiation and confusion surrounding complex imaging and treatment equipment frequently result in patients having questions or concerns about the technical aspects of their care. These circumstances can result in patient-related distress and anxiety, delay the imaging necessary for a diagnosis, and even negatively impact outcomes, particularly in the case of radiation therapy.

Medical physicists are uniquely qualified to address patient questions and concerns related to the technical aspects of their care. The current training paradigm for imaging and therapy medical physicists produces analytical patient-care professionals with a propensity for problem solving. This training also instills a comprehensive understanding of the science and technology that dominate the fields of diagnostic imaging and radiation therapy. Expanding this education and knowledge to also include formal training in patient communication will allow medical physicists to further expand their roles to directly impact patient care.

This symposium will discuss new roles for medical physicists, where they establish independent professional relationships with radiation oncology patients. Speakers from institutions of different sizes and practice environments will discuss how new patient-facing roles are utilized to improve the patient experience, increase the quality of patient care, and facilitate new responsibilities. In addition, the role of the Medical Physics 3.0 Committee in promoting and training medical physicists for new responsibilities in direct patient care will be discussed.

Learning Objectives:

1. To outline the benefits of medical physicists establishing independent professional relationships with patients
2. To explore how current patient-facing initiatives are increasing the quality of patient care and facilitating new patient care responsibilities
3. To understand the role of the Medical Physics 3.0 Committee in promoting and training medical physicists for new patient-facing responsibilities

A Dosimetric Evaluation of ^{223}Ra -Dichloride Using a Realistic Model of the Metastatic Castrate-Resistant Prostate Cancer Microenvironment and Whole-Body Pharmacokinetics

A Strunets*, D Adam, J Jeffery, B Bednarz, University of Wisconsin, Madison, WI

Purpose: The mechanism of action of ^{223}Ra -dichloride is not well understood despite the growing use of the radiopharmaceutical for the treatment of metastatic castrate-resistant prostate cancer in the bone. To support preclinical studies of ^{223}Ra -dichloride we have developed an advanced microdosimetric model that combines a detailed anatomical model of bony anatomy and a whole-body pharmacokinetic (PK) model of radium once injected into the blood. **Methods:** A high-resolution CT scan ($10\ \mu\text{m} \times 10\ \mu\text{m} \times 10\ \mu\text{m}$) was taken of a mouse femur ex vivo using the MiLabs U-CT scanner (MiLabs, Netherlands). Multiple geometric regions in a section of the bone were segmented in MATLAB (MathWorks Inc., Natick, MA) using an intensity-based analysis. The non-uniform activity distribution of ^{223}Ra -dichloride was calculated in the bony anatomy based on the whole-body PK model of radium provided in the ICRP Report 137 using advanced PK modeling with the SimBiology application in MATLAB. Microdosimetric simulations were performed in the model using the general-purpose Monte Carlo code Geant4 accounting for the decay products of ^{223}Ra and its daughters. **Results:** The results of the PK modeling of the bony anatomy indicate that the endosteum and the cortical surface components showed the most rapid uptake and clearance. The non-exchangeable cortical and trabecular volumes showed the slowest uptake and clearance. The mean dose to the trabecular, endosteum, and marrow components were in accordance with previously published values. **Conclusion:** This work offers a method to understand the dosimetric behavior of ^{223}Ra -dichloride via the combined use of PK modeling, a microCT based geometric model, and GEANT4 Monte Carlo simulations. The model may provide further insight into the behavior of ^{223}Ra -dichloride and lead to more effective determinations of normal tissue toxicity and

therapeutic efficacy of metastatic castrate-resistant prostate cancer treatment regimens.

Woodruff School of Mechanical Engineering, Georgia Institute of Technology, Atlanta, GA

Purpose: Cancer risk models stemming from atomic bomb survivor data still rely on the results of the DS86 and DS02 dosimetry systems published by the Radiation Effects Research Foundation (RERF). This study investigates the dosimetry impact on the pregnant female (PF) population of atomic bomb survivors by utilizing a newly created series of kneeling and lying pregnant female computational phantoms. **Methods:** Utilizing the original standing series of J45 PF phantoms, a new series of both kneeling and lying J45 PF phantoms has been constructed to include gestational ages of 8, 15, 25, and 38 weeks. Kneeling phantoms were constructed using scripting methods within the 3D modeling program Rhinoceros®. Lying phantoms were created by rotating the original standing J45 series of PF phantoms in 3D space. Organ doses for both posture phantoms were computed via Monte Carlo transport code PHITS using particle fluences provided by DS02 for both Hiroshima and Nagasaki exposures. Maternal and fetal organ doses from the J45 PF phantoms were compared to the corresponding maternal organ and uterine wall, respectively, in the non-pregnant stylized adult female phantom used in DS02. **Results:** For kneeling phantoms, organ doses from photon spectra were overestimated compared to DS02 by as much as 40% for certain fetal and maternal organs. For lying phantoms, fetal organ doses from photon spectra were underestimated up to 25% while maternal organ doses were overestimated up to 15% related to DS02 organ doses. Neutron contributions to organ doses exhibited from neutron contributions exhibit an increasing overestimation in DS02 as gestational age increases. **Conclusion:** This work highlights the degree to which fetal and maternal dosimetry varies from the DS02 report with the introduction of newly created computational phantoms for both the kneeling and lying survivor cohort of pregnant women.

New Dosimetric Standard for Radiotherapy: Bounded Dose Volumetric Histogram Derived from Gamma Criteria

P Olcott*, Y Voronenko, A Da Silva, OM Oderinde, RefleXion Medical, Hayward, CA

Purpose: Radiotherapy quality assurance (QA) requires quantitative methods to compare two different dose distributions to determine whether the differences are significant or within tolerances. The gamma index (GI), which is based on predetermined dosimetric criteria, is the most popular method for comparing 1, 2, or 3D dose distributions. This study proposed a gamma-defined bounded dose-volume histogram (bDVH) QA technique, which is based on a dose difference (DD) and a distance-to-agreement (DTA) tolerance to better reveal the dosimetric cause of plan failure/error. **Methods:** An algorithm that translates gamma criteria to a bDVH was developed. Gamma criteria of 1%/1mm, 2%/2mm and 3%/3mm were evaluated in three clinically relevant SBRT treatment plans for NSCLC with a dose calculation grid of 2x2x2 mm. Log file-based dose reconstruction is performed for QA deliveries of the 3 patient treatment plans. A DVH is extracted for each delivery and compared to the bDVH based on the 3 gamma criteria. Delivery is within tolerance if 100% of the points on the delivered DVH fall within the bDVH. All deliveries were synthetically shifted by 2x the distance criterion or scaled by 2x the dose criterion and tested again. **Results:** The bDVH test passed for all deliveries that met the gamma criteria from log file-based dose reconstruction at the 2%/2mm and 3%/3mm levels at 100% of points falling within the bDVH bounds. The bDVH test also failed at less than 100% when the dose was shifted or scaled for all 1%/1mm, 2%/2mm, and 3%/3mm tests. **Conclusion:** A bounded DVH generated based on gamma criteria can now be used as a dosimetric test for patient-specific quality assurance. For the first time, a DVH can be dosimetrically evaluated to determine whether it is within machine tolerances or it presents a risk.

In Vivo Relative Dosimetry with XACT Imaging: A Feasibility Study

K Prather^{1*}, G Gonzalez², P Pandey³, S Wang³, L Xiang³, Y Chen², (1) University of Oklahoma College of Medicine, Oklahoma City, OK, (2) University Of Oklahoma Health Sciences Center, Oklahoma City, OK, (3) University of California, Irvine, Irvine, CA

Purpose: One of the potential applications capitalizing on the thermoacoustic phenomenon is X-ray acoustic computed tomography (XACT), which utilizes acoustic waves generated by clinical X-ray beams. The field of XACT has garnered growing interest as a potential tool for in vivo dosimetry at no extra radiation. This study aims to investigate the feasibility of using XACT as a relative dosimetry tool without the use of markers. **Methods:** XA signals generated from an X-ray beam in water were collected by a single element ultrasound transducer (Fig. 1a). The XA signal was amplified by a 60-dB preamplifier and acquired on an oscilloscope with 1024 averaging. The beam was delivered by a Varian TrueBeam system at 10 or 6 MV flattening filter free (FFF) energy with 4-μs pulse duration. To capture the change in X-ray dose with increasing water depth, the height of the transducer was varied from 2.60 cm to 13.00 cm at multi-millimeter steps. The peak-to-peak amplitude of the beam edge XA signal was plotted against transducer depth, and the XACT image was reconstructed in MATLAB using the back-projection method after high-pass filtering. **Results:** XA signals from the near and far edges of the beam corresponding to the field size are identified (Fig. 1b). As the transducer depth is increased, the signal amplitude decreases, while the signal profile remains largely unchanged (Fig. 2a). Fig. 2b demonstrates the linear relationship between the near-edge XA signal amplitude and transducer depth, which is comparable to the percentage depth dose (PDD) curves of 10 and 6 MV beams. A reconstruction of the depth plane is shown in Fig. 3, with the edges of the beam visible at 4 cm apart. **Conclusion:** This study demonstrates the feasibility of relative dosimetry using XACT imaging. Further investigation for a robust method to quantify XA signals is warranted.

Model Based Reconstruction Algorithm for Transperineal XACT Imaging

L Sun^{1*}, P Pandey², Y Chen³, S Ahmad⁴, L Xiang⁵, (1) University of California Irvine, (2) University Of California, Irvine, (3) University of Oklahoma Health Science Center, Oklahoma City, OK, (4) University of Oklahoma Health Sciences Center, Oklahoma City, OK, (5) University of California, Irvine, Irvine, CA

Purpose: Radiation dosimetry is a crucial process in radiation therapy to ensure that the correct dose is accurately delivered to the desired location. Despite wide use in clinical intervention, the delivered radiation dose can only be planned and verified via simulation with phantoms, while in vivo and in-line verification of the delivered dose is still absent in the clinic making precision radiotherapy challenging. We have proposed a new imaging modality called X-ray-induced Acoustic Computed tomography (XACT) for in vivo dosimetry during radiotherapy. Specifically, we are developing model-based image reconstruction algorithm for XACT XACT imaging using transperineal ultrasound matrix array. **Methods:** Model-based reconstruction algorithm was employed to address the limited-view problem in transperineal sensor geometry. The algorithm builds up an exact X-ray acoustic propagation model in time domains to predict the signal. The reconstruction is performed by minimizing the least square error between the measured signals and predicted signals. The model-based reconstruction results are evaluated by comparing against the ground-truth images. **Results:** Model-based reconstruction achieves more satisfactory results than back-projection algorithm with less streak-type artifacts and more low-frequency information. The time-reversal reconstruction has similar performance as model-based reconstruction qualitatively. However, quantitatively, the voxel value has larger difference between time-reversal reconstruction and the ground-truth images while the model-based reconstruction has more similar voxel values. The model-based reconstruction algorithm is less time-consuming than the time-reversal algorithm when reconstructing small objects. For large objects, the acoustic model needs to be calculated during each iteration due to memory issues, making it more time-consuming than the time-reversal reconstruction. **Conclusion:** Model-based reconstruction algorithm is effective in the reconstruction of transperineal XACT imaging, which can be valuable in prostate radiation therapy. The study also demonstrated the potential of using transperineal XACT imaging as an in-vivo dosimetry tool for radiation beam localization during the prostate treatment.

Investigation into the Relationship Patient Setup Accuracy and In-Vivo Transit Dosimetry for Image-Guided Volumetrically Modulated Total Body Irradiation (TBI)

S Taneja*, J Teruel, M Malin, P Galavis, A McCarthy, S Ayyalasomayajula, C Hitchen, N Gerber, Y Yuan, D Barbee, NYU Langone Medical Center, New York, NY

Purpose: In-vivo dosimetry for conventional total body irradiation (TBI) utilize point detectors placed along the patient surface to confirm the delivered dose matches prescription dose. However, in the volumetrically modulated arc therapy (VMAT) approach to TBI, the electronic portal imager device (EPID) can be utilized to acquire a 2-dimensional transmission fluence plane. This work explores the relationship between patient setup accuracy with transit in-vivo dosimetry. **Methods:** A total of 192 fields were investigated. Each VMAT plan consisted of four isocenters: head, chest, abdomen, and pelvis. Prior to treatment, the patient was imaged at the head, pelvis, and chest. Optimal couch shifts were determined for each isocenter under image guidance. The optimal IGRT shifts were determined using an in-house application that minimized dose deviation using criteria established through plan uncertainty analysis performed in Eclipse. Translational couch residuals were recorded and defined as the difference in the global shift calculated and the optimal couch position with shifts. Transit dosimetry was measured per arc, and analyzed using SNC PerFRACTION with a gamma criteria of 10%/5mm, 5%/5mm, and 5%/7mm. **Results:** Based on plan uncertainty analysis, clinical threshold for couch residuals were set to 7 mm (5 mm for chest isocenter) as there would be minimal impact on target coverage and organ sparing at those levels. Transit dosimetry showed that the average pass rate across all fields was 99.6%, 97.0%, and 99.2% for 10%/5mm, 5%/5mm, and 5%/7mm gamma criteria, respectively. Pearson correlation tests showed that there was weak correlation between gamma criteria and couch residuals. At stringent 3%/5mm gamma criteria, moderate correlation was found between lateral couch residuals for the head and chest and the head and chest arc analysis. **Conclusion:** Transit dosimetry showed high pass rates using our couch residual tolerances, which confirmed the plan uncertainty analysis performed during treatment planning.

Small-Cavity Detector Perturbation and Quality Correction Factors in Magnetic Resonance Imaging-Guided Radiotherapy Small Photon Beams

Y Cervantes-Espinosa^{1,2*}, J Duchaine^{1,2}, I Billas^{3,4}, S Duane³, H Bouchard^{1,2,5}, (1) Universite de Montreal, Departement de physique, Montreal, QC, CA, (2) Centre de recherche du Centre hospitalier de l'Universite de Montreal, QC, CA (3) National Physical Laboratory Teddington, UK (4) The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, London, UK (5) Departement de radio-oncologie, Centre hospitalier de l'Universite de Montreal, QC, CA

Purpose: Provide physical insights on detector dose-response to multiple megavoltage photon beam sizes coupled to magnetic fields and determine optimal orientations for measurements. **Methods:** Small-cavity detector (solid-state: PTW60012 and PTW60019, ionization chambers: PTW31010, PTW31021, and PTW31022) dose-responses in water are determined with Monte Carlo simulations (EGSnrc), using Elekta Unity 7 MV FFF phase-spaces of field widths between 0.25 and 10 cm, for four detector axis orientations: perpendicular to the B-field (1.5 T) with the beam parallel (orientation 1) or perpendicular (orientation 2 or 3 with FLorentz towards stem or tip); perpendicular to the beam and parallel to B-field (orientation 4). The B-field effect on perturbation factors is evaluated. The overall perturbation factor (P_{MC}) accounts for the extracavitary components, atomic composition, and density. For each orientation, the density (P_{ρ}) and volume averaging (P_{vol}) perturbation factors and quality correction factors ($k_{Q(B)}$) are calculated. **Results:** For solid-state detectors, P_{ρ} is unaffected by the B-field and field size. For chambers in B=1.5 T, it increases up to 1.564 ± 0.001 with decreasing field size over all orientations. For chambers, the B-field effect on P_{MC} is only significant for field widths <1 cm, increasing with decreasing field size in all orientations. For solid-state detectors, the B-field effect on P_{MC} exhibits different trends with orientation, indicating that the beam incident angle and geometry play a crucial role. A maximal effect of 1.221 ± 0.005 occurs in orientation 2. P_{vol} remains the most significant perturbation both with and without magnetic fields. In most cases, the B-field effect on P_{vol} is 1% or less, except for chambers PTW31021 and PTW31022 that over-respond and under-respond in orientations 2 and 3, respectively, at smaller fields. **Conclusion:** Solid-state detectors dose-response is strongly affected by the B-field in all orientations. In general, ionization chambers yield a $k_{Q(B)}$ closer to unity, especially in orientations 2 and 4.

A Non-Parametric Analysis to Identify High-Risk Vs. Low-Risk Anatomic Regions Associated with Reduced Overall Survival in the RTOG 0617 Clinical Trial Data

J Zhu^{1*}, M Thor^{2*}, A Apte², J Oh², A Rimner², J Deasy², A Tannenbaum¹, (1) Stony Brook University, Stony Brook, NY, (2) Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: Radiation dose to the cardio-pulmonary system has been identified as a new key detriment for risk of death in locally-advanced non-small cell lung cancer (LA-NSCLC). However, primarily one-dimensional dose metrics of pre-defined structures have typically been used for deducing this association. Here, we introduce an approach based on a metric called the unbalanced optimal mass transport (OMT) distance, which uses neither pre-selection of sub-regions nor normalization (total mass need not be preserved). The method ranked risk of death in the RTOG 0617 based on the distance. **Methods:** The 409 patients retrieved from The Cancer Imaging Archive with evaluable data were randomly split into training and validation subsets. Multi-step B spline image registration was used to deform CT scans and the associated dose distributions to a chosen patient. Pairwise unbalanced OMT distances of all patients were efficiently computed through a newly proposed

approximation method via vector-valued OMT, which measured the dose spread pattern and total dose amount differences. The distances were translated into risk scores by C-indices. Risk status in validation data was measured as distances to the training reference patients. Lastly, high-risk and low-risk regions were deduced according to the 50 riskiest (or least risky, respectively) reference patients. The locations of the sub-regions were qualitatively compared to those of eight deep learning auto-segmented cardio-pulmonary substructures. **Results:** The identified riskiest region overlapped with the base of the heart, including the ascending aorta, pulmonary artery and the superior part of the left atrium. In contrast, the 'safe' distributions mostly avoided all cardio-pulmonary substructures except for parts of the superior vena cava and right pulmonary artery. **Conclusion:** This OMT-based approach provides a tool to identify regions associated with survival without requiring pre-defined contours. For the RTOG 0617 dataset, base of the heart was identified as a critical region that influenced overall survival.

Blood Dose Calculation in Radiotherapy

A Hammi¹*, S Tattenberg², F Hueso-Gonzalez³, (1) TU Dortmund University, Brookline, MA, (2) Massachusetts General Hospital, Somerville, MA, (3) Massachusetts General Hospital, Boston, MA

Purpose: To understand how radiation modality and dose distribution impacts the dose delivered to the circulating lymphocytes, a dynamic computational model was developed to estimate the dose to the circulating blood for a variety of radiation treatment modalities. **Methods:** To describe the 4D propagation of blood particles through organs and radiation fields, an explicit Monte Carlo blood flow model was developed based on the whole-body hemodynamics. For head-and-neck patients, the large-scale architecture of cerebral arteries is extracted from MRA images. The propagation of the blood was described as laminar along the vasculatures and through radiation fields. A dynamic delivery model was implemented to simulate different radiation modalities such as proton pencil beam scanning (PBS) and passive scattering (PS) as well as photon therapy. The model included dynamic details of clinical delivery system, such as up-/down-ramping of the current as well as the dead time during steering between spot positions and switching between energy layers were all taken into account. **Results:** For a 2 Gy fraction, PBS reduced the average dose to the circulating blood by 1.9% compared to PS and by 30% compared to photon therapy. The fraction of blood receiving any dose was only 1.1% for PBS, compared to 7.3% and 18.1% for PS and photon therapy, respectively. The blood volume receiving at least 0.07 Gy, which is known to deplete the lymphocyte count by 2 percentage points, increased from 0.65% for PBS to 1.4% for PS and 2.1% for photon therapy. **Conclusion:** A computational model able to estimate the dose accumulated by the circulating blood for different radiation modalities and various dose rates and fractionation schemes was developed. Said model enables us to analyze a radiation modality's potential impact on the circulating lymphocyte count, which may be especially important given the growing interest in immunotherapy.

Enabling Few-View 3D Tomographic Image Reconstruction by Geometry-Informed Deep Learning

L Shen^{*}, W Zhao, D Capaldi, J Pauly, L Xing, Stanford University, Stanford, CA

Purpose: Traditionally, a tomographic image is formulated as an inverse problem for a given set of measured data from different angular views. Here, we propose a geometric-integrated deep learning model for tomographic imaging of 2D-3D reconstruction with ultra-sparse sampling across various patients. **Methods:** We propose a geometry-informed deep learning framework for 3D tomographic image reconstruction. Specifically, the proposed framework consists of three modules: a) a 2D projection generation network is developed to learn to generate novel-view projections from the given sparse views; b) a geometric back-projection operator transforms the 2D projections to 3D images, referred to as geometric preserving images, which geometrically relates the pixelated 2D input data to the corresponding ray lines in 3D space; and c) a 3D image refinement network learns to refine and generate the final 3D images. To evaluate the proposed approach, we experiment on a public CT dataset containing 1018 lung CT images, where 80% and 20% data are for training and testing, with the projection images are digitally produced from CT images using cone-beam CT geometry. **Results:** We deploy the trained model on the held-out testing set for few-view 3D image reconstruction, and compare the results with ground truth. For single-/two-/three-view reconstruction, average NRMSE / SSIM / PSNR values over all testing data are 0.368 / 0.734 / 20.770, 0.300 / 0.807 / 22.687 and 0.274 / 0.838 / 23.669, respectively. Beyond, we observe the proposed model could generate images closely to the target images although anatomic structures of different patients have a large variance, indicating the potential of the proposed model for volumetric imaging even with few views. **Conclusion:** We present a novel geometric-integrated deep learning model for volumetric imaging with ultra-sparse sampling across patients, which may present a useful solution in image-guided interventional procedures with simplified imaging system design.

Head-And-Neck IMRT Auto-Planning Through Fluence Map Prediction Using Progressive Growing of Generative Adversarial Networks

X Li¹*, QJ Wu¹, Q Wu¹, C Wang¹, Y Sheng¹, W Wang¹, H Stephens¹, F Yin¹, Y Ge², (1) Duke University Medical Center, Durham, NC, (2) University of North Carolina at Charlotte, Charlotte, NC

Purpose: To develop an IMRT auto-planning algorithm for head-and-neck cases, where optimal fluence maps were predicted from patient anatomy using Progressive Growing of Generative Adversarial Networks (PGG). **Methods:** PGG enhances the traditional architecture of Generative Adversarial Networks (GAN) with a multi-resolution design that is potentially more effective at capturing the complexity of the head-and-neck cases. In PGG, input was a series of 128x128 2D projections representing patient anatomy for 9 template beam angles. The networks were trained in 6 stages, where the output fluence map dimensions were 4x4, 8x8, ..., and 128x128 for 9 beams. Upon a new stage, up-sampling layers and convolutional layers were added to the generator. Generator output gradually changed from up-sampling of previous stage's output to the average of previous output and new convolutional layers' result. Ground truth (128x128) was downsampled by average filters to the same dimension with the output for loss calculation. Furthermore, an additional discriminator taking higher resolution input was added to the existing discriminator group with a gradually increasing weight. The discriminator group contains discriminators using (downsampled) ground truth, anatomic input, and generator prediction with different resolutions. Training, validation, and test patient numbers were 200, 16, and 15. For test patients, last stage's output was post-processed into predicted fluence maps and was converted into IMRT plans in TPS (PGG plans). **Results:** Preliminary results showed that PGG plans had overall acceptable plan quality for test patients, except that the maximum dose is high (whole-body D_{2cc}=123.0%). PGG plan D_{mean} in parotid L/R (22.2±2.5Gy/23.4±3.0Gy), oral cavity (24.6±7.0Gy), larynx (22.1±5.7Gy), pharynx (35.4±2.9Gy) showed no clinically relevant difference from benchmark plans (23.1±2.0Gy/23.9±2.3Gy/23.9±4.3Gy/22.7±4.8Gy/34.7±2.5Gy). PGG plan D_{0.1cc} in brain stem (17.5±3.8Gy) and cord+5mm (30.5±2.5Gy) was higher than in benchmark plans (15.5±2.7Gy/25.8±1.9Gy). **Conclusion:** The PGG-based head-and-neck IMRT planning algorithm has demonstrated encouraging plan quality. Further development and training are underway to improve performance.

Improvements in Beam's Eye View Fiducial Tracking Using A Novel Multilayer Imager

TC Harris^{1, 2, 3*}, J Seco^{2, 3}, D Ferguson⁴, M Jacobson¹, M Myronakis¹, I Valencia Lozano¹, M Lehmann⁵, P Huber⁵, R Fueglistaller⁵, D Morf⁵, HJ Mamon¹, JD Mancias¹, NE Martin¹, R Berbeco¹, (1) Department of Radiation Oncology, Brigham and Women's Hospital, Dana Farber Cancer Institute and Harvard Medical School, Boston, MA, (2) BioMedical Physics in Radiation Oncology, DKFZ, Heidelberg, Germany, (3) Department of Physics, University of Heidelberg, Heidelberg, Germany, (4) Department of Radiation Oncology, University of California San Francisco, San Francisco, CA, (5) Varian Medical Systems, Baden-Dattwil, Switzerland

Purpose: Electronic portal image devices (EPIDs) have been investigated previously for beams-eye view (BEV) applications such as tumor tracking but are limited by low contrast-to-noise ratio (CNR) and detective quantum efficiency (DQE). We used a novel multilayer imager (MLI) with better performance, consisting of four stacked flat-panels, to measure improvements in fiducial tracking during liver stereotactic body radiation therapy (SBRT) procedures. **Methods:** The prototype MLI was installed on a clinical TrueBeam linac in place of the conventional DMI single-layer EPID. The panel was extended during volumetric modulated arc therapy SBRT treatments in order to passively acquire data. A frame grabber card was connected to the imaging system. Images were acquired for six patients receiving SBRT to liver metastases over two fractions each, one with the MLI using all 4 layers and one with the MLI using the top layer only, representing a standard EPID. The acquired frames were processed by a previously published tracking algorithm modified to identify implanted radiopaque fiducials. Truth data was determined using respiratory traces combined with partial manual tracking. Results for 4- and 1-layer mode were compared against truth data for tracking accuracy and efficiency. Tracking and noise improvements as a function of gantry angle were determined. **Results:** Tracking efficiency with 4-layers improved to 82.8% versus 58.4% for the 1-layer mode, a relative improvement of 41.7%. Fiducial tracking with 1-layer returned a root mean square error (RMSE) of 2.1mm compared to 4-layer RMSE of 1.5mm, a statistically significant ($p<0.001$) improvement of 0.6mm. The increase in successfully tracked frames correlated strongly with reduction in noise using 4-layer mode ($r=0.913$). **Conclusion:** Increases in MV photon detection efficiency by utilization of a multi-layer imager (MLI) results in improved fiducial tracking for liver SBRT treatments. Future clinical applications utilizing BEV imaging may be enhanced by including similar noise reduction strategies.

Quantifying Radiation-Induced Lung Injury as a Function of Regional Radiation Therapy Dose Using Hyperpolarized-¹²⁹Xe MRI

L Rankine^{1, 2*}, Z Wang², E Bier², C Kelsey², S Das¹, L Marks¹, B Driehuys², (1) The University of North Carolina at Chapel Hill, Chapel Hill, NC, (2) Duke University, Durham, NC

Purpose: To establish a relationship between regional changes in lung gas exchange properties and radiation therapy (RT) dose. **Methods:** Six patients receiving conventional (2Gy/fx) RT for lung cancer underwent breath-hold hyperpolarized (HP)-¹²⁹Xe gas exchange MRI. Subjects were imaged pre- and 3-months post-RT. Gas exchange MRI utilizes the solubility and chemical shift of ¹²⁹Xe to facilitate 3D imaging of xenon in the lung airspaces (ventilation), alveolar interstitial barrier, and red blood cells (RBC). Voxel-wise ¹²⁹Xe signal ratios of barrier/airspace and RBC/airspace were computed to quantify the interstitial barrier uptake and RBC gas transfer properties of the regional lung tissue, the latter representing an end-to-end measure of function since it is a surrogate for oxygen transfer from alveoli to the bloodstream. Sequential MRI were rigidly registered, and deformed back to the planning CT. We excluded voxels in areas of high dose gradient (≥ 3 Gy/mm) and those with low ventilated xenon signal (signal-to-noise ratio < 5), and binned voxels according to the RT dose received (5Gy bin-width). The per-voxel changes in ventilation, barrier uptake, and RBC gas transfer were computed via registered image subtraction. In addition, whole-lung average changes in HP-¹²⁹Xe-measured function were calculated for comparison against changes in the pulmonary function tests (PFTs), forced vital capacity (FVC) and diffusing capacity for carbon monoxide (DLCO). **Results:** A least squares fit of data between 5-50Gy showed that ventilation decreased linearly ($R^2=0.96$) by 0.25% Gy⁻¹ between pre- and 3-month post-RT imaging, barrier uptake increased linearly ($R^2=0.94$) by 0.74% Gy⁻¹ (as expected from alveolar interstitial thickening post-RT), and RBC transfer decreased by 0.48% Gy⁻¹ ($R^2=0.73$). Whole-lung increases in barrier signal correlated significantly with decreases in both Δ FVC ($R^2=0.88$, $P<0.01$) and Δ DLCO ($R^2=0.71$, $P<0.04$). **Conclusion:** Hyperpolarized-¹²⁹Xe MRI can detect RT-induced, dose-dependent changes in regional lung function and may prove useful in diagnosing, grading, and quantifying RILI.

Predicting Locoregional Recurrence Through Multi-Modality and Multi-View Deep Learning for in Head & Neck Cancer

J Guo^{1*}, R Wang², Z Zhou³, K Wang⁴, R Xu⁵, J Wang⁶, (1) Xidian University, (2) Xidian University, CN, (3) University of Central Missouri, Warrensburg, MISSOURI, (4) UT Southwestern Medical Center, Dallas, TX, (5) Putian University, (6) UT Southwestern Medical Center, Dallas, TX

Purpose: Locoregional recurrence (LRR) remains one of leading causes in head and neck (H&N) cancer treatment failure despite the advancement of multidisciplinary management. Accurately predicting LRR in early stage can make an optimal personalized treatment plan. We aim to develop a multi-modality and multi-view convolutional neural network (mMmV-CNN) for LRR prediction. **Methods:** Totally 206 patients are used in this study, which includes the image and clinical parameters with H&N cancer received radiation treatment from September 2005 to November 2015. In mMmV-CNN, a dimension reduction operator is developed by rotating the 3D CT and PET data along the vertical axis and the average projection along horizontal axis is calculated to obtain 2D image in different directions to make fully use of the information from 3D data. The multi-view strategy is then adopted to improve the performance of 2D CNN for extracting image feature by aggregating features extracted from different views. As such, the number of network parameters is greatly reduced, and the spatial 3D context information can be effectively used as well. Furthermore, we design a multi-modality deep neural network which can be trained in an end-to-end manner and jointly optimize the deep features of CT, PET and clinical parameters. **Results:** Five-fold cross-validation is performed in this study. The area under the curve (AUC), sensitivity, specificity and accuracy when combining CT, PET and clinical data can achieve 0.8052, 0.7347, 0.8089, 0.7913, respectively. **Conclusion:** In this study, a new mMmV-CNN model was developed for accurately identifying H&N cancer patients at high-risk for LRR after definitive radiation or chemoradiation therapy. Compared with the single-view method, the multi-view method fully utilizes image data from different angles to obtain more discriminative information. Furthermore, the experimental results demonstrated that mMmV-CNN can obtain better performance by combining CT, PET and clinical features.

A Development of An In-House Software for Motion Monitoring During the Stereotactic Paraspinal Treatment

Q Fan^{*}, H Pham, P Zhang, X Li, T Li, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: Stereotactic paraspinal treatment has become increasingly popular due to its favorable clinical outcome. An often-overlooked factor that compromises the effectiveness of such treatment is the patients' involuntary intrafraction motion. This work introduces an in-house software that quantifies such motion for accurate motion monitoring. **Methods:** The software requires a separate full-trajectory CBCT after patient setup to establish reference projections. Once treatment starts, the software reads in the intrafraction motion review (IMR) image acquired by TrueBeam and compares it against the corresponding reference projection to instantly determine the 2D shifts of the vertebrae being monitored. To evaluate its performance, an anthropomorphic phantom was shifted 5 mm in three orthogonal directions, separately and altogether, immediately after the full-trajectory CBCT but prior to treatment. For each scenario of shift, the same nine-angle fixed-gantry IMRT plan was delivered. At each angle, three IMR images were acquired sequentially every 200 MU. For each IMR image, the software-reported 2D shift was compared with ground truth. These tests were repeated with three degree of rotation, pitch, and roll, respectively. **Results:** The maximum standard deviation of the software-reported shifts for each set of three IMR images was 0.16 mm, with 93rd percentile below 0.03 mm. For translational shift, the maximum registration error was 0.44 mm, with 93rd percentile below 0.26 mm. Left unaccounted for, rotation and pitch degraded the registration accuracy mainly in the longitudinal direction while roll degraded it mainly in the lateral direction. The maximum registration errors under rotation, pitch, and roll were 2.97, 1.44, 2.72 mm, respectively. **Conclusion:** Our in-house software has high repeatability and accuracy in registering IMR images with the reference projections for motion monitoring. Rotation, pitch, and roll degrade registration accuracy and need to be accounted for in future work.

The presented study is partially supported by Varian Medical Systems Research Collaborations.

A Real-Time Surveillance System to Improve the Safety of MRI in Radiation Oncology

G Tang*, P Medin, A Pompos, S Jiang, Y Yan, UT Southwestern Medical Center, Dallas, TX

Purpose: To improve safety around MRI simulators and MRI-LINACs using an in-house developed Real-time Location System. **Methods:** A Real-Time Location System (RTLS) was developed using Bluetooth Low Energy (BLE) technology. A grid of Bluetooth Low Energy (BLE) sensors was installed throughout the radiation oncology treatment facility at University of Texas Southwestern Medical Center (UTSW), and an artificial intelligence (AI)-based localization engine was developed that enabled us to locate staff, patients, and devices within the facility at a high accuracy (99.99%). Based on the RTLS infrastructure, a suite of applications was developed to locate, verify and time tagged subjects. At each machine console, an iPad installed with the electronic checklist application, called RO-Lifeguard, helps the care team to locate and verify patients and patient-specific accessories prior to treatment. To increase the safety of our MRI simulator and MRI-LINACs, a warning system was implemented in RO-Lifeguard to alert the care team when a tagged MR-unsafe device approaches MR Zone 3. The warning can be issued by audible alarm and/or by a warning message on the RO-Lifeguard screen. **Results:** The whole radiation therapy facility was divided into 450 zones, each of which is given an MR safety level. Each tagged subject (person and/or device) is also assigned an MR safety status. The RTLS engine was able to identify subjects' location with high accuracy in treatment areas. When the MR safety policy logic is activated in the RTLS system, the entire facility is under MR safety surveillance in real-time. **Conclusion:** MRI simulators and MR-LINACs are powerful tools that improve tissue delineation and offer a great solution to adaptive radiation therapy for moving targets, but they also require an increased commitment to safety practices. Our RTLS-based MR safety surveillance system provides an extra layer of protection in areas where MRI simulators and MR-LINACs are present.

Purpose: To carry out a large international validation of how dose prediction quality translates to plan quality in a radiotherapy knowledge-based planning (KBP) process. **Methods:** We collected dose predictions for head-and-neck cancer radiotherapy from 21 different research groups internationally who participated in the OpenKBP Grand Challenge. Each research group used the same training dataset (n=200) and validation dataset (n=40) to develop their methods. These methods predicted dose on a testing dataset (n=100), and those 2100 unique dose predictions were input to a previously published plan optimization method to generate 2100 treatment plans. The predictions and plans were compared to the ground truth dose via: (1) error, the mean absolute voxel-by-voxel difference in dose; and (2) quality, the mean and maximum deviation across 23 dose-volume histogram (DVH) criteria. **Results:** The range in median prediction error among the top 20 methods was 2.3Gy to 12.0Gy, which was 6.8Gy wider than the range in median plan error of 2.1Gy to 5.0Gy. One method also achieved significantly lower prediction error (P<0.05; one-sided Wilcoxon test) than all the other methods, however, it generated plans with error that was not significantly lower than 28.6% of the other methods. Additionally, predicted dose was consistently lower quality than plan dose. Half (n=1050) of all predictions and plans had an average deviation that was 0.1Gy worse and 0.8Gy better than the ground truth dose, respectively. Similarly, half of all predictions had a maximum deviation that was 3.7Gy worse than the ground truth dose, which was 1.0Gy worse than half of all plans. **Conclusion:** Many dose prediction methods can achieve low error, however, optimization often improves upon the predictions and eliminates significant differences between prediction methods. Thus, it is critical that we improve the optimization stage in KBP to get better utility out of the existing high-quality dose prediction methods.

Development of a Novel Dual-Modality Balloon Implant for Simultaneous HDR Brachytherapy and Magnetic Nanoparticle Hyperthermia of Brain Tumor Resection Cavities

S Wan^{1*}, D Rodrigues², P Stauffer¹, Y Yu¹, J Kwiatkowski³, K Judy⁴, O Khanna⁴, M Bloem⁵, R Goldstein⁶, M Hurwitz¹, W Shi¹, (1) Department of Radiation Oncology, Philadelphia, PA, (2) University of Maryland School of Medicine, Baltimore, MD, (3) Mae Group, MA, (4) Thomas Jefferson University, Neurosurgery Department, Philadelphia, PA, (5) Pheonix Deventures, CA, (6) AMF Life System, MI

Purpose: Glioblastoma multiforme is an aggressive brain tumor that generally recurs locally and has a dismal median survival < 18 months. In vivo studies have shown that thermal enhancement ratio (TER) of up to 5 can be achieved when hyperthermia and radiation are applied simultaneously, which is not currently possible. The goal of this project is to develop a novel thermobrachytherapy (TBT) balloon implant to accomplish this. Our phase I development has 3 specific aims: i) to

fabricate TBT balloons; ii) to evaluate the device for compatibility of hyperthermia and HDR and to characterize thermal and radiation dosimetry in laboratory studies; and iii) to characterize heating patterns in perfused brain tissue via in vivo animal studies and to evaluate reliability and heating performance. **Methods:** The TBT balloon has two layers: an inner layer filled with saline to expand the resection cavity into approximately spherical shape, and an outer layer filled with magnetic nanoparticle (MNP) solution that absorbs energy from an external magnetic field to generate heat. The balloon is connected to a shaft that houses 4 ports to fill inner and outer layers, insert an HDR source into the balloon center and a fiberoptic sensor into the outer balloon for temperature monitoring. Five TBT balloons were fabricated. Gafchromic film was used to determine HDR dwell position to achieve radiation dose distribution centered at the balloon center. Optically stimulated luminescent dosimeters were used to measure radiation dose. **Results:** The presence of MNP, a 133 kHz magnetic field, and 43-55°C heating did not affect radiation dose significantly. Thermal mapping demonstrated spherically symmetric heating in phantom and will continue in vivo. **Conclusion:** Novel dual-modality balloons have been fabricated and tested in the lab. Because of the positive lab results, we will continue with in vivo dosimetry in preparation for phase II clinical development.

Prescription Tradeoff Decision Support for Pancreas SBRT: From Templates to Artificial Intelligence Models

Y Xie^{1*}, R Li¹, W Wang¹, M Hito², L Zhang³, W Giles¹, H Stephens¹, Q Wu¹, F Yin¹, Y Ge⁴, Q Wu¹, Y Sheng¹, (1) Duke University Medical Center, Durham, NC, (2) Princeton University, (3) North Carolina State University, (4) University of North Carolina at Charlotte, Charlotte, NC

Purpose: Radiation oncologists typically employ template constraints for dose prescription and OAR sparing. However, dose prescription and OAR constraints often form competing constraint pairs which require tradeoff discussions between the planner and radiation oncologist. In this study, we designed a novel artificial intelligence (AI) tool to support radiation oncologists in making optimal tradeoff decisions. It that can estimate achievable tradeoff scenarios before treatment planning starts. **Methods:** This decision support tool has an effective user interface module that integrates with a treatment planning system to facilitate the prescription decision process. It is powered by a machine learning core which is trained to learn the balance between PTV coverage and OAR sparing from a dataset of 98 pancreatic SBRT cases retrospectively selected for this study. A 10-fold cross validation was performed comparing clinical plan's PTV coverage (V100%) with model predicted values. These comparisons were further stratified by attending physicians to gain additional insights into decision making process. Cases with large discrepancy were identified, analyzed, and re-planned to validate and assure the achievability (i.e. accuracy) of predictions. **Results:** The clinical plan PTV V100% was $87.7 \pm 14.5\%$ while the model predicted value was $90.5 \pm 9.6\%$ ($p=0.005$). Model agreement discrepancy was observed among attending physicians. Among all 98 cases, nine cases were identified with large variation from model predictions. For the re-planned cases, an average of 15.3% improvement was achieved over the original clinical plans, indicating the AI model's accuracy and benefits for clinical planning guidance. **Conclusion:** The AI decision support assistant provides dynamic and interactive tradeoff guidance. Its decision support prior to treatment planning can save valuable efforts from both the planning team and radiation oncologist. Moreover, this tool should also work effectively as a training tool providing valuable tradeoff insights for fresh resident who are new to the treatment site.

Understanding Physician's Preference in Treatment Planning of Stereotactic Body Radiation Therapy of Prostate Cancer

Y Gao*, C Shen, Y Gonzalez, X Jia, The University of Texas Southwestern Medical Center, Dallas, TX

Purpose: Understanding physician's preference in treatment planning is necessary to develop automatic treatment planning approaches capable of generating plans favorable by the physician. The purpose of this study is to develop a deep learning based Virtual Physician Network (VPN) that can understand physician's preference on plan approval for prostate cancer Stereotactic Body Radiation Therapy (SBRT) plans and suggest where to improve, if a plan is rejected. **Methods:** The VPN takes one Planning Target Volume (PTV) and eight Organs at Risk (OAR) contours, as well as a dose distribution of a plan seeking approval as input. It outputs the probability of approving the plan, and a dose distribution indicating improvements to be applied to the input dose. VPN includes two sub-networks. VPN1 uses an attention-gated U-Net to predict where to improve in the input dose. VPN2 has the first half architecture of VPN1 followed by fully-connected layers to output a probability of having the given plan approved. Due to the lack of unapproved plans in our database, two networks are alternatively trained under an adversarial framework. The intermediate results generated by VPN1 in the training process are suboptimal dose, which can naturally serve as training data for VPN2. 44 prostate cancer patients who received 45 Gy in 5-fraction SBRT were used in 4-fold cross-validation. **Results:** VPN can differentiate high- and low- quality plans with Area under the curve 0.91 ± 0.02 . For unapproved plans, after applying VPN's suggestion on dose improvement, V50 of bladder, rectum, and penile bulb, max dose of urethra, V95 and D95 of PTV agreed with ground truth with differences of $0.59 \pm 0.78\%$, $0.8 \pm 1.01\%$, $0.04 \pm 0.03\%$, $0.75 \pm 0.46\text{Gy}$, $0.34 \pm 0.21\%$, and $0.75 \pm 1.27\text{Gy}$. **Conclusion:** VPN was developed to accurately predict a physician's preference in plan approval and can provide useful suggestions on how to improve the dose distribution.

Use of CBCT for Reducing QACT Frequency in Intensity Modulated Proton Therapy: Head and Neck

W Yao*, B Zhang, D Han, J Polf, S Vedam, G Lasio, B Yi, University of Maryland School of Medicine, Baltimore, MD

Purpose: Anatomic variation has a significant dosimetric impact in intensity modulated proton therapy. Traditionally weekly or bi-weekly CT scans, called QACTs, are used to monitor the anatomic and the resultant dose change to determine if an adaptive plan is needed. Frequent CT scans result in unwanted patient dose and clinical workload. This work proposes a CBCT-based approach to reduce the frequency of QACTs by analyzing patient setup CBCTs. **Methods:** we retrospectively analyzed 20 head and neck patients, associated with 885 CBCTs, 105 QACTs, and 22 adaptive plans. For each CBCT, water equivalent thickness (WET) along the pencil beam path between the target surface and the patient body was calculated. For each treatment plan, the WET of the first day CBCT (1st CBCT) was used as the reference, and the mean WET change in each CBCT from the 1st CBCT was used as the surrogate of proton range deviation. Using CBCTs acquired prior to a QACT, a linear regression model was generated to predict the mean WET change on QACT day. The impact of range deviation on target dose was calculated as (1) the predicted mean WET change weighted by the monitor units of each fields and (2) the ratio of mean WET change in (1) over the effective diameter of the target. **Results:** When the estimated mean WET change was larger than 8 mm or 8% of the effective diameter of the target, a QACT was required, and otherwise if the change was less than 8 mm AND 8%, the QACT could be skipped. Overall, 40 QACTs could be reduced from 105 QACTs. At least one QACT could have been omitted in 18 out of the 20 cases. **Conclusion:** This study shows that QACT frequency can be greatly reduced by calculating range deviation in patient setup CBCTs.

Development and Evaluation of a Bi-Polar Gated Respiratory Motion Management Strategy for Lung SBRT

Z Li¹*, L Zhang², J Qiu², S Zhang³, X Zheng², Q Wu⁴, (1) Department of Radiation Oncology, Shanghai Sixth People's Hospital, (2) Department of Radiation Oncology, Fudan University Huadong Hospital, (3) Fudan University, (4) Duke University Medical Center, Durham, NC

Purpose: A novel bi-polar (BP) gated motion management strategy for lung SBRT is proposed. The feasibility is evaluated geometrically and dosimetrically. **Methods:** In BP strategy, patient holds the breath at the end of inhale and exhale under audio/video coaching with dose only been delivered during breath hold. 10 previous lung SBRT patients with 4DCT were selected, each having tumor motion larger than 1cm. BP was compared with other strategies: free breathing (FB), gating at end of inhale (GI), exhale (GE), and real-time tracking (RT). Lung volume and tumor position were used to determine the end-exhale and end-inhale phases. The GTV was contoured at each 10-phases of 4DCT to determine the ITV for each strategy. PTV is formed by 1mm expansion of ITV. IMRT/VMAT plans were generated to give 60Gy to >95% of PTV and lung dose was compared. Breathing patterns' stability and repeatability were investigated on 8 volunteers and recorded by RPM and analyzed. **Results:** The breath-hold of the BP strategy is found to be comfortable over 3 minutes, with repeatability in periodicity at 1.00 ± 0.03 and duty cycle at 65%. Using GI as reference, the ITV for FB, GE, RT, and BP are 1.83 ± 0.50 , 1.00 ± 0.25 , 0.63 ± 0.14 , 0.59 ± 0.26 , respectively. RT is larger than BP due to the limited number of phases in 4DCT that produce larger GTV volume in fast-moving phases. In IMRT plans from 3 patients, the lung V5Gy normalized to GI are 1.33, 1.17, 1.02 and 0.95, respectively, with similar trends in VMAT plans. **Conclusion:** The bi-polar strategy is feasible for lung SBRT. The breathing pattern can sustain a long treatment time with a high duty cycle. Compared to other strategies, it has the smaller ITV, therefore a smaller treated volume and lower normal tissue toxicities. It is less complex to implement than real time tracking.

Predicting the Efficacy of Spacer Placement for Pancreatic Cancer Using a Novel Patient-Specific Virtual Spacer

H Hooshangnejad¹*, K Ding², (1) Johns Hopkins University, School of Medicine, Biomedical Engineering, Baltimore, MD, (2) Johns Hopkins University, School of Medicine, Radiation Oncology and Molecular Radiation Sciences, Baltimore, MD

Purpose: Stereotactic body radiation therapy (SBRT) is an effective way to achieve local-regional control for pancreatic cancer but is limited by proximal organs' at risk (OARs). Our previous clinical trial demonstrated that endoscopic ultrasound-guided injection of hydrogel spacer increases separation between target and duodenum. Yet, spacer's clinical benefits highly depend on patient anatomy. We developed a virtual spacer for pancreatic hydrogel spacer to generate augmented data to design a decision support system (DSS) and predict patient-specific dosimetric benefits. **Methods:** A finite element method oriented spacer simulation algorithm (FEMOSSA) is developed and defined using the material properties, boundary conditions, surface interfaces, and interactions based on patient contour. Finite element analysis software is used to solve the differential equation system generated by FEMOSSA. Simulation accuracy was evaluated by pre-post injection CTs from four cases and quantified by dice similarity coefficient (DSC), overlap volume histogram (OVH), and radial nearest neighbor distance (RNND). Four virtual spacer scenarios were simulated for 15 SBRT patients: no injection, injection in pancreas interface with duodenal sections D1-D2, D1-D2-D3, and D1-D2-D3-D4. 60 corresponding SBRT plans (33Gy/5 fractions) are used for designing a Bayesian DSS. **Results:** Average target and duodenal DSC increased, 0.86 to 0.89 and 0.44 to 0.63, respectively. Average mean and 5th percentile RNNDs differed by 0.5 and 2.1mm. OVH thresholds show average of less than 0.75mm difference. Results demonstrate a spacer-location-independent decrease in duodenal V20Gy and a highly spacer-location-dependent change in V33Gy. L1cc and L20cc (tumor expansion overlapping 1cc and 20cc duodenal volume) are good predictors of V20Gy and V33Gy. L1cc>14mm results in V33Gy=0. Bayesian DSS predicts spacer injection related improvement in BED with root mean squared error of 3.6Gys. **Conclusion:** A novel patient-specific virtual spacer is developed and validated for pancreas SBRT, and used to design DSS that indicates hydrogel efficacy, optimum location, and expected improvement.

Stereotactic Arrhythmia Radioablation for Treating Refractory Ventricular Tachycardia

S Oh¹*, E Liu², M Trombetta¹, G Shaw², A Thosani², J Sohn¹, (1) Division of Radiation Oncology, Cancer Institute, Allegheny General Hospital, Allegheny Health Network, Pittsburgh, PA (2) Division of Cardiac Electrophysiology, Cardiovascular Institute, Allegheny General Hospital, Allegheny Health Network, Pittsburgh, PA

Purpose: To report the feasibility of single fraction stereotactic arrhythmia radioablation (STAR) in patients with refractory ventricular tachycardia (VT) based on co-registration of electroanatomic (EA) map and planning images. **Methods:** A cardiac electrophysiologist acquires EA maps using the Carto3® system (Biosense Webster, Irvine, CA, USA) and defines the target region during an electrophysiology study. The EA map consists of 3D cardiac anatomy and electrical activity at any given mapped point. The EA target map is registered to the planning CT by aligning the left-ventricle (LV), right-ventricle (RV), left-atrium (LA), and available reference structures with defined contours on the MR/CT image based on iterative closest point algorithm. In-house software was developed for converting the EA image format to DICOM and registering reference structures. The simulation, planning, and treatment is performed with a standard STAR technique: a single fraction of 25 Gy using volumetric-modulated arc therapy or dynamic conformal arc therapy depending on the target shape. **Results:** Three patients with refractory VT were treated by defining the target based on registering EA maps and contours on MR/CT. Dice similarity indices between transferred reference map and contours are 0.83 ± 0.04 and 0.72 ± 0.04 for LV and LA/RV, respectively. The target area is confirmed based on the consensus of cardiac electrophysiologists and radiation oncologists and expanded to an internal target volume (ITV) and a planning target volume (PTV), which provides a 5-mm margin on the ITV. **Conclusion:** The quality of the transferred map on the image was sufficient to localize the treatment region accurately although we continue to refine the transferred target map. Longer follow-up is required to determine the true safety and efficacy of this therapy.

Single-Isocenter/Multi-Target (SIMT) SRS to Multiple Brain Lesions Via Dynamic Conformal Arcs (DCA)-Based VMAT with MLC Aperture Shape Controller

S Land^{*}, A Palmiero, M Bernard, D Pokhrel, University of Kentucky, Lexington, KY

Purpose: Applying SIMT-SRS to multiple brain lesions has improved treatment efficiency, patient compliance, patient comfort, and clinic workflow. When targeting multiple brain lesions using highly modulated SIMT-VMAT, the inherent risk of small field dosimetry errors can compromise the treatment quality. Herein, an MLC aperture-shape controlled method is proposed to mitigate the effects of small field dosimetry errors. **Methods:** Seven complex SRS patients, each with 2-8 brain lesions, were selected with an average target size of 13.04 ± 8.83 cc. Treatment plans were developed for each patient using single-isocenter HyperArc VMAT with Encompass device and a 10X-FFF beam, prescribing 20 Gy to each lesion. Alternatively, patients were re-planned using modified HyperArc VMAT, implementing a DCA-based dose and a high priority MLC aperture-shape controller prior to optimization. Identical HyperArc geometry, isocenter location, planning parameters, and objectives were used. **Results:** For similar target coverage, conformity, and dose gradient, DCA-VMAT increased average dose to gross tumor volume by 1.5 Gy. It showed slightly higher V8Gy and V12Gy values, increasing by 4.2 cc and 0.3 cc on average, respectively. However, critical organ (optic apparatus, brainstem, and hippocampi) maximal doses and mean brain doses were decreased with DCA-VMAT. Moreover, the DCA-VMAT plan decreased the total monitor units, beam modulation factor, and beam-on time by an average of 1846 MU, 0.92, and 1.37 min, respectively. Independent dose verification through Monte Carlo (MC) code

showed treatment planning system agreement for DCA-VMAT within 3%, decreased from the 6% of HyperArc VMAT. **Conclusion:** Modified HyperArc VMAT, utilizing DCA-based dose and MLC aperture-shape controller, provided similar plan quality with substantially decreased total monitor units, beam modulation, and beam-on time. This arguably suggests that the modifications further improve SIMT HyperArc treatments for multiple brain lesions. Independent MC calculation showed reduction of small field dosimetry errors and likely patient setup uncertainties via DCA-VMAT.

TH-F-TRACK 6-05

Comparison Between the HYPERSCINT RP200 Scintillation Detector and Other Small Field Detectors for 10MV FFF SRS Beam Modelling On a VersaHD Linear Accelerator

J Morin, JF Cabana, M Goulet*, D Theriault, CISSS - Chaudiere-Appalaches, Levis, QC, CA

Purpose: Plastic scintillation detectors (PSDs) have advantageous dosimetric properties, including small size and energy independence, which make them ideal candidates for small field dosimetry. This work aims to quantify the performance of the HYPERSCINT RP200 (Medscent inc., Quebec city, Canada) in the process of beam modelisation for a small field stereotactic radiosurgery (SRS) program. **Methods:** Dose profiles, percent depth doses and output factors were acquired as part of the commissioning of a 10MV FFF field on a VersaHD linear accelerator (Elekta). These measurements were carried out using a HYPERSCINT RP200, a Razor diode (IBA), GafChromic EBT3 films (Ashland), an Advanced Markus parallel plate ion chamber (PTW), an Exradin A26 cylindrical ion chamber and an Exradin A1SL cylindrical ion chamber (Standard Imaging). Comparisons between each detector were made using percentage differences and distance to agreement criteria. **Results:** Better than 0.3 gamma index (1%/1mm) was achieved between the HYPERSCINT RP200, the Razor diodes and the GafChromic EBT3 film in small field dose profiles. Lower than 0.5% dose difference was met between the PSD and the Advanced Markus in percent depth doses. Smaller than 2% agreement was achieved when comparing output factors from the RP200 and every other detectors. Average differences $\pm$ standard deviations from output factors measurements were as follow: Razor Diode: $(1.1 \pm 0.4)\%$; GafChromic films: $(0.8 \pm 1.1)\%$; A26 ion chamber: $(0.3 \pm 0.3)\%$; A1SL ion chamber: $(0.5 \pm 0.4)\%$. **Conclusion:** These results demonstrate the capability of the HYPERSCINT RP200 to perform accurate small field dosimetry and beam data acquisition. This versatility in profiles, PDDs and output factor acquisition would allow for significant time savings during the commissioning process of small radiation fields. In the author's institution, the 10MV FFF beam modelisation for SRS was entirely performed using data from this PSD detector.

TH-F-TRACK 6-06

Assessment of the Dosimetric Impact of Rogue Leaf Pair Openings in Modulated Stereotactic Radiosurgery Plans

K Jones^{1*}, A Templeton², Y Liao¹, J Van Schelt¹, Z Grelewicz¹, J Turian¹, (1) Rush University Medical Center, Chicago, IL, (2) Auckland DHB, Auckland, New Zealand

Purpose: Optimization of modulated stereotactic radiosurgery (SRS) plans sometimes results in (i) leaf pair openings that do not irradiate the planning target volume (PTV) and (ii) individual leaf ends far (>2 mm) outside the PTV. Our goal is to understand the dosimetric impact of these rogue leaf openings. **Methods:** Single fraction, modulated Varian Eclipse SRS plans from 10 patients were selected retrospectively. After projecting a 2 mm expansion of the PTV (PTV+2mm) onto the isocenter plane, leaf pair openings not irradiating the PTV+2mm were flagged as superfluous. Individual leaves were also flagged as nonconformist if there was a gap between the leaf end and the PTV+2mm projections. Two modified plans were generated with in-house software while respecting machine parameters: for both "clean" and "conformed" plans, superfluous leaf openings were pushed behind the jaws. Additionally, in "conformed" plans, the nonconformist leaf ends were pushed to the edge of the PTV+2mm to enforce conformality. The doses for the modified plans were recalculated, renormalized to the same PTV coverage, and DVH metrics were compared. **Results:** Clean and conformed plans reduced total plan fluence by up to 12.9 and 14.7%, respectively. Despite this reduction in fluence, small changes in the maximum and minimum doses to 0.002cc of the PTV were observed (largest changes of 1.68 and -1.95%, respectively). Although conformed plans exhibited large relative changes in normal brain V2Gy, V5Gy, and V12Gy (up to -24.4, -15.8, and -16.4%, respectively) the maximum absolute change in V12Gy was -0.39 cc. **Conclusion:** Based on analysis of 10 patient plans, modulated SRS plans contain rogue leaf openings that unnecessarily irradiate normal tissue. Post processing can remove these rogue leaf positions without compromising PTV coverage. The resulting modified plans reduce normal brain V2Gy, V5Gy, and V12Gy.

TH-F-TRACK 6-07

Modeling Dosimetric Impact of Treatment Delivery Errors in Robotic Radiosurgery: Experimental Validation and Applications

M Liu^{1, 2*}, J E Cygler^{1, 2, 3}, E Vandervoort^{1, 2, 3}, (1) The Ottawa Hospital Cancer Centre, Ottawa, ON, Canada (2) Carleton University, Ottawa, ON, Canada (3) University of Ottawa, Ottawa, ON, CA

Purpose: A dose perturbation model is proposed to assess dose to target(s) that models delivery errors for treatments using respiratory motion tracking on CyberKnife. **Methods:** Motion-tracking residual errors are modeled as a spatial convolution of the planned dose with a probability distribution functions derived from data recorded in system log files. Uncorrected rotations are modeled by rotating the target volume about the imaging isocentre. The model estimates the accumulated dose volume by giving equal weights to each perturbation. For experimental validations, ten different experimental conditions are considered, including in-phase and out-of-phase internal and external breathing motion patterns (periodic motion and patient waveforms), with and without uncorrected rotations and for homogenous and heterogeneous phantoms emulating liver anatomy. The measured dose (using EBT3 radiochromic films) is compared to the perturbed dose using the gamma pass rate (2%/2mm or stricter criteria), and the penumbral spread and systematic dose shift if a motion phantom is employed. Four case studies are provided that demonstrate how the model can be used to assess plan robustness to delivery errors. It can also be used to evaluate the suitability of a patient-specific planning target volume (PTV) margins. **Results:** The gamma analyses ($> 96\%$ using 2%/2mm criteria) and the comparison of penumbral widths (≤ 2 mm) and systematic dose shift (< 2 mm) have validated the performance of this model. Dose to targets considering delivery errors can be significantly improved if treatments are planned following certain guidelines. **Conclusion:** The dose perturbation model is validated under various experimental conditions. It can be used to assess retrospectively dose to targets, evaluate the suitability of patient-specific PTV margins, or per-patient sensitivity to errors before treatment. It could enable adaptive planning processes, patient-specific PTV margins, and inform tolerances of treatments to uncorrected rotations.

This work was supported by The Ontario Consortium for Adaptive Interventions in Radiation Oncology, and a research grant from Accuray, Inc., CA.

Stanford VMAT TBI Experience: Automation in Treatment Planning

TH-F-TRACK 7-03

X. Gu, UT Southwestern Medical Center:

UT South Western VMAT TBI Experience: Automation in Treatment Planning and Delivery

Modern total body irradiation (TBI) uses inverse planning with volumetric modulated arc therapy (VMAT) and multiple iso-centers to achieve uniform dose for the total body while protecting critical organs such as lungs and kidneys. The feasibility and early clinical experience have been published in the literature. The entire process was extremely time consuming and complex. With different treatment planning systems and delivery platforms, this education session can share experts' clinical experience and technology development to automate and streamline processes of treatment planning, patient setup, and treatment delivery. Knowledge gained from this session can be applied and generalized to other treatment sites involving large treatment volumes such as total bone marrow and total lymph node irradiation. In this session, three experts from different institutions will discuss their clinical experiences of clinical implementation of modern TBI.

The learning objectives are:

1. Learn how to use an automated workflow to combine the head-first and feet-first CT scans to a total body CT scan.
2. Learn how to use an automated workflow to divide planning target volumes and to create multiple iso-centers and dose junction regions.
3. Learn how to use automations to streamline the planning, patient setup, and delivery processes for adult and pediatric patients.
4. Learn the early clinical experiences and clinical outcomes of VMAT TBI.

Ping Xia received research grants from AVO and Philips outside of this research topic

A Chatbot for the Staff in Radiotherapy Using Artificial Intelligence and Machine Learning

K Li¹, J Chow^{2*}, (1) York University, Toronto, ON, CA, (2) Princess Margaret Cancer Centre, Toronto, ON, CA

Purpose: A chatbot personalized by artificial intelligence and machine learning is built to provide educational information for staff in radiotherapy. The topics covered include interdisciplinary knowledge in radiation oncology, medical physics, radiotherapy, and radiation safety. **Methods:** The Bot was constructed using the IBM Watson Assistant functionalities on the IBM cloud. The Bot had ability to communicate with radiation staff by answering some simple questions regarding radiotherapy, or by multiple choice to the user from a list of options. A layered structure approach was used in the workflow of the Bot to interact with the user. Through selecting different topics in the list and communication between the Bot and user, he/she will finally acquire the requested information. In addition, communications between the Bot and user will be used in machine training leading to a more accurate response to the user's question. **Results:** The user interface of the Bot is a front-end window operating on an internet of things such as smartphone, tablet or laptop. The user can type in a question or anything to communicate with the Bot. In the communication, if the Bot cannot identify what the user needs, the Bot will provide a list of options to the user as guidance. Through selecting different topics on the list, another list with more detailed breakdown of the topic will pop up, so that the user can obtain his/her request accurately and quickly. The Bot acquires knowledge through interactions with the users. **Conclusion:** It is concluded that a chatbot with characterization supported by machine learning can provide information regarding radiotherapy to the radiation staff more efficiency, and can be used in staff training. This Bot is particularly useful for quick search such as looking for physics data or a review of some radiation safety protocol conveniently.

This work is currently supported by the Planning and Dissemination Grants, Institute Community Support, Canadian Institute of Health Research.

PO-GePV-E-02

Clinical Diagnostic Reference Levels in Interventional Neuroradiology in Qatar

H Al Naemi^{1*}, V Tsapaki², A Mohamed³, A Own⁴, S Patro⁵, A Aly⁶, M Kharita⁷, (1) Hamad Medical Corporation, Al Dawha, DA, (2) Konstantopoulou Hospital, 142 33, Nea Ionia, Athens, Greece, (3) Hamad Medical Corporation, QA, (4) Hamad Medical Corporation, QA, (5) Hamad Medical Corporation, QA, (6) Hamad Medical Corporation, QA, (7) Hamad Medical Corporation, QA

Purpose: The objectives of this study were to: 1) evaluate patient radiation exposure in neuroradiology interventional (INR) procedures and 2) establish Diagnostic Reference Levels (DRLs) for stroke (S), brain aneurysms (AN) and brain arteriovenous malformation (AVM) clinical indications. **Methods:** Adult patient data undergoing cerebral endovascular treatment for S, AN and AVM were retrospectively collected using specially designed collection forms. The methodology described in the International Commission on Radiological Protection (ICRP) Report 135 was followed to establish clinical DRLs in terms of Kerma-Area Product (KAP), frontal (CDf) and lateral Cumulative Dose (CDl), fluoroscopy time (T), total number of images (Ni) and total number of runs (Nr). Collection forms were prepared in excel format in order to assist data analysis. The forms aimed to include patient demographic information (gender, age, weight, height, etc) X-ray modality technical parameters (fluoroscopy time (T), number of images (N), number of runs (r) and operator information (contact details, years of experience). Only adult patients (16≥ years of age) would be included in the study. **Results:** This study included data from 209 adult patients. National DRLs in terms of KAP, CDf, CDl, T, Ni and Nr for S, AN and AVM were 78 Gy cm², 380 mGy, 118 mGy, 12 min, 440, 157 for stroke, 85 Gy cm², 610 mGy, 96 mGy, 20 min, 720, 20 for AN and 180 Gy cm², 1144 mGy, 540 mGy, 36 min, 1380 and 30, respectively. Comparison was restricted as most recent literature refers to the technique and not the clinical indication. **Conclusion:** This is the first study reporting national DRLs based on clinical indication for INR procedures. The established national clinical DRL values will further facilitate patient dose optimization and quality improvement process within Hamad Medical Corporation and the state of Qatar.

PO-GePV-E-03

Brachytherapy Quality: An Innovative Approach to Addressing Institution and Practitioner Proficiency

M Roumeliotis*, T Meyer, S Quirk, Tom Baker Cancer Centre, Calgary, AB

Purpose: To establish a technology-enhanced simulation environment for brachytherapy that facilitates implant quality assessment through simulated end-to-end delivery. **Methods:** Implantable anthropomorphic phantoms were developed to facilitate simulated implants for permanent seed implant brachytherapy for prostate and breast procedures. Institutional implant quality is primarily evaluated by seed placement accuracy, which is the difference between the planned and delivered seed locations. Implant quality is, in part, a measure of the quality of the brachytherapy commissioning process and programmatic implementation, which is a core competency of Medical Physicists. Separately, Radiation Oncologists were also evaluated for two qualitative metrics commonly used to assess proficiency in medical simulation tasks; a global rating scale and a procedural checklist. **Results:** Simulated implants were performed by five learner and five expert multi-disciplinary teams. The mean and standard deviation of seed placement accuracy was 8.1 ± 3.5 mm and 6.1 ± 2.6 mm for the learner and expert cohorts, respectively. Based on the expert cohort, the passing tolerance for institutional credentialing was set at two standard deviations above the mean values, which was 8.1 ± 3.4 mm. The median (range) procedural time-to-complete was 64 minutes (60 to 77) and 43 minutes (41 to 50) for learners and experts, respectively. In all metrics, expert team proficiency was superior to learner team proficiency. **Conclusion:** Anthropomorphic prostate and breast phantoms have been developed and characterized for use in technology-enhanced simulation education programs. Baseline institutional credentialing criteria have been defined, which will be later refined for greater participation in a multi-institutional study. Benchmark learner and expert practitioner performance was assessed, which provided validation evidence that the simulated implants are representative of the clinical experience. Next steps include quantifying learner progression in implant quality to approach expert proficiency.

Authors Roumeliotis and Meyer are Directors of Okolo Health, a company with financial interest in utilizing brachytherapy software and hardware devices discussed in this work.

PO-GePV-E-04

Development of Diagnostic X-Ray Sources – A Multi-Vendor Overview

R Behling*, XtraininX - Behling Technical Consulting, Norderstedt, DE

Purpose: The speed of scientific and industrial development of new diagnostic and therapeutic X-ray sources remains tremendous. Studying the history of medical X-rays and the evolution of the technology of its sources has been sparking fascination and heuristic insight over more than a century. Still to date, and despite of their deficiencies, vacuum electronic X-ray tubes and high voltage generators remain the dominant and most affordable sources of medical

diagnostic X-rays. **Methods:** This presentation will illustrate the various branches of the development of the technology and will pay credit to some of those scientists, craftsmen, business leaders, and artisans, who have driven this field of innovation. **Results:** Taking a multi-vendor perspective, this paper will discuss in depth the paths taken for improvement of medical X-ray tubes for radiography, CT and angiography. Thanks to contributions from various industrial sources, it presents a brief, but comprehensive overview. **Conclusion:** The development of modern diagnostic X-ray sources will continue to stay dynamic. There is no reasonable alternative to braking radiation generated by vacuum electronic devices.

PO-GePV-E-05

Enhancing Medical Physics Teaching with Image Repositories and Shared Resources

P Sprawls^{1*}, (1) Emory University and Sprawls Educational Foundation, Black Mountain, NC

Purpose: Provide a process to increase the effectiveness of medical physics teaching and enhance the professional performance of medical physicists, both as classroom/conference presenters/discussion leaders and as creators of visual learning resources. Also, to promote the value of collaborative teaching and the sharing of resources to enhance the teaching and learning of medical physics around the world. This is based on the concept that effective mental knowledge structures, especially for clinical applications of physical principles including diagnostic radiology, are based on images and visual representations of physical interactions and applications. Of major significance, it is how radiology residents learn. **Methods:** A comprehensive model and method has been developed providing for the publication and sharing of images and related visuals that can be used by medical physics educators in their teaching activities. It is based on teaching image Repositories on the websites of individual institutions or organizations. An article providing information and guidance on the creation and operation of Repositories has been published in an international medical physics journal and is available in all countries. Included are details on creating appropriate images and visuals for teaching, optimizing for web search engines, copyright and academic recognition issues, and management of Repositories. **Results:** Repositories are being developed and populated with teaching images by individual institutions and organizations and are available as open resources to all educators. A major value is it provides individual medical physicists an opportunity to publish and receive recognition for their creative efforts and contribute to medical physics education on a global basis. **Conclusion:** Teaching medical physics, especially for clinical applications including diagnostic radiology, is most effective when using images and visuals with presentations and discussions by medical physicists sharing their knowledge and experience. The development of Repositories increases the availability of high-quality images and visuals for that purpose.

PO-GePV-E-06

A Simulation-Based Mastery Learning Program for Ultrasound-Guided Interstitial Prostate Brachytherapy Using a Low-Cost 3D Printed Phantom

Z Xiong*, Y Zhong, M Joo, S Eraj, B Gannavarapu, H Morgan, S All, B Hryckushko, X Jia, M Folkert, P Medin, T Chiu, The University of Texas Southwestern Medical Center, Dallas TX

Purpose: There has been a decline in the utilization of brachytherapy even though it has been shown beneficial for a number of indications. One of the reasons for this decline is inadequate training due to an insufficient patient caseload. Simulation-based mastery learning (SBML) has been observed to improve procedural skills among medical trainees. In this work, we developed an SBML program for interstitial transrectal ultrasound (TRUS)-based prostate LDR/HDR brachytherapy using a low-cost prostate phantom developed in-house. **Methods:** The SBML program is hands-on consisting of all components of interstitial brachytherapy, including (a) preparation of training materials including fabrication of prostate phantoms and dummy radioactive seeds, (b) mock calibration of radioactive seeds, (c) instruction in brachytherapy procedures/safety, (d) operation of survey meter, TRUS, and brachytherapy applicator, (e) brachytherapy needle placement, (f) treatment planning and treatment delivery, (g) quality assurance and radiation survey, (h) review of potential hazards, and (i) post-implant dosimetry. Pre-session and post-session surveys were taken by trainees to assess confidence in each step of the procedure, with scoring ranging from 1 (extremely uncomfortable) to 5 (extremely comfortable). **Results:** Each prostate phantom and dummy seed set were fabricated in 1.5-hours by trainees, with material costs being approximately \$30 for each phantom. Trainees in our SBML laboratory included seven physician residents and five medical physics residents. After participation in the laboratory, confidence in overall workflow increased from 2.1 to 4.2 ($p=0.005$), patient preparation from 2.2 to 3.5 ($p=0.038$), equipment operation from 1.9 to 4.1 ($p=0.005$), and familiarity with treatment planning from 1.7 to 3.9 ($p=0.013$). The confidence levels increased in all evaluation categories. **Conclusion:** This SBML approach supplements patient caseload and is a valuable opportunity for trainees to increase their knowledge and confidence in prostate LDR/HDR brachytherapy procedures. Low-cost prostate phantoms and dummy seeds make SBML affordable, promoting increased utilization of brachytherapy.

PO-GePV-E-07

Introduction of Mind Mapping Technique to Enhance Medical Physics Graduate Studies

I Z Wang^{1,2*}, F West², (1) Roswell Park Comprehensive Cancer Center, Buffalo, NY, (2) University at Buffalo, Buffalo, NY

Purpose: Challenges exist in medical physics education due to its interdisciplinary nature requiring clinical knowledges and critical thinking skills. Medical physics professionals are also involved in advancing technology and safety in healthcare through their scientific and clinical research. Trainees also participate in such research developments either through graduate dissertation projects or residency rotations. In this work, we introduced the mind mapping technique to assist graduate students to succeed in their medical physics studies. **Methods:** The mind mapping technique utilizes a colorful spider diagram to help structure information from various sources visually resembling the human thinking process. The idea of “mind mapping” was first introduced by Tony Buzan in the 1970s and has since become popular with many educators. It has been applied in the education of many fields including medicine and basic sciences that are related to medical physics. Mind mapping tools have been introduced to some students in our graduate program in two areas, study of didactic courses and innovation of research projects. **Results:** Example mind maps will be presented. Mind maps in didactic courses, e.g., anatomy/physiology and therapy physics, demonstrated that organizing information through mind mapping assisted students in memory retention and concept understanding. Mind mapping on how to motivate students in their research bridged gaps between professor and students to help students more effectively achieve their goals. Mind maps developed by students during literature search and brain storming helped find opportunities for research projects through connections that have yet to be investigated. **Conclusion:** Mind mapping is a useful tool to some students in their didactic course studies and research projects. Developing mind maps visually make study more efficient and enjoyable by stimulating both brain hemispheres. It can also assist students to organize thoughts and balance logical and creative thinking in an interdisciplinary field such as medical physics.

PO-GePV-E-08

To Investigate the Effectiveness of Supervised Multisensory Instruction and Flipped Instruction in Physics Resident Education

J Dise*, J Zoberi, O Green, N Knutson, G Hugo, Washington University School of Medicine, St. Louis, MO

Purpose: To investigate the effectiveness of supervised multisensory instruction and flipped instruction in physics resident education. **Methods:** The SRS/SBRT physics group is trialing a didactic overhaul to better tailor teaching techniques to individual physics residents. A multisensory instruction technique is being implemented to utilize seven defined styles of learning. For optimal implementation, a weekly curriculum has been developed where each resident is provided a combination of new clinical responsibility, new reading material, discussion time with faculty physicists, and a flipped instruction presentation. Each piece of curriculum provided to the physics resident is designed so that both the didactic resources and interpersonal resources provide unique perspective.

The stereotactic radiation therapy physics rotation is four months: two months in the first year and two months in the second year. In the first year, the rotation is focused on treatment planning. Each week of the rotation focuses on a particular site and an associated IGRT such as lung SBRT without gating, lung SBRT with gating, liver SBRT, etc.. In the second year, the rotation is focused on small field dosimetry and stereotactic beam commissioning. Each week of the rotation focuses on a specific aspect of small field commissioning such as output factor measurements, profile measurements, treatment planning system validation, etc.. **Results:** Currently, six residents have completed the new first year rotation and three residents have completed the second year rotation. The feedback for each rotation is variable depending on the residents' learning styles. Each has favored the tasks of the rotation that better suit their preferred learning styles. **Conclusion:** Compared to a comprehension focused environment, the performance of the physics residents on exams demonstrate greater grasp of content. An evaluation sheet of the curriculum is being developed for physics residents to provide feedback designed to adjust each week of curriculum.

PO-GePV-E-09

Dosimetrist Knowledge Transfer Using Intelligent Agents

R McBeth*, M Mashayekhi, Z Trivedi, D Nguyen, S Jiang, M Lin, UT Southwestern Medical Center, Dallas, TX

Purpose: Despite the recent advanced developments in radiation therapy planning, treatment planning for head-and-neck cancers remains challenging due to multiple dose prescriptions and numerous organs-at-risk close to targets, particularly for difficult patient cases. Additionally, studies have shown that plan quality strongly depends on planner experience and skills. It is desirable to transfer this knowledge from experienced planners to trainees at the lowest possible cost so trainee plans can better meet clinical practice and physician preference. The potential for using an intelligent agent to transfer this valuable clinical knowledge was investigated in this work. **Methods:** A clinically deployed AI dose predictor for head-and-neck cancers was retrained, using a transfer learning technique, on the historic treatment plans of experienced dosimetrists. This new model was then used to generate 3D dose distributions for comparison with 10 plans created by physics residents. These were then compared using qualitative and quantitative clinical metrics to evaluate the potential for training junior planners with this intelligent agent. **Results:** Preliminary results show that an AI 3D dose predictor can be used to guide trainees when learning to create treatment plans. The generated dose distribution mimics the collective experience of the clinical practice and highlights areas for improvement with no educational oversight. The highlighted changes help to drive the planner closer to the pareto optimal surface. The dose prediction also displays overall plan dose distribution styles, such as posterior sparing or reducing dose leakage. **Conclusion:** An AI dose predictor for head-and-neck cancers can be used to highlight plan quality issues in trainee plans. With additional training and infrastructure, this intelligent agent can be a powerful learning tool and used to guide for plan quality improvements of junior dosimetrist and has the potential to assist them in meeting clinical goals in reduced planning time.

PO-GePV-E-10

The Experience of Writing a Medical Physics Article to Young Readers/Reviewers

Z Ouyang*, T Arsenault, K Lyons, University Hospitals Seidman Cancer Center, Cleveland, OH

Purpose: Public education is an important aspect of medical physics education. Within the scope of public education, one of the most challenging tasks is to explain medical physics related concepts to the younger population (pre-teens, early teens, etc). This work shares the experience of writing a medical physics article to young readers/reviewers. **Methods:** An educational article titled "Treating Cancer with X-Ray Radiation Therapy" was written, targeting a reader group with age 8 to 15. The article briefly discusses the concept of cancer, production of X-ray using a LINAC, biology related to radiation therapy, etc. A group of young reviewers were invited to review and give comments about the article. At the time of reviewing, all reviewers were younger than 15, and were guided by a science mentor. The young reviewers were asked to summarize the main point of the article, explain its importance, and list the interesting and confusing parts. The young reviewers were also given the opportunity to ask further questions. **Results:** With three rounds of editing, the young reviewers, science mentor, editors, and authors reached an agreement in the final version of the article. The young reviewers find the concepts challenging, but are able to understand them. Some find the concept "X-ray production" interesting. Figures requested by the young reviewers include: a schematic of a LINAC, and radiation damages of DNAs. The concept "bremsstrahlung" was agreed to be too difficult and omitted from the final version. **Conclusion:** The experience of writing a medical physics article to young readers/reviewers is successful. The young reviewers are enthusiastic and are able to comprehend some abstract concepts in medical physics. The language of the article, illustrations, guidance from a science mentor, and interactive editing are essential in this experience.

PO-GePV-E-11

Development of a Flipped-Classroom Style Medical Physics Course for Radiation Therapist Students

M Hyun*, A Besemer, S Wisnoskie, Y Lei, S Li, D Schott, S Wang, D Zheng, J Koth, L Bartenhagen, University of Nebraska Medical Center, Omaha, NE

Purpose: The goal of this work was to convert an in-person, lecture-centered introductory medical physics course for radiation therapist (RT) students to a remote flipped-classroom approach, and to evaluate this approach through peer-review. We aimed for students to engage in more active and collaborative learning while maintaining a safe learning environment during the ongoing global pandemic. **Methods:** Traditionally, our RT medical physics course was team-taught using in-person lectures. This year, a flipped-classroom approach was developed where these lectures, pre-recorded, were converted to pre-class work. The originally scheduled class times were used for discussion sessions, which were conducted via Zoom. These included a brief review and then employed several methods to engage the students in active learning such as cold-calling, polls, group problem-solving, "game show" style activities, and dedicated Q&A time. Student feedback was solicited throughout the course, and the teaching team held regular meetings to share best practices. The efficacy of this approach was evaluated by reviewing periodic student feedback and end-of-semester course evaluations. Additionally, a teaching peer-review program was developed and implemented to improve collaboration and teaching quality among the team. **Results:** Implementing this new approach introduced challenges, both technological (e.g., video and audio quality, unfamiliarity with available tools and platforms) and pedagogical (e.g., student resistance to cold-calling, non-compliance completing pre-class work). However, student feedback from post-lecture surveys and course evaluations indicated high levels of satisfaction with the pre-class videos and the active-learning style of the discussion and review sessions. Several opportunities for improvement were identified from student feedback and peer-review. Future work will include the use of eLearning modules, monitoring pre-classwork compliance, and other strategies to further improve student engagement and learning outcomes. **Conclusion:** The teaching team successfully implemented a remote, flipped-classroom approach for our RT medical physics course along with a robust faculty peer-review program.

PO-GePV-E-12

Development of Visual Learning of AAPM Task Group Reports

M Chan¹*, J Wu², J Wu³, D Wang⁴, (1) Memorial Sloan Kettering Cancer Center, Basking Ridge, NJ, (2) Georgetown University, Washington DC, (3) Rice University, Houston, TX, (4) Memorial Sloan Kettering Cancer Center, Middletown, NJ

Purpose: Studies show that 83% of human learning occurs visually, demonstrating the clear importance of visual learning strategies. Visual learning utilizes graphs, charts, maps, diagrams, and other forms of visual stimulation to effectively process and interpret information. AAPM provides all sorts of materials, references, TG reports, and free resources on its website. However, many medical physicists still find that most AAPM TG reports are lengthy and difficult to interpret. This work aims to improve medical physicist learning of TG reports through the development of visual learning techniques based on adult learning theories. **Methods:** We have used Python, HTML, CSS, and JavaScript to develop the learning module to aid physicists in understanding the AAPM TG

reports. The website was also built with web scraping to allow keyword search within publicly available AAPM TG reports. We have selected the TG-100 as an example and extracted the essence of it, converting the central ideas of risk analysis methodologies into visual aids. The resulting visual teaching modules contain infographic techniques and a web-based learning module. **Results:** A web-based learning module was developed. As an example, we have successfully transformed the complex TG-100 risk analysis methodology into infographics. The website displays infographics that visually represent risk analysis methodologies and also allows a physicist to search a word within any AAPM TG reports that are available within one click from the AAPM Publication webpage. Once found by search, the title and ID of the TG report will be displayed, and the report can be viewed by clicking on the title. **Conclusion:** AAPM TG reports can be converted and displayed using both the infographic form and computer-based learning modules for ease of learning. Our work capitalized on what medical physicists already know and incorporated user-friendly interfaces on selected AAPM TG reports.

PO-GePV-E-13

Incorporating Statistical Learning and Artificial Intelligence Education to Medical Physics Graduate Training

C Cardenas*, L Court, University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: To evaluate the value of a web-based educational tool developed to introduce medical physics graduate trainees to novel topics in statistical learning and artificial intelligence (AI). **Methods:** A self-paced tutorial-course was containing modules introducing trainees to 1) Python programming, 2) DICOM file operations, 3) Statistical Learning concepts, and 4) Deep Learning concepts was created. The materials were developed such as that no prior programming and/or statistical learning/AI background were required. This course was developed using Python and Jupyter notebooks, with many notebooks covering materials in each of the four topics. Eight first-year medical physics PhD graduate trainees at our institution used this tutorial-course materials over the course of a twelve-week research-tutorial to enhance knowledge for their projects. Weekly-meetings were held to go over materials covered and evaluate research progress. After completion of the self-paced course and research-tutorial, all trainees were asked to complete a survey to assess the value of the educational tool. **Results:** All trainees completed the tutorial-course while taking a typical first-year academic course load. 100% of trainees thought the tutorial-course was helpful in developing a strong background in statistical learning and AI. 75% of trainees feel confident that the tutorial has prepared them well to implement AI techniques into their PhD research. Several trainees submitted abstracts on their research-tutorial work for the AAPM annual meeting. One trainee won the Young Investigator Symposium award at the 2020 SWAAPM meeting based on her research-tutorial results. **Conclusion:** Training in statistical learning and AI are currently not part of the medical physics graduate education. We developed a structured self-paced tutorial-course to introduce trainees to basic principals in these topics while they worked on individual research projects. The course was positively-received by the trainees and has potential in bridging the gap in knowledge for future medical physicists in these fields.

PO-GePV-E-14

Implementation of Ra-223 Radiopharmaceutical Program in Radiation Oncology at a Small Community Cancer Center

S Lee*, G Lasio, M Guerrero, H Xu, S Chen, Y Kwok, University of Maryland School of Medicine, Baltimore, MD

Purpose: Ra-223 has recently been adopted as a targeted radiopharmaceutical therapy for castration resistant prostate cancer patients with bone metastasis. Ra-223 therapy increases life expectancy with a relatively simple procedure involving the injection of Ra-223 for up to 6 fractions every four weeks. This treatment could be a routine procedure in a nuclear medicine department, its implementation is challenging in a small radiation oncology center, due to lack of staff experience. The purpose of this work is to give a guidance and share the experience for an independent small radiation oncology center about to launch the program. **Methods:** Physicians, physicists and nurses worked as a team in the process led by a physicist who will serve as RSO. Communication among staffs is critical for a successful workflow. We followed the code of Maryland regulation specific to radioactive material license consistent with federal nuclear regulatory commission. There were three phases of program build-up. It is imperative to obtain the license in the first place for some agreement states submission of detailed documentation of whole radiation safety procedures is essential. Secondly, emergency plan and safety training for the staffs were performed. The last phase involved equipment acceptance and QA, source logistics and workflow development. **Results:** The documentation of radiation safety procedures, staff training and acceptance and initial calibration of dose calibrator and well chambers and workflow development using ARIA® EMR were completed for first treatment. At our institution, we have treated 10 fractions of Ra-223 injections without any incident for 5 months since the launch of the program. **Conclusion:** The implementation involves team effort of administrators, physicians, nurses and physicists. For a small cancer center, a physicist who also should serve as a RSO plays as a leading role to establish and oversee radiation safety program as well as workflow establishment.

PO-GePV-E-15

VICTORIA: Online Monte Carlo and DICOM Data Viewer

E Badun¹*, F Tessier², R Townson², M Bazalova-Carter¹, (1) University of Victoria, Victoria, BC, CA, (2) National Research Council Canada, Ottawa, ON, CA

Purpose: To build a web-based DICOM and Monte Carlo (MC) dose viewer 'Voxel Interactive Contour Tool for Online Radiation Intensity Analytics (VICTORIA)' for the visualization and comparison of dose distributions with underlying anatomy that is free, accessible, simple to use, secure, and requires no downloads. The web viewer should be useful for researchers using .egsphant and .3ddose file types from the EGSnrc toolkit, or researchers in low- and middle-income countries without access to treatment planning systems. **Methods:** VICTORIA was coded in Javascript using D3.js and Conerstone.js to assist in visualization and file parsing. All processing is done client-side to avoid uploading files with patient information over the web. VICTORIA currently accepts .egsphant, .3ddose, CT DICOM, and RT DICOM file types, and can calculate dose differences between dose files. Web Workers were employed to cache the density slices to improve speed. **Results:** VICTORIA visualizes the position, density, dose, material, and dose profiles where the user clicks. Clicks can be used to navigate the image, sliders control the window and level of patient anatomy, and dose contours can be added or removed. The user can export the visualization and dose profiles to .png and .csv, respectively. Multiple different density and dose distributions may be loaded and compared. Using Google Chrome, a 21.7 MB .egsphant file took 1.4 s to load, and navigating slices before caching took 9.2 ms, while after caching it took 3.1 ms. A batch of 171 DICOM CT files with a total size of 90.4 MB took 13.2 s to load, while navigating slices took 45.5 ms before and 14.1 ms after caching, respectively. **Conclusion:** VICTORIA is a convenient web-based MC and CT dose comparison and visualizer tool that is free and accessible.

PO-GePV-E-16

A Practical Way to Strengthen Radiation Safety Culture in Healthcare

D Gilley*, O Holmberg, IAEA, Vienna

Purpose: The incorporation of radiation safety culture into healthcare settings can help prevent injuries and deaths and help reduce unnecessary or unintended radiation dose to patients and staff overall. While there is broad agreement on the importance of safety culture, it is challenging to provide appropriate educational materials to a global, multidisciplinary audience from a wide range of economic environments. The IAEA's training material entitled "Strengthening Radiation Safety Culture in Medicine" has been developed to fill the gap in this area. **Methods:** Analysis of events in the SAFRON incident learning systems indicated that over 60% of reported events could have contributing factors relating to poor safety culture. A Technical Meeting held in November 2018 concluded that training material was needed that could improve safety culture practices in medical applications using ionizing radiation. Course

material was subsequently developed, and in 2021 the IAEA launched the Radiation Safety: Trait Talks handbook for strengthening radiation safety culture in healthcare. **Results:** The entire program, funded through the US Extra Budgetary Funds, is freely available. The course is structured around 10 important principles – traits – that contribute to a strong safety culture. These are adopted from the nuclear and aviation industry, and applicable to the use of radiation in medicine. Each trait includes case studies, accompanying exercises, and digital presentations. The material can be provided as a two-day instructor lead workshop or as individual modules tailored to the needs of the medical institutions. The educational material includes a student handbook, digital material, and an instructor's handbook. **Conclusion:** The Radiation Safety Culture: Trait Talks Handbook is available for free download on the IAEA website, aiming to fill the gap in training material for strengthening radiation safety culture in medicine in a wide range of settings.

PO-GePV-E-17

Brain Functional Connectivity Reveals RTMS Effectiveness Pain Reduction in Non-Specific Chronic Low Back Pain Patients

M Masoumbeigi^{1*}, N Riyahi-Alam^{1,2}, R Kordi^{3,4}, M Rostami⁵, A Jafari¹, A Rahimiforushani⁶, H Hashemi⁷, (1) Medical Physics and Biomedical Engineering Department, School of Medicine, Tehran University of Medical Sciences, Tehran, Iran, (2) PERFORM Preventive Medicine and Health Care Centre, Concordia University, Montreal, Quebec, Canada (3) Sports Medicine Department, School of Medicine, Tehran University of Medical Sciences, Tehran, Iran (4) Sport Medicine Research Center, Neuroscience institute, Tehran University of Medical Sciences, Tehran, Iran (5) Neurosurgery Department, School of Medicine, Tehran University of Medical Sciences, Tehran, Iran (6) Epidemiology and Biostatistics Department, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran (7) Radiology Department, School of Medicine, Tehran University of Medical Sciences, Tehran, Iran

Purpose: Non-specific chronic low back pain (CLBP) is one of the most common worldwide painful syndrome among the adult population without clear medical evidence and specific diagnosis, while the cure of CLBP patients is resistant to diverse pharmacological and non-pharmacological prescriptions. Repetitive transcranial magnetic stimulation (rTMS) as a non-invasive technique in spite of its prospective treatment effectiveness has not been examined deeply for the recovery solution of CLBP, yet. This study aimed to find out pre and post rTMS stimulation in neuronal vesicle activities using resting-fMRI brain functional connectivity (FC) data analysis. **Methods:** The pain intensity of nine non-specific CLBP patients (age 50±10.39) was determined by the conventional method of visual analog scale (VAS) before and 2-4 days after 20 Hz rTMS via an eight-shaped coil over the motor cortex. Stimuli were provided in field intensity of 95% of the motor thresholds and trains of 40 pulses, followed by a 28sec rest period. The rs-fMRI data were collected using a Siemens 3T MRI scanner with the standard 64-channel head coil, while, anterior cingulate cortex (ACC) as a key pain region selected for seed-based connectivity (SBC) analysis with other pain regions in every session. **Results:** Pre and post rTMS stimulation execution results showed the mean pain intensity of patients as 8.17±1.20 and 3.85±0.95, respectively (recovery rate=53%). The functional connectivity beta values represent Fisher-transformed correlation coefficients between ACC and insula, supramarginal gyrus (SMG), and prefrontal cortex (PFC) in pre-stimulation session were 0.67, 0.44, and 0.53, while in post-stimulation session significantly decreased as 0.54, 0.28, and 0.45, respectively (p-FDR < 0.05). **Conclusion:** Significant decremental brain connectivity coefficients in conformity with conventional VAS evaluation of CLBP patients showed the recovery in pain-related regions as the criteria for the effectiveness of rTMS pain reduction in CLBP patients.

Effective Resident Training in the Medical Physics 3.0 Era

C Buckley*, J Gagneur, D Robertson, M Fatyga, S Chungbin, E Clouser, M Foster, G Penoncello, D Harrington, J Ashman, Y Rong, Mayo Clinic Arizona, Phoenix, AZ

Purpose: The world of medical physics is changing, from prescriptive and technical, to dynamic and patient-facing. Residency education needs to change with it, to prepare future leaders to thrive in this new ecosystem. Our residency made improvements and enhancements to multiple modules to begin incorporating this training. **Methods:** Earlier this year, we incorporated new facets, to guide the transition from a technical emphasis to one that resonates with the Medical Physics 3.0 ethos: expanding our role in patient care, with a mindset of both safety and value. We added role-playing exercises, in which staff physicists play the part of worried patients or caregivers and the residents are transmitting their knowledge. Residents learn about our significant advances in nomenclature, automation, and development of standard operating procedures—all of which have contributed to meaningful simplification. During coaching for motion management simulations, residents are getting both communication training and decision-making training, in addition to routine technical aspects. The resident's self-evaluated confidence score is surveyed prior to and after each training module for both technical and communication competency; this is paired with the staff's evaluation of their performance and both are tracked. **Results:** Our residents who have received this enhanced education are still in training, but we believe that they will be poised to drive systems level change, both in their work environments, and in the radiation oncology community. **Conclusion:** Enhancing the full value of physicists towards human health, from industry to clinic to research, is important in resident education. We are embracing Medical Physics 3.0 in our residency program by enhancing our curriculum, offering new and different opportunities to demonstrate independent professional relationships with our patients, and finding innovative ways to partner with our physician colleagues to leverage all of our unique skills in the pursuit of better patient treatment.

PO-GePV-E-19

Design and Implementation of An Interactive Virtual Reality Interface for Experimental Medical Physics Education

J Jing^{1,2*}, H Lin¹, J Chow², (1) Hefei University of Technology, Hefei, Ah, CN, (2) Princess Margaret Cancer Centre, Toronto, ON, CA

Purpose: Teaching of experimental medical physics plays an important role in fostering students' abilities in the operation, observation, analyzing and solving problem. Due to the restriction and influence of the COVID-19 pandemic, it is difficult for schools to set up experiments in the laboratory to teach medical physics in order to meet the learning needs of students in China. The aim of this study is to design and implement an interactive virtual reality interface for medical physics students during the pandemic. **Methods:** The necessity of interactive virtual reality technology in medical physics experiment was analyzed. The virtual experiment system was designed to provide students with multi-level open-learning resources. A medical physics interactive virtual system based on the NI ELVIS hardware platform, NI LabVIEW software, and Moodle e-learning platform were created to simulate doing experiment in reality. A comparative study on the theoretical and virtual experimental results was conducted utilizing medical physics experiments as examples. **Results:** In experimental medical physics teaching, interactive virtual reality technology was flexibly applied in the 3D-displays of modern medical equipment, laboratory instruments and machine. Students could access and control those physics equipment and instrument in the virtual space to complete an experiment by following a given instruction. **Conclusion:** Applying interactive virtual reality technology in medical physics teaching can greatly change the traditional teaching concepts. The virtual interface could break through the difficulties of teaching in the real space, attract the attention of students to stimulate their interests in learning, and thereby enhance them to understand the appropriate teaching content. Consequently, there are broad prospects for its development and application.

Teaching Research Project of Education bureau of Anhui province, China 2018JYXM1001, 2019JYXM0039 and 2019 JYXM0052, Reform Project of HFUT Informatization Teaching KCCXX1904.

SSGAN: Unpaired MR-To-CT Image Synthesis with Spatial Sequence GAN

L Kong^{1*}, W Jiang², D Huang¹, Q Zhou³, Z Chen³, W Zhang³, H Sheng³, C Yang³, B Qu⁴, (1) College of Engineering, Huaqiao University, Quanzhou, (2) Department of Radiotherapy, Yantai Yuhuangding Hospital, Qingdao University School of Medicine, Yantai, Shandong, 264000, China, (3) Manteia Medical Technologies (4) PLA General Hospital, Beijing, CN

Purpose: Existing work on unpaired MR-to-CT image synthesis performs well at the 2D level. However, there is still some limitations regarding the synthetic image quality in the three dimensions. For instance, there is a lack of continuity between the previous and subsequent layers of the 3D sCT image, which is manifested in uneven levels in tissues and bones. In addition, the HU value of the 3D synthetic CT image has minor variations, indicating losing structural details in coronal and sagittal planes. Moreover, there is lack of shape consistency with the original MR. In order to solve the above problems, an effective spatial sequence generative adverse network (ssgan) was proposed to achieve unpaired MR to CT image synthesis. **Methods:** The convolutional long short-term memory (Conv-LSTM) model was embedded in the generator to guarantee the 3D spatial continuity of synthesis images by using a mixture of the input 2D images in different spatial orders. Secondly, three projection discriminators were introduced to discriminate the authenticity of the three projected images along axial, coronal and sagittal planes. Moreover, a non-local module was incorporated into the discriminator to further enhance the strength of distinguishing the voxel intensity relationship in the adjacent layers. **Results:** The feasibility and effectiveness of our SSGAN was demonstrated using unpaired head and neck MR and CT images. The synthetic CT (sCT) generated using our SSGAN shows superior similarity to the real CT in both 3D continuity and intensity authenticity. In addition, the cross-modality registration experiment illustrates that our SSGAN generates better sCT with highest mutual information **Conclusion:** the novel SSGAN method can provide better quality 3D sCT images from unpaired MR data compared with others methods.

PO-GePV-E-21

Fork-Net: Synthesis-Based Unsupervised Multi-Modality Image Registration

L Kong^{1*}, Z Li², Q Zhou¹, D Huang³, Y Yin², (1) Manteia Medical Technologies, Milwaukee (2) Department of Radiation Oncology Physics and Technology, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Ji'nan, Shandong province, CN, (3) College of Engineering, Huaqiao University, Quanzhou

Purpose: Multi-modality image registration plays an important role in disease diagnosis and staging, tumor delineation, and prognostic analysis. However, it is often challenging due to the distinct image variations among different modalities. In this study, we proposed a synthesis-based unsupervised multi-modality registration network--Fork-Net. **Methods:** In Fork-Net, the generator, discriminator and registration network were integrated into a single model with a reused encoder. The moving image was first synthesized into the same mode as the fixed image, and then registered through registration network, turning the multi-modality registration task into a mono-modality registration problem. A new Synthesis-Registration-Consistency loss was thus developed to strengthen the consistency constraint between generator and registration network. The method was demonstrated using two brain datasets: one open access (BraTS, 2018) for T1-T2 MRI registration and one in-house dataset for MR-CT registration. The model performance was compared with the state-of-the-art image synthesis and registration methods. The quality of the image synthesis was evaluated using mean absolute error (MAE) and larger peak signal-to-noise ratio (PSNR). The registration accuracy was evaluated through the Dice of the target contour before and after registration, and the average gradient of deformation field (aGDF). **Results:** Regarding synthetic image quality, Fork-net has smaller MAE and larger PSNR. The target contours using registered images through ForkNet has the highest Dice, i.e., 0.74 ± 0.12 and 0.68 ± 0.14 for dataset 1 and 2, respectively. ForkNet has the smallest aGDF, indicating smoothest deformation. In addition, the architecture of Fork-Net is superior to other models with less adjustable parameters and less memory requirement. **Conclusion:** The proposed synthesis-based unsupervised multi-modality registration network is superior in terms of synthesis quality, registration accuracy, and smoothness of the deformation field as compared with current state-of-the-art methods. It may be implemented into clinical workflow, facilitating routine practice of multi-modality image registration.

PO-GePV-E-22

A Novel Leaf Sequencing Optimization Method with Deep Reinforcement Learning

W Zhang^{1*}, L Kong¹, Q Zhou¹, S Xu², (1) Manteia Medical Technologies, Xiamen, CN, (2) Chinese PLA General Hospital, Beijing, CN

Purpose: Due to the machine limitations inherent in the design of multi-leaf collimator (MLC), the current leaf sequence algorithm has problems such as insufficient execution efficiency and delivery accuracy. This study designed a leaf sequencing method based on reinforcement learning, trying to solve the above problems. **Methods:** The training engine consists of MLC simulation environment, data generator and discrete action network structure. First, a simulated fluence map was obtained through the data generator, which, together with the current collimator position and the cumulative conformal intensity map, was entered into agent network. The predicted collimator movement and monitor units was applied to environment, which made a new collimator state and intensity map. The reward was calculated with the final target and was back-propagated to complete a whole cycle. The design of MLC simulation environment would consider machine parameters and constraints, which greatly reduced the action space of discrete action model. The Bezier curve and elastic transformation were innovatively used in the data generator to simulate the intensity distribution, making the training target closer to the actual fluence map. Using nasopharyngeal carcinoma IMRT as a test bench, we tested and compared the accuracy difference between the proposed and traditional leaf sequencing algorithms. **Results:** During test using fluence map extracted from 20 IMRT plans of nasopharyngeal carcinoma, with an intensity level of 64, the proposed method achieved a relative intensity difference of 1.25% with 15 segments, while the traditional algorithm requires 40 segments to achieve 1.58%. When the strength level increased to 128, the method achieved 0.78% with 15 segments, while the traditional algorithm required 50 segments to achieve 1.06%. **Conclusion:** Our novel leaf-sequencing method based on reinforcement learning has obvious advantages in execution efficiency and delivery accuracy. Experiments shows that this method has great potential in the field of MLC leaf-sequencing.

PO-GePV-E-23

Enriching a Fully Remote Medical Physics Lab Culture: A Self-Assessment

S Hernandez^{*1,2}, R Mumme², A Olanrewaju², B Marquez^{1,2}, C Nguyen², C Sjogreen², C Cardenas^{1,2}, C Yu^{1,2}, M El Basha^{1,2}, D Mann², D Rhee^{1,2}, H Ziyace², J Yang², K Huang^{1,2}, K Nealon^{1,2}, K Oh², L Gomes², R Douglas², S Gay², T Netherton^{1,2}, W Cao², Y Xiao², Y Zhao^{1,2}, L Court^{1,2}, M Gronberg^{1,2}(1) UT MD Anderson UTHealth Graduate School of Biomedical Sciences, Houston, TX (2) The University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: COVID-19 drastically changed work environments and subsequently the medical physics trainee experience. To better understand and address the effects of this change, we performed a self-assessment of our lab culture. **Methods:** In an anonymous survey, we asked each lab member to identify and rank up to 10 values of a healthy lab culture. The participants then scored how well the lab embodied their contributed values before and during COVID-19 (1-5 scale). The results of the survey were analyzed in a live group session. In another live session, we performed a literature review where groups of 4-5 members were tasked with reviewing and presenting 2 peer-reviewed lab culture manuscripts. In three additional live sessions, we finalized 10 values, reflected on how well the lab embodied each value and proposed action items to address any deficiencies. Most of the lab was present at each session and the discussions were facilitated in large (21 people) and small (3-4 people) groups. **Results:** Values identified as being necessary to sustain a healthy lab culture were attitude, accountability, teamwork/collaboration, communication, diversity/inclusion, emotional intelligence, integrity, training, well-being, and adaptability/crisis-

management. The most frequently occurring and highest-ranked value among responses were teamwork/collaboration and attitude, respectively. The satisfaction score averaged over all values before and during COVID-19 was 4.39 ± 0.77 and 4.17 ± 0.95 , respectively. Changes made to the lab as a result of our self-assessment included simulating trainee office environments with 'coding hour' zoom rooms, dedicating a monthly meeting to socializing, and creating a wellness channel on Microsoft Teams. **Conclusion:** We successfully assessed the culture of our lab before and during COVID-19 using an anonymous survey and five, 2-3-hour group sessions. We determined 10 values for our group to embody, identified weak points in our lab culture, and proactively proposed and enacted solutions to address them.

IROC Houston Performance Impacted by Covid-19

S Cheng*, T Nguyen, N Hernandez, B Lewis, N Pajot, L Acuna Scafati, A Molineu, S Kry, UT MD Anderson Cancer Center, Houston, TX

Purpose: To describe and the effects of the Covid-19 pandemic on anthropomorphic phantom mailings and credentialing status inquiries (CSI). **Methods:** IROC Houston provides many services and quality control programs to support institutions that participate in clinical trials, including OSLD output checks, credentialing, and anthropomorphic phantom end-to-end remote audits. The phantoms are used for credentialing for NCI sponsored clinical trials as well as standard QA purposes. The CSI forms are submitted by institutions wishing to be credentialed for multi-institutional clinical trials. Phantom shipment numbers from 2019 and 2020 were compared to determine the effect that the pandemic had on the number of NCI credentialing phantoms and QA phantoms mailed. CSI numbers were also compared to determine the impact seen in credentialing requests. **Results:** 657 phantoms were shipped in 2019 and 623 phantoms were shipped in 2020. Overall, QA phantoms decreased by 77 and NCI phantom requests increased by 43 creating an overall decrease of 34 (5%) phantoms. A total of 4075 and 3744 CSI requests were completed in 2019 and 2020 respectively producing a decrease of 331 (8%) submissions. **Conclusion:** Though the overall number of phantoms shipped was less in 2020 than it was in 2019, it was not substantially less and was within the fluctuation that we typically see year to year. The CSI numbers dropped in March, April and May and then increased in the summer. This is likely due to many institutions stopping clinical trials temporarily when Covid-19 was first spreading in the United States. As institutions implemented safety protocols, they were able to reopen clinical trials and we saw requests likewise increased.

This work received funding from the NIH/NCI grants #CA180803

PO-GePV-P-02

Quality Assurance for Small-Field VMAT SRS And Conventional-Field IMRT Using the Exradin W1 Scintillator

Z Huang*, X Han, C Yang, J Wang, W Hu, Fudan University Shanghai Cancer Center

Purpose: The plastic scintillator detector Exradin W1 has been proved to provide good dosimetry for a small field owing to its good water equivalence and small sensitive volume. However, few studies have reported on its dosimetry for fields of conventional size. The purpose of this study is to assess the accuracy of the Exradin W1 in measuring conventional-field IMRT plans and small-field VMAT SRS plans, and then to assess its clinical value in dose verification and providing quality assurance for clinical radiotherapy plans for different field sizes. **Methods:** 47 cases (i.e., 29 cases with IMRT clinical plans for conventional fields and 18 cases with VMAT SRS plans for a PTV < 8cm³) in our center were included in this study. The Exradin W1 and Exradin A19 standard ionization chamber were used for IMRT plans, and the Exradin W1 and Exradin A16 microchamber were used for the VMAT SRS plans. Finally, the measurements were compared with those of the TPS and the average differences were calculated. **Results:** For the 29 IMRT plans, the mean difference between the Exradin W1 and TPS was $0.16 \pm 1.83\%$; while for Exradin A19 chamber radio was $0.97 \pm 1.77\%$, which was significantly higher than that of the Exradin A19 chamber ($p = 0.048$). For the 18 VMAT SRS plans, the mean difference between the Exradin W1 and TPS was $1.13 \pm 1.33\%$ and the ratio for Exradin A19 microchamber was $0.93 \pm 1.57\%$. The accuracy of the Exradin W1 was nearly the same as that of the Exradin A16 and no statistical difference was observed. **Conclusion:** The Exradin W1 has good accuracy in measuring doses for conventional-field IMRT plans and small-field VMAT SRS plans, which makes it a more comprehensive radiation detector than others available and will be convenient for use in a clinic.

PO-GePV-P-03

An Automated, Vendor-Neutral Method for CT Protocols Documentation

E Eastman*, D Zhang, Y Zhou, Cedars-Sinai Medical Center, Los Angeles, CA

Purpose: The large number of protocols on each computed tomography (CT) scanner makes protocol review a laborious task to complete manually, especially for institutions with multiple CT scanners. Vendor-specific naming conventions, variable protocol templates, and immutable documents make the constant review of protocols time-consuming and prone to errors. The purpose of this study was to develop an automated, vendor-neutral software solution to reformat the protocol export files obtained from CT scanners to facilitate the protocol review process. **Methods:** Instead of manually maintaining a protocol book with all acquisition and reconstruction parameters for dozens of protocols on each CT scanner, we proposed taking advantage of the exported protocol files (in either .csv or .xml formats). Since these files are not reader- and print-friendly, a Python script-based program was created to identify and store values for the following parameters: tube potential, tube current, automatic exposure control reference, pitch, minimum and maximum tube current (if applicable), tube rotation time, collimation, computed tomography dose index (CTDI), CTDI notification value, dose-length product (DLP), slice thickness, slice interval, displayed field of view (DFOV), reconstruction kernel, and iterative reconstruction algorithm setting. An additional Python program was written to identify changes between two sets of protocols from the same scanner exported at different points in time. **Results:** The consistent, vendor-neutral format accelerates the identification of relevant protocol parameters, making protocol documentation and reviewing much easier. The additional comparison program automatically identifies changes in protocols between two points in time, allowing the protocol management team to quickly review the changes for accuracy. **Conclusion:** The program we developed saves the protocol management team a significant amount of time that would be spent manually parsing the raw protocol outputs or entering protocol changes. The program also opens new possibilities for more comprehensive analyses of protocols across vendors and throughout time.

PO-GePV-P-04

An Automatic CT Quality Assurance Program

E Eastman*, D Zhang, Y Zhou, Cedars-Sinai Medical Center, Los Angeles, CA

Purpose: The purpose of this study was to develop a digital, self-regulating program to monitor CT quality assurance (QA) results. There are two main goals of the study. The first was to transition from physical to digital records. The second was to reduce the QA review time spent by medical physicists. **Methods:** The program consists of two elements. The first element is a set of digital forms used to record daily, weekly, and monthly quality assurance results for all CT scanners. The daily test includes CT number, noise, and uniformity. The weekly test includes SMPTE pattern check. The monthly test includes visual

inspections, laser alignment, and vendor-recommended quantitative tests such as spatial resolution, contrast scale, and slice thickness. These Excel forms are stored on a cloud drive and incorporate limits specified by vendors and the American College of Radiology (ACR). The second element is a Python-based program that searches the forms for out of tolerance results and blank entries, generates weekly summaries, and sends email alerts when they are found. Pandas library was used for all data manipulation, while Pywin32 library was used for sending out email alerts. This program automatically runs daily using Windows Task Scheduler on a desktop computer. The accuracy of the program was evaluated for 2 months. **Results:** A defined group of users received an email alert whenever there were failures, warnings, or missing records. The results of the manual review all agreed with the program results. In addition, the program detected missing entries that the human review did not capture. For our enterprise health system with 20 CT scanners, it saves 100 minutes of a medical physicist's time per week. **Conclusion:** We successfully implemented an automated method for CT QA documentation and review. This method not only avoids human errors, but also can increase productivity.

PO-GePV-P-05

Connecting Tableau to An Oncology Informatics System to Identify Treatment Planning Workflow Delays

A Witzum^{1*}, P Sharma², E Hirata¹, (1) University of California, San Francisco, San Francisco, CA, (2) University Of San Francisco, CA

Purpose: Over one-third of patient treatment plans at our institution are approved by the physician the day of, or the day prior to the new treatment start date. With the mean number of new starts increasing to over 10 per day, it is important to quickly identify plans held up at any stage in the planning process. This work develops a Tableau dashboard to visualize the status of quality check list (QCL) tasks for upcoming new start appointments. **Methods:** The Mosaic SQL database was connected to Tableau, a commercial data visualization toolkit. The treatment planning workflow was separated into seven components: simulation, contouring, planning, quality assurance, physics check, document approval, and therapist check. Each of these elements were classified as pending, completed, or in progress, with further information such as staff responsible, elapsed time, and any notes from Mosaic shown where relevant. Upcoming patient new start appointments were extracted from the database, sorted by date, and stratified by clinic location. Filters were added to allow users to search for patients or drill-down to specific start dates, clinic locations, and machines. **Results:** A web-based platform was created through which users can get an overview of plan status for upcoming new start appointments. Elapsed time of QCL tasks can be used to identify when and where tasks are held up, and the responsible staff member initials make it easy to identify a point of contact for follow-up. Notes from the QCL in Mosaic are displayed with a hover-over action, allowing additional information to be relayed. Comments can be added directly to the Tableau dashboard to facilitate communication about plans between staff. **Conclusion:** Tableau allows for a clean web-based display of information and eliminates multi-click searches within Mosaic. Thoughtful data visualization and simple filters facilitate a proactive approach to workflow bottlenecks and challenges.

PO-GePV-P-06

Implementation, Utilization, and Time Analysis of An Optional Physics Pre-Planning Check

B Juneja^{1*}, L Kim¹, (1) MD Anderson Cancer Center at Cooper, Camden, NJ

Purpose: TG-100 gives examples of checks that should be performed before treatment-planning, not afterwards as is commonly done. We have implemented a "physics pre-plan check," an optional check, performed at dosimetrist request, of 36 items that affect dose-calculation or plan-optimization with the intent of catching errors that would require repeating those steps. In this study, we report on utilization and time required for this additional check. **Methods:** For 3487 patients between February 2017 and February 2021, we recorded if and when a pre-plan check was requested and whether the check was performed. We calculated hours spent between contour completion and plan completion with and without pre-plan check. **Results:** Pre-plan checks were requested for 663 (19.0%) patients, but requests steadily declined over time from 43.9% in 2017 to 6.7% in 2021. 5.4% of checks were requested after planning but prior to plan documentation/upload. The likelihood of a request had a high positive correlation (0.899) with days remaining to the first fraction. Of the requested checks, 575 (86.7%) were completed. The remaining requests were eventually canceled by the dosimetrist. The median time from request to check completion was 2.3 hours. For canceled requests, the median time from request to cancellation was 5.6 hours. On average, a pre-plan check added 3.6 hours overall to the planning process. Plans without checks were completed in 9 hours compared to 12.6 hours for plans with checks (p-value: 9.014E-7). **Conclusion:** Our institutional experience is that the wait for a physics pre-plan check generally exceeded the expected time savings from catching an error early, and our dosimetry staff has mostly opted to forgo it. To retain the benefits of pre-plan checks, we developed a tool to automate the checking of 14 items and developed a checklist for the remainder for the dosimetrist to use without requiring a physicist.

PO-GePV-P-07

Automatic Parameter Extraction from Scanners to Wiki for CT Protocol Management

L Qin^{1*}, K McCall², P Dipiro¹, (1) Dana-Farber Cancer Institute, Boston, MA, (2) Henry Ford Health System, Detroit, MI

Purpose: Joint Commission requires that all CT protocols are reviewed by a site's CT protocol optimization team. All protocols contain several series, each with multiple parameters (including kVp, mAs, pitch, resolution, etc), which require documentation and tracking, both being time consuming and labor intensive. We aimed to export protocol files from our scanners, and export scan parameters to a readily accessible and tracked wiki page. **Methods:** CT vendors export protocols in different formats, including .PROTO format for GE scanners, and .xml format for Siemens scanners. We developed Matlab programs to extract scan parameters directly from these protocol files, which are arranged in structured tables and written in a wiki format that can be displayed on web pages. Whenever scan parameters are changed on the scanners, a technologist exports the protocols to update the wiki. All history of protocol changes is also saved on the wiki. **Results:** The wiki-based CT protocol reviewing system allows immediate access to CT scan protocol parameters without requiring physical presence at the scanners. All essential scan parameters are summarized in one table rather than under multiple tags on vendor specific interfaces. This allows much quicker protocol comparison if discrepancies are noted during our CT radiation dose review process. The wiki site also serves as a reference for physicists and technologists to build similar protocols on new scanners, which can be laborious if from different vendors. **Conclusion:** Extracting CT scan parameters automatically from the scanners and exporting them in a wiki allows easily accessible protocol documentation and monitoring.

PO-GePV-P-08

Scripting Occupational Badge Dosimetry Analysis for a Large Number of Clinics Using MATLAB

K Woods^{1*}, C Douglas, N Busse, Colorado Associates in Medical Physics, Colorado Springs, CO

Purpose: To create a MATLAB code to automate and streamline occupational badge dosimetry monitoring and reporting for the oversight of a large number of hospitals and clinics. **Methods:** As part of a physics group that is responsible for radiation safety for about 50 institutions, it is often difficult and time-consuming to review dosimeter badge reports on a large scale. For this work, we only looked at sites that are covered by our physics group that use Landauer dosimeters. Landauer provides a tabular spreadsheet of badge measurements that can be downloaded from their website. However, challenges arise from the number of sites covered, site-specific ALARA levels, site-specific effective dose equivalent (EDE) factors, missed or unreported badges, and fetal badges. Manual analysis for the total number of sites as well as specificity of each site makes it tedious to notify any individual of exceeding ALARA levels. A MATLAB code was generated to organize badge categories, summarize any exceeding badge tolerances, and generate PDF reports for analysis. **Results:** The MATLAB script generates a modified Excel spreadsheet that organizes badge categories into separate tabs as follows: total deep dose equivalent badges, fetal

badges, extremity badges, EDE conversion doses, area monitoring, and missed or unreturned badges. Each tab is sorted in descending order with conditional formatting of any exceeding ALARA values. A summary tab is generated as a quick reference that includes only badges exceeding ALARA levels, any fetal badge readings, and any missed or unreturned badges. A word notification document is generated for any individual that exceeds an ALARA level. **Conclusion:** MATLAB is a powerful tool that can generate an organized spreadsheet and efficiently analyze necessary occupational dosimeter badge measurements.

PO-GePV-P-09

Value of Peer Review: An Outreach Facility Perspective

M Meineke PhD, S Walston DO, A Fogle CMD, D Christ DMP, G Graeper, MSc, M Weldon, MSc, J Pichler, MSc, N Gupta PhD, K Hintenlang PhD*, The Ohio State University, Department of Radiation Oncology, Columbus, OH

Purpose: Peer review for outreach facilities is a valuable safety and quality tool. We describe an approach utilized to overcome the challenge of converging an outreach community practice with an affiliated academic clinic for a consistent level of excellence. **Methods:** The RO outreach practice developed a robust program to provide peer learning that promotes CQI in treatment practices. Prospective and retrospective processes are implemented through two primary mechanism, case-oriented and practice-oriented peer review. **Results:** Case-Oriented Peer Review Prospective peer review is performed with a four-layer peer review system on all patients' treatment courses for curative and palliative cases. Three days a week the outreach facility team participate in an affiliated academic center's dedicated 90 minute time slots for disease site groups. Pretreatment chart rounds include planned cases where indications, volumes, dose/fractionation and beam arrangements are considered. Review is recorded in a patient specific chart round task within RIS. Academic input facilitates an open discussion with all department staff represented. These prospective peer reviews are cascaded to the outreach facility chart rounds in an additional once/week time slot. A Chart Rounds widget enables electronic attendance records and patient specified tasks. Case-oriented peer reviews are performed subsequently by dosimetry, physicist and therapists prior to treatment initiation. Multidisciplinary level review is performed at the academic center and outreach facility tumor boards. Practice-oriented Peer Review The outreach staff participate in numerous Standing Committees. This peer review also includes a prospective, concurrent or retrospective case for educational purposes, professional feedback and future learning. Staff teach and review their CEU's. **Conclusion:** This peer review implementation helps establish a closer working relationship with the academic center and the process improves patient care and consistency. Scheduling complications between the groups are addressed. A successful comprehensive peer review program has been implemented, which can be applied to networked facilities.

PO-GePV-P-10

Comparison of Estimated Radiation Dose Indices for Abdominal Pediatric Computed Tomography Examinations - Patient Chronological Age Versus Patient Water Equivalent Diameter

W O'Connell*, E Silvestrini Hernandez, Northwell Health, Cortlandt Manor, NY

Purpose: To compare estimated radiation dose indices for abdominal pediatric computed tomography examinations when analyzed against patient chronological age versus patient water equivalent diameter. **Methods:** For the calendar years 2019 and 2020, a radiation dose index monitoring (RDIM) system collected dose indices, water equivalent diameter and chronological age for 3,236 pediatric CT examinations of the abdomen and abdomen/pelvis performed on forty-four (44) CT scanners located at sixteen (16) acute care hospitals and twelve (12) ambulatory imaging facilities. The RDIM harvested Dose Linear Product (DLP); Volumetric Computed Tomography Dose Index (CTDIVOL); Effective Dose (ICRP-103); Water Equivalent Diameter (WED); and Chronological Age (years) for selected pediatric single-phase examinations of the abdomen and abdomen/pelvis. **Results:** Enterprise-wide comparison of estimated dose indices confirm the benefits associated with acquisition parameters guided by patient attenuation coefficients as determined by water equivalent diameter estimates from CT localizer radiographs. **Conclusion:** The project confirms the benefit of CT localizer radiographs in setting acquisition parameters based on estimates of patient attenuation of radiation across the scan range.

PO-GePV-P-11

Optimizing Quality Assurance with Total QA® Implementation

R Sullivan^{1*}, D Bridges², X Zhao³, Y Yuan⁴, S Shen⁵, R Popple⁶, (1) University of Alabama in Birmingham, Homewood, AL, (2) University of Alabama at Birmingham, Birmingham, AL, (3) University of Alabama - Birmingham, Birmingham, AL, (4) Medstar Georgetown University Hospital, Washington DC, (5) University of Alabama Birmingham, Birmingham, AL, (6) University of Alabama Birmingham, Birmingham, AL

Purpose: To implement an easy-to-use cloud based quality assurance (QA) service to replace an existing framework of utilizing in-house spreadsheets and code to perform and analyze linac, brachytherapy, and CT QA. **Methods:** Performing, recording, and storing QA are essential to radiation therapy. The tasks of recording, analyzing, and storing normally employ customized, in-house spreadsheets and code that have to be internally maintained. Maintaining such a system can become complicated and error prone. Total QA® (Image Owl, Inc.), a QA creation, record, storage, analysis, and presentation service, is designed to meet an institution's QA needs and AAPM task group recommendations. For comparison, in-house safety, dosimetry, and mechanical QA tools, code, and spreadsheets for linacs, brachytherapy, and CT scanners were recreated in TQA and reviewed to assess the accuracy and validity of cloud-based system. After a satisfactory evaluation, a year's worth of QA were entered into TQA to create baseline metrics for each machine. **Results:** All existing linac, brachytherapy, and CT QA were successfully constructed in TQA to meet AAPM task group recommendations. Test creation, revisions, and maintenance were easier in TQA. Data entry, local and global analysis, and trend creations were faster and simpler in TQA. TQA eliminated the risk of accidentally altering spreadsheet formulas and/or code. TQA data was easily accessible and readily presentable for QA documentation necessary for regulatory/accreditation procedures and visits. **Conclusion:** Utilizing TQA to handle a clinics QA essential needs is more efficient, beneficial, and robust than maintaining in-house spreadsheets and code. TQA provides an easy, single point of access to facilitate any clinic's desire to organize, record, store, and present QA data.

PO-GePV-P-12

An Integrated, Automated Framework for Review and Approval of Policies and Procedures

J Neylon*, D Low, N Agazaryan, David Geffen School of Medicine at UCLA, Los Angeles, CA

Purpose: Develop and implement a scalable framework for housing policy and procedure documents, with automated version control, approval workflows, and review cycle notifications. **Methods:** After exploring several commercial options (all found to be lacking in one regard or another), we ventured to build our own solution which would allow full control and customization. Microsoft Sharepoint was utilized as the backend data storage for our document library and instantiated with several custom categories of metadata to classify each document and allow easy navigation and filtering. An automated approval workflow was developed in Microsoft Power Automate, which allowed programmatic customization and where the metadata was again utilized for logic-based decision-making. Both the document library and approval workflow were integrated with Microsoft Teams and Outlook for front-end user interactions and document browsing. **Results:** Power automate provides programmatic logic to fully customize and automate a sequential approval chain workflow, sending notifications through email and Teams. The Sharepoint document library provides built-in version tracking and customizable permissions groups to restrict editing while also granting widespread availability through Teams integration. **Conclusion:** Moving from a file-based-system stored on a network drive to a cloud-based, automated in-house solution for review cycles and approval workflows will simplify and streamline the management of departmental policy and procedure

documents. Improving the contemporaneity and availability of policies and procedures should improve compliance with the information therein, and have a positive impact on overall quality program.

PO-GePV-P-13

In-House Incident Learning System for Failure Modes and Effects Analysis Utilizing Microsoft Sharepoints and Powerapps

D Soultan*, T Thompson, S Vieux, M Bragg, A Hoover, Kansas University Medical Center, Kansas City, KS

Purpose: We propose a simple in-house internal incident learning system utilizing available Office 365 features; Sharepoints and Powerapps. The goal of the designed app is to periodically perform and update our Failure Modes and Effects Analysis FMEA prospective risk management for continuous quality improvement using collected data and failure information of processes and/or equipment that are encountered throughout our daily workflows. **Methods:** We have broken down treatment workflows at our radiation oncology department by modality and technique. We chose GYN HDR Brachytherapy as a starting point. A radiation oncologist, medical physicist, oncology nurse, therapist and practice director teamed up to discuss the GYN HDR process map, to review identified failure modes from old data, and to approve the preliminary ranking and risk priority numbers RPN derived from AAPM TG100. 6 failure types and 19 failure modes were mapped to the consequences compromising treatment. A Sharepoint list in Office 365 organization workspace was created and founded the database for the Powerapp. The Powerapp building step is mainly automated and allows customization and connection to multiple data sources including SQL and excel spreadsheets. Patient MRN is entered by the user, a date of the encounter is selected, and dropdown menus of preidentified failure modes, associated causes and consequences are built-in to choose from, in addition to a free text box to enter comments. **Results:** The app was published for use by the GYN HDR Brachytherapy care team and being evaluated. The next step is to expand the app to include all modalities and techniques in our department. **Conclusion:** We have created a simple incident learning system for our department internal use that is expected to help us collect and accumulate relevant, accurate and reliable data to perform consistent and continuous FMEA at our department and compare our results to published data and reports.

PO-GePV-P-14

Proton Radiosurgery: Small PBS Field Dosimetry Validation

M Bussiere*, J Daartz, J Verburg, N Depauw, H Kooy, J Loeffler, P Chapman, H Shih, Massachusetts General Hospital, Boston, MA

Purpose: We present on the validation of small-collimated field dose calculations and delivery to enable the transition of a clinical proton radiosurgery (PSRS) program from a passive scattering (PS) to pencil beam scanning (PBS) delivery technique. **Methods:** 250 PSRS PS fields treated in the previous two-years at our institution were used to establish base parameters including range, modulation, aperture diameter and field aspect ratio. Previous Monte Carlo simulations of the treatment planning system's (TPS) small field halo algorithm and limited measurements paved the way to a more comprehensive validation for PSRS. Micro-diamond detectors were used to measure central axis depth dose profiles of PBS fields satisfying parameter combinations described above. Output measurements were repeated in a solid water phantom to establish equivalence when applying a solid water to water ratio to account for differences in scatter within the mediums. The solid water setup is intended for use for subsequent patient specific QA. Film were calibrated for doses between 50-1,300 cGyRBE. An alignment template was incorporated into a phantom to ensure setup reproducibility. The phantom allows the micro-diamond detector and films measurements to be performed simultaneously. Dose profiles were assessed using a hybrid 2/3D gamma-analysis. **Results:** In-water dose measurement agreement was -1.7 ± 2.9 and 2.5 ± 5.1 %, at isocenter and 10 mm depth, respectively. Distal and proximal SOBP 90% depth agreement was 0.10 ± 0.66 and 0.74 ± 0.48 mm, respectively. PASS rates for isocentric profile gamma-analysis within 2% global dose, 1 mm distance to agreement and 10% threshold was 97.2 ± 4.8 %. **Conclusion:** Measurements performed for small PBS collimated fields with a variety of range shifters and delivery parameters confirms the TPS can properly model small fields used for proton PSRS.

PO-GePV-P-15

Pre-ESD Evaluation in Early Gastric Cancer

Y Gao¹, R Zhang², W Bai³, W Zhang^{4*}, (1) Hebei General Hospital, Shijiazhuang, CN, (2) The 4th Hospital of Hebei Medical University, Shijiazhuang, Hebei, CN, (3) The Fourth Hospital of Hebei Medical University, Shijiazhuang, CN, (4) Shijin Irrigation District Affairs Center, Hebei Province, CN

Purpose: Comparative analysis of the pathological diagnosis of endoscopic gastric biopsy and endoscopic submucosal dissection in patients with early gastric cancer and precancerous lesions in our hospital. Evaluate the size, nature and depth of the lesions before ESD, to reduce the risk of additional surgery after ESD. **Methods:** From January 2016 to December 2019, the 75 patients with gastric mucosal HGIN, severe atypical hyperplasia and in situ carcinoma which were treated by ESD were include. The relationship between lesion area, expression of white light endoscopy, magnification endoscopy, narrowband imaging endoscopy and postoperative pathological classification and depth of lesion was analyzed. **Results:** There were 75 patients with a total of 79 lesions. The coincidence rate of preoperative and postoperative pathology was LGIN 100.00% (4/4), HGIN 97.83% (45/46), Adenocarcinoma 89.66% (26/29). There was no significant difference between preoperative and postoperative pathological evaluation ($X^2=0.458$, $P=0.795$). The type of lesion and the degree of malignancy were independent with the location and size of the lesion. The endoscopic features of high grade intraepithelial neoplasia and early gastric cancer were clear border, irregular microvessel and irregular surface microstructure. Lesions > 3 cm, surface ulcer, spontaneous bleeding may be the risk factors for deeper lesions. **Conclusion:** 1. Endoscopic submucosal dissection is not only a means for the treatment of early gastric cancer and precancerous lesions, but also an important method for clear pathological diagnosis. 2. Magnification endoscopy combined with NBI can find early detection of HGIN and early gastric cancer. Preoperative biopsy had guidance significance in diagnosis and treatment, which can reduce the missed diagnosis of early gastric cancer.

PO-GePV-P-16

Risk Factors of Early Gastric Cancer Identified by Screening Endoscopy

Y Gao^{1*}, W Zhang², (1) Hebei General Hospital, Shijiazhuang, CN, (2) Shijin Irrigation District Affairs Center, Hebei Province, CN

Purpose: A customized screening program for gastric cancer would optimize the benefits of screening endoscopy. This study investigated the risk factors for gastric cancer detected during screening and factors affecting clinical outcomes. **Methods:** The patients in Hebei General Hospital from January 2014 to December 2020 were selected as the research objects. The clinical outcomes of early gastric cancer identified during screening (screening group) were compared with age, sex, Helicobacter pylori infection, Family history, environment and bad habits of diagnosis matched subjects who were diagnosed with early gastric cancer in the outpatient clinic (outpatient group). **Results:** Of 39530 subjects, 226 were diagnosed with early gastric cancer. The median age of the screening group was 61.2 years (interquartile range 56–71 years), and the male-to-female ratio was 2.1:1. When comparing with the control group, Helicobacter pylori infection (odds ratio [OR] 2.721, $P < 0.001$), carcinoembryonic antigen (OR 9.623, $P = 0.004$), family history of gastric cancer (OR 3.154, $P = 0.005$), and drinking (OR 4.311, $P < 0.001$) were independent positive risk factors, and the use of aspirin a negative risk factor for gastric cancer (OR 0.345, $P = 0.011$) in multivariate analysis. The 5-year survival rate was significantly higher in the screening group than in the outpatient group ($P < 0.001$). Conditional Logistic regression was used for single factor and multivariate analysis, and OR value and 95% confidence interval were calculated. **Conclusion:** The high incidence of gastric cancer is related to many factors, especially the eating habits of pickled vegetables, smoking and drinking. Comprehensive measures should be taken to reduce its incidence.

PO-GePV-P-17

Influencing Factors of Daily Activities in Patients with Early Gastric Cancer After Endoscopic Treatment

Y Gao¹, W Zhang², R Zhang^{3*}, W Bai⁴, (1) Hebei General Hospital, Shijiazhuang, CN, (2) Shijin Irrigation District Affairs Center, Hebei Province, CN, (3) The 4th Hospital of Hebei Medical University, Shijiazhuang, Hebei, CN, (4) The Fourth Hospital of Hebei Medical University, Shijiazhuang, CN

Purpose: To analyze the influencing factors of daily activities in patients with early gastric cancer after endoscopic treatment. **Methods:** Retrospective analysis the clinical data of 226 patients with early gastric cancer who underwent endoscopic submucosal dissection or endoscopic mucosal resection was performed in the Endoscopy Center of Hebei General Hospital from January 2014 to December 2020. We affiliated the university, including age, gender, base Basic disease, tumor size, location, morphology, postoperative pathological type and depth of invasion, postoperative complications, etc. Collect patients' daily activity scores during admission and discharge. Analyze the influencing factors of daily activities in patients with early gastric cancer after endoscopic treatment. **Results:** Age and postoperative bleeding were negatively correlated with postoperative daily activity scores ($r=-0.215$, $P<0.001$; $r=-0.155$, $P=0.025$). Logistic regression analysis showed that age was an independent risk factor for the decrease in daily activity score after operation (OR=1.085, 95%CI 1.003~1.204, $P=0.028$). **Conclusion:** The perioperative nursing work and health education for the elderly patients with early gastric cancer who undergo endoscopic treatment should be strengthened, and the patients' postoperative daily life ability should be closely monitored.

PO-GePV-P-18

The Diagnostic Rate and Analysis of the Clinical Pathological Features of Early Gastric Cancer

W Zhang¹, Y Gao^{2*}, (1) Shijin Irrigation District Affairs Center, Hebei Province, CN, (2) Hebei General Hospital, Shijiazhuang, CN

Purpose: To calculate the diagnosis rate of early gastric cancer, and to analyze the relationship between clinicopathological features and lymph node metastasis of early gastric cancer. **Methods:** The clinical and pathological data of 201 patients with early gastric cancer who were admitted to Hebei General Hospital were collected from Jan. 2018 to Dec. 2020, and the early diagnosis rate was calculated. They were divided into lymph node negative group (121 cases) and lymph node positive group (80 cases), and the related factors were compared and analyzed. **Results:** The early diagnosis rates in 2018-2020 were 12.36%, 14.14%, and 15.17%, respectively. The average early diagnosis rate in 3 years was 12.40%. Gender, depth of invasion, and degree of differentiation were significantly associated with lymph node metastasis ($P<0.05$). Gender and depth of invasion were independent risk factors for lymph node metastasis ($P<0.05$). The AUC for predicting lymph node metastasis by gender was 0.682 (95% CI: 0.508-0.856); the AUC for predicting lymph node metastasis by depth of invasion was 0.722 (95% CI: 0.573-0.871); when the two factors were combined, the AUC for predicting lymph node metastasis was 0.806 (95% CI: 0.696-0.917), both higher than the AUC of individual gender or depth of invasion. Female and submucosal infiltration were independent risk factors for lymph node metastasis, and their predictive value for lymph node metastasis was higher when combined than when alone. **Conclusion:** The early diagnosis rate of early gastric cancer is about 12% in our hospital in the past 3 years. Female patients, submucosal infiltration or low differentiation degree of early gastric cancer are prone to lymph node metastasis, which should be carefully treated under endoscopic treatment.

PO-GePV-P-19

Regional Workshops as a Method to Facilitate the Implementation of Task Group Recommendations: The Experience of AAPM Task Group 275

S Parker^{1*}, L Fong de los Santos², A Greener³, G Kim⁴, D Schofield⁵, K Smith⁶, M Wells⁷, E Yorke⁸, E Ford⁹, (1) Wake Forest Baptist Health High Point Medical Center, High Point, NC, (2) Mayo Clinic, Rochester, MN, (3) VA Medical Center, East Orange, NJ, (4) University of California, San Diego, La Jolla, CA, (5) AdventHealth Orlando, Clermont, FL, (6) Mary Bird Perkins Cancer Center, Baton Rouge, LA, (7) Piedmont Healthcare, Atlanta, GA, (8) Memorial Sloan-Kettering Cancer Center, New York, NY, (9) University of Washington, Seattle, WA

Purpose: To share the experience of AAPM Task Group 275 (TG275) in developing and delivering regional workshops to encourage the implementation of TG recommendations. **Methods:** A one-day workshop curriculum was developed by nine task group members to familiarize participants with the work and recommendations of TG275: Strategies for Effective Physics Plan and Chart Review in Radiation Therapy. In addition to a didactic component, at least 40% of each session's allotted time was devoted to active learning activities including individual exercises, small group activities, and full group discussions. Morning sessions included an overview of the work of TG275 along with education on the data collection phases. Afternoon sessions included education about the analysis phase, key recommendations, and suggestions for clinical incorporation of TG275 recommendations. The target audience included medical physicists with responsibility for plan review and chart checks. Each workshop was sponsored by an AAPM Chapter and feedback was gathered through program and speaker evaluations. **Results:** To date, two workshops have been held. The first was in-person with seventeen attendees and facilitated by two TG275 members. The second was virtual with fifteen attendees and facilitated by four members. Minor adjustments were made to the curriculum after the first workshop based on attendee feedback. The curriculum proved adaptable to both in-person and virtual formats. Attendees were actively engaged throughout both workshops. CAMPEP credits were offered in both instances with SAMs credits offered for the second workshop. Average program evaluation scores were 4.75 and 4.82 out of 5 for the two workshops respectively. **Conclusion:** A workshop curriculum was developed with the goal of familiarizing participants with the work and recommendations of AAPM TG275. To date, two workshops have been held. Workshops are a potentially useful mechanism to encourage the implementation of AAPM Task Group recommendations.

PO-GePV-P-20

Syed Template for Interstitial HDR: A 3D Printed Alternative

S George^{*}, A Gomez, T Romaguera, R Tolakanahalli, A Gutierrez, J Contreras, Miami Cancer Institute, Baptist Health South Florida, Miami, FL

Purpose: To have a template that is easy to handle during the Gynecological interstitial procedure. **Methods:** The Syed templates that are commercially available are very bulky and difficult to handle during the procedure. Suturing the template to perineum of the patient is very difficult. In addition to this due to the bulk of the template, it is easily movable when the patient is in discomfort which can lead to a re-plan on the subsequent fractions of treatments. The commercially available Syed Implants are about 3 cm in thickness and the passage of needles through that to position inside the tumor is difficult. Thinking about an alternative, we decided to use the 3D printer that was available in the department. Multiple iterations of Syed Templates were created and evaluated, dummy plans were created and checked to make sure practically this template is able to be used for improving patient comfort as well as positioning accuracy. **Results:** Using the 3D printer, we are able to print and deliver treatment with the guidance of a thinner and robust template by developing an in-house CAD plan data-file. **Conclusion:** Innovative technologies such as 3D printing is able to give clinically relevant solutions for day to day use.

PO-GePV-P-21

A Decentralized and Autonomous Blockchain-Based Medical Physics Education Platform: Toward a New Paradigm

B Zhang^{1*}, S Becker², J Zhou³, S Chen⁴, B Yi⁵, (1) University of Maryland School of Medicine, Baltimore, MD, (2) University of Maryland School of Medicine, Baltimore, MD, (3) Rutgers - Cancer Institute of New Jersey, Belleville, NJ, (4) University of Maryland School of Medicine, Baltimore, MD, (5) University of Maryland School of Medicine, Baltimore, MD

Purpose: Create a decentralized blockchain-based education platform to meet the modern medical physics education needs nationally and globally. **Methods:** The platform uses on two enterprise-level open source packages: Open edX and Hyperleger Fabric. The Open edX platform is responsible for course creation and hosting while the Hyperledger-based blockchain manages the course system. The blockchain 1)grants course creation permission; 2)issues course completion certificate; and 3)validates the course certificate upon request. The chaincodes of the blockchain are implemented through Go programming language. **Results:** We have successfully built up such a decentralized and autonomous education platform locally. An initial group of users such as all full or emeritus AAPM members can be enrolled through email verification and issued a private/public keypair. Other users are open to register and are subject to a single enrollment vote from an enrolled user. Any users can obtain time-constrained permission to create or modify a course, which are also subject to vote. Whether to publish a new course or a course improvement is also determined by consensus. Participation in the vote grants users reward points which determine the voting power of the user along with a power abuse prevention mechanism. Inactivity in participation would lead to the removal of a user. Furthermore, any activity be can monitored by any user anytime through the ledgers. Our local implementation is ready to migrate to a cloud-based environment. **Conclusion:** This blockchain-based medical physics education platform does not have a centralized authority to control its access and contents. Anyone can suggest what to teach and what to learn. The platform enables a decision based on collective intelligence and helps to create medical physics courses from the needs of the users, by the talents and visions of the whole medical physics community. This also can provide free medical physics education globally.

PO-GePV-P-22

Recommendations for Treatment Planning Dose Indices for Single-Isocenter Single Target VMAT Brain Stereotactic Radiosurgery/Radiotherapy; A Retrospective Analysis

D Pearson, D Newell*, K Joseph, University of Toledo, Toledo, OH

Purpose: Dose indices are effective variables that may serve as predictors in determining the plan quality for Stereotactic Radiosurgery (SRS) and Stereotactic Radiotherapy (SRT) treatments of brain lesions. The purpose of this study is to provide recommendations for dose indices versus target volumes based upon an institutional retrospective analysis of Linac based VMAT brain SRS/SRT treatments utilizing the Edge Radiosurgery System (Varian Medical Systems Inc, Palo Alto, CA). This study compares the dose indices of VMAT brain SRS/SRT treatments of patients treated at The University of Toledo Medical Center against previously established institutional guidelines for dose indices of this kind of treatment based upon Dynamic Conformal-Arc (DCA) radiotherapy. **Methods:** One hundred and forty patients with approved treatment plans planned in RayStation V.8A (8.0.1.10) TPS treated with VMAT SRS/SRT on Varian EDGE radiosurgery system using 6FFF with single brain metasis were randomly selected. Plans were grouped into three categories based upon lesion volume; small (0.10-2.0 cc, n=80), medium (2-10 cc, n=35), large (10-40 cc, n=24). Gradient Indices (GI), RTOG conformity indices (CI(RTOG)), and Paddick Conformity Indices (CI), were computed for each plan using a script developed in house and calculated via a collapsed cone dose calculation algorithm V.4.1 with a 1mm dose grid resolution. Plan indices for each plan were tabulated. **Results:** For patients presenting with small brain lesions (n=80), medium lesions (n=36), and (n=24) large lesions the recommendations suggested for plan quality metrics are presented in Table 1 of supporting documents. **Conclusion:** This study provides recommendations based upon an institutional retrospective analysis for plan indices versus lesion volumes for VMAT brain SRS/SRT Linac based treatments; serving as a guide to assess brain VMAT SRS/SRT plan quality. We recommend plan quality metrics be calculated for patients, preferably using scripts to allow this to be accepted into the clinical workflow.

PO-GePV-P-23

Volumetric Study for Hearing Preservation Using Fractionated Radiosurgery

A Rashid*, Y Niu, D Pang, Georgetown University Hospital, Washington, DC

Purpose: To determine clinically relevant SBRT volumetric dose tolerance limits of hearing preservation in 1 to 5 fractions for Cyberknife based on statistical analysis of outcomes data. **Methods:** Retrospectively analyzed sixty-nine acoustic neuroma Cyberknife cases treated in 3 or 5 fractions. A logistic-dose response model of data was performed using the DVH Evaluator software. The selected endpoint was 50 dB of hearing loss in one ear, which is part of the Gardner-Robertson criteria for serviceable hearing. A 5 fraction regimen was chosen for the aggregate analysis to minimize the uncertainty of the alpha/beta parameter. QUANTEC used an alpha/beta parameter of 3 Gy and we iteratively determined that the alpha/beta parameter with maximally likelihood fit was 4.2 Gy. Confidence bands were estimated using the profile likelihood method. **Results:** QUANTEC recommends keeping single fraction maximum dose to the cochlea below 14 Gy to maintain less than 25% risk of serviceable hearing loss, so we also chose 25% as the risk level for comparisons, which corresponded to cochlea Dmax=25.6Gy/5fx in this updated analysis. In regard to volume effects, the cochlea D0.05cc<=20Gy/5fx and the median cochlea dose D50%<=20Gy/5fx both corresponded to 25% risk. **Conclusion:** The 50dB threshold level for serviceable hearing can be used to estimate the rate of hearing risk analysis from multisession acoustic neuroma radiosurgery. The resultant risk levels from the clinical datasets were compared to the QUANTEC 25% risk expectation, providing optimism for clinic use. Potentially the differential dose tolerance of the various volumes of the hearing apparatus could be exploited to improve hearing preservation.

PO-GePV-P-24

Dosimetric Benefits of Target-Tracking-Optimization Based Partial-Arc VMAT Technique for Mono-Isocenter Multiple Pulmonary Metastases ABC-SBRT

C Gong*, X Xiang, J Xiong, H Wu, The First Affiliated Hospital of Nanchang University, Nanchang, 36CN

Purpose: Treating multiple pulmonary metastases with stereotactic body radiation therapy (SBRT) becomes more challenging and promising. The purpose of the present study was firstly to apply the target-tracking-optimization based partial-arcs VMAT technique to further optimize and improve the dose distributions of target volumes and organs at risk (OARs) for mono-isocenter multiple pulmonary metastases active breathing control (ABC)-SBRT. **Methods:** Eighteen patients with multiple pulmonary metastases underwent mono-isocenter highly conformal coplanar partial-arcs VMAT SBRT treatment in our institution were retrospectively identified. All patients received ABC-CT simulation, ABC-gated kilovoltage cone-beam CTs (kV-CBCTs) and ABC-gated radiotherapy. A single-isocenter was placed among the lesions and doses were 60Gy in 8 fractions. Plans were calculated in Monaco TPS with target-tracking-optimization based partial-arcs VMAT (TTO-VMAT) technique and normalized to at least 95% of the planning target volume (PTV) receiving 100% of the prescribed dose. For comparison, single-isocenter without TTO-VMAT (unTTO-VMAT) and conventional multiple-isocenters VMAT plans (MultIso-VMAT) were created respectively. Dosimetric evaluation of planning target volume (PTV) and OARs were analyzed and compared. **Results:** The present TTO-VMAT SBRT showed better dosimetric advantages compared to other two methods. For gradient indexes (GIs), R50, R100 and D2cm, TTO-VMAT plans were superior to all plans, the unTTO-VMAT was slightly inferior to the MultIso-VMAT plans. There was no clinically significant difference in conformity indices, heterogeneity index, lung-V30 and other OARs among all SBRT plans. The normal lung V5(p = 0.04), V10(p = 0.02), V20 (p = 0.03) in TTO-VMAT were lower than those in MultIso-VMAT and unTTO-VMAT plans. **Conclusion:** The proposed target-tracking-optimization based partial-arcs VMAT optimization algorithm successfully improved dosimetric performance for mono-isocenter multiple pulmonary metastases SBRT and reduced doses to the normal lung and some of other OARs. This TTO-VMAT has the capability of immediate clinical application.

PO-GePV-P-25

Dosimetric Evaluation of Aperture-Based and Beamlet-Based Optimization for Conventional IMRT/VMAT and SBRT

D Wu^{1*}, A Eldib², Q Jiang³, L Chen⁴, C Ma⁵, (1) The People's Hospital of Guangxi Zhuang Autonomous Region, Nanning, Guangxi, CN, (2) Fox Chase Cancer Center, Philadelphia, PA, (3) The First Affiliated Hospital of Chongqing Medical University, Chongqing, CN, (4) Fox Chase Cancer Center, Philadelphia, PA, (5) Fox Chase Cancer Center, Philadelphia, PA

Purpose: The quality of radiotherapy plans depends on many factors such as optimization methods, dose constraints and delivery techniques. This study investigates the plan quality for conventional IMRT/VMAT and SBRT utilizing aperture-based and beamlet-based treatment optimization algorithms. **Methods:** The Varian Eclipse and Prowess RT-Pro TPS were used in this study, which employed beamlet-based and/or direct-aperture optimization (DAO) for IMRT/VMAT planning. Thirty-six patients were re-planned using Prowess with matching beam configuration and dose constraints, who were previously planned using Eclipse and treated on Varian accelerators. Treatment sites included head and neck, lung, liver and prostate. Plan quality was evaluated using the homogeneity index (HI), conformity index (CI), Dmax(D1%), Dmin(D99%), and dose falloff outside the target (Glouter) for conventional IMRT/VMAT, and R50% and D2cm for SBRT additionally. Statistical significance was tested using a paired Student's t-test for normality distribution and a Wilcoxon signed rank tests for non-normality distribution. **Results:** For IMRT, the same results were found in CI and Glouter except for small differences in Dmax, Dmin and HI between beamlet-based optimization (Eclipse) and DAO (Prowess). For VMAT, HI, Dmax and Glouter were identical for Eclipse and Prowess (both using DAO) except for small variations of CI and Dmin. Higher dose volumes were found for prostate OAR with DAO. Identical SBRT plan quality (CI, HI, Dmax, Dmin, R50% and D2cm) was obtained using either IMRT or VMAT delivery techniques for the two TPS/optimization methods when Dp was assigned to 65-85% isodose lines. **Conclusion:** Our study showed that both TPS using DAO and/or beamlet-based optimization produced high-quality plans that met our clinical acceptance criteria. DAO is more efficient than beamlet-based optimization because of the avoidance of leaf sequencing but its random nature in field shape selection results in larger HI (Dmax) for conventional IMRT/VMAT, which is not a problem for SBRT.

PO-GePV-P-26

First Quality Assurance Implementation of Treatment Planning System for Pencil Beam Scanning Proton Radiotherapy

W Xiong*, G Yu, M Kang, S Huang, H Lin, New York Proton Center, New York, NY

Purpose: A quality assurance (QA) program for pencil beam scanning (PBS) proton treatment planning system (TPS) was developed and implemented along with monthly CT QA. **Methods:** A program consisted of a periodic test procedure that was designed for PBS TPS quality assurance (QA). The program includes verification of the CT calibration for proton dose calculation algorithm, CT images transferred to TPS, and software functions in TPS. The consistency of the dose calculation algorithm included dose comparison between standard SFO/MFO plan and forwardly re-calculated plans. The consistency of CT images of Catphan transferred to TPS was examined, i.e patient orientation, image geometry, tissue density, and contour dimensions. The aspects of software evaluated include proton layer energy, monitor unit, dose calculation, conversion between HU number to electron density, and proton Relative Stopping Power ratio (RSP). **Results:** The maximum Energy layer for standard SOBP created on randomly CT images from one of our 3 CT simulators kept the same as 117.167MeV, overall the MU was 39993±23 MU, within the selected range 40000±800 MU, the geometry range is (9.62±0.1) cm, within selected range (9.65±0.2)cm, WED is (10.08±0.07), within preselected (10.0±0.2)cm. The maximum dose of the SOBP plan is (96.8±0.6) which is within (97±2)%, and the mean dose is (95.9±0.2)%, within (96±1)%. **Conclusion:** Based on TG53, TG185, and TG224, we are the first to develop the TPS QA program for our PBS proton planning. The program is efficient and effective to check the integrity of the TPS. Test results for the dose calculation algorithm are satisfactory. The implementation of the PBS TPS QA programs verified the consistency of TPS performance which can be traced back to the commission and verification of initial TPS. Periodic testing would have to be followed to ensure the TPS consistently meets the desired treatment quality.

PO-GePV-P-27

Evaluation of Varian Identify SGRT System for Localization of Cranial Targets

V Stakhursky^{1*}, W Chang², M Sewell³, I Stakhurska⁴, S Kriminski⁵, (1) USONCOLOGY CMOH, Philadelphia, PA, (2) U Oncology, Philadelphia, PA, (3) US Oncology, Snellville, GA, (4) Karlsruher Institut Fur Technologie Studienkolleg, Karlsruher, DE, (5) Health Quest, Wappingers Falls, NY

Purpose: Identify (Varian, Palo Alto, CA) surface-guided localization system is a new imaging option offered to monitor inter-fractional and intra-fractional motion of patients. This study evaluates accuracy of target localization for non-coplanar beam treatments using Identify. **Methods:** An anthropomorphic head phantom was scanned using GE Discovery RT, 0.625mm slice thickness, and a multi-arc non-coplanar plan was created in Eclipse TPS (Varian). The DICOM structures of head contour and plan isocenter were sent to Identify server for surface image processing. The head phantom was placed on 6D TrueBeam (Varian) treatment couch in 10 different positions varying 3 translational (<1.5cm) and 3 rotational (<3deg) degrees of freedom, emulating inter-fractional variations. For each phantom placement CBCT imaging was performed using 1mm slice thickness. Imaging followed by a 6-DOF 3D automatic registration to reference image. Registration accuracy was manually reviewed by checking positions of three fiducials. The calculated shift parameters were compared to those generated by Identify system based on comparison of optically rendered head surface and radiographic external contour. After applying CBCT shifts the couch angle was shifted to +90deg position and Identify registration parameter were recorded. **Results:** For 0-degree couch position the maximum magnitude of translational offset recorded was 0.8mm (avg 0.7mm), with largest component in vertical direction (0.5mm). Rotational errors were 0.4deg(yaw), 0.1deg(roll) and 0.2deg(pitch). When Identify was generating shifts based on comparison of optical surface to optical surface captured during the first treatment session, translational match improved to 0.4mm magnitude, 0.2deg(yaw), 0.1deg(roll) and 0.1deg(pitch). When Identify tracked positional shifts during couch angle changes (+90, +45deg), the translational offset magnitude was 0.6mm and rotational errors were under 0.6deg. **Conclusion:** Identify surface guided positioning system is capable of localizing cranial targets with a better than 1 mm precision for non-coplanar treatments.

PO-GePV-P-28

Multichannel Vaginal Cylinder with Intrauterine Tube Applicators for Treating Vaginal, Cervical and Endometrial Cancer

M Jacobs¹, B Li², K Dou^{2*}, (1) Mercy Medical Center, Baltimore, MD, (2) MedStar Health, Mercy Medical Center, Baltimore, MD

Purpose: Our institution offered patients brachytherapy with the single (SCVC) or multichannel vaginal cylinder (MCVC) for vaginal cancer and with the tandem and ring (TR) for cervical and endometrial cancer treatment. Each modality has advantages in some aspects over others. A combination of multichannel vaginal cylinder with intrauterine tube (MCVC-IUT) has shown a superior capability of treating vaginal, cervical and endometrial cancer in one procedure over to two procedures using, respectively, TR and cylinder applicators. The current work presents dosimetric evaluation and clinical application of MCVC-IUT applicator set in treating vaginal, cervical and endometrial cancer. **Methods:** Three sizes of MCVC in diameter 25, 30 and 35 mm and three types of intrauterine tubes of 20mm/15 deg, 40mm/30deg and 60mm/45deg were offered to patients. Each was assessed with physical measurements and CT scanning. The dwell source position of the cuffed catheters and intrauterine tubes was verified with a source position simulator and Gafchromic film EBT3. An Elekta Oncentra version 4.5.3 was served as a planning system. Radiation was delivered by an Elekta Flexitron. Radiation dose was prescribed either to the depth or the planned treatment volume (PTV) and point A. IPSA was used for radiation dose optimization. **Results:** Radiation dose 700cGy for a MCVC-IUT system was prescribed to the point A and PTV at 5mm away from the surface of a 25mm-MCVC with treatment length of 50mm. A Smit Sleeve was used for guiding intrauterine tube and identifying cervix. MCVC was able to sculpture radiation dose to the PTV while sparing dose to nearby organs at risk such as rectum and bladder. A

final dose distribution featured a joint dose distribution of tandem and ring with a cylinder. **Conclusion:** MCVC IUT applicators integrated outstanding dosimetric features from TR and MCVC in an effective treatment of vaginal, cervical and endometrial cancers.

PO-GePV-P-29

Daily KV Image Protocol of Prostate Patient Setup with Minimal CBCT

J Zhou^{1*}, Y Zhang², W Feng³, N Yue⁴, (1) Rutgers - Cancer Institute of New Jersey, Belleville, NJ, (2) Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, (3) Saint Barnabas Medical Center, Tenafly, NJ, (4) Rutgers University, New Brunswick, NJ

Purpose: This study's intent is to test if first 3 fractions of a new IGRT protocol consisting of 3 CBCTs followed by daily kV pair and weekly CBCT are able to represent of all remaining treatment fractions. In this study, we are focused on discussing the setup errors of CBCTs. We will discuss neither the setup errors of kV pairs or between kV pairs and CBCT. **Methods:** We would like to compare a new IGRT protocol includes 3 CBCT followed by daily kV pair and weekly CBCT with the current IGRT protocol includes daily CBCT. We randomly selected 10 prostate patients who have daily CBCT in the entire treatment course (total 350 set of CBCT). Our evaluation criterion is the fraction of CBCT position mismatches in the first 3 fractions. An additional CBCT is acquired if only 1 fraction mismatches among the first three. We define as 'new protocol eligible' (eGroup) the group of patients for whom the setups with daily CBCT images match within the pre-selected thresholds of 5, 10, and 15 mm those of the consecutive CBCTs for at least 50% of the fractions. A new protocol ineligible (iGroup) is defined as the group of patients other than eGroup. **Results:** The fractions of patients in the eGroup were 10%, 80% and 90%, when the setup thresholds selected were 5, 10 and 15mm respectively. The sensitivities of determining iGroup from the first 3 fractions of CBCT were 0.88, 1.0, and 1.0, and the specificities were 1.0, 0.75 and 1.0 with thresholds 5, 10 and 15 mm respectively. **Conclusion:** The method suggested here well categorized cases for our new IGRT protocol. More patients are eGroup eligible if larger setup threshold is used. CBCT frequency in the daily kV plus weekly CBCT protocol may need to increase for protocol ineligible patients.

PO-GePV-P-30

Comparison of Physical and EQD2 Plan Parameters Between Two Kinds of Hybrid Plans for Stage III NSCLC

h wang*, Y Zhou, Z Xu, Shanghai Chest Hospital Shanghai Jiaotong University, Shanghai, 31CN

Purpose: To compare physical and EQD2 plan parameters between two kinds of hybrid plans for stage III NSCLC. **Methods:** Two kinds of hybrid plans named CFRT&SBRT and CFRT&SIB were retrospectively made for 20 patients with stage III NSCLC. Prescription dose of CFRT&SBRT plans was 30×2Gy for PTVLN (lymph node) and sequential 4×12.5Gy for PTVPT (primary tumor), while prescription dose of CFRT&SIB plans was 26×2Gy for PTVLN and sequential 4×2Gy for PTVLN combined with 4×12.5Gy for PTVPT. Physical dose of SBRT and SIB plans were respectively superposed with 30 and 26 fractions dose of CFRT to acquire physical plan parameters of CFRT&SBRT and CFRT&SIB plans. SBRT and SIB plan dose were then corrected by voxel-wise EQD2 dose using an in-house Matlab script. EQD2 corrected SBRT and SIB dose were respectively superposed with 30 and 26 fractions dose of CFRT to acquire EQD2 plan parameters of CFRT&SBRT and CFRT&SIB plans. The physical and EQD2 plan parameters were respectively compared between two kinds of hybrid plans. Non-transit electronic portal imaging device (EPID) dosimetry analysis was performed to rule out dosimetric errors during hybrid plans delivery. **Results:** Physical plan parameters of PTVLN D2, HI, and CI60Gy, PTV(PT+LN) CI60Gy, esophageal V50 and Dmax had more advantages in CFRT&SIB plans, while EQD2 plan parameters of PTVLN HI and spinal cord Dmax were more advantageous in CFRT&SIB plans. There were no statistical difference in other physical and EQD2 parameters for two kinds of hybrid plans. The delivery errors of hybrid plans components were acceptable using the criterion of 2%/2mm and passing rate more than 90%. **Conclusion:** All physical dose volume objectives were met for two kinds of hybrid plans. CFRT&SIB plans had more advantages over CFRT&SBRT plans on physical and EQD2 plan parameters.

PO-GePV-P-31

Using Edge Detectors for Field Output Factor Measurements

V Stakhursky^{1*}, M Sewell², S Kriminski³, I Stakhurska⁴, (1) USONCOLOGY CMOH, Philadelphia, PA, (2) US Oncology, Snellville, GA, (3) Health Quest, Wappingers Falls, NY, (4) Karlsruher Institut Fur Technologie Studienkolleg, Karlsruher, DE

Purpose: Sun Nuclear Corporation (SNC) Edge Detector sensors are often picked as detectors of choice for measurements of small fields output factors (OF) due to their small measurement volume and high sensitivity. However these detectors show increased response for the measurement of larger field output factors. Here we review the limitations of edge detectors for large field output measurements. **Methods:** 4 Edge Detectors were chosen to evaluate TrueBeam output factors for fields in the range of 1cmx1cm to 40cmx40cm. The measurements were done using PTW water tank at 5cm depth and 95cm SSD. Each detector was used to measure output factors for 4 TrueBeam energies, 6x, 6xFFF, 10x and 15x. The field output measurements were initially normalized to 10cmx10cm field output for each of the detectors. Similarly, CC13 mini ion chamber (PTW) was used to measure the outputs for fields 3cmx3cm and higher. All the measured data was compared to output factors measured using Standard Imaging A19 ion chamber. Statistical uncertainty was evaluated for Edge Detector sample group for each field size measurement and the average output factor compared to ion chamber measurement. **Results:** PTW CC13 and SI A19 chambers showed excellent agreement for field sizes 5cmx5cm and larger. Edge Detectors matched the ion chamber output factors in the range of 5cmx5cm-10cmx10cm for low X energies 6x and 6xFFF and between 5cmx5cm and 15cmx15cm for 10x and 15x energies. For larger fields, edge detectors overresponded, and relative output factors exceeded ion chamber measurements with effect more pronounced for larger fields. The largest deviation noted was 2.3%(6x), 2.2%(6xFFF), 1.5%(10x), 1.2%(15x) for 40cmx40cm field. **Conclusion:** While being a good tool for measurement of small field dosimetry, edge detector measurements for fields 15cmx15cm and larger should be treated with care. Normalization of OF should be done to output at 5x5-10x10cm field.

PO-GePV-P-32

Design and Implementation of Internal Shielding to Reduce Electron Back Scattering

M Xu^{1*}, R Foster¹, S Mihalcik^{1,2}, (1) Northwestern Medicine Cancer Centers, Geneva and Warrenville, IL, (2) Radiation Oncology Consultants, Ltd., Oak Brook, IL

Purpose: The objective was to report implementation of internal shielding to reduce electron back scattering in mouth-lip treatment. **Methods:** A customized mouth guard was designed to reduce electron back scattering (EBS) to protect the normal organs beyond the irradiated area. The mouth stent was made by a commercially available BiteLok by Klarity with lead foil to shield the transmission radiation. EZ-bolus pellets were coated surrounding lead to attenuate the electron back scattering in the interface of lead and internal normal tissue. The delivered dose was verified by OSLD in vivo dosimetry confirmed the prescribed dose. **Results:** An incident electron beam of 6 MeV was used to treat the upper lip of 1.0-cm thickness. Additional 1.0-cm thick bolus was applied to the lip surface to ensure the skin dose achieved. The energy Em at 2.0-cm depth was 1.76 MeV. The minimum lead thickness for shielding Em was 0.9 mm. Based upon the characterization on the interface of lead and soft material, EBS was estimated around 67%. The depth upstream in tissue for EBS approximately was estimated to be 5.9-mm range for a 10% transmission of EBS. These obtained thickness values of lead and EZ-bolus provide fundamental parameters in the mouth guard/stent design. An OSLD in vivo dosimetry further verified 1.8% deviation in measured and prescribed doses in the device used. **Conclusion:** The commercial BiteLok and EZ-bolus can be utilized to make an internal shielding device as a mouth guard to shield electron irradiation and reduce EBS. The design can be implemented quickly and reliably in clinic electron beam setup. In vivo dosimetry further verifies the shielding effects met design goal on the

transmitted dose through lead and residual EBS.

PO-GePV-P-33

Comparison of Intracranial Stereotactic Radiotherapy (SRS/SRT) Plan Quality Using CyberKnife, Eclipse MLC and Cone Techniques

X Zhang*, S Jang, S Lee, A Hirsch, K Mak, M Dyer, M Truong, Boston Medical Center, Boston, MA

Purpose: To compare intracranial SRS/SRT plan quality among CyberKnife (CK), Multi-leaf collimator (MLC), and Cone techniques. **Methods:** Three groups of patients treated with CK were selected; group one (14 patients) with gross target volume (GTV) of 0.4 – 4.7 cc was re-planned with Eclipse Cone & MLC, group two (12 patients) with GTV of 0.1-1.3 cc was re-planned with Cone, and group three (12 patients) with GTV of 0.9 - 74.4 cc was re-planned with MLC. Plan quality was evaluated with Paddick's conformity index (CI), Gradient index (GI: the ratio of isodose volume V50%/V100%) to represent the normal tissue dose. One isocenter with the coplanar beam and the same GTV dose coverage were used for plan comparison. **Results:** For CK/MLC/Cone comparison in group one, three Cone-plans with GTV (>2.5cc) could not meet the GTV coverage and were eliminated from the comparison. The median CI was 1.16 (1.06-1.39), 1.18 (1.03-1.55) and 1.46 (1.06-2.9), and the median GI was 3.67 (2.68-4.38), 4.68(4.25-5.33) and 2.51(2.26-4.72), respectively. MLC-plans were not attempted for tumor volume of < 0.4 cc due to the MLC limitation. CK and MLC-plans were comparable in CI and were superior to Cone-plans. Cone-plans showed the lowest GI, and MLC-plans had the highest GI among all three techniques. Further comparison on MLC/CK and Cone/CK plans showed a good agreement with the group one results using patients with more different tumor size ranges. **Conclusion:** The Cone-plans were highly affected by tumor shape and size, and showed the most inferior CI and superior GI than the other two methods. The MLC-plans had some limitations for small size targets and also received the highest normal tissue doses in low dose areas. The CK-plans did not have any tumor size restriction, and the plan quality was either comparable or in between the other two methods.

PO-GePV-P-34

IAEA Guidance on the Certification of Clinically Qualified Medical Physicists

G Loreti*, D van der Merwe, International Atomic Energy Agency, Vienna, AT

Purpose: The global shortage of medical physicists has been highlighted in publications and by professional organizations using different platforms, e.g. IDMP. The International Medical Physics Certification Board (IMPCB) was formed in 2010 and one of their major objectives is to support the practice of medical physics through a certification programme in accordance with the International Organisation for Medical Physics (IOMP) guidelines. In the past decade, the IAEA has also produced consensus guidance to promote the profession. **Methods:** The lack of recognition of clinically qualified medical physicists (CQMPs) as health professionals, implies that formal national certification has not been widely adopted. In 2018, the IAEA embarked on a consultation process with professionals, as well as regional and international organizations, in order to produce guidance to encourage the formation of national certification bodies. **Results:** In February 2021, the IAEA published the Training Course Series No. 71 Guidance on the Certification of CQMPs (TCS71). The publication, endorsed by the IOMP and IMPCB, was launched through an IAEA press release; and outreach through emails and social media in collaboration with the co-endorsing organizations. Consultations with a focus group of expert medical physicists from different regions, highlighted the need for further practical guidance. Although certification is implemented in some Member States, the framework is applied variably. Medical physics practice is often approved by a radiation regulator or a national professional society, and not a health authority; hospitals accept certification from foreign certification bodies and/or regular re-certification is not based on continuing education. **Conclusion:** The IAEA aims to enhance the recognition of CQMPs as health professionals, in alignment with ILO's International Standard Classification of Occupations. TCS71 provides guidance on the application of best practices in the education of medical physicists, alignment of CQMP competencies to international standards and establishment of national certification bodies to recognize CQMPs.

PO-GePV-P-35

Application of Intensity Modulated Arc Therapy (IMAT) with Multi-ISO Planning Method to Sparing of Organs at Risk

W Bai¹, Y Gao², W Zhang³, Z Dong⁴, D Zhao⁵, H Yang⁶, R Zhang^{1*}, (1) The Fourth Hospital of Hebei Medical University, Shijiazhuang, CN, (2) Hebei General Hospital, Shijiazhuang, CN, (3) Shijin Irrigation District Affairs Center, Hebei Province, CN, (4) Affiliated Hospital of Hebei University, CN, (5) Yuanshi County Hospital, CN, (6) Tangshan People, s Hospital, CN

Purpose: We propose a new type of treatment that employs multi-isocenter technique instead conventional mono-isocenter approach and drastically reduce dose to the underlying sensitive structures often present in these cases. **Methods:** Two sets of IMAT plans(group A with multi-ISO centers and group B with mono-isocenter)were generated on Pinnacle 9.10 planning system formulated for a set of three representative cases: bilateral breast cancer,brain metastasis from lung carcinoma with intracranial lesions<=3, a scalp sarcoma,respectively. The dose distribution of the tumor and organs at risk and the delivery efficiency of the two sets of plans were compared. **Results:** Both sets of plans in two groups satisfied all clinical requirements and for targets there were no clinically significant difference in HI, CI and other PTV dose coverage.Paired comparison results of dose distributions indicated that group A plans were significantly superior to group B plans in organs at risk. In the bilateral breast case,V30 of heartin group A was better than that of group B. Especially for the brain cases that lesion located near by the stem, multi-isocenter plan reduced the stem dose about 950 cGy compared to the mono -isocenter plans. However, there were not such trend in middle ears and spinal cord. In the scalp case reduced the max and mean doses delivered to the brain by 30Gy (from 54Gy to 24Gy) and 7Gy (from 15Gy to 8Gy), respectively. In terms of monitor units and treatment time group A were slightly higher than group B. **Conclusion:** Multi-ISO IMAT is a feasible and practical method to significantly protect some OARs for superficial lesions while compromise a little planning efficiency. The benefits of this technique and its applicability should be further investigated.

PO-GePV-P-36

CyberKnife 0-View (xSight Spine) Tracking for Lung Tumors: Is It Safe at Distances Greater Than 5cm?

M Curry*, C Busselberg, M White, J Conlon, MercyOne Des Moines, Grimes, IA

Purpose: To determine the safety of delivering radiation with the CyberKnife system to a lung lesion using a 0-view plan where the tumor lies more than 5 cm from the spine tracking center. **Methods:** The CIRS lung motion phantom has an anatomical spine built in for spine tracking on the CyberKnife system. The ball cube built into the CIRS phantom is within a 5cm radius of the spine. Therefore, an external ball cube was placed in a reproducible fashion outside of the phantom. This way the spine within the phantom was leveraged to deliver radiation to a ball cube that was 20cm away from the spine tracking align center. The Accuray Precision Planning System version 3.0.1 was used to generate a treatment plan to deliver dose to the ball cube while tracking on the spine (0-view lung tracking). The initial end-to-end delivery was done without any ball cube motion. A future delivery will incorporate motion. After the radiation was delivered the Accuray provided E2E film analysis software v4.0 was used to calculate a targeting error. TG-135 recommends a targeting error of less than 1.5mm for extreme end-to-end scenarios. **Results:** The initial analysis within the E2E software yielded a targeting error of 1.77mm. **Conclusion:** Though this is a bit higher than the recommendation given in TG-135, given the extreme nature of this delivery the result is quite impressive. Since the ball cube was at 20cm from the spine, the precision planning system was forced to eliminate many more beams than normal during the optimization (using VOLO). The reduction in beams caused the treatment plan used for the initial delivery to provide less dose coverage to the ball cube as normally would be by a plan which was allowed more beams.

PO-GePV-P-37

Retrospective MR Image Review of Stereotactic Radiosurgery for Up to 7 Metastases

K Dou^{1*}, M Jacobs², A Halthore², C Okoye², F Lerma¹, J Rodger¹, C Rosen¹, (1) MedStar Health, Mercy Medical Center, Baltimore, MD, (2) Mercy Medical Center, Baltimore, MD

Purpose: Stereotactic radiosurgery (SRS) is an established treatment option for patients with a limited number of brain metastases. SRS uses a high dose of radiation to treat tumors. SRS has shown advantages in the increased local control compared with whole brain radiotherapy (WBRT). However, SRS might bring about a risk of radiation induced side effect to be observed months to years after SRS. The current research is to review SRS treated metastases on MR images followed up to 8 years after SRS. **Methods:** This is a retrospective imaging study on brain SRS for patients with up to 7 brain metastases. SRS treatment option with a single iso-center technique was offered to the patients with 2 or more brain metastases. The 1- mm magnetic resonance (MR) images with contrast was registered with 1mm-CT images. Identified target volumes were delineated on the registered MR and CT images. A Varian Eclipse version 15.1 treatment planning system was used for treatment planning. Daily image guidance was used for target localization and patient alignment. The treatment was delivered with volumetric modulated arc therapy with 6MV flattened filter free (6MV FFF) mode at a rate of 1400 MU per minute from a Varian TrueBeam linear accelerator. **Results:** Followed up MR images in the mean 5 years (ranging from 2 to 8 years) after SRS showed an evolution of metastases (treated volume (TV)). A good control of metastases was seen from months to years after SRS. Some patients had necrosis formed within the treated volume and then degraded with time. Severe side effects from SRS are not observed by reviewing the MR images. **Conclusion:** A review of the followed up MR images indicated that both single and multiple iso-center technique are able to achieve similar tumor control. A single iso-center SRS is suggested for multiple metastases.

PO-GePV-P-38

A New General Maximum Intensity Projection Technology Via the Hybrid of U-Net and Radial Basis Function Neural Network

Z Chao*, Shenzhen Institutes of Advanced Technology Chinese Academy of Sciences Shenzhen CN

Purpose: To develop a new general neural network-based technology that can better and clearly display the projected images. **Methods:** We propose a new method based on the hybrid of convolutional neural network (CNN) and radial basis function neural network (RBFNN) to synthesize the projection image. We first adopted CNN to obtain feature or enhanced images to be projected; subsequently, the RBF neural network performed further synthesis processing for these data; finally, the projection images were obtained. For experimental data, in order to increase the robustness of the proposed algorithm, the following three different types of datasets were adopted: the vascular projection of the brain, the bronchial projection of the lung parenchyma, and the vascular projection of the liver. In addition, radiologist evaluation and five classic metrics of image definition were implemented for effective analysis. **Results:** Compared to the traditional MIP technology and other neural network structures, the proposed method achieved the best comprehensive subjective evaluation and the best image quality-based objective metrics evaluation. **Conclusion:** The use of a large number of different types of data and superior experimental results proved the versatility and robustness of the proposed method. The new neural-network-based technology can display higher quality projected images.

PO-GePV-P-39

Imaging QA On CyberKnife According to TG-135_ a Practical Approach

S George*, S Davis, R Tolakanahalli, V Mishra, A Gutierrez, Miami Cancer Institute, Miami, FL

Purpose: "Report of AAPM TG 135: Quality assurance for robotic radiosurgery" recommends monthly and annual QA of the imaging system specifically for the signal to noise ratio, contrast-to-noise ratio, relative modulation transfer function and spatial resolution of the amorphous silicon detector. These tests are easily performed and analyzed on any other treatment modalities with customized phantoms and analysis software. With the complexity of the image extraction process and the image characteristics of the CyberKnife® system, it is a very difficult task to generate a report comparable to any other modalities on this area of Quality Assurance. **Methods:** By using the QC-kV-1 Phantom, the slanting phantom support table with inserted fiducial markers and PIPSpro™ software from Standard Imaging, we were able to generate customized plan for the imaging QA procedure and was able to analyze the images on a regular basis to generate reports. **Results:** Monthly QA and annual QA reports, according to the industry standards are generated and evaluated for the suggested tests in TG-135. **Conclusion:** Using the Imager extraction interface of the IDMS system, we are able to export the images from CyberKnife® and appropriate software and hardware combination we are able to generate standardized reports according to TG-135 requirements for Imaging QA.

PO-GePV-P-40

Inter-Fractional Dosimetric Variation Due to Daily Patient Position Variations in the Accelerated Partial Breast Irradiation with High Dose Rate Brachytherapy (HDR) Using the Multichannel SAVI Applicator with the 3 Fractionation Schema

U Robins*, T Romaguera, R Tolakanahalli, M Rodrigues, Miami Cancer Institute, Miami, FL

Purpose: To determine the inter-fractional dosimetric variation of accelerated partial breast irradiation (APBI) using the SAVI applicator due to daily patient positioning variations, through the first and second day of treatment. **Methods:** A CT is taken for treatment planning purpose, the PTV_eval is created according to the ASTRO recommendations and a treatment plan is made with a prescription of 22.5Gy in 3 fraction to the PTV_eval. Short CT scans were taken before the first treatment on day 1 and second fraction treatment on day2 to ensure no change in the integrity of the applicator and its position with respect to the anatomy. For the purpose of this study. Plans were created on the CTs of the first and second fractions, the dwell times and the source activity of the treatment plan were used in the comparison plans to keep the activity-hour intact. **Results:** The deviation of the PTV_Eval coverage -D90% varied between 0.08% and 6%. The variation in dose to skin ranged from 0.4Gy - 2.1Gy for 2cc and from 1.1 - 2.8Gy for 0.03cc. For the CW/ribs, the deviation of dose for the 2cc ranged from 0.3 to 4.6Gy and for the 0.03cc was from 0.7Gy to 6.5Gy. **Conclusion:** The positioning of the ipsilateral arm plays an important role in the variation of the proximity of the critical structures to the applicator. This variation determines changes in the new PTV_EVAL. Greater variation in dose was noted for 0.03cc as compared to 2cc for both CW/ribs and Skin. Variation in the coverage of PTV-Eval can be as high as 6%. As result of our finding, the highest grade of reproducibility in the patient setup is recommended to minimize the dosimetric variations.

PO-GePV-P-41

Clinical Experience of Pre-Selection Criterion of Patients with Left Breast Cancer for Free Breathing Vs Deep Inspiration Breath-Hold Radiotherapy Technique

T Reynolds*, M Ozer, MN Oncology, St Paul, MN

Purpose: The benefits of deep-inspiration breath-hold (DIBH) radiation technique (RT) for left breast patients (LBPs) are well known, but there is little awareness about challenges and risks associated with this technique. We propose the upfront criterion, based on estimation of heart V20Gy (volume of the heart which receives 20 Gy), to select the LBPs for free breathing (FB) RT. **Methods:** 38 patients, who were referred for adjuvant radiotherapy after left breast conserving surgery were analyzed in this study. All patients were simulated in the supine position and immobilized with breast board. Minimal computer tomography (CT) scan including heart volume was acquired for all patients. Heart V20Gy was estimated using pre-selection heart V20Gy method (based of maximum heart distance included in the field), and FB CT was acquired for patient with V20Gy<5% and DIBH for patients with V20Gy>5%. Using this

selection, 23 patients were selected for FB RT and 15 patients for DIBH RT. The prescription doses were 42.56 Gy/16 Fx and 40.05 Gy/15 Fx. Patients were treated with tangential conformal fields with a multileaf collimator using 6 MV and 10 MV. To avoid hot spots field-in-field techniques was used. All plans were normalized for $V95\% \geq 95\%$ with maximum dose of 107%. **Results:** All 23 pre-selected for FB RT patients complied the criterion calculated $V20Gy < 5\%$ with mean $V20Gy = 1.11$ Gy. Mean heart doses were in the range of 0.94 – 3.67 Gy with an average of 1.89 ± 0.84 Gy. 87% of the FB RT patients had mean heart dose of < 3 Gy. **Conclusion:** This work demonstrates the assessment of pre-selection criterion, based on evaluation of heart $V20Gy$, with respect to selecting the treatment technique of FB or DIBH for LBPs in order to avoid unnecessary complexity from simulation to treatment and also reducing the patient burden on DIBH techniques.

PO-GePV-P-42

Dosimetric Evaluation of Sub-Millimeter Robotic Corrections for Multiple Metastases Single Isocenter Plans

L Muller*, H Tillery, St Peters, Albany, NY

Purpose: To quantify the dosimetric impact of 6DOF corrections for multiple-metastasis, single-isocenter SRS cases. Clinical practices vary on whether or not corrections are applied with couch rotations. This study aims to determine the dosimetric impact of this choice. **Methods:** Using a 21 Varian IX with fine beam isocenter and ExacTrac couch, patient specific QA was performed for several multi-met patients using a Sun Nuclear SRS Mapcheck. Plans included non-coplanar IMRT and VMAT optimized using Eclipse V15.6 and Brainlab's Elements Multiple Mets. The measurements were done in two ways. The first had the SRS Mapcheck precisely set up at isocenter at couch 180 (Varian scale) using the light field and verified by multiple physicists. The patient plans were delivered with all collimator angles and couch kicks (True Composite). The second setup utilized the ExacTrac system to correct the Stereophan position at each couch angle. Residual ExacTrac setup was limited to 0.2mm and 0.2 degrees. Measured doses were compared with plans calculated using Acuros with a 1mm dose grid size. A 3%, 1mm, 10% gamma index was used. **Results:** The residual setup correction from the light field couch 180 setup with ExacTrac was always under 0.7mm and 0.7%. Average gamma passing rates for the light field setup was 80.4%, whereas average gamma passing rates with the ExacTrac couch corrections was 93.0%. Note that this Varian IX has a couch walkout with a radius of 0.6mm. **Conclusion:** We have demonstrated that for couches with non-negligible walkout, ExacTrac setup corrections produce demonstrably better agreement between planned and calculated doses. This work supports current clinical practice to verify and adjust the patient at each couch angle.

PO-GePV-P-43

Comparison of Intrafractional Motion Monitoring During Spine Stereotactic Body Radiation Therapy Using Multiple Immobilization Systems

S Krafft*, E Han, T Briere, The University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: Given the proximity to spinal cord or cauda equina, spinal SBRT requires highly conformal doses with steep dose gradients. As a result, precise positioning and immobilization of the patient must be achieved and maintained for the duration of simulation/treatment. Our goal was to evaluate differences in intrafractional monitoring via ExacTrac during spinal SBRT resulting from a change in immobilization systems used in our clinic. **Methods:** Eight patients with a total of 10 spinal metastatic lesions were prospectively enrolled in a trial designed to evaluate setup/motion error for various combinations of immobilization and image guidance. All patients underwent 3 fraction spinal SBRT and were simulated/treated with one of two SBRT systems – Elekta BlueBAG/BodyFix (n=7) or Klarity SBRT system (n=3). After initial alignment to external marks, residual 6D alignment corrections were applied using the ExacTrac positioning system and subsequently verified to be within $1\text{mm}/1^\circ$. The ExacTrac x-rays system was further utilized to assess intrafractional motion and corrections were applied as necessary such that an overall positioning accuracy of $1\text{mm}/1^\circ$ was maintained. **Results:** Records for 28 treatment fractions were evaluated. The intrafractional shifts necessary to maintain $1\text{mm}/1^\circ$ positioning accuracy were applied in 3/19 (15.7%) and 1/9 (11.1%) fractions with the BlueBAG/BodyFix and Klarity SBRT systems, respectively. During one fraction with the Klarity SBRT system, intrafractional shifts were applied twice, otherwise all shifts were applied once mid-treatment. All applied shifts were $< 2\text{mm}/2^\circ$ in each direction. The averaged translational magnitude of applied intrafractional shifts was 1.4mm and 2.0mm for the BlueBAG/BodyFix and Klarity SBRT systems, respectively. **Conclusion:** Both spinal SBRT immobilization solutions achieve comparable results across the limited number of treatment fractions evaluated. Future study with a larger cohort is warranted. Some intrafractional motion was observed with both systems and demonstrates the necessity of motion management during treatment delivery for spinal SBRT.

PO-GePV-P-44

Validation of the Varian Machine Performance Check Enhanced Couch Accuracy

J Donaghue¹*, S Gajdos², (1) Cleveland Clinic Fairview, Cleveland, OH, (2) Cleveland Clinic Akron General, Akron, OH

Purpose: To determine suitability of the Varian Machine Performance Check (MPC) enhanced couch utility for couch isocentricity testing. This tool uses a specific phantom that contains fiducials for imaging at various gantry, collimator, and couch angles. The intent was to validate the use of MPC as a tool to address isocenter deviation issues. **Methods:** A phantom with a single BB was placed at the isocenter of the gantry, collimator, and couch by means of the Winston Lutz technique. The appropriate translations to reach to the isocenter were determined using an open-source python package. The BB phantom was then analyzed at couch 0, 90, 270 with gantry pointing down. Once at the actual machine isocenter, the actual isocenter size was determined by a Winston-Lutz measurement and this data was compared back to the MPC enhanced couch results. With early tests, the final shift to actual isocenter was not done, and larger discrepancies between measurement and MPC were found. **Results:** It was found that applying table isocenter offsets to the BB phantom was necessary to replicate the MPC values. The gantry isocenter measurement using the Winston Lutz test was not sensitive to minor offsets from actual isocenter. When the magnitude of the shift vector was less than 0.3 mm, the MPC analysis of the couch isocenter was within an average of 0.13 ± 0.12 mm of the Winston Lutz measurement. **Conclusion:** The accuracy of the MPC enhanced couch results as it pertains to the max table offset parameter was confirmed to be within acceptable limits. The MPC utility is an accurate tool for isocenter measurement.

PO-GePV-P-45

Machine Off-Isocenter Winston-Lutz Test in Single-Iso Multi-Mets Intracranial Stereotactic Radiosurgery

D Hu¹*, C Ruan², D Cail¹, J Bredfeldt¹, (1) Department of Radiation Oncology, Brigham and Women Hospital, Dana Farber Cancer Institute, Harvard Medical School, Boston, MA (2) Department of Radiology, Brigham and Women Hospital, Harvard Medical School, Boston, MA

Purpose: Develop a clinically feasible off-isocenter Winston-Lutz test to evaluate the capability of LINAC machine performance in single-iso and multi-mets intracranial stereotactic radiosurgery (SRS). **Methods:** A Brainlab Winston-Lutz test phantom containing one metallic ball (5mm diameter) was attached to tabletop using the mounting device. The distance between machine isocenter and ball center was 8.0cm along the couch direction. Six fields were generated to acquire the MV images with various combinations of gantry angles (0, 90, 180 and 270 degrees) and couch angles (0, 90 and 270 degrees). The field size was defined by MLC position of 3cmx3cm. The off-isocenter Winston-Lutz test was performed on a Varian Edge with HD-MLC. The acquired test images were analyzed using Doselab Pro, Python Pylinac. The delta value was calculated as the difference between field center and ball center in X and Y directions on image. Total delta is Root Sum Square of X and Y delta values. The results were compared with manual measurement in Aria Offline Review. **Results:** The off-isocenter test can be completed within 10 minutes after regular Winston-Lutz test was performed. Image quality was acceptable despite the asymmetric radiation penumbra on field border and the increased field size uncertainty due to off-isocenter effect. Consistent results were observed. The maximum and

mean total delta were 0.84mm and 0.46mm, 0.85mm and 0.46mm, 0.89mm and 0.47mm analyzed using Doselab Pro, Python Pylinac and manual measurement, respectively. When compared among the three methods for each off-isocenter test image, the delta in X and Y directions agreed within ± 0.2 mm. The total delta agreed well within ± 0.2 mm for each image. **Conclusion:** A practical off-isocenter Winston-Lutz test was developed, and its accuracy was validated in this study. The test can be easily integrated into machine morning QA or serve as an independent check for physicist to implement periodically.

PO-GePV-P-46

Phantom Validation of a CT-Based Navigation System Adapted for Interstitial Liver Procedures

T Banks*, T Chiu, Z Xiong, M Folkert, UT Southwestern Medical Center, Dallas, TX

Purpose: To adapt a commercial CT-based neurosurgical navigation system for use in interstitial liver procedures and validate its performance on a representational liver phantom. CT-based navigation technology has been shown to improve efficacy and safety in neurosurgical procedures and offers potential to do the same for interstitial liver procedures, which are used in radiation oncology practice for implanting targeting fiducials or brachytherapy source transfer needles to facilitate precise delivery of radiation to lesions. **Methods:** A mobile intraoperative CT scanner and partnered optical-tracking navigation system were used as the imaging and navigation platforms. The default neurosurgical navigation software was augmented to display segmented structures from radiation-therapy treatment-planning software, enabling visualization of target and avoidance structures during image-guided needle placement. Fiducial needles were tested for compatibility and reliability with the navigation system. A phantom was fabricated in house containing pseudo costal/vascular avoidance structures and lesions visible on CT images, and this phantom was used to test the radiation oncologist's ability to accurately and reproducibly place fiducials in a target region without intersecting avoidance structures. **Results:** The navigation software was successfully modified to receive and display physician-drawn segmented structures, and this feature was utilized in tests involving the pseudo liver phantom. A pre-loaded fiducial needle was found to be compatible with the optical-tracking system and its tip location was accurately and reproducibly tracked in the navigation environment. The pseudo liver phantom was accurately and reproducibly implanted with fiducials in pre-planned locations by the radiation oncologist. **Conclusion:** We adapted a CT-based navigation system for use in interstitial liver procedures and developed a pseudo liver phantom to test the accuracy and reproducibility of navigated fiducial placement at pre-planned target locations in a controlled, simulated setting. This system could facilitate safe practices for fiducial-marker and/or brachytherapy-needle placement and permit faster radiation treatment throughput.

PO-GePV-P-47

Clinical Evaluation of Portal Dosimetry Ion Chamber Array and Mobius 3D for FiF Breast IMRT QA

S Gill¹*, R Wynn², M Huq³, S Wang⁴, (1) University of Pittsburgh Medical College UPMC Hillman Cancer Center, Erie, PA, (2) Loyola University Chicago, (3) UPMC Hillman Cancer Center and University of Pittsburgh School of Medicine, Pittsburgh, PA, (4) UPMC Hillman Cancer Center at Erie, Erie, PA

Purpose: The purpose of this study is to compare the Gamma analysis between Portal Dosimetry QA (PDQA), Ion chamber based 2D-array (Matrixx) and Mobius 3D for Field-in-Field (FiF) left breast IMRT. Motivation to pursue this study is to find easier way reference for point dose calculation compatible in RadCalc for secondary check. We decided to perform the secondary check with Gamma analysis comparison between Mobius3D, PDQA and 2D array, to determine the optimal clinical QA procedure. **Methods:** We evaluated number of left sided breast FiF IMRT plans. QA plans were calculated for 2D array and Varian Portal Dosimetry software (using portal dose image prediction module) and were delivered on a Varian linac. Also Plans were exported to Mobius3D software for Gamma analysis. Gamma criteria (3%/3mm >95%) was utilized for all the data analysis: OmniPro software for Matrixx; Varian software for PDQA and Mobius 3D. **Results:** For composite plans, Mobius 3D, PDQA & 2D-array Gamma analysis, average 3%/3mm Gamma is more than the passing criteria of 95%. For Mobius 3D, average Gamma (3%/3mm) is 99.2%. For Portal dosimetry average Gamma is 100%. For 2D array, average Gamma is 95.64%. All three software's results were in the same trends for passing rate. Per field Gamma analysis were performed for PDQA and 2D array. Average Gamma for per field comparison for 2D array is 91.54 % and for PDQA is 94.08 %. **Conclusion:** Mobius 3D, 2D array and PDQA can all be used with satisfactory results for the secondary plan check for FiF breast IMRT QA. For the composite plans, PDQA results shown 100% passing rate. Mobius 3D results are comparable with Portal Dosimetry, and Ion chamber based 2D array is more sensitive to the plan as of resolution. From our analysis, PDQA and Mobius are equally optimal for this QA task.

PO-GePV-P-48

Effect of Gantry Angle on Portal Dosimetry Vs Ion Chamber Array of Linac Based IMRT QA

S Gill¹*, R Wynn², M Huq³, S Wang⁴, (1) University of Pittsburgh Medical College UPMC Hillman Cancer Center, Erie, PA, (2) Loyola University Chicago, (3) UPMC Hillman Cancer Center and University of Pittsburgh School of Medicine, Pittsburgh, PA, (4) UPMC Hillman Cancer Center at Erie, Erie, PA

Purpose: Comparison of QA techniques for accelerated partial breast irradiation (APBI) IMRT using EPID and ion chamber based 2D array and to verify the response electronic portal imaging device (EPID) and 2D array with respect to treatment gantry angle vs gantry zero. **Methods:** Currently, all static IMRT QA plans are delivered at gantry angle zero. For APBI, comparison of patient QA between 2D array (Matrixx) and Linac based Portal Dosimetry QA (PDQA) was performed. QA plans were created at gantry angle of zero degree as well as planned gantry angles for both PDQA as well as Matrixx. QA plans were delivered on the Varian linac. Gamma analysis for each field and for composite plan was compared between PDQA and 2D array at both gantry zero and planned gantry angles. Gamma analysis for PDQA was analyzed using Varian Portal Dosimetry software and for Matrixx using OmniPro IMRT QA software. **Results:** 2D Gamma analysis results were analyzed for Portal Dosimetry and for Matrixx. Portal Dosimetry at gantry zero (2%/2mm Gamma criteria) resulted in fields 1 to field 5 are 96.8%; 94%, 96.5 %, 93.4% and 92.2% of the pixels passing Gamma criteria, respectively. Composite plan 2%/2mm Gamma analysis is 88.6%. Gamma analysis at planned gantry angles are: 97.5%, 95.1%, 96.9%; 94.8% and 93.5%, respectively. Composite plan result is 92.5%. For Matrixx Gamma analysis for composite plan for gantry zero is 89.37%. Composite at planned gantry angles is 89.16%. **Conclusion:** Both portal imager and 2D ion chamber array can be used for APBI IMRT QA. QA results are better with portal imager as compared to 2D array. However, portal imager results show more variation with gantry angle vs gantry zero. Gamma analysis results at planned gantry angle for Portal Dosimetry are better than gantry zero for both field-by-field analysis and composite plan analysis.

PO-GePV-P-49

Report of Image Distortion Based on Five Consecutive Years of Annual QA On Six MRI Scanners Used for Radiation Therapy

L Lu*, X Yang, B Raterman, X Jiang, M Meineke, D Hintenlang, N Gupta, Ohio State Univ, Columbus, OH

Purpose: To determine MRI image distortion based on five consecutive years of annual measurements on six MRI scanners used for radiation therapy. **Methods:** We used a commercial MRI image phantom MRID3D to perform annual image distortion checks and monitor the stability of the distortion over a period of five years from 2016 to 2020 for six 1.5T and 3T MRI scanners that provided images for the treatment planning of radiation therapy. The phantom was scanned on these MRI machines with 1 mm image slice thickness to acquire 3D images by following the imaging protocol of Gamma Knife and Linac-based SBRT/SRS. For each imaging scan the phantom was aligned to its geometric center using the MRI's lasers and the localizer. Using the MRID3D software we investigated: (1) the magnitude of the image distortion; (2) the dependence of distortion magnitude on the distance from the imaging isocenter; (3) the difference in distortion magnitude for 1.5T and 3T machines; and (4) the stability of distortion across the five-year period. **Results:** The image distortion

magnitude depended on the distance from the imaging isocenter. For most MRI scanners the distortion magnitude was under 1 mm when within 10 cm of the isocenter. The magnitude increased with increasing distance from the isocenter and could reach 2 mm at the distance of 15 cm. In general, a 3T machine had worse distortion than that of a 1.5T machine but the distortion could still be less than 1 mm when the distance from the isocenter was less than 10 cm. Slight fluctuation in distortion was observed during 5 years. **Conclusion:** MRI image distortion varies for machines and manufacturers. It depends on the distance from the imaging isocenter. Additional margin due to MRI image distortion needs to be accounted for during treatment planning, especially for Gamma Knife or SRS/SBRT.

PO-GePV-P-50

An Implementation Strategy for Introducing Automated Treatment Planning into the Clinic

J Jackson*, H Kang, J Wick, J Roeske Loyola University Medical Center, Maywood, IL

Purpose: The purpose of this study is to design an implementation strategy for introducing new automated treatment planning scripts into clinical use. Deployment of automated planning for clinical use requires thoughtful preparation that ensures safety and consideration of additional failure modes introduced by automation of treatment planning tasks. **Methods:** The Eclipse Scripting Application Programming Interface (ESAPI) was used to develop an automated treatment planning script to be used for radiotherapy patients. A workflow was mapped to assist in clinical implementation of this script. The steps in this workflow involved: assessing clinical need for automation, discussions with dosimetry staff regarding preservation of current planning workflow, iterative testing for bugs and performance, code review by another physicist or programmer, introduction of unexpected inputs to find potential hidden failure modes, and training for physics and dosimetry staff. After release for clinical use, we also considered feedback from dosimetry staff for new features and updates as well as conducted ongoing physics review to assess the need for script changes due to adjustments in treatment planning strategy. **Results:** By following a regimented implementation procedure, we were able to deploy an automated planning script which is customized to our site's particular planning workflow. This procedure helped discover several failure modes that may have been missed otherwise. Blocks of code were added to prevent these failure modes which included potential incorrect isocenter placement and transient bugs that could have caused program crashes with rare, unexpected inputs. **Conclusion:** Automated treatment planning has the ability to reduce time spent planning, standardize plan quality, and reduce the probability of failure modes that are more likely to occur with manual planning. The time spent evaluating a new automated planning script is considerable, and the steps involved should be carefully planned prior to implementation.

Dosimetric Evaluation of O-Arm Cone Beam Computed Tomography (CBCT) Scan Modes for Pediatric Head Scans

A Shankar*, E Olguin, F Bova, M Arreola, University of Florida, Gainesville, FL

Purpose: To evaluate the additional doses to pediatric patients while using various CBCT acquisition modes in an O-arm and compare the volume Computed Tomography Dose Index (CTDI_v) values to conventional CT scans. **Methods:** O-arms (O2 O-arm, Medtronic, Minneapolis, MN) are increasingly being used for neurosurgery and interventional procedures in clinical settings for pediatric patients. Due to the latent carcinogenic risks of radiation and increased life expectancy of pediatric patients, doses accrued during surgical procedures is a serious concern, in addition to doses from pre-op conventional CT scans. To analyze this further, CTDI_v measurements were performed for various pediatric patient sizes and O-arm acquisition modes including standard, low dose, HD3D and enhanced3D. The CTDI_v values obtained for all patient sizes were averaged and compared to a Stealth and reference pediatric head protocol used in clinical practice. **Results:** The CTDI_v values measured were 16.7, 7.3, 25.2 and 70.2 mGy for standard, low dose, HD3D and enhanced3D modes respectively. The doses from conventional CT stealth protocol and reference pediatric head protocol were 32.4 and 33.7 mGy, respectively. **Conclusion:** Based upon the measured CTDI_v values, all modes except enhanced3D will result in lower radiation risk to pediatric patients when compared to conventional CT scans. Low dose mode is recommended for image registration purposes, if image quality is not a concern, to minimize radiation burden. Enhanced3D mode should only be utilized if the benefits outweigh the risks for diagnostic purposes.

PO-GePV-I-02

Evaluation of the Displayed Average Glandular Dose of Hologic Digital Breast Tomosynthesis (DBT) Systems

O Osunbayo*, J Feng, UTHHealth McGovern Medical School, Houston, TX

Purpose: To investigate how the displayed average glandular dose (AGD) of Hologic DBT systems compares to computed AGD, and how this comparison is modulated by thickness, and the assumptions in women breast glandularity. **Methods:** For 2, 4, 6, and 8 cm of BR-12, exposures were acquired using the Auto-Filter AEC mode on six Hologic DBT systems. Entrance exposures and HVL were measured using a RaySafe X2 solid state detector, and the displayed entrance skin dose (ESD), displayed AGD, and displayed exposure index (EI) were recorded. The AGD was first estimated under the assumption of 50% glandularity, 50% adipose tissue composition. It was then computed using the assumption of breast composition for the average woman aged 40-49 years old (100%, 65%, 35% and 14% glandularity for 2-, 4-, 6- and 8-cm breast thickness, respectively). The AGD computed using these assumptions was compared to the displayed AGD. **Results:** Under the assumption of 50% glandularity, the absolute percentage difference between the computed AGD and displayed AGD ranged from 0.3% (for 2 cm of BR-12 in 3D) to 20.5% (2 cm in 2D). The deviation is most apparent at the largest thickness in 3D, where the displayed AGD overestimates the computed AGD. Using the assumption of glandularity based on the average woman aged 40-49 years old, the absolute percentage difference between the computed AGD and displayed AGD ranged from 0.04% (2 cm in 2D) to 23.2% (8 cm in 2D). The deviation is most apparent at the largest thickness in both 2D and 3D mode, where the displayed AGD underestimates the computed AGD. **Conclusion:** This study suggests that the discrepancy between displayed AGD and computed AGD may be correlated with the breast thickness. More data is needed to support this conclusion. The displayed AGD may overestimate or underestimate AGD based on the breast composition.

PO-GePV-I-03

Contrast-Enhanced Dual-Energy Digital Breast Tomosynthesis (CE-DE-DBT) Imaging: Iodine Concentration Estimation

B Chen*, Z Zhang, D Xia, E Sidky, X Pan, University of Chicago, Chicago, IL

Purpose: To demonstrate the feasibility of estimation of iodine-contrast concentration in contrast-enhanced dual-energy digital breast tomosynthesis (CE-DE-DBT) through accurate image reconstruction within transverse planes. **Methods:** A digital breast phantom within a transverse plane was considered, that includes three iodine-contrast-enhanced ROIs. A typical DBT scanning configuration was employed for the transverse plane, with source-to-rotation and source-to-detector distances as 36 cm and 72 cm, and a detector of 37.5 cm consisting of 512 bins. Dual-energy data were generated over two overlapping scanning arcs with 80- and 140-kVp spectra, using a non-linear-data model incorporating the polychromatic X-ray spectrum. Three different angular ranges, 14°, 20°, and 30°, were investigated with an angular interval of 1° per view. 80- and 140-kVp images were reconstructed by a new directional total variation (DTV) algorithm

and were decomposed into basis images of breast tissue and iodine contrast. From basis images, monochromatic images at 34 keV were composed and assessed for artifacts reduction, and iodine-contrast concentrations were estimated. **Results:** The study reveals that, for the three limited-angular ranges, the DTV algorithm yields monochromatic images with minimized leaking artifacts that are otherwise observed in images obtained with existing algorithms. Furthermore, the iodine-contrast concentrations were accurately estimated, as compared to the results obtained with the full-scan data of 360° by using existing algorithms. Additional detailed results will be presented at the conference. **Conclusion:** It has been demonstrated in this work that monochromatic images with reduced artifacts can be obtained within transverse planes in DBT by use of the new DTV algorithm, which can lead to accurate estimation of iodine-contrast concentration in CE-DE-DBT. Future study will investigate the impact of additional physical factors, such as scatter.

PO-GePV-I-04

Design of a Display Test Pattern to Assess Ambient Light Levels in a Radiologists' Reading Environment

C Guo^{1*}, A Sanchez², Z Lu^{1,3}, E Marshall^{1,3}, J Chung¹, I Reiser^{1,3}, (1) University of Chicago Medical Center, Chicago, IL, (2) Vanderbilt University, Nashville, TN, (3) University of Chicago, Chicago, IL

Purpose: During the COVID-19 pandemic, many radiologists transitioned to remote reading at home. One concern when reading in a non-controlled reading environment is the appropriateness of ambient light levels. The purpose of this study was to develop a visual test pattern-based evaluation method to assess ambient light appropriateness. **Methods:** A series of six test patterns were created by adding letters at different contrasts to a uniform background. Each pattern contained 5 to 10 letters, distributed in a uniform, random fashion, to create an element of search. The choice of letters was loosely based on a Snellen chart. The uniform background pixel values ranged from 0 to 98% at 6 different levels. In a controlled reading environment and by use of a medical-grade DICOM GSDF calibrated display, three readers identified the lowest detectable contrast letter at two ambient light level settings (30 and 200 lux). To assess the generalizability of the approach, at each background brightness level, four sets of patterns were read. **Results:** In the darkest background, readers were able to detect the lowest contrast letter in 11 out of 12 reads (91% correct) at low ambient light levels (30 lux), but at 200 lux they were never able to detect the lowest contrast letter. In the second darkest background, low contrast detectability was 100% at 30 lux and 50% at 200 lux. The low contrast detectability was not affected by ambient light level in brighter backgrounds. **Conclusion:** The results indicate that these display test patterns enable the identification of excessive ambient light levels that potentially interfere with radiologists' low-contrast detection performance, particularly in darker luminance regions of the images. This test pattern-based approach does not require external photometers and can be readily implemented into PACS.

PO-GePV-I-05

Design of Nested Halbach Rings for Portable MRI Scanners

M Ergor¹, N Dogan², A Bingolbali^{1*}, (1) Yildiz Technical University, Istanbul, TR, (2) Gebze Technical University, Gebze/Kocaeli, TR

Purpose: Advantages of magnetic resonance imaging (MRI) in medicine is well known and crucial, but developing a portable MRI device is challenging. A magnet system used to create a static magnetic field (B_0) in a portable MRI scanner should be simple, and lightweight. A lightweight Halbach magnet system might be used to yield suitable B_0 for portable MRI scanners. In this study, a lightweight Halbach magnet system was designed and its performance was evaluated for portable MRI scanners. **Methods:** In this study, B_0 was formed with multiple layer dipole Halbach rings that consist of octagon shape NdFeB (neodymium-iron-boron) permanent magnets. Two Halbach rings were placed facing each other with the same magnetization direction. Aluminum was chosen as the holder material. Investigation of the obtained magnetic field was made with Comsol Multiphysics simulations. Homogeneity of the magnetic field was also calculated. **Results:** As a result of the simulations, 0.37 T magnetic field was obtained and its stability was achieved along 60 mm on the x-axis, 38 mm on the y-axis, and 32 mm on the z-axis. Gradient results were also obtained from the permanent magnets system. **Conclusion:** Nested Halbach rings were used for the magnet system of portable MRI scanners. We present the light and inexpensive magnet design, but more studies should be done for a better understanding of the system. Homogeneity of the system and also the field of view (FOV) should be improved with further studies.

PO-GePV-I-06

An Easy-To-Use Tool for Annual MRI Performance Evaluation Using the ACR Large Phantom

J Storrs^{1*}, H Khosravi¹, A Fatemi^{1,2}, (1) University of Mississippi Medical Center, Jackson, MS, (2) Merit Health Cancer Center, SpinTecx.LLC, Madison, MS

Purpose: The ACR MRI Accreditation Program uses approved ACR phantoms for performance evaluation and quality control. A guidance documents standardize analysis by specifying seven quantitative procedures for evaluating scanner performance. These are evaluated at least annually by a qualified physicist, while three are performed weekly by technologists. The purpose of this work was to develop a fast, interactive tool to quickly assess ACR QC scans of the Large Phantom for use during annual evaluation and troubleshooting. **Methods:** An interactive program for inspecting scans of the ACR large phantom was developed using Matlab. The tool accepts ACR T1 sagittal, T1 axial and PD+T2 axial series (or site axial series) and evaluates them using procedures as described in the ACR guidance document. For steps that rely on subjective input (windowing, ROI selection, etc), the most pessimistic (i.e. least beneficial toward action limits) choice is selected. Results are displayed as an interactive annotated stack. Measurements are overlaid (lines, ROIs, boxes, text) on each slice with color-coding to indicate action limit outcomes (green=pass, yellow=warning, red=fail). Clicking on a measurement adjusts the presentation to best visualize the measurement and opens relevant graphs for inspection (e.g. 1D profiles). Images and results can then be saved and exported for reporting. **Results:** The tool was developed using archived annual and weekly QC scans from six scanners. The tool was then installed on a laptop and used during annual performance evaluation (5 scanners) and acceptance testing (2 scanners). Images were transferred to the laptop using USB export for evaluation. Results were rapid and because they follow the manual procedures, were easy to inspect interpret and verify in real-time. **Conclusion:** An interactive tool was developed for evaluation of the ACR large phantom. The tool closely follows ACR guidance which aids rapid interpretation and understanding.

Developing and Validating a Radiomics Classification Model for Glioma Grading Using Multiplanar Reconstructive Magnetic Resonance T1-Weighted Imaging: A Reliable Multi-Institutional Study

J Ding^{1*}, Q Qiu², P Cong³, J Chen², J Duan², X Cao², Y Yin², (1)School of Physics and Electronics, Shandong Normal University, Jinan, P.R.China(2)Department of Radiation Oncology, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, P.R.China.(3)Department of Oncology, The Second Hospital, Cheeloo College of Medicine, Shandong University, Jinan, P.R.China.

Purpose: Evaluation of a multiple plane reconstruction (MPR) T1-weighted imaging radiomics method for grading gliomas **Methods:** A total of 102 glioma patients treated in Shandong Cancer Hospital and Institute were selected as the training cohort. 16 patients from the tumor imaging file (TCIA) and 28 patients from the Second Hospital of Shandong University were enrolled in the validation cohort. Radiomics features, including axial, coronal, and sagittal planes, were extracted from the MPR T1-WI images of each patient. Then the feature is removed by Spearman correlation test and recursive feature removal (RFE) method

to make the feature non-redundant and predictive. Then, a single and combined classification model of the MPR plane is established and evaluated by using a variety of machine learning algorithms, such as support vector machine (SVM), logistic regression (LR), and random forest (RF). Finally, the classification model is further verified by the external validation cohort. **Results:** The optimal feature numbers of SVM, LR, and RF are 16, 14, and 10 respectively. The AUCs of the combination model was the highest in the training cohort (SVM 0.86 ± 0.06 , LR 0.89 ± 0.05 , and RF 0.81 ± 0.07 , respectively) and the validation cohort (SVM 0.84, LR 0.79, and RF 0.78, respectively), which was significantly higher than that of other single MPR classification models. **Conclusion:** MPR radiomics can be used to grade gliomas, and the combined model composed of axial, coronal, and sagittal MPR images is more satisfactory than the single model.

PO-GePV-I-08

Fast T1 Mapping Optimization: A Phantom Study

Z Razi^{1*}, Z Zhang², Z Mullaghy¹, A Lloyd³, H Liu¹, M Arreola¹, (1) University of Florida, Gainesville, FL, (2) Washington University School of Medicine, Saint Louis, MO (3) University of Florida Health, Gainesville, FL

Purpose: The universal pipeline for T1 mapping is to acquire series of images with different T1 weightings and fitting the signal intensity to T1 relaxation for each pixel location. Optimization of T1 relaxometry is mostly focused on the efficiency of T1 estimation while trading off the total length of the experiment and T1 mapping computation. This research investigates the number of TIs to optimize the precision of T1 measurements using the classical inversion recovery (IR) technique. **Methods:** The standardized ACR phantom was scanned using IR sequences with a constant TR = 6000 ms and a range of TIs. A Matlab script was developed for the T1 mapping calculation based on the Barral JK methodology. Parametric maps were generated for 11 series of images each with different numbers of TIs (ranging from 3-6), and different choices of TI. The T1 map generated with 15TIs was considered to be the reference T1 map. The MultiScale_Structural Similarity Index (MS_SSIM) was the chosen method for image analysis. The SSIM was computed between the reference map and each other experimental maps. One-Way ANOVA and Tukey comparison was used for statistical analysis. **Results:** The p-value is less than 0.05 and the mean differences between the MS_SSIM of the different TIs is statistically significant. Also, the difference between the mean of 3TI vs. 4TI and 3TI vs. 5TI is statistically significant. The high predicted R2 value equal to 91.5% indicates that the model generates precise predictions for new observations. The groups of T1 maps generated with 3TIs showed statistically significant similarity to the reference map comparing with maps generated with 15TIs. **Conclusion:** T1 mapping generated using 3TIs provide comparable results to the T1 mapping generated using 15TIs. This reduces scanner time for experiments.

Commissioning of Commercial Quantitative R2* Mapping Software for Clinical Use

B Taylor*, H Chen, H Liu, J Yung, P Hou, K Brock, RJ Stafford, Imaging Physics, The University of Texas M.D. Anderson Cancer Center, Houston, TX

Purpose: In acceptance and annual testing of MR systems, physicists are key in assuring the high performance in acquisition, hardware fidelity and image quality. With the increase in dependence on quantitative measurements for patient management, there is an urgent need for physicists to commission the post-processing software used to generate this information. Here we illustrate a commissioning process developed for an FDA-cleared R2* mapping software package, which is used for such tasks as quantifying liver iron concentration. **Methods:** For initial commissioning, we created a digital reference object (DRO) to represent ground truth measurements for comparison with software output. DROs were generated using in-house software, with and without additive noise (SNR=5-20 on first TE), and logarithmically spaced R2* values with signal modeling to replicate the output of a clinical multi-echo gradient-echo protocol. R2* calculations using both a two-parameter and three-parameter fit were used to compare to the ground truth DRO value. For assuring for consistency in a software upgrade, six patients with recent iron overload scans were evaluated. A three-parameter fit was applied to calculate the R2* map on both software platforms. According to our clinical standard operating procedure, three ROIs were made on each R2* map from both software platforms. Results from two software were compared to assess their agreement. **Results:** DRO analysis demonstrated that the software's accuracy is dependent on the native liver R2*, acquisition parameters and that a 3-parameter fit should be used especially if moderate or higher liver iron overload is suspected. In our patient data for a range of 38-815 Hz, there was perfect agreement of mean ROI measurements between both software platforms. **Conclusion:** Using both DRO and patient data, we tested available software for its performance in calculating MR R2* measurements. This methodology can be applied to other applications when commissioning software for clinical use.

Differential Diagnosis of Hepatocellular Carcinoma and Cirrhotic Nodules Via Radiomics Models Based on Magnetic Resonance Images

C Ma^{1*}, Y Wang², (1) Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, 37, CN

Purpose: This study is to distinguish hepatocellular carcinoma and cirrhotic nodules using MR-radiomics features extracted from four different phases MRI images. **Methods:** In this study, the five kind of magnetic resonance images of 23 patients with hepatocellular carcinoma (HCC) were collected. Among them, 12 patients with liver cirrhosis were used to obtain cirrhotic nodules(CN).The dataset was used to extract MR-radiomics features from regions of interest (ROI). Using, then, statistical methods to screen MR-radiomics features, which could distinguish HCC and CN. And the ability of radiomics features distinguished HCC and CN was estimated by receiver operating characteristic (ROC) curve. **Results:** A total of 106 radiomics features were extracted, of which almost features showed relatively statistical difference ($p < 0.05$). They were 86 features in delay phase of contrast MRI, 86 features in spir phase of T2WI, 86 features in T1WI and 88 features in T2WI. Among them, the area under the curves (AUC) of these features larger than 0.05 were 74 features in delay phase of contrast MRI, 68 features in spir phase of T2WI, 77 features in T1WI and 75 features in T2WI. **Conclusion:** Radiomics features extracted from MRI images have the potential to distinguish HCC and CN.

PO-GePV-I-11

3D Computational Approach to Morphological Brain Abnormalities in Autism

S Brindle*, C Saben, R Makkia, University of Mary Washington, Stafford, VA

Purpose: Autism Spectrum Disorder (ASD) is defined as an idiopathic lifelong neurodevelopmental disorder that develops in early childhood. Its prevalence is broad, yet its nature remains elusive and inconsistent. This research describes a detailed research project related to the construction of computational phantoms, including certain brain structures which can be used in radiological, therapeutic, and diagnostic capacities. **Methods:** A collection of three hybrid computational brain phantoms corresponding to two pediatric ASD patients and one control patient were constructed using high quality magnetic resonance imaging (MRI) sets. A total of 12 brain structures, four from each patient, were outlined from radiological images via the 3DSlicer segmentation software and were imported to the three-dimensional (3D) modeling software package Rhinoceros for additional geometric manipulation and analysis. Rhinoceros allowed

the conversion of the segmentation into a non-uniform rational basis spline (NURBS) or mesh surface-based phantom. **Results:** This set of new phantoms can be used in the future to study the optimization of image quality and radiation dose for patients on the spectrum who have unique neuro-morphology. Given the wide neurological, behavioral, and morphological variations in patients with autism, individualized treatment plans involving an accurate, representative computational model are valuable. **Conclusion:** The aim is to develop a repository of data collected from these phantoms into a comprehensive dosimetry database. This novel set of computational brain models present morphological details that are crucial during radiation dose evaluation for ASD patients enduring diagnostic imaging or radiotherapy.

PO-GePV-I-12

CT-Based Radiomic Signature and Clinic Information Predicts Brain Metastasis in Lung Adenocarcinoma

C Ma*, X Dong, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, 37CN

Purpose: This study evaluates computed tomography (CT) radiomic features and clinical information for their capability to predict risk factors for brain metastasis (BM) in patients with lung adenocarcinoma. **Methods:** The analysis retrospectively included $n=20$ BM patients and $n=40$ lung adenocarcinoma without BM. And the phenotype of the primary tumor was quantified on pre-treatment CT-scans using 106 radiomic features. Univariate and multivariate analysis was performed to evaluate clinic information using the X2 test and logistics regression. Radiomics statistical comparison between subgroups was evaluated by concordance index (CI). **Results:** Univariate analysis of brain Metastasis showed that age ≤ 60 years old, T4, N2-3, other distant metastases and the pretreatment of $LYM < 1.1 \times 10^9/L$, $LYM\% < 20$, $LDH > 250 U/L$, $CEA > 6.5 ng/ml$, $NSE > 16.3 ng/ml$ were risk factors for brain metastases of lung adenocarcinoma ($P < 0.05$). Multivariate logistic regression analysis showed that age, N stage, other distant metastases, CEA, NSE were independent risk factors. Radiomics showed a significant difference in first order features between subgroups. **Conclusion:** The occurrence of brain metastasis is related to the survival of patients with lung adenocarcinoma. The combination of functional CT radiomics parameters and clinical information could represent a novel integrated approach to predict brain metastatic disease with more accuracy than clinical information alone.

PO-GePV-I-13

Evaluation of Coronary CTA On the Anomalies Origin of Coronary Artery: Location, Types, and Hemodynamic Variation

H Zhao*, W Jiao, Q Liu, J Qiu, Shandong First Medical University & Shandong Academy of Medical Sciences, Tai'an, CN

Purpose: To evaluate the location, types, and hemodynamic variation of coronary artery with anomalies origin by 128-slice Siemens dual-source computed tomography. **Methods:** A total number of 14820 coronary CTA were carried out in Hospital. According to Greenberg classification method, CTA images with abnormal origin were screened out (excluding myocardial bridging). The epidemic characters of sex, clinical symptoms, ECG, coronary atherosclerosis with coronary artery with anomalous origin were analyzed retrospectively. The correlation was analyzed between the atherosclerosis incidence and the characters of anomalous right coronary artery originating from the left coronary sinus with interarterial course, including the variation trend of the aortic-pulmonary artery space, take off angle, proximal and distal diameter of right coronary artery during the cardiac cycle. The results were analyzed by chi-square and Fisher exact test. P value < 0.05 was considered to indicate a statistically significant. All statistical data were analysed with SPSS 26.0 software. **Results:** 244 patient (1.6464%) with anomalous origin of coronary were reviewed in 14,820 patient. 139 patient (57%) with anomalous origin of the right coronary artery were most common in 244 patient. Sex ($P=0.672$), clinical symptoms ($P=0.181$), ECG abnormalities ($P=0.171$) with abnormal origin of coronary artery had no statistically significant with normal origin. The atherosclerosis incidence with ipsilateral anomalous coronary artery origination is not significant higher than that with normal coronary arteries origination ($P=0.038$). The atherosclerosis incidence with right coronary artery originating from the left coronary sinus with interarterial course is not significant correlated with the variation rate of take off angle ($P=0.806$), the aortic-pulmonary space ($P=0.670$), the proximal diameter ($P=0.671$) and the distal diameter ($P=0.099$) during the cardiac cycle. **Conclusion:** Coronary CTA can accurate and noninvasive assess depiction of coronary artery origin anomalies of location, types; especially in delineating the ostial origin and proximal path of an anomalous coronary more advantages.

This work was supported by Shandong medical and health science and technology development plan project (202009040454), Tai'an science and technology development plan (guidance plan) project (2019NS156), Innovative training program for College Students (S202010439080), Jianfeng Q. was supported by the Taishan Scholars Program of Shandong Province (TS201712065).

PO-GePV-I-14

Residual Convolutional Neural Network for Noise Reduction in Megavoltage Computed Tomography (MVCT)

Z Zhao^{1,2*}, Y Zhang^{2,3}, J Zhang², Y Wang², J Dong¹, J Zhu², (1) Shandong Provincial Key Laboratory of Network based Intelligent Computing, School of Information Science and Engineering, University of Jinan, Jinan, Shandong province, CN, (2) Department of Oncology Physics and Technology, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, Shandong province, CN, (3) School of Physics and Technology, Wuhan University, Wuhan, Hubei province, CN

Purpose: Clinical application of megavoltage Computed Tomography (MVCT) is limited to three-dimensional visualization and position of the patient. The noise and low soft tissue contrast of MVCT make it hard to provide an accurate image registration for image-guided radiotherapy (IGRT) and accurate delineation for adaptive radiotherapy (ART), resulting in the less clinical potential of MVCT. In this work, we developed a -based approach to improve MVCT image quality. **Methods:** Kilovoltage CT (KVCT) and MVCT images of 34 head and neck (H&N) cancer patients were retrospectively analyzed in this study. The method incorporated a deconvolution network and shortcut connections into a Convolutional Neural Network (CNN) model, to learn a mapping between MVCT images and paired planning KVCT images. Compared with a CNN, the method enhances the transfer and reuse of features using shortcut connections. The peak signal-to-noise ratio (PSNR), structural similarity (SSIM), and root mean squared error (RMSE) were used to quantify the correction accuracy of the proposed algorithm. Also, the method is compared to -based (BM3D + DFR) MVCT image enhancement method. **Results:** The PSNR, SSIM, and RMSE were improved in processed images relative to the original MVCT images. Specifically, the PSNR and SSIM of the processed images improved to 29.4dB and 0.93 compared with 24.6dB and 0.88 in the original MVCT images, and the RMSE decreased from 23.5HU to 13.6HU. The proposed method processed images with less noise and higher soft tissue contrast in comparison with -based method. **Conclusion:** The MVCT image quality could be improved in the proposed method. The processed MVCT increases the feasibility of depicting the anatomical delineation of tumors and organs at risk, and therefore enables the promising application of image-guided and adaptive helical TomoTherapy.

Evaluating Motion Correction in a Commercial Subtraction CT Registration Algorithm

A Heshmat*, I Barreto, L Rill, M Arreola, University of Florida, Gainesville, FL

Purpose: The purpose of this study was to assess the accuracy of algorithms in registering pre- and post-contrast images with and without motion using a subtraction CT software. **Methods:** A pre-contrast image of a cylindrical CT phantom was acquired. Five 28-mm wide water rods were replaced with iodine rods and the phantom was displaced vertically by 30 mm, in 5-mm increments, and post contrast images were acquired. Subtraction images were evaluated using a Matlab code by generating line profiles for each rod. The line profile data was used to estimate the diameter of each rod under stationary and all shifted positions by performing a linear interpolation to find the location in the image where the CT number exceeded 50 HU, and the location where it dropped below 50 HU. The difference in these locations determined the diameter of rods in each subtracted image. The rod diameters in the shifted images were compared with the rod diameters in the stationary image. **Results:** The motion correction was successful and maintained similar rods shape, location, and CT number for all displacements up to 25 mm. For example, the measured vertical diameter of the 9 o'clock rod decreased by 4.1 mm (-8.5% -10.6%). However, moving the phantom by 30 mm, more than the rod's diameter size (28 mm), resulted in misregistration and inaccurate subtraction. **Conclusion:** The subtraction algorithm corrected for motion between the pre- and post-contrast scans for displacements less than the size of the iodine rod.

PO-GePV-I-16

Improvement of A Tissue Equivalent Material for Multi-Modality Imaging

H Zhang^{1*}, J Qiu², (1) Duke University, Kunshan, Jiangsu, (2) Shandong First Medical University & Shandong Academy of Medical Sciences, Tai'an, CN

Purpose: Phantoms are vital to evaluate imaging techniques; nonetheless, presently available phantom construction materials are not adequate for studies involving both magnetic resonance imaging (MRI) and computed tomography (CT). The purpose of this study is utilizing effective ingredients to fabricate a sort of synthetic material, which is adapt to multimodality imaging experiments. **Methods:** Agarose, gadopentetate dimeglumine (Gd-DTPA), micro-pearl powder, sodium chloride (NaCl) and sodium fluoride (NaF) was added during the formation of tissue-equivalent material (TMM). Both CT and MR scanning were performed, the T1 and T2 relaxation time and CT numbers (HU) were obtained for various combinations of water-based agarose gels. **Results:** The concentration of agarose (0- 4.5%) had little effect on the CT number of TMM, but had a significant effect on the T1 and T2 relaxation times (especially the T2 value), specifically the increase in agarose concentration, relaxation time reduce. The concentration of Gd-DTPA had a great influence on the T1 relaxation time of the material. The content of micro-pearl powder hardly changed the T1 or T2 relaxation time of the agarose gels. However, agarose loaded with micro-pearl powder was stable (in the range of 0-2%; gradient concentrations appear after the range is exceeded), and different concentrations produced TMMs that showed different CT values across different human tissues. **Conclusion:** The water-based agarose gel of the present study has tissue equivalency in dose attenuation with X-rays and relaxation times with MRI. It is an powerful tool for designing multimodality imaging phantoms.

PO-GePV-I-17

Beam-Shaping Filter and Dosimetric Characterization of the Airo Mobile CT Scanner

A Siddique*, Q Chen, J Zhang, University of Kentucky, Lexington, KY

Purpose: For a conventional CT with a 32 cm body phantom, the ratio between the peripheral and the center CTDI measurement (the P/C ratio) is close to 2. For the Airo mobile CT, the P/C ratio is approximately 4. This study is to investigate what causes the ratio difference and how it impacts radiation dose and image quality. **Methods:** We measured the HVL at the iso-center to verify the x-ray beam quality. For the assessment of the beam-shaping filter, exposure was measured under service mode with a RaySafe R/F detector in 14 lateral positions starting from the iso-center. The measurements were made with 2cm intervals between them for 120kV, 192mAs using service mode. All measurements were normalized to the measurement at the iso-center. The center and peripheral CTDIs were measured with a 32-cm body phantom for 80kV, 100kV, and 120kV. The image uniformity between the center and edge was analyzed. For comparison the same experiment was repeated in a Siemens Confidence. **Results:** The x-ray quality is comparable (6.85 vs. 7.84mmAl). The higher P/C ratio in the Airo is due to the beam-shaping filter where a flat filter is applied, while a bowtie filter is used for the Siemens Confidence. For the Airo, the P/C ratios are 4.83, 4.03, 3.64 for 80kV, 100kV, and 120kV, respectively. The P/C ratio for the Confidence is 2.11 at 120kV. The dose distribution across the body phantom is more homogeneous in the Confidence than the Airo. The use of a bowtie filter can homogenize the photon flux at the detectors and reduce radiation to the patient in those peripheral regions of the body. **Conclusion:** The Airo with a flat filter delivers relatively more radiation to patient especially to the skin. It may be of a concern for a complicated orthopedic procedure.

PO-GePV-I-18

CT Image Standardization for Radiomic Feature Enhancement in Non-Small Cell Lung Cancer

M Selim^{1*}, J Chen², B Fei³, G Zhang⁴, J Zhang⁵, (1) University of Kentucky, (2) University Of Kentucky, (3) University of Texas (UT) at Dallas and UT Southwestern Medical Center, Richardson, TX, (4) Uthealth, (5) University of Kentucky, Lexington, KY

Purpose: This study is to develop an end-to-end fully automatic CT image standardization approach named RadiomicGAN to improve the stability of radiomics features in NSCLC. **Methods:** RadiomicGAN was developed based on transfer learning and Generative Adversarial Network (GAN), which can efficiently learn the standard image feature distributions from relatively small medical image data. The performance of RadiomicGAN was enhanced by leveraging the wide dynamic range of CT imaging. Specifically, the model adaptively identified the effective pixel range in the current training cycle and smartly optimized its loss in the next training cycle. CT images for training and testing were acquired in a Siemens Sensation Force using three different kernels (B157, B164, Br40) and different slice thickness (0.5, 1, 1.5 and 3mm). The training data included a total of 14,372 images, while each test data contained 387 images. The RadiomicGAN was also trained and tested using CT images of a chest phantom. Radiomic features were extracted from the lung nodule delineated manually with the IBEX. In total, 1,401 radiomics features were evaluated and compared before and after image normalization. **Results:** RadiomicGAN achieves significantly better image normalization performance than other state-of-art models. In average, using B164 as the standard image reconstruction kernel, the averaged absolute error of the 1,401 radiomics features before and after normalization reduced from 51.82% to 29.8% for images reconstructed using B157 and from 78.45% to 30.5% for images reconstructed using Br40. The existing CT image standardization models such as Choe et al, GANai and STAN-CT reduced the error to 44.7%, 42.1%, and 40.5% respectively for B157, and 56.1%, 54.5%, and 48.6% respectively for Br40. **Conclusion:** RadiomicGAN provides a better end-to-end solution for CT image standardization and normalization. Further evaluation with larger amount of patient data are warranted.

This study is partially supported by NIH

PO-GePV-I-19

Evaluation of Spatial Resolution Variability in Whole Body Bone Scans

K Brown, R Al-Senan*, Penn State University, Hershey, PA

Purpose: To assess the variability in spatial resolution observed in whole body bone scans completed on different scintillation camera imaging devices within the same facility as reported by clinical staff. **Methods:** Upon installation of new scintillation camera, clinical staff reported variability in spatial resolution among cameras of same model and detector specifications when performing whole body bone scans. Static intrinsic and extrinsic spatial resolution FWHM measurements obtained with a four-quadrant bar phantom during annual/acceptance testing of the units were compared. The clinical whole body bone scan was replicated with two capillary line sources containing ^{99m}Tc spaced 20 cm apart and perpendicular to the direction of table travel. Detector contouring was

active and automatically adjusted the position of each detector relative to the line sources. Distances from the line sources to the camera heads were measured for all acquisitions. Static acquisitions of the line sources was obtained at same distance as measured above. **Results:** Comparison of static intrinsic and extrinsic FWHM measurements among the cameras showed minor variation. Significant variation in FWHM measurements of line sources between imaging devices was observed. The cause of variation was determined to be variability in the default table height position settings which resulted in variation in collimator-to-source distances on each imaging device. Default table height was set by the service engineer at the time of installation of each unit and was not standardized across the camera systems. The default table height setting was standardized and measurements were repeated. **Conclusion:** Variability in default table height settings for whole body bone scans resulted in reduced and inconsistent spatial resolution in clinical studies among imaging devices. Recommend routine verification of table height settings during whole body bone scans and inter-comparison of QC data to ensure optimum image quality during clinical scans.

PO-GePV-I-20

TOPAS for Imaging: A Monte Carlo Simulation Tool for PET/SPECT/CBCT Imaging

J Feld^{1*}, C Zhang², G Cojocaru³, S Longawa⁴, H Paganetti⁵, J Schuemann⁶, (1) Mass General Hospital and Massachusetts Institute of Technology, (2) Mass General Hospital And Boston University, (3) Mass General Hospital And Massachusetts Institute Of Technology, (4) Mass General Hospital And Massachusetts Institute Of Technology, (5) Department of Radiation Oncology, Massachusetts General Hospital and Harvard Medical School, Boston, Massachusetts, USA, Boston, MA, (6) Department of Radiation Oncology, Massachusetts General Hospital and Harvard Medical School, Boston, Massachusetts, USA, Boston, MA

Purpose: To develop an extension of medical imaging devices for the TOPAS Monte Carlo (MC) system. **Methods:** MC methods have been extensively used to simulate imaging systems, but there have so far been no examples for the TOPAS MC. We designed easily modifiable classes for the detector geometries, sources, and scorers in PET, SPECT, and CBCT systems. The output file is scored in CASToR (Customizable and Advanced Software for Tomographic Reconstruction) format that can directly be processed for image reconstruction using CASToR. **Results:** We developed TOPAS for Imaging, an extension of TOPAS designed to generate the geometries of PET, SPECT, and CBCT and record their measurements of simulated radioactive sources for reconstruction in CASToR. First comparisons to experimental data for validating the PET system will be presented. **Conclusion:** TOPAS for Imaging promises to advance our understanding of imaging systems by enabling researchers to have more platforms for simulating their systems.

This project was funded by the AAPM, MIT, and NIH.

PO-GePV-I-21

Sparse-View CT Reconstruction Via Generative Adversarial Network (GAN) Using Fully Convolutional DenseNet (FC-DenseNet)

I Park*, J Chun, B Choi, S Yoo, J Kim, H Kim / Department of Radiation Oncology, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea

Purpose: Sparse-view CT benefits from reduction in dose of radiation to patient with fewer projection views than general. Conventional filtered-back projection (FBP) algorithm is limited due to the insufficient projection information required to sparse-view CT reconstruction. The iterative reconstruction complement the disadvantage, while it is mostly time-inefficient and challenging to dramatically reduce the number of projection views. Deep-learning-based sparse-view reconstruction could address the drawbacks. Though various trials made thus far, this work proposes a reconstruction with Generative Adversarial Network (GAN) based model that utilizes FC-DenseNet as a backbone network architecture. **Methods:** The input and output of the network were set to be sparse-view CT (45-view), and ground-truth CT (720-view), which were obtained from FBP algorithm. Patient cohort consisted of 74 scans of head-and-neck patients: 37, 28, and 9 scans used for training, validating, and testing the proposed network. We trained GAN using FC-DenseNet and used L1 loss, L2 loss, and gradient difference loss to obtain training results. The metrics for reconstruction accuracy of the trained network employed Mean Absolute Error (MAE), Peak Signal to Noise Ratio (PSNR), and Structural Similarity Index (SSIM). **Results:** The results indicated that Our proposed model can improve the sparse-view CT image quality with minimal streaking artifacts. The generated image for our proposed model was assessed by MAE, PSNR, and SSIM. The original sparse-view CT reconstruction image for conventional FBP algorithm results 53.03, 51.28, 0.97. The model with L1 loss results 16.88, 44.52, 0.86. The model with L2 loss results 24.41, 36.59, 0.92. The model with gradient difference loss results 17.10, 31.86, 0.59. **Conclusion:** Our proposed network adopted GAN network architecture for sparse-view CT image reconstruction. It demonstrated that the trained network could achieve much more accurate reconstructed image than conventional FBP.

PO-GePV-I-22

Study of Cariporide Effect on Tumor Intracellular PH (pHi) Using Chemical Exchange Saturation Transfer (CEST) MRI

M Mozaffari*, N Nystrom, A Li, M Bellyou, T Scholl, R Bartha, Roberts Research Institute, Western University, London, ON, CA

Purpose: pHi is a hallmark of tumor microenvironment response to therapies. NHE1 is an acid-extruding membrane transport protein in cells.¹ In CEST-MRI contrast is produced by exciting exchangeable tissue protons at their specific absorption frequency and observing the transfer of magnetization to bulk tissue water. Amine and amide concentration-independent detection (AACID) is an approach that uses the sensitivity of amine and amide proton to CETS contrast.² The AACID value inversely relates to pHi. One way to achieve tumor acidification as a therapeutic strategy is by blocking the NHE1 transporter. Cariporide is a potent inhibitor of NHE1. We have shown that cariporide can selectively acidify U87MG glioma in mice.³ Our goal was to determine whether it also selectively acidifies a rat C6 glioma tumor model following injection by mapping tumor pHi. **Methods:** Cells were injected into the brain of six rats. To evaluate the effect of cariporide on tumor pHi, rats received an IP injection of the drug two weeks after implantation while inside a 9.4T scanner to measure the change in pHi following injection. **Results:** Five minutes after injection, CEST-MRI was collected for three hours. For data analysis, we compared the first maximum change in AACID value post-injection with the pre-injection. After one hour, the average AACID value in the tumor significantly increased. The average AACID value in tumor post-injection was 5.4% higher compared to pre-injection. The average AACID value in contralateral tissue also increased in a similar way. **Conclusion:** We did not observe selective tumor acidification following injection as was observed in the previous study. The reason for this discrepancy is currently unknown but may be related to potential differences in tumor vasculature that may limit the ability of cariporide to infiltrate the tumor.⁴ Future work includes increasing cariporide dose and modifying our quantification method of the AACID measurement.

PO-GePV-I-23

Conformance Analysis Between Positive Beam Limitation Quality Control Methods in Digital Roentgen-Ray Imaging

R Perez Franco*, M Fadhel, D Vergara, A Mustafa, I Bercha, Yale New Haven Hospital, Yale School of Medicine, New Haven, CT

Purpose: Conformance between alternate methods that evaluate the positive beam limitation (PBL) of X-ray systems is determined using Bland-Altman analysis. **Methods:** The PBL of GE Precision, Fuji Velocity and Philips Easy-Diagnost systems was evaluated using the gold-standard and two alternate methods, light-field-width and DR-coin. First, the tube was set at a detent position where the PBL engaged. The gold-standard method was carried by placing a CR imaging plate at a known distance from the image receptor and exposing it. For the light-field-width method, the light field projected on the Bucky's surface was measured with a measuring tape. For the DR-coin method, coins were placed on the Bucky's surface at the edges of the light field and the DR

detector inside the Bucky was exposed. All field sizes were measured in PACS and magnification corrected. Measurement cohorts were collected for both wall and table Buckies for the aforementioned units. The two methods were compared for conformance with the gold-standard using Bland-Altman technique. This method relies on plotting difference of results obtained using different methods against the average of results obtained by the two methods. **Results:** The mean difference between the gold-standard and DR-coin method for PBL assessment is -0.50 and the standard deviation of differences is 0.76. The mean difference between the gold-standard and light-field-width method for PBL assessment is 0.0 and the standard deviation of differences is 0.81. **Conclusion:** Preliminary results suggest that the DR-coin to gold-standard methods demonstrate slightly lesser variation between the observations as compared to the light-field-width method. This analysis along with our practical experience in the field favors the use of the DR-coin based method if the CR-based method is not available. Therefore, the DR-coin method is a more promising alternative to the conventional CR-based PBL assessment, given the shrinking availability of CR-based imaging in clinics.

PO-GePV-I-24

Direct Measurement of the Surface Dose Using a Plane-Parallel Ionization Chamber for Interventional Radiology

C Nakatake^{1*}, F Araki², T Ohno³, S Tochiwara⁴, D Sakabe⁵, T Sakamoto⁶, Y Yano⁷, M Fukamatsu⁸, K Nishimura⁹, (1) Kumamoto University, Kumamoto, JP, (2) Kumamoto University, Kumamoto, JP, (3) Kumamoto University, Kumamoto, JP, (4) Department of Radiology, Kumamoto University Hospital, Kumamoto, JP, (5) Department of Radiology, Kumamoto University Hospital, Kumamoto, JP, (6) Department of Radiology, Saiseikai Kumamoto Hospital, Kumamoto, JP, (7) Department of Radiology, Japanese Red Cross Kumamoto Hospital, Kumamoto, JP, (8) Department of Radiology, National Hospital Organization Kumamoto Medical Center, Kumamoto, JP, (9) Department of Radiology, Kumamoto Chuo Hospital, Kumamoto, JP

Purpose: To directly measure the entrance surface dose (ESD) of a phantom using a plane-parallel ionization chamber for interventional radiology (IVR) procedures. **Methods:** A PTW 23344 plane-parallel chamber was calibrated in terms of the dose at a 1-cm depth determined using a PTW 30013 Farmer-type chamber. The ESD for six IVR devices of three manufacturers in three institutions was measured using the PTW 23344 chamber. The front surface of the PTW23344 was set at an IVR reference point on the examination tabletop located 15 cm below the isocenter. The irradiation conditions of the IVR procedures were determined according to the automatic exposure control for the abdomen and head in the digital acquisition mode and fluoroscopy mode. The ESD is presented as a function of a half-value layer (HVL (mm Al)) for the given quality index (QI) values, which are defined as the ratio of the effective energy to the maximum energy of photons. The relationship between the ESD and incident air kerma, $K_{air,si}$, was also analyzed. $K_{air,si}$ was calculated using x-ray fluence spectra for the IVR irradiation conditions created by the SpekCalc program. **Results:** The calibration coefficient of the PTW 23344 chamber was mostly constant for x-ray beam qualities with tube voltages of 60–140 kVp and HVLs of 2.24–9.22 mm Al. The ESD increased with an increasing tube voltage for x-ray beams with the same HVL, and even for the same QI. In addition, the ESD achieved a good linear relationship with $K_{air,si}$, regardless of the x-ray beam quality. **Conclusion:** To reduce the ESD, reducing the tube voltage and using the x-ray beam quality with the QI close to unity was found to be effective. It is also possible to estimate the ESD using $K_{air,si}$ based on the irradiation conditions for IVR procedures.

This study was funded by a research grant (2019) from the Japanese Society of Radiological Technology (JSRT), and was also partially supported by JSPS KAKENHI of the Ministry of Education, Culture, Sports, Science, and Technology through Grant No. JP19K08203. The authors have no conflicts of interest to disclose.

PO-GePV-I-25

Optimisation of Radiation Dose and Image Quality for Six Different Flat Panel Detectors Using a Semi-Anatomical Chest Phantom

B Pearl^{1*}, R Livingstone, Christian Medical College, Vellore, Tamil NaduIN

Purpose: To evaluate the impact of radiation dose on image quality in six different flat panel detectors (FPD) and optimize radiation dose by altering exposure factors in low and high kVp chest radiography. **Methods:** Radiographic images of a semi-anatomical chest phantom were acquired from 6 FPDs from 4 different digital radiography (DR) manufacturers. Dose-area-product (DAP) was measured for three different protocols (Standard, AEC and low radiation dose) utilising 70 and 110 kVp. To normalize measurements across all FPDs, a standard DAP value of 51.05 μGym^2 obtained at 70 kVp and 9.43 μGym^2 at 110 kVp was used. The lowest possible radiation dose to provide acceptable image quality was achieved by manually adjusting mAs for both tube potentials. While selecting AEC exposure parameters, density, dose level or exposure (speed) classes were altered to obtain optimal radiation dose and image quality. Contrast to noise ratio (CNR), signal to noise ratio (SNR), figure of merit (FOM), contrast detail of the lung, heart and diaphragm regions and spatial resolution were quantified using a workstation. **Results:** In comparison with standard protocol, radiation dose reduction of 21%, 21.6%, 59.5%, 60.7%, 62.2% and 67.6% was achieved in GE Definium8k, Siemens Fusion, Fujifilm FGX, Fujifilm FGXR, Philips Digital Diagnost and Siemens Aristos with low dose protocol at 70 kVp. However, at 110 kVp, radiation dose could be reduced by 15.7%, 34.8% for Philips Digital Diagnost and Siemens Aristos alone. **Conclusion:** This study demonstrates the feasibility of using a semi-anatomical chest phantom in the optimisation of radiation dose and image quality for different FPDs. The FOM was a good indicator in assessing image quality between different detectors.

PO-GePV-I-26

1D and 2D MTF Measurement for a Dual-Detector Image Receptor Using the Noise Response (NR) Method Compared with Using the Standard Edge Method

A Jain^{1*}, X Wu², S Settler Nagesh², A Shields², N Artz¹, D Bednarek², S Rudin², (1) Children's Mercy Kansas City, Kansas City, MO, (2) Canon Stroke and Vascular Research Center (CSVRC), Buffalo, NY

Purpose: To compare the modulation transfer functions (MTF) of a new dual-detector image receptor measured using the Noise-Response (NR) method and the standard edge-response method. **Methods:** The NR method was used to measure both 1D and 2D MTF's for the two built-in detectors of the Canon Alphenix system (194-micron pixel FPD and 76-micron pixel HiDef). A cascaded-linear-systems analysis based relationship between the noise power spectrum (NPS) and the MTF of a generalized detector system was used. A two-dimensional NPS was calculated for each detector at 7 different exposures (4 to 100 uR) with the RQA5 x-ray spectrum. To obtain the 2D MTF, the 1D MTF at each angle was determined using the radial component of the NPS at the corresponding angle. Each 1D NPS was plotted versus the mean signal level for all spatial frequencies; a linear regression was fitted to this data to isolate the quantum-noise component, the shape of which partly depends on the system resolution. The spatial-frequency response of the resulting slopes was used to obtain the corresponding 1D MTF. The set of 1D MTF's over all angles provides the 2D MTF. The NR 1D MTF's along the rows for both detectors were compared to those obtained using the standard edge-response method. **Results:** The 1D MTF's obtained using the noise and edge methods for both detectors agree within experimental uncertainty and demonstrate the improved resolution of the HiDef detector over the standard FPD. The 2D MTF shows the magnitude of reduced resolution along the diagonals. **Conclusion:** The noise-response method is a simple technique which can be used to accurately measure the 2D MTF of digital x-ray imagers, without the need for precision edge or slit devices. The unique capability of the NR method to provide a two-dimensional MTF provides more detailed detector/system characterization, including any potential non-isotropy.

Clinical Evaluation of Deep Learning Based Auto-Contouring Software for Prostate Radiotherapy

M Kirk^{1*}, B Anderson¹, H Prichard¹, L Ryan¹, X Zhang¹, Y Wang², (1) Mass General/North Shore, Danvers, MA, (2) Massachusetts General Hospital, Boston, MA

Purpose: Deep learning-based auto-contouring (DLC) may be used to reduce the time required to generate organs-at-risk (OAR). In this study, we investigate both the time and accuracy of the DLC OARs compared to manually drawn OARs for prostate radiotherapy. **Methods:** The OARs of ten prostate patients were contoured by the DLC software and four experts (EC) (Senior dosimetrists with an average of 15 years of experience). The time to manually draw the Penile Bulb, Femurs, Bladder and Rectum was recorded. Additionally, the experts adjusted the DLC contours (User Adj DLC) and recorded the time. The Dice Similarity Coefficient (DSC) and the Mean Distance to Agreement (MDA) were used for comparisons. **Results:** The use of DLC resulted in a statistically significant ($p < 0.05$) reduction in contouring time, from a mean time for EC contours of 28 minutes (SD=10min) to a mean time of 10 minutes (SD=2min) for the User Adj DLC. The mean DSC values for the DLCs were: Penile Bulb = 0.62, Femurs = 0.94, Bladder = 0.94, and Rectum = 0.83. The DSC values for the mean User Adj DLC were: Penile Bulb = 0.69, Left and Right Femur = 0.96, Bladder = 0.94, and Rectum = 0.88. The mean MDA values for the DLCs were: Penile Bulb = 2.43mm, Femurs = 0.85mm, Bladder = 0.92 and Rectum = 2.31 mm. The MDA values for the mean User Adj DLC were: Penile Bulb = 1.90 mm, Left and Right Femur = 0.77 mm, Bladder = 0.81 mm, and Rectum = 1.57 mm. **Conclusion:** The use of auto contouring provides a starting point for the creation of OARs allowing for a significant time reduction. User adjustment of the DLC based contours resulted in a significant increase ($p < 0.05$) in DSC values and decrease in MDA values for all the OARs.

PO-GePV-M-02

Comparison of Deep Learning Based Auto-Contouring Software to Expert Inter-Observer Variability in Prostate Radiotherapy

M Kirk^{1*}, B Anderson¹, H Prichard¹, L Ryan¹, X Zhang¹, Y Wang², (1) Mass General/North Shore, Danvers, MA, (2) Massachusetts General Hospital, Boston, MA

Purpose: Deep learning-based auto-counter (DLC) may be used to reduce the time required to generate organs at risk (OAR). In this study, we investigate the accuracy of DLC contouring relative to inter-observer variability. **Methods:** Ten prostate patients were contoured by four experts, senior dosimetrists with an average of 15 years of experience (EC). The penile bulb, femurs, bladder and rectum were contoured by the DLC software and each expert. The Dice Similarity Coefficient (DSC) and Mean Distance to Agreement (MDA) was used to compare the DLC contours to multiple EC contours. The worst DSC value for the Deep learning vs Experts (DLC-EC) combinations and inter-expert (EC-EC) combinations for each patient were used for the statistical analysis. This ensured that lower performing outliers were included. **Results:** No statistically significant ($p < 0.05$) differences were measured for the worst DSC metric for each case. The single-worst DSC for the DLC-EC and EC-EC were: penile bulb (0.30 vs 0.31), Femurs (0.87 vs 0.87), bladder (0.74 vs 0.74), and rectum (0.76 vs 0.77). The average-worst DSC were: penile bulb (0.49 vs 0.49), Femurs (0.92 vs 0.92), bladder (0.91 vs 0.90), and rectum (0.81 vs 0.82). The mean DSC values for DLC-EC were: Penile Bulb = 0.62, Femur = 0.94, Bladder = 0.94, and Rectum = 0.83. The mean DSC values for EC-EC were: Penile Bulb = 0.60, Femur = 0.93, Bladder = 0.92, and Rectum = 0.86. The mean MDA values: Penile Bulb = 2.43mm, Femurs = 0.85mm, Bladder = 0.92mm, and Rectum = 2.31mm. By comparison, the mean MDA values for the EC-EC inter-comparison are: Penile Bulb = 2.39mm, Femurs = 1.15mm, Bladder = 1.02mm, and Rectum = 2.26mm. **Conclusion:** The use of DLC based auto-contouring provides contours that are comparable to expert inter-observer variability.

PO-GePV-M-03

A 2D-3D Hybrid Convolutional Neural Network for Lung Lobe Auto-Segmentation on Standard Slice Thickness CT of Patients Receiving Radiotherapy

H Gu^{1*}, (1) Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai, CN

Purpose: Accurate segmentation of lung lobe on routine CT images of locally advanced stagelung cancer patients undergoing radiotherapy can help radiation oncologists to implement lobar-level treatment planning, dose assessment and efficacy prediction. We aim to establish a novel 2D-3D hybrid convolutional neural network (CNN) to provide reliable lung lobe auto-segmentation results in the clinical setting. **Methods:** We retrospectively collected and evaluated thorax CT scans of 95 locally advanced Non-small-cell lung cancer (NSCLC) patients treated at our institution from June 2019 to February 2020. The CT images were acquired with 5mm slice-thickness. Two CNNs were used for lung lobe segmentation, a 3D CNN for extracting 3D contextual information and a 2D CNN for extracting texture information. Contouring quality was evaluated using three quantitative metrics and visual evaluation was performed to assess the clinical acceptability. **Results:** For the 25 cases in the test group, Dice Similarity Coefficient (DSC) of all lung lobes contours exceeded 0.75, which met the pass criteria of the segmentation result. Our model achieved high performances with DSC as high as 0.9579, 0.9459, 0.9472, 0.9452 and 0.8968 for left upper lobe (LUL), left lower lobe (LLL), right upper lobe (RUL), right lower lobe (RLL) and right middle lobe (RML), respectively. Clinician's visual assessment showed that 118/125 lobe contours met the requirements for clinical use, only 7 contours need manual correction. **Conclusion:** Our 2D-3D hybrid CNN model achieved accurate automatic segmentation of lung lobes on conventional slice-thickness CT of locally advanced lung cancer patients, and has good clinical practicability.

Automatic Contouring QA Approach Using a Deep-Learning-Based Auto-Contouring System

D Rhee^{1*}, C Anakwenze¹, B Rigaud¹, A Jhingran¹, C Cardenas¹, L Zhang¹, S Prajapati¹, S Kry¹, K Brock¹, B Beadle², W Shaw³, D O'reilly³, J Parkes⁴, H Burger⁴, N Fakie⁴, C Trauernicht⁵, H Simonds⁵, L Court¹, (1) University of Texas MD Anderson Cancer Center, Houston, TX, (2) Stanford University, Stanford, CA, (3) University of The Free State, Bloemfontein, ZA, (4) University Of Cape Town, Cape Town, ZA, (5) Stellenbosch University, Stellenbosch, ZA

Purpose: To establish a similarity metric to automatically flag clinically unacceptable contours in the female pelvis. **Methods:** Six female pelvic structures (Uterus/Cervix, CTVn, Para-aortic lymph nodes (PAN), Bladder, Rectum, and Kidneys) were generated using manual and auto-contouring. **Methods:** clinically acceptable and unacceptable contours were generated manually, and two auto-contours per structure were generated with two independently developed deep learning-based auto-contouring systems. These structures were generated on 87 CT image sets from 4 hospitals. The clinical acceptability of one of the two auto-contours ("primary contour") was confirmed by radiation oncologists, and the second auto-contour was used for QA purposes. Eleven similarity metrics (Dice-Similarity Coefficient (DSC), Hausdorff distance, 95% Hausdorff distance, mean surface distance, and surface DSC with incremental thicknesses of 1-10 mm) were calculated between primary and QA contours. The metrics were tested individually and in various combinations as inputs for a support vector machine. Model inputs were used to determine the optimal decision boundary between clinically acceptable and unacceptable contours. Four different kernels (linear, radial basis function (RBF), sigmoid, and polynomial) were tested when multiple metrics were used as inputs for the support vector machine. **Results:** The highest accuracies were achieved using surface DSCs with a thickness of 1, 2, or 3 mm and they were 0.91/0.90/0.89/0.92/0.95/0.97 for

UteroCervix/CTVn/PAN/bladder/rectum/kidneys, respectively. The average accuracies across different structures were 0.90/0.88/0.70/0.88 for linear/RBF/sigmoid/polynomial kernels, respectively, and therefore, the linear kernel was the most accurate when multiple metrics were used as inputs for the support vector machine. However, multiple metrics did not improve the accuracy significantly compared to a surface DSC as an input. **Conclusion:** We distinguished clinically acceptable contours from clinically unacceptable contours with an accuracy higher than 0.9 for the relevant structures in the female pelvis; the most accurate similarity metric was surface DSC with a thickness of 1, 2, or 3 mm.

PO-GePV-M-05

Radiation Induced Lung Damage Tissue Segmentation and Classification Framework

A Szmul^{1*}, E Chandyl^{1,4}, C Veiga¹, A Stavropoulou¹, J Jacob^{1,2}, D Landau³, C Hiley⁴, J McClelland¹, (1) Centre for Medical Image Computing, University College London, London, UK, (2) Department of Respiratory Medicine, University College London, London, UK, (3) Guys & St Thomas NHS Foundation Trust, London, UK, (4) Cancer Institute, UCL, London, UK

Purpose: Radiation-induced lung damage (RILD) is a common side effect of radiotherapy. The ability to automatically segment, classify and quantify different types of parenchymal change is essential to uncover underlying patterns of RILD and their evolution over time. **Methods:** The following five labels were introduced to classify parenchymal morphological appearance: A) default lung parenchyma; B) non-textured ground glass opacity; C) textured ground glass opacity; D) solid density with air-bronchograms; E) solid density. We utilized a two-stage ground truth data generation approach, akin to active learning. Manual segmentations were used to train an initial auto-segmentation method. These results were manually refined and used to train the final auto-segmentation algorithm. The auto-segmentation algorithm was an ensemble of six 2D-Unets with different loss functions and numbers of input channels. **Results:** Our development dataset consisted of 40 cases, each with a pre-radiotherapy, 3, 6, 12, and 24 month follow-up CT scan (n=200 CTs). The method was assessed on a hold-out test dataset of 6 cases (n=30 CTs). The Dice Score Coefficient (DSC) achieved for each tissue class were: A) 0.99 and 0.98, B) 0.71 and 0.44, C) 0.56 and 0.26, D) 0.79 and 0.47, and E) 0.96 and 0.92, for development and test subsets respectively. The lowest values for the test subsets were caused by imaging artefacts or in regions where annotations were less certain. We also performed qualitative evaluation on the test dataset presenting manual and auto-segmentations to a blinded independent radiologist to rate them as 'clinically acceptable', 'minor disagreement' or 'major disagreement'. The auto-segmentation ratings were similar to the manual segmentations, both having slightly over 80% of cases rated as 'clinically acceptable'. **Conclusion:** The proposed framework for auto-segmentation of different lung tissue classes produces acceptable results in the majority of cases and will be useful for future studies of RILD.

Hybrid Approach of Auto-Segmentation Based on Pixel Level Edge Detection

D Tewatia^{1*}, R Tolakanahalli², RW Pyzalski³, (1) University of Wisconsin-Madison, Madison, WI, (2) Miami Cancer Institute, Miami, FL, (3) Retiree of University of Wisconsin-Madison, Madison, WI

Purpose: To explore semi-automatic approach for segmenting regions of interest based on pixel level information. **Methods:** Due to recent advances in machine learning and big data technologies, in radiotherapy field there is great interest in utilizing these advances to study treatment response, automating the organ segmentation, tracking moving tumors, online daily adaption of treatment plans and more. But in all of these studies possibility of achieving reliable results is directly proportional to reduction in inter-observer variability. We have developed a hybrid auto segmentation tool. Unlike atlas, model and deep learning based auto-contouring approaches users can interact in the automation process if necessary. To make it understand better our tool is like having a driverless car but rider can take control whenever it is necessary. Our INTERactive CONTouring (Intcont) tool draws contour around an edged region of interest (ROI). It combines automatic edge finding with the operator oversight and occasional intervention if the contour line deviates from the expected path. This is a universal tool and can be applied to segment tumor volumes as well as organs at risk. Moreover, Intcont allows to change local threshold at the edge if expert wants to include or exclude the actual edge from ROI (tighter or looser boundary around ROI). **Results:** Intcont has successfully drawn reliable ROIs on all datasets we considered during development of the tool. **Conclusion:** Intcont offers a novel approach to image contouring that provides combination of automated contouring with user interaction. It avoids contouring artifacts often introduced by fully automated contouring system and at the same time it is less subjective than outright manual drawing or manual editing when contours created by automated methods have artifacts. Rigorous analysis of the "correctness" of contours from Intcont will be done soon.

PO-GePV-M-07

Performance of a Convolutional Neural Network-Based Algorithm for Automatic Segmentation of the Whole Heart in Non-Contrast Radiotherapy Planning CTs with Image Artifacts

D Mehta^{1*}, B Park², J Jung³, M Mille⁴, B Ky⁵, W Kenworthy⁶, C Lee⁷, Y Yeom⁸, W Bosch⁹, S MacDonald¹⁰, O Cahlon¹¹, J Bekelman¹², C Lee¹³, (1) East Carolina University, (2) East Carolina University, (3) East Carolina University, Greenville, NC, (4) National Cancer Institute, Bethesda, MD, (5) University of Pennsylvania, Philadelphia, PA, (6) University of Pennsylvania, Philadelphia, PA, (7) University of Michigan, Ann Arbor, MI, (8) National Cancer Institute, Rockville, MD, (9) Washington University, Saint Louis, MO, (10) (11) New York, NY, (12) University of Penn, Philadelphia, PA, (13) National Cancer Institute, Rockville, MD

Purpose: To evaluate the performance of a convolution neural network-based algorithm for automatic segmentation of the whole heart from non-contrast radiotherapy planning CTs with image artifacts **Methods:** We obtained non-contrast planning CTs with manual contours of the whole heart of 100 breast cancer patients in the Radiotherapy Comparative Effectiveness (RadComp) clinical trial. We employed a convolutional neural network, U-net, for the automatic segmentation of the whole heart. A total of 66 patients without image artifacts were used for training and 34 patients with image artifacts were used for testing the performance of the segmentation method. At least a single CT slice contained image artifacts: left breast (n=4), right breast (n=6), both breasts (n=15), heart (n=2), and other regions (n=7). The results were then compared with manual delineations to evaluate the performance of our method in terms of geometric similarities using dice similarity coefficients (DSC). **Results:** The initial training set ran 400 epochs, which stabilized in approximately 46 hours. The DSCs for the image sets with artifacts in left breast, right breast, both breasts, heart, and other regions were 0.90 ± 0.03 , 0.90 ± 0.04 , 0.91 ± 0.04 , 0.91 ± 0.01 , and 0.79 ± 0.15 , respectively. The lowest DSCs were observed in large patients extending outside the field of view. **Conclusion:** When compared to DSC results from literature based on convolutional neural network, we found that image artifacts substantially reduce the performance of automatic segmentations. We

plan to evaluate the dosimetric impact of the image artifacts.

This work was funded in part by the intramural program of the National Institutes of Health, National Cancer Institute, Division of Cancer Epidemiology and Genetics.

A 3D Multi-Modality Lung Tumor Segmentation Method Based on Deep Learning

S Wang^{1*}, L Yuan², E Weiss³, R Mahon⁴, (1) Virginia Commonwealth University, Richmond, VA, (2) Virginia Commonwealth University Medical Center, Richmond, VA, (3) Virginia Commonwealth University, Richmond, VA, (4) Washington University in St. Louis, St. Louis, MO

Purpose: To develop an automatic lung tumor segmentation method based on multi-modality images and deep learning. **Methods:** A 3D segmentation neural network using PET and CT multi-modality image inputs were constructed based on the U-Net. The network architecture consists of two parallel convolution arms for independent feature extraction from the simulation CT and the diagnostic PET at multiple resolution levels. The extracted features were concatenated and fed into a single deconvolution path. The resulting tumor probability map was post-processed through the conditional random field and thresholded to obtain the tumor segmentation. The performance of this 3D multi-modality network was compared with that of the previously constructed 2D multi-modality network and the 2D and 3D CT-only single-modality networks. Furthermore, a volume-stratified training/validation strategy was evaluated for segmentation performance improvement. The networks were trained/validated/tested (3:1:1 split ratio) on 290 pairs of diagnostic PETs and planning CTs (166 SBRT and 124 conventionally-fractionated) from lung cancer patients treated at our clinic, with manual physician contours as the ground truth. The segmentation performance of the networks was evaluated via the DICE similarity coefficient (DSC) and the Hausdorff Distance (HD). **Results:** The mean DSC and HD of the single-modality models were 0.75 ± 0.16 and 8.5 ± 5.8 mm for 2D, and 0.77 ± 0.12 and 7.6 ± 4.7 mm for 3D, respectively. The mean DSC and HD of the multi-modality networks were 0.78 ± 0.15 and 7.6 ± 4.7 mm for 2D, and 0.79 ± 0.10 and 5.8 ± 3.2 mm for 3D, respectively. The small GTVs benefited from separate training/validation with a threshold of 25mL identified as ideal. The best overall performance was obtained by the multi-modality volume-stratified 3D model, with the overall DSC and HD of 0.83 ± 0.09 and 5.9 ± 2.5 mm, respectively. **Conclusion:** The 3D multi-modality deep learning network outperformed its 2D counterpart and the single-modality networks. The volume-based stratification can further improve the segmentation results.

PO-GePV-M-09

A High-Throughput, High-Availability Automated Planning Tool for Radiotherapy Clinics in Low-Resource Settings

B Marquez^{1,2*}, S Gay², R Douglas², L Zhang², K Huang^{1,2}, M El Basha^{1,2}, C Cardenas^{1,2}, L Court^{1,2}, (1) University of Texas MD Anderson UTHealth Graduate School of Biomedical Sciences, (2) University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: To assess the throughput and reliability of a web-based, automated radiotherapy planning tool (Radiation Planning Assistant, RPA) designed to support low-resource clinics. **Methods:** The RPA architecture consists of several, multi-capacity computing modules that process patients in a serial manner. Baseline timings for each module were measured by processing 25 cervix and 25 head & neck (H&N) patient datasets through the entire workflow. Each module was modeled in a manufacturing discrete event simulator (ManPy), and programmed with their respective timing data, to evaluate serial and parallel workflows. Model accuracy was evaluated by comparing the simulator's completion times for single- and multi-patient queues to those of the real RPA system. Finally, many module downtime scenarios were simulated to determine their impact on baseline performance of the RPA's daily throughput. **Results:** An independent t-test indicated that mean processing times were not significantly different between the RPA and the model ($p > 0.05$). The model gave an expectation value for plans successfully processed in 24 hours: 483 cervix plans, 255 H&N contours, or 258 H&N plans when all systems are operating. Cervix plan generation remained within 5% of its baseline throughput until any given module (except the plan/dose QA module) went down for 3+ hours. H&N contour generation remained within 5% of its baseline when either of its two contouring module's downtime did not exceed 1 hour. H&N plan generation remained within 5% of its baseline until at least 2 of 5 available VMAT optimization modules' downtime exceeded 1 hour, or any other module downtime exceeded 3 hours. Plan calculation and report generation module downtimes had <5% effect on output through 4 hours downtime. **Conclusion:** The RPA architecture is robust to downtime of its individual modules, thus having the ability to reliably address resource shortage in radiotherapy clinics.

Development of Gell: A GPU-Powered Ultra-Large-Scale Cell-Based Simulator

J Du^{1*}, Y Zhou², L Jin², K Sheng¹, (1) UCLA School of Medicine, Los Angeles, CA, (2) UCLA School of Engineering, Los Angeles, CA

Purpose: To understand macroscopic imaging feature formation as a result of underlying cancer cell biology and growth dynamics, we build a novel fast GPU-powered cell-based simulation platform-Gell suited for ultra-large-scale tumor growth modeling. **Methods:** Tumor development is a multifaced and multiscale problem. At the biochemical microenvironment level, we implemented a fast paralleled PDE solver for the secretion, diffusion, uptake, and decay of oxygen and Vascular Endothelial Growth Factor (VEGF) with computational complexity proportional to volume voxel number. At the single-cell level, we included modules to describe cell proliferation, growth, death, nutrient uptake, and angiogenic factor release. At the multicellular level, we described the mechanical interactions for cell-cell adhesive and repulsion with computational complexity proportional to the number of cells. We combined these modules to simulate HCC827 non-small cell lung carcinoma spheroids' growth and compared the results with state-of-the-art CPU simulator PhysiCell. **Results:** Gell simulation results of the approximately constant spheroid diameter growth speed and the crack-like necrotic core microstructure are consistent with PhysiCell simulation and in vitro experimental observation. However, the computational time for 18 days of in vitro spheroid growth was reduced from 76 hours using CPU-based PhysiCell (dual 6-core Intel Xeon X5690) to seven minutes using GPU-based Gell (Nvidia RTX 2080Ti). In a large multicellular simulation test for a 1-hour biological process of 16 million cells, the simulation was accelerated by over one thousand times compared with PhysiCell. **Conclusion:** In this work, we developed a fast GPU-based simulator, Gell, for avascular multicellular processes. The GPU implementation afforded 1000X acceleration over the CPU method. The acceleration is essential to overcoming the bottleneck in CPU simulation for ultra-large-scale, morphologically complex centimeter-level tumors and tumor vasculature that form medical image features.

Radiomic Analysis of Limited-Sized Data Using Unsupervised Methods: Prediction of HPV Status in Head and Neck Cancer

J Oh^{1*}, A Apte¹, A Iyer¹, A Tannenbaum², J Deasy¹, (1) Memorial Sloan Kettering Cancer Center, New York, NY, (2) Stony Brook University

Purpose: Working with limited-sized data is a common challenge in medicine. We investigated a promising unsupervised approach to radiomics that combines unsupervised optimal mass transport (OMT) on a network of radiomic features. tSNE (t-stochastic neighborhood embedding) was then used to cluster and visualize the results in 2-D with the novel Wasserstein metric. We demonstrate this approach on the important problem of predicting HPV status in head-and-

neck squamous cell cancer (HNSCC) patients with contrast enhanced computed tomography (CT) images. **Methods:** Radiomic analysis was performed on 77 HNSCC patients with pre-treatment CT scans downloaded from The Cancer Imaging Archive (TCIA). Using the CERR radiomics toolbox, 67 radiomic features were extracted from primary tumors manually contoured on all evaluable artifact-free slices. First, a partial correlation network was constructed, where a link between two nodes was determined using a partial correlation coefficient after conditioning on all other features. To further remove potential false positive links, a lasso-type regularization was applied to the resultant network. On the largest connected network component, an OMT metric called the W_1 Wasserstein distance was computed for all pairs of samples, and then the resultant distance matrix was input into tSNE to map the samples to a low-dimensional space. **Results:** The cohort had 13 HPV positive tumors. The resultant Wasserstein distance matrix computed in the largest network component with 10 radiomic features was fed into tSNE, using the OMT-based distance as a cost function. In the mapped two-dimensional space, tumors with HPV positivity were better clustered with a Chi-squared p-value of 0.0008 than the tSNE result with the Euclidean distance. **Conclusion:** We demonstrated that radiomic features represented as a network can predict HPV positivity in head and neck cancer with good accuracy, employing tSNE coupled with an OMT based metric. The unsupervised result could further be refined using supervised methods.

The IAEA Directory of Radiotherapy Centres (DIRAC): Current Figures and New Developments

P Kazantsev, M Carrara, E Titovich, Y Pynda, D van der Merwe, International Atomic Energy Agency, AUSTRIA

Purpose: IAEA has maintained DIRAC since 1959. Nowadays, it is the only high-quality source of information on worldwide radiotherapy (RT) infrastructure and is publicly accessible on the web at [//dirac.iaea.org](http://dirac.iaea.org). The web portal allows data input by contributors and visualization of hospital, national and regional data using modern business intelligence tools. **Methods:** DIRAC is continuously updated by individuals and national focal points, and the updates are verified by the IAEA data curation team. Part of the DIRAC information is publicly available on the website, but more detailed analyses are provided upon request for non-commercial use only. Each request for information is processed individually. A major update of DIRAC data structure has been deployed recently. In addition, the website has been updated to include a tool to quantify the bibliometric impact of DIRAC. **Results:** To date, DIRAC records include over 7900 RT centres equipped with over 17600 RT units. Of those, 14258 are external beam units, 3319 brachytherapy units (including electronic BT) and 105 light ion facilities (as of 2021.02.22). Over the last 20 years, 140 peer-reviewed publications directly referred to DIRAC, and over 2300 articles cited these papers. DIRAC structure was expanded to include details of collimation, imaging and motion management systems of RT treatment units, specific features and algorithms of treatment planning systems for both tele- and brachytherapy, conventional CT scanners and simulators. Additionally, data collection and representation structure for light ion therapy facilities has been revised. **Conclusion:** DIRAC supports academic and health care research, particularly in the analysis of national, regional and global availability of RT infrastructure. Developments in the DIRAC structure and its web-based interface are expanding with advances in RT technology, techniques, process and services.

Treatment Management Selection of HPV-Positive Oropharynx Cancer Patients Using Artificial Intelligence on Electronic Medical Records and Radiomics

T Bejarano^{1*}, Samuels², I Mihaylov², M (1) University of Virginia, Charlottesville, VA, (2) University of Miami, Miami, FL

Purpose: Human papillomavirus (HPV)-associated oropharyngeal squamous cell carcinoma (OPSCC) can be treated with definitive radiotherapy (RT), combined chemoradiotherapy (CRT), and/or transoral robotic surgery (TORS). TORS is a surgical approach that provides a comparable overall survival (OS) rate of approximately 90% at 2 years with the potential for less toxicity, lower cost, and shorter treatment regimen. However, approximately one-third of TORS patients require adjuvant CRT (with the highest combined treatment toxicity profile) due to extranodal extension (ENE) or positive surgical margins on the final pathology. In retrospect, the decision for these patients to undergo TORS is unfavorable. This study describes a treatment management selection procedure which utilizes artificial intelligence (AI), applied to clinical and imaging data, such that it identifies the patients contraindicated for TORS. **Methods:** Electronic medical records (EMR) for 55 subjects were retrospectively reviewed. Patient data included demographics, history, vital signs, and labs. Radiomics from diagnostic CTs were also utilized. After statistical pre-processing and remapping to equivalent numerical representations, three statistically significant textures were added to the analyses. Extracted data were used as an input into a deep neural network (DNN) that computed a probabilistic value for each patient, indicating whether TORS is a suitable disease management option. The DNN (based on Google's TensorFlow) incorporated a supervised learning technique used to mimic the physician's decision-making. A 5-fold cross-validation was utilized for evaluating the model's performance. **Results:** The DNN was successfully implemented with variable parameters, allowing flexibility and easy reconfigurability. An average AUC of 0.89 was achieved using significant EMR and imaging data. **Conclusion:** Treatment selection of HPV-associated OPSCC patients may be facilitated by AI techniques, applied to commonly tallied clinical variables, and combined with diagnostic imaging radiomics. The proposed methodology will help in discriminating patients who would ultimately require tri-modality therapy with the highest toxicity profile.

Hyperpolarized Gas MRI Ventilation Synthesis From CT: Comparison of Conventional and Deep Learning Methods

J Astley*, A Biancardi, M Walker, P Hughes, H Marshall, G Collier, M Hatton, J Wild, B Tahir, The University of Sheffield, Sheffield, United Kingdom

Purpose: Hyperpolarized gas MRI can visualize and quantify regional lung ventilation with exquisite detail. However, clinical uptake is limited to a few centres worldwide due to the requirement of highly specialized equipment and exogenous contrast. Alternative, non-contrast techniques have been proposed to model ventilation, including multi-inflation CT-based models of ventilation that have shown moderate spatial correlations with hyperpolarized gas MRI. Recent advances in deep learning (DL) using convolutional neural networks (CNNs) have shown great promise for numerous medical imaging applications, including image synthesis. Here, we propose a multi-channel 3D CNN approach for synthesizing hyperpolarized gas MRI scans using multi-inflation CT and a conventional density-based CT ventilation imaging (CTVI) model as inputs. We compare the accuracy of the CNN-based ventilation images with those generated by the conventional CTVI model. **Methods:** The dataset comprises paired inspiratory and expiratory CT and helium-3 hyperpolarized gas MRI for 47 patients with a range of pulmonary pathologies. A VNet CNN with a root mean square error loss function was used for image synthesis. We performed 6-fold cross-validation on the dataset and evaluated the correlation of the synthetic ventilation and hyperpolarized gas MRI scans at full resolution using Spearman's ρ on all lung voxels. The combined DL and CTVI model was compared to the conventional CTVI model. **Results:** Qualitatively, there are numerous examples of the CNN-generated synthetic ventilation images accurately replicating ventilation defects in the hyperpolarized gas MRI scans. Quantitatively, the CNN approach yielded statistically significant improvements in Spearman's correlation compared to the CTVI model ($p < 0.0001$) with mean $\pm$ SD ρ of 0.5 ± 0.2 vs 0.4 ± 0.2 . **Conclusion:** We propose a multi-channel CNN-based approach to generate synthetic ventilation images from routinely acquired multi-inflation CT and CTVI models. We show that a synergy between conventional model-based CTVI and DL yields statistically significant improvements in spatial correlation compared with conventional CTVI modelling.

Limitations of the Structural Similarity Index in Medical Image Synthesis Evaluation

D Gourdeau^{1,2,3*}, S Duchesne^{1,2}, L Archambault^{2,3}, (1) Université Laval (2) CERVO Brain research center (3) CHUQ Hotel-Dieu de Québec

Purpose: Structural similarity (SSIM) is a popular image quality metrics used in the medical image synthesis community because of its higher correlation with human visual quality assessment. It has been widely adopted, but its limitations are often overlooked. SSIM is designed to work on a positive intensity scale, which is not the case in medical imaging. Intensity scales like the Hounsfield units contain negative numbers, and image normalization techniques can also introduce negative numbers. **Methods:** To quantify the impact of misusing the SSIM metric, we trained two uncorrelated image synthesis models to perform T2 MRI synthesis from T1 MRI. The synthesized images are strictly positive and their real SSIM can be evaluated. The real SSIM score was compared to a SSIM score computed on the same synthetic images, but after subtracting the mean tissue value from the ground truth to mimic Z-normalization. Next, the suitability of SSIM as a loss function is evaluated by training two synthesis models, once to synthesize strictly positive T2, and once to synthesize Z-normalized T2. The quality of models is evaluated using MAE and PSNR. **Results:** SSIM was reduced from 0.895 to 0.774 in model 1 and from 0.891 to 0.784 in model 2 when the tissue mean was subtracted from the synthetic images. This means that SSIM is underestimated on images with negative values, and it introduced an error that changed the relative ranking of models. This error can be clinically significant considering the small SSIM difference between state-of-the-art models. Secondly, training a synthesis model with SSIM as loss function on images with negative values drastically reduces image quality, with the mean relative error increasing from 8.65% to 22.78%. **Conclusion:** We show that it is inappropriate to use SSIM on images containing negative values. Finally, we propose reporting guidelines for easier comparisons between articles.

Predicting Successful Clinical Candidates for Marker-Less Lung Tumor Tracking with a Deep Learning Classification Model

M Lafreniere*, G Valdes, M Descovich, University of California San Francisco, San Francisco, CA

Purpose: Robotic radiosurgery allows for marker-less lung tumor tracking by detecting pattern variations in tumor density in 2D orthogonal x-ray images. The ability to detect and track a lung lesion depends on its size, density, and location, and has to be evaluated on a case-by-case basis. The current method for identifying which patient can be successfully treated with marker-less lung tumor tracking is a time-consuming multi-step process involving CT acquisition, generation of a simulation plan, creation of the patient breathing model, and execution of the simulation plan on the treatment delivery platform. The aim of the study is to develop a tool based on binary classification of trackable and non-trackable lung tumors for automatic selection of optimal tracking methods for patient undergoing robotic radiosurgery. **Methods:** We developed a deep learning classification model and tested 5 different network architectures (AlexNet, Densenet201, InceptionResnetV2, VGG19, and NasNetLarge) to classify lung cancer lesions from digitally reconstructed radiographs (DRR) generated from planning CTs. This study included 138 IRB-approved patients. There were 109 patients with 115 lesions that were trackable and 20 patients with 29 lesions that were non-trackable, for a total of 271 images. We kept 80% of the images for training, 10% for validation, and the remaining 10% for testing. **Results:** The training time on a single 1.6GHz Intel i5 processor and 16GB of RAM was 18 minutes for AlexNet, 103 minutes for DenseNet, 170 minutes for InceptionResnetV2, 203 minutes for VGG19, and 245 minutes for NasNetLarge. There were no false classifications. The binary classification accuracy reached 100% after training, both in the validation and the testing phase, for all 5 network architectures. **Conclusion:** For patients undergoing robotic lung radiosurgery, candidates for marker-less lung tumor tracking can be successfully identified by classifying with a deep learning model DRR images sourced from simulation CT scans.

PO-GePV-M-17

Prediction of WEPL Image in Proton Radiography Using Deep Learning

Alaka B G^{1*}, D Samuel², E Bentefour³, (1) Central University of Karnataka, Kalaburgi, Karnataka, IN, (2) Central University of Karnataka, (3) University of Maryland School of Medicine, Baltimore

Purpose: To predict the WEPLs from energy-resolved dose functions (ERDF) using a deep learning algorithm. **Methods:** A solid water wedge of dimension 30 cm x 10 cm x 30 cm in the path of the scanned proton beams is simulated using Geant4. The beam energy is varied between 100 MeV to 225 MeV in steps of 3 MeV and the exit dose is estimated from the simulation. This setup is used to obtain the calibration datasets (i.e, ERDF). This database is used for training a deep-learning model. The optimized model is used to predict the WEPL for box and staircase configurations (three steps stairs). **Results:** The preliminary results show that the predicted WEPLs are in good agreement with the actual WEPLs for certain WEPL ranges. From the staircase results, the average error in predicting WEPL for 120 mm is 4.5% and the average error for 170 mm and 200 mm is 1.5%. However, the predicted WEPL varies significantly from the actual values in certain ranges of WEPL, and the work to achieve better accuracy is in progress. The advantage of the deep learning technique over the conventional technique is that the time taken for the deep learning model to predict the WEPL is considerably small (~ 1 minute to generate a 200 x 600 WEPL map). **Conclusion:** Deep learning techniques offer a new avenue of analysis in the field of proton imaging especially in reducing the computation time. The technique needs to be fine-tuned with respect to the model parameters and features in order to predict the WEPLs within clinically acceptable limits.

Using CNNs to Extract Standard Structure Names While Learning Radiomic Features

W Sleeman*, P Bose, P Ghosh, J Palta, R Kapoor, Virginia Commonwealth University, Richmond, VA

Purpose: Although there is an increased interest in Big Data for research and quality assurance in radiation oncology, the lack of use of standard nomenclature has hindered such progress. AAPM TG 263 has proposed a solution to standardize structure labels but clinical adoption for prospective or retrospective data has been sparse. Previous work in structure name standardization has included radiomic features, such as mean, kurtosis, skew, and uniformity, but the selection of features were done manually. Deep Learning has demonstrated the ability to learn such features from the data alone, and so we investigate how CNN based models can learn from imaging and dose datasets. **Methods:** We used 9,750 structures from 550 prostate patients to automatically label the following structures: Bladder, Rectum, Left Femur, Right Femur, Small Bowel, Large Bowel, PTV, and a group containing all other structures. A bounding box was centered on each structure in the dataset and a bitmap was extracted. The same bounding box was used to extract the imaging and dose data. Four CNN models were tested: structure only, structure plus image, structure plus dose, structure plus image plus dose. **Results:** Our results showed that the combination of structure, image, and dose data provided the best results with weighed F1-scores of 0.842, 0.791, 0.845, and 0.861 respectively. When tested on an external dataset of 50 patients from another institution, the F1-scores were 0.829, 0.801, 0.831, 0.857. **Conclusion:** Adding dose information to the structure bitmap and imaging data can improve the ability to correctly label delineated structures. Based on their position relative to the target, each OAR or target may follow a unique pattern of dose delivery which may be contributing to the improved results. Although very large annotated radiotherapy datasets are not yet available, CNN models can still learn radiomic features without being manually defined.

PO-GePV-M-19

CNN-Based Clinical-Dose to Low-Dose CT Simulator

S Tunissen*, J Teuwen, I Sechopoulos, Radboud University Medical Center, Nijmegen, The Netherlands

Purpose: To simulate low dose CT images from clinical dose acquisitions in order to create datasets for testing image analysis or processing algorithms. **Methods:** A dataset of 2020 paired 2D slices from 101 clinical dose (400 mA; 80 kVp) and low dose (200 mA; 80 kVp) 320 slice non-contrast brain CT scans, reconstructed using 3D iterative reconstruction, was obtained retrospectively. Rigid registration was performed between the clinical dose and low dose images to correct for patient movement. Two neural networks were separately trained on this data for, first, denoising and then, generating the necessary noise expected at lower dose. The denoising network has a U-net architecture with residual layers, which estimates the average of the distribution, denoising the images. The noise generating network is a generative adversarial network (GAN), of which the generator is a U-net with residual layers and the discriminator is a modified version of the VGG16 model. The generator has to output realistic noise patterns for low dose CT images, in which the spatial correlation and magnitude depend on the content, location, and intensity of the image. As the real input image for the discriminator, the noise pattern obtained by subtracting the denoised image from the low dose image was used. **Results:** The denoising network reduces the noise effectively, with a reduction in the pixel variance in homogeneous areas by a factor of nine. The generator of the GAN produces realistic noise patterns of low dose images, which have spatial, content and intensity dependent correlation and magnitude, and it is able to generate realistic noise even across the edge of the skull. **Conclusion:** Using the denoising and generator networks enables generating multiple low dose images from a single clinical dose image with realistic noise patterns, opening the possibility to create datasets for testing purposes.

Liver Cancer Risk Quantification Through An Artificial Neural Network Based On Personal Health Data

A Ataei^{1,*}, J Deng², W Muhammad³, (1) Florida Atlantic University, Boca Raton, FL, (2) Yale University School of Medicine, New Haven, CT, (3) Florida Atlantic University, Boca Raton, FL

Purpose: Liver cancer is the sixth most common type of cancer worldwide and is the third leading cause of cancer related mortality. Several types of cancer can form in the liver. Hepatocellular carcinoma (HCC) makes up 75%-85% of all primary liver cancers and it is a malignant disease with limited therapeutic options due to its aggressive progression. While the exact cause of liver cancer may not be known, this study models a reduction in liver cancer risk of an individual using an artificial neural network (ANN) in response to change habits/lifestyle. **Methods:** To address this challenge, an artificial neural network (ANN) was developed, trained, and tested using the health data captured in the National Health Interview Survey (NHIS) and Pancreatic, Lung, Colorectal, and Ovarian cancer (PLCO) datasets to predict liver cancer risk. The ANN was trained on 70% (training dataset) of the data using 10-fold cross-validation, while the remaining 30% was withheld for further testing (testing dataset). The testing population was also stratified into low, medium, and high risk. **Results:** The best performance of the model was observed with an area under the curve (AUC) of 0.80 and 0.81 for training and testing dataset, respectively. **Conclusion:** Our results indicate that our ANN can be used to predict liver cancer risk with changes with lifestyle. This model may provide a novel approach to identify patients at higher risk who may benefited from early diagnosis and intervention.

Deep Transfer Learning for the Multi-Label Classification of COVID-19 Presentation on Thoracic CT Scans

D Tada*, J Fuhrman, F Li, M Giger, University of Chicago, Chicago, IL

Purpose: To characterize COVID-19 by six presentations – ground glass opacity (GGO), consolidation, nodule, linear/reticular, crazy paving, and architectural distortion – on chest CT for COVID-19 patients. **Methods:** Transfer learning exhibits robust performance when labeled images are limited. A transfer learning approach was implemented through feature extraction using the VGG-19 deep convolutional neural network (CNN) pretrained on the ImageNet database. Features were extracted from the pooling layers of the network on CT sections from 41 patients (221 scans) serving as input. Each patient was confirmed to have COVID-19 via PCR test. Multi-label classification methods of Binary Relevance (BR), Classifier Chains (CC), and Label Powersets (LP) with support vector machines were utilized to predict the multi-label output of COVID-19 presentation to distinguish if a given COVID-19 presentation was present or not. ROC analysis was used to evaluate the classifier performance. **Results:** In the task of distinguishing COVID-19 on thoracic CT, the CC pipeline outperformed BR and LP classifications as determined by F1-score, Hamming loss, and relative AUC. Classification of GGO yielded an area under the ROC (AUC) of 0.95 ± 0.015, consolidation yielded an AUC of 0.60 ± 0.024, nodule yielded an AUC of 0.92 ± 0.024, consolidation linear/reticular an AUC of 0.64 ± 0.021, crazy paving yielded an AUC of 0.75 ± 0.025, and architectural distortion yielded an AUC of 0.76 ± 0.042. **Conclusion:** The proposed deep learning algorithm with VGG-19 network can identify and differentiate COVID-19 patterns on CT images, potentially improving prognostic evaluations and informing treatment decision-making for COVID-19 patients. Future methods include improvements to the deep network feature extraction, such as fine-tuning and ensemble networks, as well as an investigation of the clinical implications of COVID-19 CT patterns on an additional 916 cases recently acquired (1935 imaging studies).

Deep Learning-based COVID-19 Pneumonia Classification Using Chest CT Images: Model Generalizability

D Nguyen^{1,2,*}, F Kay³, J Tan², Y Yan², Y Ng³, P Iyengar², R Peshock³, S Jiang^{1,2,a}, (1) Medical Artificial Intelligence and Automation (MAIA) Laboratory, UT Southwestern Medical Center, Dallas, TX, USA, (2) Department of Radiation Oncology, UT Southwestern Medical Center, Dallas, TX, (3) Department of Radiology, UT Southwestern Medical Center, Dallas, TX, (a) Co-correspondence authors: {Dan.Nguyen, Steve.Jiang}@UTSouthwestern.edu

Purpose: Since the outbreak of the COVID-19 pandemic, worldwide efforts have focused on using artificial intelligence (AI) technologies on various medical data of COVID-19-positive patients to classify various aspects of the disease, with promising results. However, concerns have been raised over their generalizability, given heterogeneous factors in datasets. This study examines the severity of this problem by evaluating deep learning (DL) classification models trained to identify COVID-19-positive patients on 3D CT datasets from different countries. **Methods:** We collected one internal dataset at UT Southwestern (UTSW) (337 patients), and three external datasets from three different countries: 1) CC-CCII Dataset (China), 2) COVID-CTset (Iran), and 3) MosMedData (Russia). We divided all the data into 2 classes: 1) COVID-19-positive and 2) COVID-19-negative patients. We divided the data, by patients, into 72% training, 8% validation, and 20% testing. We trained nine identical DL-based classification models using various dataset combinations. **Results:** The models trained on a single dataset achieved accuracy/area under the receiver operating characteristics curve (AUC) values of 0.87/0.826 (UTSW), 0.97/0.988 (CC-CCII), and 0.86/0.873 (COVID-CTset) when evaluated on their own dataset. The models trained on multiple datasets and evaluated on a test set from one of the datasets used for training performed better. However, the performance dropped close to an AUC of 0.5 for all models when evaluated on an unseen dataset. Including MosMedData, which only contained positive labels, into the training did not help the performance on the other datasets. **Conclusion:** The models could identify COVID-19-positive patients if the testing data were in the same dataset as the training data. However, we observed poor performance when evaluating the model on an unseen dataset. Multiple factors contribute to these results, including patient demographics, pre-existing clinical conditions, and differences in image acquisition or reconstruction, causing a data shift among different study cohorts.

PO-GePV-M-24

Feasibility Study of Deep Learning Based Radiosensitivity Binary Classification Model Using Gene Expression Profiling

E Kim*, Y Chung, Hanyang University, Seoul, KR

Purpose: In radiotherapy, the prediction of radiosensitivity of tumors has been considered to be clinically relevant. In this prospect, the radiosensitivity prediction model was presented using deep learning in previous study, whose radiosensitivity were represented by survival fraction at 2 Gy (SF2). However, what clinically important is whether the cell is radiosensitive or radioresistant, rather than the SF2 value. This binary classification can support decision making of physician more efficiently and require fewer computational resources. With this perspective, we investigated the feasibility of the deep learning binary classification model of radiosensitive or radioresistant using gene expression profiling. **Methods:** The gene expression profiling of the National Cancer Institute-60 tumor cell line was acquired from the gene expression omnibus database. SF2 values as a radiosensitivity indicator were obtained from previous publications, which were converted to one-hot encoded radiosensitivity as 0 if SF2>0.2 (radiosensitive) and 1 if SF2>0.8 (radioresistant). In this dataset, 36 triplicated data of 12 cell lines are included. The radiosensitivity prediction model was based on convolutional neural network, which consisted of 5 convolutional layers. The six fold cross-validation approach were applied to train and validate the model. The accuracy of the model was defined as a percentage of correctly classified samples. **Results:** The classification accuracy was 97.22%. The only sample failed to classify correctly was third sample of MDAMB435 cell line, which were also failed to predict correctly in previous study. In terms of computing time, the binary model converged to the saturation point 10 times faster than the previous model for predicting the precise SF2. **Conclusion:** This study suggests that the utilization of deep learning is feasible to develop the classification model deciding whether the cell is radiosensitive or radioresistant. Since the amount of data in this study was limited, further studies with additional data would be required.

This research was supported by Basic Science Research Program through the National Research Foundation of Korea (KRF) funded by the Ministry of Education (NRF-2018R1D1A1B07049228).

PO-GePV-M-25

Intentional Deep Overfit Learning (IDOL): Leveraging Patient-Specific Overfitting in the Synthetic CT Generation Task

S Olberg^{1,2*}, J Chun^{1,3}, X Liang¹, D Nguyen¹, J Kim³, S Jiang¹, J Park¹, (1) Medical Artificial Intelligence and Automation (MAIA) Laboratory, Department of Radiation Oncology, University of Texas Southwestern Medical Center, Dallas, TX, (2) Department of Biomedical Engineering, Washington University in St. Louis, St. Louis, MO, (3) Department of Radiation Oncology, Yonsei University College of Medicine, Seoul, KR

Purpose: With the steadily increasing interest in applications of deep learning (DL)-based approaches in the radiotherapy workflow, recent years have seen continued demonstrations of the promise of state-of-the-art DL algorithms. However, there remain several unsolved challenges when considering the practical implementation of these approaches in a clinical setting. A primary challenge is the curation of a training data set of sufficient size and quality that enhances the generalizability of the trained model. In this study, we propose an alternative to the traditional combat against overfitting with the application of the Intentional Deep Overfit Learning (IDOL) framework to the synthetic CT (sCT) reconstruction task in the breast. **Methods:** Training in the IDOL framework consists of two phases: 1) conventional training with a diverse population of patient data (n = 52 patients, 100 pairs per patient) consisting of pairs of MRI and CT images for 100 epochs, and 2) overfit training with synthetically perturbed and augmented data sets (n = 50 deformed sets, 80 images per set) derived from simulation planning data of the single patient of interest for 20 additional epochs. Testing of the IDOL model was performed with setup MRI data from three treatment fractions of the patient of interest. **Results:** Compared to sCT reconstructions produced by the conventional, general model (phase 1 training only), outputs of the IDOL model are characterized by improved definition at tissue boundaries and reproduction of bony anatomy. The mean absolute error computed over 147 test images improved from 68 ± 16 HU with the general model to 22 ± 5 HU with the IDOL model. **Conclusion:** The IDOL framework, explored here in the sCT reconstruction task, represents a powerful and widely applicable departure from the conventional wisdom of combatting overfitting that is inspired by the patient-centric ethos of the era of precision medicine.

PO-GePV-M-26

A Multiple Modality Comparison of Radiomic Features for Prostate Cancer

R Delgadillo*, B Spieler, J Ford, D Kwon, F Yang, M Studenski, K Padgett, M Abramowitz, A Dal Pra, N Dogan, University of Miami, Miami, FL

Purpose: Most radiomics studies performed to date were assessed in a mostly pre-treatment setting using either MRI and CT. Unlike MR and CT images that are used for diagnostic and treatment planning purposes, CBCT images are used for daily patient setup prior to radiation delivery and may provide day-to-day radiomic feature changes of the prostate. While the predictive value of multiparametric (mp)MRI in prostate cancer (pCa) treatment is well-known, the potential of imaging features extracted from CBCT is novel for patients with pCa. The purpose of this study was to determine if there is any correlation between the prostate radiomic features between MRI, CT, and CBCT and to determine the mechanism through which they correlate. **Methods:** Twenty patients receiving radiotherapy for pCa who were treated on a variety of dose fractionations as part of IRB-approved protocols were included. Forty-two radiomic features were extracted from the prostate on CT, first fraction CBCT, and mpMRI sequences, including Apparent Diffusion Coefficient, Early and Late Dynamic Contrast Enhanced, T2-weighted, and T2 Fat-Saturated MRI. First-order intensity and second order statistical radiomic features from four gray-level matrix classes were considered. The correlation between radiomic features and prostate volume was also calculated. The Spearman correlation (R) was used to investigate the associations between the radiomics features of the aforementioned imaging modalities. Statistical significance was $p < 0.05$. The threshold for well-correlated radiomic features was $R > 0.85$. **Results:** CBCT and CT radiomic features were correlated with features from 5 and 3 mpMRI, respectively. Most well-correlated radiomic features were also well-correlated with volume. After volume-normalization, these radiomic features were no longer well-correlated between different modalities. **Conclusion:** The majority of radiomic features that correlated between CT, CBCT, and mpMRI was due to the strong volume-dependence of these features. This work highlights the importance of volume-normalization when considering radiomic features between different modalities.

This work was supported in part by a research grant from Varian Medical Systems, Palo Alto, CA. (GR013242). Dr. Abramowitz has received an honorarium from Varian.

Group-Lasso Regularized Artificial Neural Network for Embedded Feature Selection in Radiomics Study On Pediatric Patients with Craniopharyngioma Treated with Proton Therapy

W Yang*, C Hua, T Davis, J Uh, T Merchant, St. Jude Children's Research Hospital, Memphis, TN

Purpose: Conventional wrapper and filter-based feature selection methods in radiomics study analyze the correlation of features and endpoints sequentially or individually, often resulting in excluding predictive features when combining with others. In this study, we developed an embedded feature selection method for an artificial neural network (ANN) using Group-Lasso regularization to predict obesity of pediatric patients after proton therapy using magnetic resonance imaging (MRI) features. **Methods:** Eighty-four children diagnosed with craniopharyngioma (aged 1-20 years) and treated with surgery and proton therapy were included in this study. Consent forms with Institutional review board approval was obtained. The endpoints were defined as obesity in patients with the

normalized body-mass index (BMI) crossing 95% after 5-year follow-up. Imaging features were retrospectively calculated from pre-operative MRI images with T1-, T2-weighted, and FLAIR sequences using LIFEx (Orsay, France) software. Group-Lasso regularization was implemented in a 4-layer ANN developed with TensorFlow (Google, USA) for feature selection. The optimal combination of features was selected by thresholding their L2-norm of weights. Five out of 105 features were selected with the embedded method. Data augmentation was used to reduce bias of the unbalanced grouping and 5-fold cross-validation was used to reduce statistical bias of the ANN model. **Results:** The average accuracy of the testing dataset in the 5-fold cross validation was $78.3\% \pm 7.8\%$, $76.7\% \pm 9.7\%$, and $80.0\% \pm 7.7\%$ for T1, T2, and FLAIR images, respectively. The macro average area under the ROC curve (AUC) was 0.79, 0.84, and 0.92 for T1, T2, and FLAIR images, respectively. **Conclusion:** An embedded feature selection method was implemented with the Group-Lasso regularization for an ANN radiomics model. The dimension of feature space was reduced without compromising average accuracy and AUC. The prediction of obesity could be applied in a personalized treatment plan to improve the quality of post-treatment life.

PO-GePV-M-28

Technical Artifact Detection in CBCT Imaging by Binary Image Classification

M Bach*, G Spira², (1) Overath, NW, DE, (2), Cologne, DE

Purpose: To train a deep learning TensorFlow model on cone-beam computed tomography (CBCT) images with various technical artifacts using transfer learning and to label image quality afterward as acceptable (flawless) or non-acceptable (somehow destructed). **Methods:** A pre-trained 101-layer variant of the Residual Network (ResNet v2) was used to generate a deep neural network (DNN) model with custom CBCT images to classify image quality one of two categories. The first category was employed by 2081 image slices from various body regions without artifacts (except small distortions created by marker seeds). The second category included 400 images with three types of artifacts observed during clinical CBCT imaging: organ motion, ring artifacts, and unknown types. Reference images were not further sub-divided, e.g., by tube parameter or region of interest (ROI). **Results:** Training for the configuration above took about 45 minutes (on an i7-10750H). The ratio between training and verification dataset was 80:20, and the evaluated internal accuracy was better than 99%. Prediction of external images took less than 3s, and all technical artifacts are assigned, while undistorted images and those with marker seeds are labeled as flawless. The algorithm typically predicts a label score of 97% or higher for those images. **Conclusion:** Transfer learning was successfully applied to detect technical artifacts in CBCT imaging for an O-ring gantry-type linear accelerator. For other imaging modalities like CTs in treatment planning, CNN and algorithms can be easily adopted. Future workflows should include automated image processing to reduce potential errors for patient position matching between treatment plan geometry and daily cone-beam CT.

PO-GePV-M-29

Classification of Attention-Deficit/hyperactivity Disorder Using Multisite Resting-State Functional MRI: A Radiomics Features Analysis

G Liu*, L Shi, J Qiu, Shandong First Medical University & Shandong Academy of Medical Sciences, Taian, CN

Purpose: The precise pathology of ADHD is still unknown and apart from behavioral symptoms investigated by psychiatric methods, there is no standard biological test to diagnose ADHD. In this study, we aimed to utilize resting-state functional MRI (rs-fMRI) to extract radiomics features. We hypothesized that radiomics features based on rs-fMRI could be used as a potential biomarker to distinguish ADHD patients from healthy controls. **Methods:** In this study, rs-fMRI and clinical measures from 84 subjects with ADHD and 84 healthy controls were selected from 3 sites. Using preprocessed rs-fMRI, we extracted radiomics features by the 116 regions of interest (ROIs) of automated anatomical labeling (AAL) atlas. There are 93 features of 6 radiomics feature types extracted in each ROI. Finally, a total of 32364 radiomics features were obtained including 10788 features of mean regional homogeneity (mReHo), 10788 features of mean amplitude of low-frequency fluctuation (mALFF) and 10788 features of z-transformed voxel-mirrored homotopic connectivity (zVMHC). Then the Mann-Whitney U test and Spearman correlation were used to dimension reduction. The sequential backward elimination support vector machine (SBE-SVM) algorithm was used to features selection. Last, the selected features were used to train the SVM model to estimate the classification accuracy. **Results:** After dimension reduction and features selection, there were 47 radiomics features retained. By training SVM within the training dataset based on radiomics features, we got the accuracy of 98.5% (AUC = 0.998) and the accuracy in the testing dataset is 88.2% (AUC = 0.955). The classification results were further verified by permutation testing and leave-one-site-out strategy. **Conclusion:** This study provides a novel strategy to make more fully utilize of rs-fMRI base on radiomics features, which not only could effectively predict ADHD, but also have the potential to identify biomarker in it.

Low-Dose CT Images Denoising Integrating Machine Learning and Optimization

Q Xu*, Q Lyu, K Sheng, UCLA School of Medicine, Los Angeles, CA

Purpose: Although deep learning (DL) methods have shown promising performance in low-dose CT denoising, concerns have been raised regarding image fidelity loss. To better preserve the image fidelity while maintaining the strong statistical learning ability of DL, we proposed a hybrid method to combine DL with regularized optimization and then tested its performance on low-dose lung CT images. **Methods:** Lung CT images of 42 patients were reconstructed using filtered back-projection from full-dose and corresponding low-dose projections, which were downloaded from TCIA. The patients were split into train, test, and validation sets comprising 34, 4, and 4 patients, respectively. A denoising U-Net was trained to predict full-dose images from low-dose images. Low-dose images in test sets were fed into the trained U-Net to produce baseline DL-denoised images. Recovered images using the hybrid method were obtained by minimizing an objective function that penalized the L2 distance with denoised images and the L2 discrepancy with low-dose projections. To objectively evaluate the reconstruction quality, we trained an airway segmentation network on a separate lung CT dataset. Automated airway segmentation was then performed on the full-dose, DL-denoised, and hybrid recovered images using the trained model. Using the airway segmentation on the full dose images as the ground truth, we calculated the Dice coefficient and detectability of the DL-denoised and hybrid recovered image airway masks. **Results:** On average, hybrid recovered images showed an improvement of 0.00435 in Dice coefficient and 0.0165 in detectability over DL-denoised images, indicating the superior performance of our proposed method over the naive DL method. **Conclusion:** This work demonstrated a novel hybrid-denoising method combining the classical regularized reconstruction method with DL for low-dose CT reconstruction. Using automated airway segmentation for objective assessment, we showed that the hybrid method is superior to DL alone in preserving the imaging details while suppressing the noise.

Can Clinical Data Uncover Physician's Decision Making Criteria On Patient's Prescription in Radiotherapy?

Q Li¹*, J Wright¹, T McNutt¹, (1) SOM Rad Onc Physics of Johns Hopkins University Hospital, Baltimore, MD

Purpose: This project's goal is to utilize machine learning techniques to detect anomalous outlier prescriptions by modeling the radiation oncologist's

prescription decision making protocol process. The data-driven approach allows us to model the process without complete knowledge of the particular protocol used and their details. **Methods:** 14 years of clinical data (01/01/2007 – 01/01/2021) were queried from MOSAIQ, which includes all patients treated in the radiation oncology department of our institution. All features related to patients' treatment information were extracted, including treatment intent, treatment techniques, treatment site, tumor stages, tumor markers, biomarkers etc. Prescription data included number of fractions and total dose. Patients were grouped by their diagnostic code for site-specific model development. Prostate group data (6482 patients) was preprocessed, missing data was imputed, models were trained and tested with a Random Forest (RF) supervised learning base model. We trained hyper-parameter (maximum depth) to avoid overfitting. Feature importance analysis was performed by fitting the data with RF regression models. In addition, statistical analysis and visualization tools such as joyplot and scatter plot were employed to assist discovering important features and to explore the data. **Results:** Initial stage analysis shows that the treatment techniques and treatment intent are among the most important features for the Prostate group and average percentage prediction error was 70.87% for the RF model in contrast with 96.36% error from a constant mean prediction. **Conclusion:** Preliminary analysis shows that the treatment techniques are the most important features for predicting number of fractions as well as predicting total dose. Tumor stages and morphology codes are the least important features. Improvement on feature selection, imputation method, and multiple hyper-parameters optimization can potentially improve the model prediction result.

Intrafractional Tumor Motion Prediction Using Surrogates on Pancreatic Cine MRgRT

A Guta^{1*}, J Shin², B Lewis³, Z Ji⁴, J Kim⁵, T Kim⁶, (1) Washington University in St. Louis, St. Louis, MO, (2) Yonsei University College of Medicine, Seoul, KR, (3) Washington University School of Medicine in St. Louis, Saint Louis, MO, (4) Washington University St Louis, (5) Yonsei University College of Medicine, Seoul, KR, (6) Washington University in St. Louis, Saint Louis, MO

Purpose: X-ray image-guided radiotherapy (IGRT) has been a vital tool in radiation oncology to visualize and correct for inter- and intra- fractional variations during radiotherapy treatment. However, X-ray imaging lacks good soft tissue contrast, limiting direct tumor visualization. This work uses 2D cine MR images obtained on a 0.35T MRgRT system to create a pancreatic tumor position prediction model using surrogates visible on X-ray imaging. **Methods:** A retrospective dataset of cine MRI images was collected from pancreatic tumor patients treated with 0.35T MRgRT at our institution, containing a total of 56 treatment fractions and 53,759 images. In-house software was used to extract tumor position with respect to diaphragm position from cine MR images. Diaphragm positions were determined using template-based auto-segmentation and tumor positions were extracted from the MRgRT systems. Diaphragm contours were manually evaluated and adjusted. Models were developed using ridge regression and feature reduction using principal component analysis (PCA). The intra-fractional prediction model was trained on each fraction using 70% of images and tested with the remaining 30%. The inter-fractional model was trained with all fractions except 10% of image in the target fraction, and tested with the remaining 90% of images in the target fraction. Models were evaluated with mean square error (MSE) and mean absolute error (MAE). **Results:** The predicted pancreatic tumor position had an average MSE (mm²) of 0.34/0.98(X/Y), and average MAE (mm) of 0.42/0.68(X/Y), for the intra- and average MSE (mm²) of 0.90/2.1(X/Y), and average MAE (mm) of 0.66/1.00(X/Y) for the inter-fractional models, respectively. After PCA of contours the models predicted tumor position with an average MSE (mm²) of 0.37/1.1(X/Y) and average MAE (mm) of 0.45/0.74(X/Y), for the intra- and average MSE (mm²) of 2.0/6.2(X/Y), and average MAE (mm) of 0.99/1.8(X/Y) for the inter-fractional models, respectively. **Conclusion:** Intra- and inter-fraction models were developed to predict pancreatic tumor position from diaphragm position, a surrogate visible on both MR and X-ray imaging.

Three-Dimensional Dose Prediction Methodology for Gamma Knife

B Zhang^{1*}, A Babier¹, T Chan¹, M Ruschin², (1) University of Toronto, Toronto, Ontario, CA, (2) Odette Cancer Centre, Toronto, ON, CA

Purpose: To develop a machine learning-based, 3D dose prediction methodology for Gamma Knife treatment plans. **Methods:** We obtained 322 Gamma Knife (GK) treatment plans from our institution, under REB approval. To handle the sparsity, size, and granularity of GK data, several data augmentations were made. The contoured MRI and clinical dose distributions were isolated and cropped based on tumor location and scaled to a standard size through interpolation. An accompanying 3D tensor containing distance information was created for each instance of cropped data to account for tumor size. This augmented dataset for 272 patients was used to train a convolution neural network (CNN-GK) and a generative adversarial network (GAN-GK). As a baseline, the same CNN (CNN-Baseline) and GAN (GAN-Baseline) were trained on the same dataset without the GK-specific data augmentations described above. All models were used to predict the dose distribution of 50 out-of-sample patients. Predictions were compared to their clinical counterparts using the gamma criterion (4%/2mm) and conformity index. **Results:** The predictions from CNN-GK and GAN-GK were generally similar to the clinical dose distributions, with gamma passing rates of 83.1 ± 17.2% and 84.9 ± 15.3%, respectively. In contrast, the gamma passing rate of CNN-Baseline (36.2 ± 33.8%) and GAN-Baseline (40.3 ± 36.4%) were both significantly lower than their respective GK-specific models ($p < 0.001$). Additionally, for 41% of the tumours in the out-of-sample patients, both baseline models predicted dose with a gamma pass rate of 0.0%. The conformity index of CNN-GK and GAN-GK predictions differed, on average, from that of the clinical distributions by 0.092 ± 0.10 and 0.086 ± 0.11 respectively. **Conclusion:** Our methodology that uses deep learning models and GK-specific data augmentation can accurately predict 3D dose distributions for Gamma Knife treatment plans. Off-the-shelf deep learning models applied to standard GK data generally generate poor predictions.

PO-GePV-M-34

Novel Paired Intensity-Pattern Recognition Technique Based on Perfect Intensity-Geometry (PIG)

A Chu^{*}, Q Peng, M Garg, W Tome, Montefiore Medical Center/Albert Einstein college of medicine, Bronx, NY

Purpose: To present a novel paired intensity-pattern recognition technique using pointwise mutual information (PMI) and image-pair joint probability (PAB) for perfect intensity-geometry (PIG). This technique can facilitate easy pre-/post-treatment comparison for therapy monitoring. **Methods:** Mutual information (MI) has been used as an optimization metrics for the intensity-based registration, but it becomes cumbersome during the repetitive classifications. Instead of using MI, PMI-to-PAB map, which describes “the dependence of pair’s intensity pattern” vs. “sub-volume ratio (i.e. PAB)”, was calculated and optimized to approximate to a theoretical reference (PIG). The number of intensity-pattern (N_p) of a registered image pair [A, B] was resolved by repetitive classifications (k-means) in the pair’s 2D intensity histogram. The optimal N_p was determined in the recognition routine based on the expectation of “PAB/exp(-PMI)” approaching to a unity, e.g. $|1 - \text{Exp}\{\text{PAB}/\text{exp}(-\text{PMI})\}| < 0.001$. Simulated image pairs using a patient’s PTV added with regional intensity variation (to simulate “treatment response”) were tested using this novel approach against functional diffusion map (fDM) method. In addition, the sensitivity of detecting response with the MRI ADC map before and after was also tested. **Results:** The novel PIG metrics was robust and was much faster without supervised training sessions compared to the traditional MI (information gain) metrics. It resulted in the patterns of underlying intensity range representing for the same tissues, physio-pathological variants, and mismatches. In the simulation, the PIG method successfully recognized paired intensity-pattern clusters as well as the regional response. In the brain MRI ADC map test, the routine had improved sensitivity to ADC responses compared to optimal fDM (0.844 vs 0.669). Note the traditional fDM can only reach 0.398 with fixed threshold. **Conclusion:** Our novel technique using PMI and PAB for perfect intensity-geometry (PIG) offers an unsupervised learning for paired intensity-pattern recognition. This technique can facilitate easy pre- and post-treatment comparison for therapy monitoring.

PO-GePV-M-35

Machine Learning Models to Predict the Delivered Positions of Elekta Multileaf Collimator Leaves for Volumetric Modulated Arc Therapy

S Sivabhasakar^{1*}, N Papanikolaou¹, N Kirby¹, R Li¹, A Roy², (1) University of Texas Health Science Center, San Antonio, TX, (2) The University of Texas at San Antonio, San Antonio, TX

Purpose: To evaluate the performance of random forest (RF) regression, support-vector regression (SVR), and extreme gradient boosting (XGBoost) regression models in predicting the delivered positions of individual multileaf collimator (MLC) leaves. **Methods:** In this study, 43 MLC log files containing 2380 control points for volumetric modulated arc therapy (VMAT) treatment plans delivered using an Elekta linear accelerator were obtained. A total of 8 planned parameters, namely gantry angle, collimator angle, X1 jaw position, X2 jaw position, leaf gap, leaf position, leaf velocity, and leaf acceleration were extracted. The RF, SVR, and XGBoost regression models were trained using 70% of the log files. The delivered leaf positions were used as the target variable for training, and a 6-fold cross validation method was used to validate and tune the model's hyperparameters. The tuned models were tested on the remaining 30% of the MLC log files. The performance of the models was evaluated using mean absolute error (MAE), root mean square error (RMSE), R^2 value, and fitted line plots showing the relationship between delivered and predicted leaf positions. **Results:** The RF model achieved a MAE of 0.427 mm, RMSE of 0.434 mm, and R^2 of 0.957. The SVR model achieved a MAE of 0.798 mm, RMSE of 0.809 mm, and R^2 of 0.849. The XGBoost model achieved a MAE of 0.214 mm, RMSE of 0.223 mm, and R^2 of 0.989. **Conclusion:** Based on these results, the XGBoost model performed better than the RF and SVR models in predicting the delivered positions of the individual leaves for VMAT plans. Although the RF model had higher prediction errors, it still outperforms the SVR model. This study indicates that XGBoost has the potential to accurately predict the delivered MLC positions for VMAT treatment plans.

PO-GePV-M-36

Probabilistic Feature Extraction, Dose Statistic Prediction and Dose Mimicking for Automated Radiation Therapy Treatment Planning

T Zhang^{1, 2*}, R Bokrantz², J Olsson¹, (1) Department of Mathematics, KTH Royal Institute of Technology, Stockholm SE-100 44, Sweden (2) RaySearch Laboratories, Sveavägen 44, Stockholm SE-103 65, Sweden

Purpose: We propose a general framework for quantifying predictive uncertainties of dose-related quantities and leveraging this information in a dose mimicking problem in the context of automated radiation therapy treatment planning. **Methods:** A three-step pipeline, comprising feature extraction, dose statistic prediction and dose mimicking, is employed. In particular, the features are produced by a convolutional variational autoencoder and used as inputs in a previously developed nonparametric Bayesian statistical method, estimating the multivariate predictive distribution of a collection of predefined dose statistics. Specially developed objective functions are then used to construct a dose mimicking problem based on the produced distributions, creating deliverable treatment plans. **Results:** The numerical experiments are performed using a dataset of 94 retrospective treatment plans of prostate cancer patients. We show that the features extracted by the variational autoencoder captures geometric information of substantial relevance to the dose statistic prediction problem, that the estimated predictive distributions are reasonable and outperforms a benchmark method, and that the deliverable plans agree well with their clinical counterparts. **Conclusion:** We demonstrate that prediction of dose-related quantities may be extended to include uncertainty estimation and that such probabilistic information may be leveraged in a dose mimicking problem. The treatment plans produced by the proposed pipeline resemble their original counterparts well, illustrating the merits of a holistic approach to automated planning based on probabilistic modeling.

The Neurosubtyping of Autism Spectrum Disorders Based on Structural MRI Data

G Liu*, W Lu, J Qiu, Shandong First Medical University & Shandong Academy of Medical Sciences, Taian, CN

Purpose: Clinical and etiological heterogeneity remain major obstacles to biomarker identification in Autism spectrum disorders (ASD). Recently, neuroimaging raised new hope in our ability to identify the subtypes of ASD for further understand the biological mechanisms. The purpose of this study is to utilize a novel semi-supervised machine learning method termed HYDRA (heterogeneity through discriminative analysis) to identify neurosubtyping of ASD. **Methods:** In this study, brain structural MRI data and clinical measures from 261 subjects with ASD and 314 healthy controls were selected from 6 sites of the Autism Brain Image Data Exchange database (ABIDE). A novel semi-supervised clustering method was utilized to divide individuals with ASD into several subtypes by the regional volumetric measures of grey matter, white matter, and CSF. This method can identify true disease subtypes by removing the influence of confounding variations introduced by age, sex, site, and other factors. The ASD subtypes obtained in this study were contrasted by voxel-wise volumetric, clinical measures and whole brain functional connectivity. To assess the reproducibility of subtypes, we take a series of analyses, including permutation tests, split-sample tests and leave-one-site-out cross validation. **Results:** Two reproducible neuroanatomical subtypes were found. The ASD subtypes with difference voxel-wise volumetric patterns were revealed. Besides, the IQ and ADOS scores is significantly different, atypical brain functional connectivity patterns were observed in two subtypes. By using HYDRA to divide the ASD into 2 subtypes, the classification accuracies were significantly improved between ASD and healthy controls. **Conclusion:** The method revealed distinct neurosubtyping of ASD and build stable brain-behavior relationships which could facilitate better understanding neuroanatomical heterogeneity of this disease and potentially be used to improve clinical decision-making and optimize treatment in the future.

What's Behind Auto-Segmentation Models: An Interpretability Analysis of Calculation Logic of Segmentation Model for Brain Tumor

H Chen^{1*}, D Ban², X Qi³, (1) Xi'an University of Posts and telecommunications, Xi'an, 61, CN, (2) Xi'an University of Posts and telecommunications, Xi'an, 61, CN, (3) UCLA School of Medicine, Los Angeles, CA

Purpose: We proposed a workflow to exam the implicit calculation logic behind segmentation models (U-NET, XGBoost) to better understand the underlying algorithms. We attempted to fit two segmentation models respectively through decision trees in a predefined feature space. The highly similar decision paths generated from these two models will be extracted to discover the associations among features. **Methods:** 369 patients from the BraTS20 were used and regrouped into 3 subgroups: long-term survival (>15 months), mid-term survival (10-15 months), and short-term survival (<10 months). Each patient had four preoperative multimodal MR scans: T1, T2, Flair, T1ce. A total of 444 radiomics features (74 first order features, 224 features from Gray Level Cooccurrence Matrix and 146 features from Gray Level Run Length Matrix) on MR images of 4 sequences were extracted from 295 patients to train an ensemble learning segmentation model and a U-NET segmentation model respectively. The decision tree was used to fit above models. The decision paths for segmenting each subregion of glioma, including the non-enhancing tumor region (NET) and the edema area (ED) respectively for the long-term subgroup, were filtered out to extract the most common feature associations. **Results:** A total of 14,636 decision paths in the segmentation models between NET and ED (6,836 for NET and 7,800 for ED) were examined. There were three highly similar decision paths between two models, which include 8 features. The most popular feature associations between NET and ED were identified respectively, including AutoCorrelation_180_f, AutoCorrelation_90_f and median_t1c, and AutoCorrelation_180_f, Con-trast_180_t1c, AutoCorrelation_270_t1c, min_t2, etc. **Conclusion:** We demonstrated a novel workflow to analyze the underlying

workflow of feature based auto-segmentation models. This method allows us to interpret the decision logic of the black box model in the boundary segmenting process, and show a promising way to explore and improve the interpretability of machine learning model.

Outcome Prediction of Prostate Cancer Patients After Radiotherapy Using Machine Learning Models Developed with Extrapolation Data

K Oguma^{1*}, T Magome², M Someya³, T Hasegawa⁴, K Sakata⁵, (1) Graduate Division of Health Sciences, Komazawa University, Setagaya, Tokyo, JP, (2) Komazawa University, Tokyo, JP, (3) Department of Radiology, Sapporo Medical University School of Medicine, (4) Department Of Radiology, Sapporo Medical University School Of Medicine, (5) Department of Radiology, Sapporo Medical University School Of Medicine

Purpose: Outcome prediction with a small number of cases has been challenging task because of biased estimation of statistical population. Although mixup is effective technique that estimates statistical population with virtual data constructed by interpolation of training data, it could be more effective by extrapolation of limited number of training data. The purpose of this study was to develop machine learning (ML) models for prediction of prostate cancer recurrence using extrapolation data. **Methods:** The ML models trained with and without extrapolation data were compared. A total of 100 patients with prostate cancer who were treated with radiotherapy were included in this study. Effective features were selected by elastic net from 48 candidate features that include 35 clinical features and 13 dose features. The dataset was divided into training and test dataset. Virtual data were constructed by linear interpolation or linear extrapolation of two data randomly selected from training dataset. In this study, two kind of regression models (multiple linear regression: MLR and artificial neural network: ANN) were used as ML models. The ML models trained with and without extrapolation data were evaluated with the area under the receiver operating characteristic curve (AUC) for the prediction of prostate cancer recurrence in test dataset. **Results:** The AUCs of both ML models were significantly improved by using extrapolation data (MLR: $p < 0.0001$, ANN: $p < 0.0001$). The AUC of MLR with and without extrapolation data was 0.730 and, 0.671, respectively. The AUC of ANN with and without extrapolation data was 0.807 and, 0.764, respectively. **Conclusion:** Our results showed that the performance of ML models for the prediction of prostate cancer recurrence was improved by using extrapolation data.

This work was supported by JSPS KAKENHI Grant Number 18K15604.

Radiomics Analysis Improves Machine Learning Models Assessing Chronic Obstructive Pulmonary Disease

R Au^{1*}, K Makimoto¹, W Tan², J Bourbeau³, J Hogg², M Kirby¹, (1) Ryerson University, Toronto, ON, CA, (2) Centre For Heart Lung Innovation, University Of British Columbia, Vancouver, BC, CA, (3) McGill University, Montreal, QC, CA

Purpose: Computed tomography (CT) imaging can be used to quantitatively investigate chronic obstructive pulmonary disease (COPD). However, existing quantitative CT (QCT) features only assess structural characteristics (e.g. volumes and counts). Texture-based radiomics analysis is an emerging quantitative technique that investigates spatial relationships between voxel intensities and may therefore provide increased sensitivity to early or subtle disease changes. We hypothesized that CT radiomics features, in combination with existing QCT features, will increase accuracy for classifying COPD. **Methods:** Spirometry and CT images were obtained from the population-based CanCOLD study. Well-established QCT features consisted of the percentage of low-attenuation-areas below -950HU and -856HU, 15th percentile of the CT-density-histogram, low-attenuation-cluster slope, CT-tissue-volume, total-airway-count, and hypothetical airway of 10mm lumen perimeter (VIDA Diagnostics). For radiomics analysis, CT images were processed using whole lung and airway segmentation, voxel resampling, and thresholding between -1000HU-to-0HU prior to extraction of grey-level-co-occurrence, grey-level-run-length, grey-level-size-zone, grey-level-distance-zone, neighborhood-grey-tone-difference, and neighboring-grey-level-dependence texture-based radiomics features. Highly correlated features were removed and a least absolute shrinkage and selection operator feature selection method was completed. 5 iterations of a nested 10-fold cross validation training was performed using a Gaussian support vector machine with hyperparameter optimization. The mean classification accuracy was used to assess performance. Multivariable linear regression models for forced-expiratory-volume-in-1-second/forced-vital-capacity (FEV₁/FVC) were constructed. **Results:** A total of 1174 participants were evaluated (No COPD: n=582; COPD: n=592). The model trained with radiomics and QCT features had a 74.4% accuracy in classifying COPD, and was significantly greater than the accuracy from the only QCT features trained model (72.5%) ($p < 0.0001$). The combined feature model also had a stronger correlation with FEV₁/FVC ($r^2 = 0.53$, $p < 0.0001$) than the only QCT features model ($r^2 = 0.47$, $p < 0.0001$). **Conclusion:** CT radiomics features provides additional and complementary information when used with QCT features for characterizing COPD. Future studies should investigate using radiomics analysis for longitudinal COPD assessment.

Automatic Lung Field Segmentation on Chest Radiographs of COVID-19 Patients to Improve Diagnostic Deep Learning

G Schlafly*, Q Hu, F Li, K Drukker, J Fuhrman, M Giger, University of Chicago, Chicago, IL

Purpose: COVID-19 from SARS-CoV-2 targets the lungs, and thus, there is a pressing need for effective surveillance using chest radiographs (CXR). Our study aims to use a deep-learning based lung field segmentation of CXR exams to aid in the task of COVID-19 diagnosis. **Methods:** In the first stage, quadrilateral masks were generated from manually delineated anatomic-point-based regions within the CXR lung. Using an initial cohort of 631 COVID-19 positive patients, a U-Net was trained from the CXR images and masks, split into 64%/16%/20% for training/validation/testing to identify the lung field. In the second stage, the trained U-Net model was used to segment the lung region on CXRs from an additional cohort of 9,126 patients tested with RT-PCR. This dataset was split for training/validation/testing to train and evaluate a DenseNet121 in the task of differentiating COVID-19 positive and negative patients. Classification performance was evaluated using receiver operating characteristic (ROC) analysis with area under the ROC curve (AUC) as the figure of merit. Gradient-weighted class activation mappings (Grad-CAM) were generated for explainability. **Results:** On the test set, U-Net segmentation yielded a Dice coefficient of 0.96 (95% CI: 0.90, 0.98) and average Hausdorff surface distance of 14.3 mm (11.7 mm, 15.9 mm). On the second test set, the DenseNet in the positive/negative classification yielded AUC values of 0.77 (0.74, 0.80) and 0.76 (0.72, 0.76) with and without the use of the thoracic mask, respectively. While the two curves failed to show a statistically significant difference, ΔAUC of 0.01 (-0.01, 0.03) with $P = 0.16$, the Grad-CAM heatmaps showed reduced influence from outside the lung region when masks were applied to the images. **Conclusion:** Automatic lung field segmentation achieved a promising classification performance while limiting predictions from regions outside the lung. Demonstrated performance of the U-Net segmentation indicates its high potential for future COVID-19 diagnosis classifications.

A Machine Learning Classifier for Predicting Recurrence in Oropharyngeal Cancer

T Chinnery*, P Lang, A Nichols, S Mattonen, Western University, London, ON

Purpose: To develop a machine learning classifier integrating radiomic image features and clinical data to predict recurrence in oropharyngeal cancer. **Methods:** A dataset of patients (n=295) with oropharyngeal cancer (OPC) treated with chemoradiation at the London Regional Cancer Program was used for this study. Primary tumor and nodal volumes were contoured on pre-treatment planning CT images. The Quantitative Image Feature Engine was used to compute size, shape, first-order intensity, and second-order textural radiomic features from these volumes of interest. The dataset was split into independent training (n=206) and testing (n=89) datasets. Feature selection was applied to select the optimal features to predict recurrence and a support vector machine (SVM) classifier was built using the selected features on the training dataset. The SVM's performance was assessed in the testing dataset based on the metric of the AUC. A baseline model comprised of only clinical features was compared to radiomics. **Results:** A total of 63 patients (21%) developed a recurrence. Through feature selection, 20 predictive features were selected. This included one first-order intensity feature, seven textural, nine shape, and three clinical features (HPV status, smoking status, nodal stage), among both the primary tumor and nodal volumes. The SVM model achieved an AUC on the testing dataset of 0.66 [95% CI: 0.53-0.77], in comparison to an AUC of 0.49 [95% CI: 0.36-0.62] for the model comprised of clinical features alone (p=0.06). **Conclusion:** Radiomic features augmented traditional clinical features for predicting recurrence in our relatively small testing dataset. To further improve predictive performance, we plan to implement additional clinical data, as well as investigate other machine learning models. Once refined and validated, this model could assist in identifying patients at a higher risk of recurrence, who may benefit from more personalized treatment options.

CERRx: The Extended CERR Platform Integrated with Open Source Image Informatics Ecosystem

A Apte*, A Iyer, E LoCastro, J Deasy, Memorial Sloan-Kettering Cancer Center, Maywood, NJ

Purpose: CERR, a widely used computational platform for dosimetry and image analysis including a research friendly data structure, was developed in Matlab considering the ease of development and wide use by physicists and computer scientists. This work aims to make CERR independent of Matlab license and GNU Octave-compatible. Python has recently emerged as the preferred choice for building scientific computing tools due to its open source nature, user-friendly syntax and ability to serve as a "glue language". Commonly used image informatics tools such as ITK, VTK, 3DSlicer provide Python APIs to allow simplified access to their C++ library. This work enables CERR functions to be accessible in Python, thus enhancing its utility in image informatics. **Methods:** CERR was made compatible with GNU Octave to support batch computation as well as graphical user interface. Octave community-maintained packages for image and statistical analysis were used as replacements for Matlab's built-in functions and toolboxes. Oct2py package in Python was used to call CERR functions from Python. This allows CERR to be used in JupyterLab with Octave-kernel and exchanging the results of CERR computations with a variety of programming languages. **Results:** Octave-compatible CERR codebase including JupyterLab notebooks demonstrating deep learning image segmentation and feature computation are distributed as open source, GPL copyright software at <https://www.github.com/cerr/CERR>. This work has resulted in expanding CERR's utility for medical image informatics including (1) accessing CERR data structure from XNAT via JupyterLab notebooks, (2) Using CERR functionality in 3DSlicer extensions, (3) Containerizing CERR's pre and post processing for deep learning image segmentation pipeline in a license-free environment, (4) Using novel features for dosimetry, radiomics and outcomes prediction models in other open-source software. **Conclusion:** This work makes CERR a truly open-source software platform that can be easily plugged into other components of the image informatics ecosystem.

Classification of Anatomic Structures by CT-Based Radiomics for Head-Neck Radiotherapy

Y Watanabe^{1,*}, N Gopishankar², A Biswas², K Rangarajan², G Rath², (1) University of Minnesota, Minneapolis, MN, (2) All India Institute of Medical Sciences

Purpose: To show that CT images' radiomics features can classify anatomic structures in the head and neck. **Methods:** We obtained 26 sets of CT image data for patients treated at a single institution for head and neck cancers using the IMRT technique. We calculated 174 radiomics feature values by the SIBEX software, which complies with the Image Biomarker Standardization Initiatives (IBSI) protocol. The radiomics calculations were done using three processing parameters: FBN, FBS with 25 and 10 bin widths. For this study, we chose several representative anatomical structures, i.e., 27 gross tumor volumes (GTV), a total of 47 right and left parotids, 25 mandibles, one brainstem, two eyes, and two sub-mandibles, which were segmented by attending radiation oncologists for treatment planning. First, we applied the principal component analysis (PCA) method to the feature values. Using the first two principal components, we studied if we can classify the anatomical structures by the k-means clustering method. Furthermore, the quantitative differences of 174 radiomics features were visualized by plotting heatmaps and correlation plots of all feature values among the structures. **Results:** The heatmaps of 174 normalized feature values of mandible showed a clear difference from GTV and parotids. The difference between GTV and parotids were also observed. The correlation plots showed the differences in feature values among GTV, parotid, and mandible. The first two principal components' two-dimensional plot indicated the five anatomical structures in the figure's specific locations. The radiomics features calculated with FBS=10 showed the clearest classification of GTV, parotid, and mandible among three different feature calculation methods. The clustering method could successfully classify those three structures. **Conclusion:** We could classify head-neck tumors, parotids, and mandibles by radiomics features. The results imply that the radiomics can decipher the differences of biological functions, microenvironment, and cellular structures from CT images.

PO-GePV-M-45

Prediction of HPV Status in the Head and Neck Cancer Patient Using CT Derived Radiomic Features: The Impact of CT Scanner

R Reiazil^{1,2,*}, C Arrowsmith¹, M Welch³, F Abbas-aghababazadeh¹, C Eles¹, T Tadic^{1,2,3}, A Hope^{1,2,3}, S Bratman^{1,2,3}, B Haibe-kains^{1,2,3,4,5,6}, (1) Radiation Medicine Program, Princess Margaret Cancer Centre, University Health Network, (2) Department of Medical Biophysics, University of Toronto, (3) Department of Radiation Oncology, University of Toronto, (4) Ontario Institute for Cancer Research, (5) Department of Computer Science, University of Toronto, (6) Vector Institute

Purpose: In this study, we assessed the impact of scanner choice on the computed tomography (CT)-derived radiomic features to predict association of oropharyngeal cancer (OPC) with human papillomavirus (HPV). **Methods:** A total of 1,294 OPC patients with known HPV status were retrospectively included in this study. In this patient cohort, CT images were acquired with two different scanner types. We extract a total of 1,874 IBSI (International Biomarker Standard Initiative) compliant radiomic features from the primary gross tumor volume (pGTV) from each patient. Feature selection has been done by Maximum Relevance Minimum Redundancy Ensemble (mRMRE)3 technique. The dataset was subsequently stratified by CT scanner type (Toshiba scanner, GE scanner, and Mix) and splitted into train (adjusted for class imbalance) and test sets with the proportion of 75/25. Next, a random forest classifier was trained on the following configurations: (1)Toshiba-Toshiba, (2)GE-GE, (3)Toshiba-GE, (4)GE-Toshiba, (5)Mix-Mix, (6)Toshiba-Mix, (7)GE-Mix, (8)Mix-Toshiba and

(9)Mix-GE. **Results:** The highest and lowest mean AUC (area under the curve) values were 0.79 (p-value<0.001) and 0.70 (p-value<0.001) and obtained with Toshiba-Mix and Toshiba-GE respectively (Figure 1). For models trained on one scanner type, the highest and lowest result obtained when they were tested on Mix sample (i.e GE-Mix [0.75,p-value<0.001], Toshiba-Mix [0.79, p-value<0.001]) and other scanner types (i.e GE-Toshiba [0.73,p-value < 0.001], Toshiba-GE [0.70,p-value < 0.001]) respectively. We identified that there is bias in the results in favor of one scanner type (Toshiba). Models either trained or tested on the Toshiba scanner resulted in higher predictive value compared to other scanners in all the same configurations. **Conclusion:** In this study, scanner type affects the prediction accuracy of the HPV status using hand-engineered radiomics features. The optimal prediction accuracy was achieved when the training set included only one specific type of scanner which reflects a bias in radiomic features towards the scanner type.

Repeatability and Reproducibility of Radiomics in Magnetic Resonance Fingerprinting of the Brain

R Delgadillo¹, B Rich¹, Y Yang², F Yang¹. (1) Department of Radiation Oncology, University Of Miami, Miami, FL, (2) University of Science and Technology of China, Hefei, China

Purpose: Magnetic Resonance Fingerprinting (MRF) emerged as a quantitative MRI modality allowing for simultaneous measurement of multiple tissue properties in a single, time-efficient acquisition and offers enormous potential to improve diagnosis and therapeutic efficacy. Owing largely to the novelty of this technique, the feasibility of radiomics for quantitative measurements obtained using MRF has been little studied. This study aimed to assess the repeatability and reproducibility of radiomics in MRF-based relaxation time mapping of the brain. **Methods:** The imaging cohort included five healthy volunteers, each with the brain scanned on four MRI systems (two at 3.0T and two at 1.5T, all from a single vendor) located at two sites. MRF data was obtained using 2D steady-state free precession with a spiral readout trajectory. T1 and T2 maps were determined through voxel-wise pattern matching between the signal evolution and simulated dictionary. After registration of MRF-derived T1 and T2 maps to an anatomical atlas, 40 radiomics metrics related to gray-level run length, co-occurrence, zone size, and neighborhood difference were evaluated for each of the resultant parametric maps within one VOI located in the parietal lobe featuring strong spatial heterogeneity. Radiomics feature test/retest repeatability and inter-site reproducibility were measured with within-subject variability (WSV) and coefficient-of-variation (CV), respectively. **Results:** The test/retest repeatability of the studied radiomics features varied with mean±SD WSVs of 7.7%±12.1% at 1.5T and 8.2%±12.7% at 3.0T on T1 maps while varying with mean±SD WSVs of 7.9%±11.2% at 1.5T and 10.9%±13.4% at 3.0T on T2 maps. As to the inter-site reproducibility, CV of the studied radiomics features varied with mean±SDs of 7.1%±9.2% at 1.5T and 9.1%±11.9% at 3.0T on T1 maps while varying with mean±SDs of 12.0%±13.1% at 1.5T and 15.8%±18.4% at 3.0T on T2 maps. **Conclusion:** Compared to weighted images MRF-derived parametric maps may allow for more repeatable and reproducible radiomics analysis.

PO-GePV-M-47

Robustness and Performance of Radiomic Features in Diagnosing Cystic Renal Masses

A Konik^{1*}, N Miskin², Y Guo³, A Shinagare⁴, L Qin⁵, (1) , Boston, MA, (2) , (3) , (4) Brigham And Women's Hospital, (5) Dana-Farber Cancer Institute, Boston, MA

Purpose: Asses the performance of a machine learning algorithm to classify benign from potentially malignant cystic renal masses (CRM) presented in computerized tomography (CT) images based on the radiomics analyses. Evaluate the classification performance of the 1st order features alone in comparison to the inclusion of the higher order features. Investigate the effect of inter-reader variability in delineating the region of interest (ROI) for the same classification task. **Methods:** 230 region of interests (ROIs) were independently delineated by two radiologists. Through a combination of random fluctuations, dilation, and erosion operations over the original ROIs, we generated four additional sets of synthetic ROIs, which aimed to represent the inter-reader variability in a realistic manner. We evaluated the degree of variability among the ROIs visually and quantitatively based on the dice coefficient measurements. We applied a 10-fold stratified cross-validation (CV) to train and test the performance of the random forest model for the classification of CRMs. Each fold included the selection of the robust features based on ICC calculated over the 2 original and 4 synthetic sets of ROIs; removal of the highly correlated features; grid-search to tune the model training parameters; and fitting and testing the model. **Results:** The mean area under curve (AUC), sensitivity, specificity, positive predictive value, and negative predictive value calculated over the six ROIs were 0.87, 0.82, 0.90, 0.85, and 0.93, respectively, for the ~20 robust (ICC > 0.85) and uncorrelated (Pearson< 0.85) features, where 5 of them were 1st-order features. Similar results were obtained using 1st-order features only. **Conclusion:** We determined the usage of the 1st-order features alone is sufficient for the classification of cystic renal masses and the inclusion of higher order features does not necessarily improve the performance. We also determined the degree of variability introduced by the delineation process in the prediction outcome.

PO-GePV-M-48

Understanding Robustness of Deep Neural Network: A Comprehensive Robustness Analysis for a Deep Learning-Based Lung-Nodule Classification Model of CT Images with Respect to Image Noise

X Jia*, C Shen, The University of Texas Southwestern Medical Ctr, Dallas, TX

Purpose: It was found that robustness of deep neural networks (DNNs) is often a concern and the reason for DNNs being robust or not is still unclear. In this work, we performed comprehensive numerical studies to get some insights on robustness behaviors of DNNs using lung nodule classification based on CT images as a testbed. **Methods:** We trained DNNs for lung nodule classification based on CT images. We added to the input of the trained DNNs realistic CT noise at 100mAs generated under a real noise power-spectrum and monitor if the output is affected. We investigated the correlation between robustness and network architecture by systematically studying a class of 16 DNNs with different numbers of layers and widths. To understand the unrobustness behavior, we visualized the extracted low-dimensional representations of the input by DNNs with/without noise added, and characterized the robustness via the distance of the representations to the decision boundary determined by the DNN in this low-dimension representation space. **Results:** The networks were trained to achieve Area Under the Curve of 0.89-0.93 in independent testing data. CT noise was able to affect the prediction results of all the DNNs models with up to 21.4% predicted labels altered by noise. We did not observe a trend between robustness and network architectures. By visualizing the input data in the representation space, the unrobustness behavior was ascribed to the sometimes large perturbations to the sample representations by noise, as well as the unfavorable placement of the decision boundary formed in the training process. **Conclusion:** Robustness concern existed in the class of DNNs studied here for the classification problem of interest. The reasons for not being robust were identified, which may help developing training strategies to improve model robustness.

The Impact of the COVID-19 Pandemic on Cancer Care in Radiation Oncology

S Utkarsh^{1,2*}, S Andrea^{3,4,5}, M Gray⁶, D Wazer^{1,2}, K Leonard^{1,2}, R Munbodd^{1,2},

(1) Department of Radiation Oncology, Warren Alpert Medical School Of Brown University, Providence, RI, (2) Department of Radiation Oncology, Rhode Island Hospital, Providence, RI, (3) Lifespan Biostatistics Core, Rhode Island Hospital, Providence, RI, (4) VA Portland Health Care System, Portland, OR, (5) OHSU-PSU School of Public Health, Portland, OR, (6) Department of Molecular Pharmacology, Physiology, and Biotechnology, Brown University, Providence, RI

Purpose: Current studies evaluating the impact of COVID-19 on Radiation Oncology (RO) departments describe alterations in practice patterns, assess acute effects, and offer management strategies. However, there is a lack of data documenting practice alterations. We aimed to assess the early impact of the first two waves of COVID-19 on RO practice. **Methods:** Interrupted time series analyses were conducted using electronic health record data from a major RO department from January 2018 through February 2021 (164-weeks). Segmented regression models were used to estimate the immediate impact of our state's COVID-19 Wave1 and Wave2 on weekly number of CT simulations (CT) and physics initial chart reviews (PCR), and percentage of patients receiving treatments hypofractionated at javascript:void(0); 4 Gy per fraction (g4Gy). State-level COVID-19 data were used to define the start and end of Wave1 as well as the start of Wave2. **Results:** Both CT and PCR presented a sudden drop at the start of Wave1 relative to the same time period in previous years. CT dropped by 22% (95% CI: -49.7%,-3.4%) and PCR dropped by 17.9% (95% CI:-36.0%,-3.8%). In contrast, there was a sudden 11.6% increase in patients receiving treatments g4Gy. Immediately after Wave1, CT and PCR increased by 23% and 27%, respectively. Weekly rates of CT, PCR, and g4Gy at the start of Wave2 did not deviate significantly from expected pre-pandemic rates. Wave2 is ongoing but preliminary data suggest decreasing CT and PC. Short post-pandemic within and between wave follow-up limit statistical power to detect a slope change among these points. **Conclusion:** Despite RO facilities remaining fully operational during the pandemic, large fluctuations in patient volumes and workload were observed. Contributing factors included reduced cancer screenings and elective surgery, internal policies to alter treatment regimens, and patients declining treatment. Our findings may help inform preparations for future novel aberrations in workflow.

PO-GePV-M-50

Predicting Overall Survival of Patients with Glioma Via A Novel Framework Consisting of Two-Phase Feature Selection and Fused Regression Forest
H Chen^{1*}, Y Liu², X Qi³, (1) Xi'an University of Posts and telecommunications, Xi'an, 61, CN, (2) Xi'an University of Posts & Telecommunications, Xi'an, 61, CN, (3) UCLA School of Medicine, Los Angeles, CA

Purpose: Accurate survival prediction may assist clinic-decision-making for personalized treatment for glioma. We aimed to develop a novel framework, consisting of a two-phase feature selection and a fused regression forest model, to achieve robust survival prediction of patients with glioma while reducing the computational cost. **Methods:** Brats19 211 high-grade patients with glioma were included. The patients were stratified into three subgroups according to the reported survival intervals: long-term (>15 months), mid-term (10-15 months), and short-term (<10 months). Each patient had four preoperative multimodal MR scans (T1, T1ce, T2 and Flair). Each tumor was further divided into three subregions: non-enhancing tumor (NET), enhancing tumor (ET) and peritumoral edema (ED). Instead of extraction of all features from all four MRIs, we first extracted a few robust features (18 first-order and 22 geometric features) from each subregion on the MR sequence that is most relevant (or optimized out of 64 combinations) for each subregion using a clustering evaluation method. Additional 1632 high-order texture features were then extracted from their corresponding MRI sequences. Recursive feature elimination algorithm was performed to generated 3 different feature sets for three subgroups, respectively. Each feature set was used to train an independent random forest (RF) model for each patient subgroup. The final prediction model was formed by fused the RF models. **Results:** The corresponding relationship that is most conducive to feature extraction between each tumor subregion and MRI sequence were determined. The optimized imaging feature sets were determined for patient survival subgroups, respectively. The proposed framework achieved an Area Under the ROC Curve (AUC) of 0.722 with least mean square error using a 10-Fold cross-validation. **Conclusion:** We developed a novel framework for tumor subregional based treatment response prediction on multiparametric MRIs. The proposed framework effectively identified an optimized feature set and achieved superior survival prediction for patients with glioma.

A Multichannel Feature-Based Approach for Longitudinal Lung CT Registration in the Presence of Radiation Induced Lung Damage

A Stavropoulou^{1*}, A Szmul¹, E Chand^{1,2}, C Veiga¹, D Landau^{2,3}, J McClelland¹, (1) University College London, UK, (2) University College Hospital London, UK, (3) Guys & St Thomas NHS Foundation Trust, UK

Purpose: Tracking and quantifying local tissue changes in the lungs is imperative in furthering the study of radiation-induced lung damage (RILD). Traditional intensity-based registration approaches fail in this task due to dramatic geometric changes between timepoints. This work aims to successfully register longitudinal pre- and post-radiotherapy (RT) lung CT scans with considerable radiological changes due to RILD. This is achieved by extracting and registering only consistent anatomical features (lung boundaries, main airways, vessels). **Methods:** Fifteen pre-RT and 12-month post-RT CT pairs from a chemoradiation trial for lung cancer were available, all with varying degrees of RILD, ranging from mild parenchymal change to extensive consolidation and collapse. For each CT, signed distance transforms from delineations of the lungs and main airways were generated and the Frangi vesselness was calculated. These feature maps were concatenated into multi-channel images and diffeomorphic multichannel registration was performed for each image pair. For the evaluation, the pre- and post- registration landmark distance was calculated for all patients at a mean (range) of 44 (38-65) manually identified landmark pairs. Traditional intensity-based registrations were also performed for all patient datasets and evaluated in the same way as a comparison. **Results:** The mean (standard deviation) distance for all datasets decreased from 15.95 (8.09) mm pre-registration to 4.56 (5.70) mm post-registration. Qualitative improvements in image alignment were observed for all patient datasets. In comparison, the post-registration error of the traditional intensity-based registrations was higher, at 7.90 (8.97) mm and registrations of patients with presence of atelectasis and extensive consolidation failed. **Conclusion:** We have demonstrated that our novel registration method can successfully align 12-month follow up scans from RILD patients in the presence of large anatomical changes such as consolidation and atelectasis, outperforming the classical registration approach both quantitatively and through detailed visual inspection.

Explore Potential Predictive Value of Microbiota for the Efficacy of Breast Cancer Radiotherapy

A Hu^{*}, H Song, Duke University Medical Center, Durham, NC

Purpose: A growing number of studies suggest that human microbiome plays a significant role in cancer development and treatment. However, little is known about how the microbiome influences radiotherapy efficacy. The purpose of this study is to mine existing data to explore if microbiome plays any role in affecting outcome of radiotherapy of breast cancer. **Methods:** The Cancer Genome Atlas (TCGA), sponsored by National Cancer Institute and the National Human Genome Research Institute, consists of comprehensive clinical and genomic sequencing data with more than 11,000 human tumors across 33 different cancer types. In this study, we focused on a subset of 780 subjects with invasive ductal carcinoma. A total of 390 (50%) subjects received radiotherapy. We mined the genomic sequencing data for the presence of microbiome within both radiotherapy and non-treated groups and compared their presence among the

surviving and deceased groups. Our goal was to identify microbiota that may influence the survival of patients after radiotherapy. **Results:** Among radiotherapy patients, a total of 95 microorganisms were found to be significantly different ($p < 0.05$, t-test) between living and deceased groups. Among these, the presence of 30 microbiota were elevated in the deceased group, whereas 65 were elevated in the living group. Using criteria from Benjamini-Hochberg procedure to decrease false positive rate, we found marine bacterium *Maribius* was statistically significantly correlated with better survival in the radiotherapy group, with mean copy numbers 3 times higher in the surviving patients (0.72 ± 1.12) than those in the deceased (0.24 ± 0.64). In contrast, *Maribius* concentration level was not statistically different between deceased and living in the non-radiotherapy group. *Maribius* is a relatively novel marine bacterium discovered in 2007 which belongs to the Rhodobacteraceae family. **Conclusion:** Microbiome characterization may present opportunities to discover novel prognostic or predictive markers for radiotherapy outcome.

PO-GePV-M-53

Multi-Modality (PET/CT) Radiomics Based Recurrence Prediction in Head and Neck Cancers Prior to Radiotherapy

M Schelin*, R Sheu, R Bakst, J Junn, Y Yuan, The Mount Sinai Hospital, New York, NY

Purpose: Radiomics machine learning models are a way to analyze existing imaging data to derive clinically relevant information that can be applied to a customized treatment paradigm. This study investigates the use of multi-modality (PET/CT) radiomics based machine learning to predict recurrence in head and neck cancer patients. **Methods:** Head and neck contrast enhanced radiation CT simulation scans, PET scans, radiation clinical target volumes (CTV), and clinical outcomes of 201 patients were obtained from The Cancer Imaging Archive (TCIA). Pyradiomics was used to extract intensity, shape, and texture based radiomics features (110) from CT and PET scans separately for all patients. Of the 220 (PET+CT) features extracted, the top 7 performing features were obtained by sequential feature selection in order to form a model for recurrence prediction. Multi-modality and single modality manual feature selection models, based on individual feature AUROC values, were run on the dataset for comparison. **Results:** The most accurate model was a multi-modality (PET/CT) model resulting from a combination of 5 PET and 2 CT features selected by backward sequential feature selection with a logistic regression estimator and five-fold cross validation. This model achieved the largest AUROC value (0.7895) compared to multi-modality (0.7701) and single modality (0.7364-CT, 0.7355-PET) manual feature selection models. **Conclusion:** Multi-modality radiomics results in more accurate machine learning models for recurrence prediction in head and neck cancer than single modality models. Multi-modality radiomics based recurrence prediction has the potential to improve the clinical outcome of head and neck cancer patients by applying the recurrence risk to pre-treatment management and surveillance patterns.

PO-GePV-M-54

Early Treatment Response Prediction Via Longitudinal CBCT Analysis for Locally Advanced Rectal Cancer

X Pan<sup>^{1*}, C Liu², M Alidoost³, Z Wang⁴, A Raldow⁵, J Weidhass⁶, J Fu⁷, K Woods⁸, D O'Connell⁹, D Low¹⁰, K Sheng¹¹, X Qi¹², (1) Xi'an University of Posts and Telecommunications, Xi'an, shaanxi, CN, (2) , (3) Ucla, (4) UCLA School of Medicine, Los Angeles, CA, (5) Dept. of Radiation Oncology, Los Angeles, CA, (6) UCLA, Los Angeles, (7) UCLA Radiation Oncology, Los Angeles, CA, (8) , Los Angeles, CA, (9) University of California Los Angeles, Los Angeles, CA, (10) University of California, Los Angeles, Los Angeles, CA, (11) UCLA School of Medicine, Los Angeles, CA, (12) UCLA School of Medicine, Los Angeles, CA

Purpose: Early prediction of tumor response is the key for plan adaption towards individualized treatment management. We aimed to investigate the value of longitudinal radiomics analysis of daily CBCT images for earlier prediction of neoadjuvant chemoradiation treatment (nCRT) response in patients with locally advanced rectal cancer (LARC). **Methods:** A subset of 86 LARC patients who underwent nCRT with 50.4 Gy in 28 fractions was analyzed retrospectively. Clinical response scores according to Tumor Regression Grade (TRG), assessed from post-operative pathology, were collected for all patients. Among 19 cases studied, 10 patients achieved pathological complete response (pCR), 9 patients achieved partial or no response (non-pCR). Daily CBCTs were imported to Varian Ethos emulator, where segmentation of the gross tumor volume (GTV) and organ-at-risks (OARs) were automatically generated. The delivered doses based on daily patient anatomy were calculated from the CBCT of the day on Varian Ethos emulator. For each fraction, we extracted 1304 imaging features from the GTV on CBCT using PyRadiomics package. Highly correlated imaging features were eliminated according to Spearman's rank coefficient. Longitudinal correlations between the selected imaging features, dosimetric parameters and the pathological response were established using linear regression models. **Results:** Among 252 CBCTs assessed, the variations of the GTV and PTV coverage ranged 2.8% and 7.2% respectively over the course of the treatment. Dosimetric variations showed no clear relationships between pCR vs non-pCR patients. Correlations were observed using a small subset of imaging features and early treatment response detection as early as the 8th fraction. **Conclusion:** Early prediction of treatment response is possible via systematical analyses of CBCT radiomics over the treatment course. Quantitative imaging features could be used as biomarkers to predict treatment response for LARC during the treatment course. Varian Ethos emulator offers an integrated platform to streamline the process.

Assessment of Magneto-Plasmonic Nanoparticles as a Theragnostic for MRI-Based Photothermal Therapy: A Numerical 3-D Modeling Study in Mice

Z Tavangari, Iran university of medical sciences

Purpose: to present a three-dimensional photothermal therapy, finite element method based model in mice. which is developed to estimate temperature elevations of tumor due to notable optical absorption of magneto-plasmonic Nano particles imbedded in the tumor bearing mice. **Methods:** In our modelling, mice (male BALB/c, 18g weight) Geometry was acquired with Magnetic Resonance Imaging (MRI) and used slicer software for segment nanoparticle distribution. the wavelength of irradiated laser was 808nm and the size of nanoparticles was 40-70 nm. **Results:** the temperature elevation for 5 min was about 51 Celsius degree which is very promising result for this dual modality nanoparticle. **Conclusion:** Given this knowledge, controlling these parameters in photothermal treatment playing a key role:1. 3D in vivo visualization help us to selective targeting,2. The intensity of irradiated laser,3. The importance of aspect ratio 4.Correlation between nanoparticles volume fraction Overall, we found a good agreement between the experimental data and numerical modelling, obviously these agreements open new doors for further research in photo thermal therapy and enhanced models.

PO-GePV-M-56

Mixed Reality Visualization of Radiation Dose in Interventional Radiology

J Kotoku^{1*}, T Takata¹, S Nakabayashi³, H Kondo³, M Yamamoto³, S Furui³, K Shiraishi³, T Kobayashi¹, H Oba³, (1) Teikyo University, Itabashi-ku, Tokyo, JP, (2) Kameda Hospital, Chiba, JP, (3) Department of Radiology, Teikyo University School of Medicine, Tokyo, JP

Purpose: For interventional radiology, dose management has persisted as a crucially important issue to reduce radiation risks to patients and medical staff. This study examined the concept and feasibility of a real-time dose visualization system using mixed reality technology for dose management in interventional radiology. **Methods:** An earlier reported Monte-Carlo-based real-time dose estimation system for interventional radiology was adopted for our system. We also developed a system of acquiring fluoroscopic conditions to input them into the Monte Carlo system. Then, we combined the Monte Carlo system with the wearable device for three-dimensional holographic visualization. The estimated doses were transferred sequentially to the device. The patient's dose distribution

was then projected on the patient body. The visualization system also has a mechanism to detect one's position in a room to estimate the user's exposure dose based on the positional information. The dose was visualized continuously in front of the user. **Results:** An end-to-end system test was performed using a human phantom. The acquisition system accurately recognized conditions that were necessary for real-time dose estimation. The dose hologram represented the patient dose. The user dose was changed correctly depending on conditions and positions. **Conclusion:** Mixed reality dose visualization is expected to improve exposure dose management for patients and physicians by exhibiting invisible radiation exposure in real space.

PO-GePV-M-57

Use of Crowd Innovation to Toward Development of An Artificial Intelligence Based Solution for Pancreatic Tumor Management

K Bush¹*, D Toesca¹, R Baclay¹, R Li¹, M Surucu¹, R Sergeev², B Godeny², A Lamora², N Brougher², D Chang¹, (1) Stanford University, Stanford, CA, (2) Topcoder, Indianapolis, IN

Purpose: Success rates in predicting pancreatic resectability remain poor, as success is dependent on tumor size, shape, and location relative to surrounding vasculature. Pre-surgery image analysis is highly surgeon dependent, and quantitative methods remain uncommon. In this work, we determine the efficacy of using a non-traditional approach known as crowd innovation, to rapidly develop a suite of automated pancreatic tumor segmentation algorithms, for use in a pancreatic cancer management solution. **Methods:** We conducted a 10-week, prize based, competition open to Topcoder, Inc. community contestants (total prize money of \$30,000). Contestants were provided a training dataset containing 120 CT scans and contour data for pancreatic tumors and surrounding vessels (superior mesenteric artery, celiac axis/common hepatic artery, and superior mesenteric vein/portal vein), and competed in building algorithms to auto-segment a validation dataset containing 60 CT scans with no contours. An F-score metric was used to rank the contestants' algorithms using a separate, unrevealed dataset of 62 patients. F-score calculations included both the tumor and vessel contours, but with vessels weighted 7-times lower than the tumor. Contestants were offered a \$3,000 prize bonus for algorithms exceeding an F-score of 0.7 to encourage quality algorithms beyond simply winning prize money. **Results:** 167 contestants registered for the competition, across 34 countries, and submitted a total of 337 algorithms. The winning solution (average F-score=0.72) implemented a 3D-UNet model in a 3D semantic segmentation approach, which was found to be accurate in tumor and vessel delineation. All other winning algorithms used 2D model approaches. Top 5 algorithm performance was strongly correlated by patient. In 82% of patient cases, all top 5 algorithms succeeded in achieving an F-score >0.6. **Conclusion:** The use of crowd innovation for healthcare challenges has seen limited use, but offers great potential for rapid development of high quality segmentation algorithms with reasonable financial commitments.

No funding was provided by Topcoder in this research. In the presented work, Topcoder (Indianapolis, IN) was contracted under a financial agreement by Stanford University to host and manage the competition.

PO-GePV-M-58

A Navigation System for Real-Time Monitoring PDT Delivery

H Sun*, M Kim, T Zhu, University of Pennsylvania, Philadelphia, PA

Purpose: Photodynamic therapy (PDT) is used intraoperatively to treat malignant pleural mesothelioma. To achieve efficiency of PDT, it is crucial to deliver light dose uniformly. Currently, 8 light detectors are placed inside the pleural cavity to monitor the light fluence. A navigation system is developed to provide real-time information of the light dose delivery during the PDT treatment and improve the uniformity of light fluence further. **Methods:** An infrared (IR) tracking camera is used to track passive reflective markers on various wands, including treatment, contour and reference wands. Each wand can be identified automatically via its unique configuration. The newly developed software allows user communication with the camera. It also contains a user interface which visualizes the real-time feedback. The data presented is stored and can be exported for determination of the cavity geometry and light fluence calculation. These functions are integrated into the newly developed software. The calculated light fluence is also compared with data collected via the 8 detectors. **Results:** For application on a chest phantom, it showed that the light distribution was more uniform with the real-time feedback provided by the navigation system, compared to the distribution with detectors only. Furthermore, the navigation system allows 2D light fluence collection throughout the whole phantom rather than just the selected points. Light fluence distribution can be calculated based on that for further analysis. **Conclusion:** The navigation system is compatible with the latest computer operation system so that it can utilize the up-to-date hardware to speed up data processing and enable the system to provide real-time feedback. The system has been used successfully on chest phantom for the light source tracking and real-time display of 2D light fluence. It is possible to apply the system onto pleural PDT patient treatment for the purpose of a more uniform light dose delivery.

PO-GePV-M-59

A Clinical Evaluation of An Open-Source Toolkit for TG-142 Based Monthly Imaging Quality Assurance Via Comparison with Commercial Software

S Jayarathna¹*, S Howard², D Johnson¹, (1) The University of Kansas Medical Center, Kansas City, KS, (2) The University of Kansas Cancer Center, Overland Park, KS

Purpose: To assess and evaluate the quantitative differences of imaging parameters for TG-142 monthly quality assurance (QA) of MV- EPID (electron portal imaging device) and kV-CBCT (cone beam computed tomography) image post-processing utilizing an open-source toolkit Pylinac (PL) in comparison with the commercially available software PIPSpro (PP). **Methods:** The QC3 MV imaging phantom (Standard Imaging) and Catphan 504 CT phantom (The Phantom Lab) were imaged upon multiple Varian linear accelerators as specified by the manufacturer. Modular transfer functions (MTF) were measured using PL and PP respectively. The Catphan phantom was imaged via half-fan CBCT and analyzed in PL and PP to evaluate Hounsfield Unit (HU) uniformity, HU linearity, and spatial resolution. The results of each software system were then compared against each other and against the baseline previously established at our institution. **Results:** For MV imaging the MTF value differences obtained by PL were found to be 14 % higher than those established in PP for all the frequencies considered. PL based kV-CBCT testing revealed HU uniformity values greater by ~ 9% for all 5 regions of interests. For HU linearity, a difference of < 2% was found, both PL/PI reporting HU greater than standard values. kV-CBCT MTF comparisons demonstrate that PL values differ by < 2% for frequencies < 0.3 lp/mm, deviating more than 5% beyond that. **Conclusion:** PL and PP measured imaging parameters demonstrated similar results. PL can allow for quick and reliable estimation of the TG-142 related image post-processing parameters. The presented results warrant further investigation into other systems and phantom combinations to fully incorporate the PL in a clinical environment. Nevertheless, the use of the software to establish and monitor baseline conditions as outlined by TG142 and manufacturers maybe a cost-effective solution for further automation in the field.

PO-GePV-M-61

Range Modulated Proton Radiography Using High Energy Therapeutic Proton Scanning Pencil Beams

C Pelas¹*, N Alsoubi², S Ahmad¹, I Ali¹, (1) University of Oklahoma Health Sciences, Oklahoma City, OK, (2) Department of Engineering and Physics, University of Central Oklahoma, Edmond, OK

Purpose: To investigate visibility of range modulated proton radiography using scanning pencil beam proton from high energy MEVION proton therapy

machine. The image quality including uniformity, linearity, contrast and spatial resolutions of the proton radiographs obtained were evaluated quantitatively. **Methods:** High energy proton beams from the scanning pencil beam MEVION proton therapy machines were used to obtain radiographs of different phantoms. These phantoms include LEEDS which is used for quality assurance of diagnostic KV photon beams. The proton radiographs of pelvis and head phantoms were acquired to evaluate visibility of proton radiography on the scale of patients. A phosphorus scintillation detector was used to acquire the proton radiographs. The effects of different beam parameters such as dose, depth, modulation, and separation between the detector and the object being imaged on the image quality of proton radiographs were evaluated quantitatively. **Results:** The contrast and spatial resolutions of the proton radiographs were decreasing with increasing depth of the testing objects in phantom, increasing spot size, increasing separation between the spot sizes and increasing range modulation. Both resolutions of the proton radiographs were affected by the proton beam scattering in the medium where it was degraded with increasing depth in phantom and increasing range modulation. Proton radiographic images showed high contrast of the soft tissue features in the beam view, while the intensity of photon radiographic images showed mainly high contrast of bone anatomy. The proton radiographs were affected by head and pelvis phantom thickness irregularities where the water equivalent depths across the image were largely variable. **Conclusion:** Proton radiography has a potential for image guided proton therapy as an alternative to photon radiography using attachable diagnostic kV photon beam systems. The use of range modulation of pencil beam scanning proton therapy system provides an approach to account for variations in patient thickness.

PO-GePV-M-62

Image Artifacts from High-Z Materials in Proton Radiography Using High Energy 250 MeV Therapeutic Proton Beam

I Ali^{1*}, S Ahmad¹, N Alsoub², (1) University of Oklahoma Health Sciences, Oklahoma City, OK, (2) Department of Engineering and Physics, University of Central Oklahoma, Edmond, OK

Purpose: To investigate image artifacts induced by high-z materials in proton radiographs obtained by high energy beams from a proton therapy machine. **Methods:** A high energy 250-MeV beam from the MEVION proton therapy system was used to irradiate a phantom that included different materials with low, intermediate and high z-composition and different shapes. The image quality of the proton radiographs was evaluated with the LEEDS phantom that is used usually for diagnostic kV-photon radiographs. The MEVION proton therapy machine provided open field beams of 25 mm diameter and depth ranges 5-32 cm. The proton images of different phantoms were captured with high spatial resolution and sensitivity phosphorus plates that are usually used in computed radiography. The proton radiographic images were captured at different depths of solid water 1-34 cm and separation between the phantom and CR plates downstream the proton beam. **Results:** The intensities in the proton radiographs showed strong interference patterns around high-z materials. The interference patterns depended on the composition of the density, position, shape and depth of the high-z objects in phantom. The image intensity varied significantly between the instructive and destructive interference patterns up to nearly 10% which resulted from the interference of the primary and scattered protons in the beam. The interference patterns varied with depth in phantom and position of the high-z materials in the beam path. These scatter patterns occur upstream with the energetic protons and in the Bragg peak dose deposition region. These interference patterns affected the imaged quality where they degraded the spatial and contrast resolutions of the proton radiographs. **Conclusion:** High-z materials induced strong image artifacts in proton radiographs acquired from high energy therapeutic proton beams. The intensity patterns resulting the interference of energetic primary and scattered protons affects the image quality of proton radiographs particularly spatial and contrast resolution.

PO-GePV-M-63

The Effects of Compton Camera Data Acquisition Timing and Readout On Prompt Gamma Images Acquired at Clinical Proton Beam Dose Rates

J Pol^{1*}, P Maggi¹, R Panthi², D Mackin³, S Peterson⁴, S Beddar³, (1) University of Maryland School of Medicine, Baltimore, MD, (2) Rush University Medical Center, Chicago, IL, (3) MD Anderson Cancer Center, Houston, TX, (4) University of Cape Town, Rondebosch, ZA

Purpose: The purpose of this study was to determine how the characteristics of the data-acquisition (DAQ) electronics of a Compton camera (CC) affect the quality of the recorded prompt gamma (PG) interaction data and the reconstructed PG images, during clinical proton beam delivery. **Methods:** We used the Monte-Carlo-plus-Detector-Effect (MCDE) model to simulate the delivery of a 150 MeV clinical proton pencil beam to a tissue-equivalent plastic phantom at a low dose rate of 1.0×10^3 p+/sec, representing a rate at which only one gamma is estimated to interact in the CC at a time, and clinical dose rates from 1.0×10^9 p+/s up to 1.0×10^{10} p+/s. We studied how the recorded PG interaction data, at each dose rate, changed as two characteristics of the DAQ electronics of a CC were changed: (1) the number of data readout channels; and (2) the active charge collection, readout, and reset time. **Results:** As the dose rate increased, the number of recorded PG single-, double-, and triple-scatter events recorded decreased by a factor of 45x for the current CC DAQ configuration. However, as the DAQ readout channels increased and the readout/reset timing decreased, the number of recorded events decreased by $<5\times$ at the highest clinical dose rate. The increased readout channels and reduced readout/reset timing also resulted in a higher percentage of the recorded double- and triple-scatters being “true” events (caused by a single incident gamma) and not “false” events (caused by multiple incident gammas). **Conclusion:** The increase in the number and the quality of recorded double- and triple-scatter events resulted in a significant improvement to the reconstructed PG images, especially at the highest clinical dose rates.

A Novel Lung-Avoidance Planning Strategy Based On 4DCT-Ventilation Imaging and CT Density Characteristics for Stage III Non-Small-Cell Lung Cancer Patients

A Feng^{*}, A Feng, Z Xu, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai, CN

Purpose: Functional planning based merely on 4DCT-ventilation imaging has limitations. In this study, we proposed a radiotherapy planning strategy based on 4DCT-ventilation imaging and CT density characteristics. **Methods:** For twenty stage III non-small-cell lung cancer (NSCLC) patients, clinical plans and lung-avoidance plans were generated. Through deformable image registration (DIR) and quantitative image analysis, a 4DCT-ventilation map was calculated. High-, medium- and low-ventilation regions of the lung were defined based on the ventilation value. In addition, the total lung was also divided into high-, medium-, and low-density areas according to the threshold. The lung-avoidance plan aimed to reduce the dose to functional and high-density lungs while meeting standard target and critical structure constraints. Standard and dose-function metrics were compared between the clinical and lung-avoidance plans. **Results:** Lung avoidance plans led to significant reductions in high-function and high-density lung doses, without significantly increasing other organs-at-risk (OARs) doses, but at the expense of a significantly degraded homogeneity index (HI) and conformity index (CI) ($p<0.05$) of PTV and a slight increase in monitor units (MU) as well as the number of segments ($p>0.05$). Compared with the clinical plan, the mean lung dose (MLD) in the high-function area and high-density area was reduced by 0.59 Gy and 0.57 Gy, respectively. **Conclusion:** A lung-avoidance plan based on 4DCT-ventilation imaging and CT density characteristics is feasible and implementable, with potential clinical benefits. Clinical trials will be crucial to show the clinical relevance of this lung-avoidance planning strategy.

PO-GePV-M-65

A First In-Phantom Quantitative Concept Validation for a Prospective Respiratory Signal-Guided 4D CT Protocol

A Boschini^{1*}, M Fusella², S Sapiognoli², M Pausco², (1) AULSS2 Marca Trevigiana, Treviso, IT, (2) Istituto Oncologico Veneto, Padua, IT

Purpose: To quantitatively validate in-phantom effectiveness of a respiratory signal-guided 4D CT protocol based on retrospective reconstruction in GE CT scanners outlined by Pan et al. (2017) with the purpose of reducing breathing artifacts. This protocol has the striking advantage of not requiring any off-line data processing, new software or hardware besides the scanner itself. **Methods:** A custom made slab-like wooden insert was fit inside a CIRS motion phantom. Five motion curves were generated and loaded into the phantom during CT examination on a GE Optima 580 scanner. The motion curves simulate an increasingly irregular breathing pattern, ranging from a sinusoidal (meant to establish a baseline) to a breath-hold like signal. CT examinations were performed with and without using Pan et al.'s manual prospective gating 4D CT protocol. The wooden insert AP and LL motions were compared in each scenario by the means of in-house R-based image processing code. **Results:** For each CT acquisition, total angular deviations in the wooden insert motion are calculated. Considering ordinary examinations, compared to the sinusoidal baseline acquisition, a regular breathing profile one would display +22.1% angular deviations, increasing to +107.5%, +182.1% and +256.9% as the loaded motion curves raise in their degree of irregularity. If the gating signal-guided protocol is applied, though, these percentage ratios in the irregular profiles drop to +11.8%, +54.1% and +43.32% respectively. **Conclusion:** In-phantom qualitative validation of this protocol had already been provided by Pan et al. (2017) and Werner et al. (2020) with further development of AI integration. Concerning breathing artifact reduction, the concept of the applied protocol has proven itself to be effective from a quantitative point of view. Further work will be needed to include in this validation C-C motion.

PO-GePV-M-66

Impact of 4DCT Artifacts on Local Control for Lung SBRT

L Rakotondravohitra^{*}, J Adamson, Duke University Medical Center, Durham, NC

Purpose: SBRT is a standard treatment for lung metastasis. Depending on patient abilities to provide consistent breathing pattern, 4DCT scans are used to delineate ITVs, hence the image quality of 4DCT is of uppermost importance for treatment planning and can potentially affect treatment outcome. A retrospective evaluation of 4DCT image artifacts is conducted and is correlated to local recurrence. **Methods:** This study uses clinical research protocol approved data of 96 patients diagnosed with lung metastases, 4DCT data sets with 10 phases were used for treatment planning, especially for the definition of the internal target volume (ITV). 4DCT artifacts were classified based on the severity of artifacts following the criteria outline in a prior study: images were classified as having minimal artifacts if they had ≤ 4 individual double structure artifacts at diaphragm or heart, and no interpolation artifacts in image center. Images were classified as having greater artifacts if they contained >4 individual double structure artifacts at diaphragm or heart, or any interpolation artifacts in image center. The dominant motion directions were recorded. The size of the GTV and proximity to closest artifacts were measured. Using RPM data, motion amplitude, standard deviation of patient breathing period, standard deviation of normalized patient breathing signal peak-to-peak amplitude during 4D CT acquisition are considered for covariates analysis. **Results:** The local failure control was observed for 8.3% (8/96) of patients. The preliminary artifacts scoring results shows that 11 out of 42 have severe CT artifacts, 31/42 have less or equal than 3 double structure artifacts at diaphragm. No correlation was found between 4DCT artifacts and local failure. **Conclusion:** Moderate 4DCT artifacts occurred in a non-negligible number of patients, however this was not found to have a measureable impact on local control. Future analysis will entail inclusion of more subjects and a multivariate analysis.

PO-GePV-M-67

Fiducial Registration-Error Analysis of PCA Lung Model for DVF Assessment

O Trejo^{1*}, S Samant², G Yan³, B Lu⁴, (1) University of Florida, Hampton, FL, (2) University of Florida, Gainesville, FL, (3) University of Florida, Gainesville, FL, (4) University of Florida, Gainesville, FL

Purpose: Original PCA lung model formulated by Zhang (2007) was validated using centroid position of a target volume. We (1) extend the analysis to the lung region using fiducial registration-error (FRE) analysis, which is more sensitive to accuracy of the deformation algorithm used to construct the model, and a more granulated evaluation of the deformation vector field (DVF). We (2) carry out preliminary analysis of the model to estimate DVF for lung ROI as well as target ROI for subsequent CT session, which can be used for margin assessment from respiration changes. **Methods:** We used public DIR-LAB 4DCT datasets and perform B-spline based deformable image registration (DIR) to acquire the displacement vector fields. Then perform FRE analysis between the actual and predicted landmark positions. Next, using two 4DCT images of the same patient acquired 30 minutes apart, the PCA model constructed from initial 4DCT was used to estimate subsequent 4DCT. Residual analysis was performed over each phase of breathing cycle to quantify differences between estimated and actual motions. **Results:** Mean FRE value for the DIR-LAB 4DCT cases was 1.6mm, consistent with gold-standard image-registration results, validating high fidelity of the PCA algorithm. When predicting a second 4DCT session, the mean residual over voxels in the lung region was 2.4mm. The directional components in eigenmode one and two indicate the first component is dominated by superior-inferior motion near the diaphragm, the second component is less predictable and has comparable contribution in all directions. **Conclusion:** The FRE evaluation is consistent with the previous centroid position evaluation. The PCA model can be used with surrogate information acquired during treatment to reconstruct target and organ motion for the purpose of dose accumulation. Our patient case study may indicate that the first principal component explains common diaphragm-dominated motion and the second component describes cycle-specific information.

PO-GePV-M-68

Impact of Flattening-Filter-Free Field on Online Adaptive Radiotherapy Using Virtual Couch Shift (VCS) Technique

Q Liu, J Liang^{*}, D Yan, William Beaumont Hospital, Royal Oak, MI

Purpose: Virtual couch shift (VCS) technique shifts MLC apertures rather than treatment couch to correct patient setup errors. When adapted to flattening-filter-free (FFF) linacs such as the MR-linac, VCS may lead to very different fluence pattern due to the non-flattened radiation field. This study aims to evaluate this effect for various anatomic sites. **Methods:** Four most commonly treated sites on MR-linacs (metastatic node, pancreatic, prostate and rectal cancers) were selected for this simulation study. Reference IMRT plan (P0) was generated in Pinnacle using 6MV FFF beam on an Elekta Versa linac with Agility MLC head. Translational shifts of 5, 10, 15 and 20-mm were introduced by shifting isocenter in the opposite direction. A Pinnacle script was developed to generate shifted MLC apertures taking beam divergence into account. For shift-only plan, dose distribution was computed with the original MUs. Shift-only plan was subsequently copied and re-optimized with segment weight optimization (SWO) using the same objectives from P0. Various dosimetric indices for planning target volume (PTV) and organs-at-risk (OARs) were collected and compared between P0, shift-only and SWO. **Results:** Shift-only resulted in decreased dose to PTV in the shifted direction and mostly affected V_{rx} (PTV received prescription dose). Dose reduction increased with shift distance and target size, and appeared more pronounced for shifts in the superior-inferior (SI) directions. For prostate and rectal cases, V_{rx} could drop by ~20% for 10-mm shift and ~50-60% for 20-mm shift. The impact on OAR indices (D0.5cc and D5cc) was relatively small and didn't show a clear trend. SWO quickly converged within ~20 optimization iterations. All SWO plans achieved comparable plan qualities as P0 except for one extreme situation (rectal case with 20-mm SI shift). **Conclusion:** Shift-only method mostly affects target coverage. Simple SWO is effective in restoring plan qualities even with relatively large shift.

PO-GePV-M-69

Adaptive Radiation Therapy with Deformable Image Registration and 4D Dose Calculation

I Ali^{1*}, N Alsobou², S Ahmad¹, (1) University of Oklahoma Health Sciences Center, Oklahoma City, OK, (2) Department of Engineering and Physics, University of Central Oklahoma, Edmond, OK

Purpose: To develop a four-dimensional (4D) dose optimization and calculation algorithm on 4D-CT-number maps with tissue heterogeneity using displacement-vector-fields (DVF) from different deformable-image-registration algorithms (DIR) in order to consider for anatomical variations and respiratory motion to achieve adaptive radiation therapy. **Methods:** A simulation study was performed to remap CT-numbers and dose distributions using DVF that were obtained from DIR. The DVF represented a voxel-by-voxel motion of the tumor and surrounding organs-at-risk in the region of interest. These DVF were employed to modify the intensity maps from 3D-conformal and intensity-modulation optimized plans to perform 4D-optimization on remapped CT-numbers to account for heterogeneity to consider anatomical variations and respiratory motion. **Results:** The DVF obtained from deformable image registration correlated linearly with the motion amplitudes of the phantom. The dose calculation algorithm produced 4D-optimized plans from the stationary 3D-conformal or intensity-modulated plans using DVF's extracted from DIR algorithms. The 4D-dose profiles became narrower for the targets moving with larger motion amplitudes. It performed optimization by shrinking and remapping the dose distribution that are obtained from dose optimization on stationary images. The unfolding of the 4D-dose distributions as the patient move during dose delivery produced equivalent dose distributions optimized in 3D for the stationary targets and organs at risk. Heterogeneity correction was also considered by remapping the CT-number values in the CT images using the DVF's in order to reverse motion artifacts. **Conclusion:** This approach provides a novel algorithm to perform adaptive radiation therapy using 4D dose optimization and calculation with heterogeneity correction using remapped CT numbers which is a practical and convenient alternative to manage respiratory motion of cancer patients. The advantages of this approach include achieving equivalent conformal doses without any restriction on anatomical variations and patient breathing during dose delivery, however, it is limited by reproducibility of the DVF from DIR.

PO-GePV-M-70

Respiratory Motion Detection and Tracking of Mobile Phantoms with a Microwave Imaging System

N Alsobou^{1*}, S Ahmad², I Ali², (1) Department of Engineering and Physics, University of Central Oklahoma, Edmond, OK, (2) University of Oklahoma Health Sciences Center, Oklahoma City, OK

Purpose: To detect and classify the motion of tissue equivalent phantoms by measuring the variation in the microwave signal. A model of motion classification was developed that employs the variations in the microwave signal to obtain the 3D-motion parameters for all voxels included in the phantom volume in the microwave field of view. **Methods:** A microwave system with 10.25 GHz that was made from one transmitter and one receiver was used to detect phantom motion. Several tissue equivalent phantoms with a mobile platform that moved with different motion patterns were used to characterize the microwave signal variations. The microwave signal variations with phantom thickness, position and density were quantified. These variables were used to detect, classify and quantify the phantom motion parameters using variations in the microwave signal induced by various motion patterns that simulate patient respiratory motion patterns. **Results:** The position of the minimal intensity of the microwave signal detected by the receiver varied linearly with the position of the phantom in the microwave field of view which can be predicted within 1.0 mm from the minimal microwave intensity. The microwave intensity varied non-linearly with the density of the phantom objects equivalent to lung, breast muscle, adipose, liver tissues. Furthermore, the microwave intensity decreased non-linearly with the increase in phantom thickness. A motion classification algorithm was developed that used the microwave projections with the previous parameters to extract the 3D-motion trajectory of a mobile phantom, phantom thickness, composition of the phantom in the microwave field of view. **Conclusion:** This microwave motion detection technique has potential clinical applications that are of interest in the imaging and treatment of cancer patients with radiation therapy that are superior to just tracking an external or internal marker currently used for patient motion tracking or gating used for cancer patient treated with radiation therapy.

PO-GePV-M-71

Testing Different Materials for a Quality Assurance Phantom for Proton Radiography Using the MEVION Proton Therapy System

C Pelas^{1*}, N Alsobou², S Ahmad¹, I Ali¹, (1) University of Oklahoma Health Sciences Center, Oklahoma City, OK, (2) Department of Engineering and Physics, University of Central Oklahoma, Edmond, OK

Purpose: To test different materials and develop a quality assurance phantom to evaluate quantitatively the image quality of proton radiographs obtained from high energy scanning beams using the MEVION proton therapy system. **Methods:** Different materials and phantoms (LEEDS and CIRS) were used to quantify the different imaging quality parameters of proton radiographs that included muscle, breast, adipose, liver, lung low, lung medium, bone. The images quality parameters that were tested included linearity, uniformity contrast and spatial resolutions. The proton radiographs were obtained using a high energy proton beam of 230MeV from the MEVION pencil-beam scanning proton therapy system. Proton pencil beams of a diameter of 3.5mm in air with a spot spacing of 2.5mm were used to obtain the proton radiographs. Large open proton beams of 20x20cm² and range of 32cm in water with one energy layer modulation were used. Phosphorous scintillation plates that are usually used photon computed radiography were used to acquire the proton radiographs. **Results:** High-Z materials such as lead, copper and other metals in the LEEDs phantom used for photon radiography were not appropriate for testing the image quality of the proton radiographs. Particularly the spatial resolution objects used for photon imaging did not work with proton imaging because the proton beam scattered with large angle degrading image quality. The contrast resolution was tested variable density and size plugs similar to the LEEDS phantom. The linearity of the proton radiographs was tested with inserts that are made from different tissue-equivalent materials with densities ranging from air to bone. The uniformity of the proton radiographs was tested using a solid water block. **Conclusion:** This quality assurance phantom provides a useful tool to test and quantify the image quality of proton radiographs that can be used for image guidance with on-board imaging systems integrated with proton therapy machines.

PO-GePV-M-72

Four-Dimensional Dosimeter and Quality Assurance Phantom for Adaptive Radiation Therapy

T Meyers^{1*}, N Alsobou², S Ahmad¹, I Ali¹, (1) University of Oklahoma Health Sciences, Oklahoma City, OK, (2) Department of Engineering and Physics, University of Central Oklahoma, Edmond, OK

Purpose: To develop a 4D-dosimeter and quality assurance phantom to quantify the effects of respiratory motion on 3D-optimized dose distributions and provide dose verification of futuristic 4D-optimized treatment plans and dose calculation algorithms. **Methods:** Dose distributions were measured with a MapCheck2 phantom that was placed on a mobile platform that can move with different motion patterns with adjustable motion amplitude and frequency. This motion phantom was used to measure the dose distributions optimized and calculated in 3D including conformal, IMRT and VMAT plans. The dose distributions were measured with this phantom system static and moving with different motion amplitudes (5-35mm) to quantify motion artifacts on the dose distributions. **Results:** Respiratory motion can lead to large dose discrepancies that depends on the patient motion pattern. The increase in motion amplitudes results more blurring in the dose distribution with an increased dose deficit in the tumor and increased dose deposition in the surrounding normal tissue. For a conformal open field plan, the dose profiles changed around the 50% isodose line, with increasing dose spelling outside the field for increasing motion amplitudes 5-35mm. The central axis dose and the surrounding flat region remained unchanged. However, for an intensity modulated plan, the motion artifacts affected the dose distribution overall with underdosing in the treatment planning volume and overdosing outside the treatment field. **Conclusion:** This mobile

dosimeter and phantom system provided a powerful tool for quantifying the dose deviations induced by cyclic motion on 3D optimized dose distributions. 4D-optimized dose distribution provides an alternative technique for the management of respiratory motion to conventional techniques such as breath holding and beam gating. This 4D phantom will be a necessary dosimetric tool that can be used for the verification of dose distribution calculated by 4D-optimization and dose calculation algorithms to achieve the goals of adaptive radiation therapy.

PO-GePV-M-73

Evaluation of Longitudinal Variation and Impact of Dose Calculation Algorithms Within a CBCT-Based Online Adaptive Workflow

G Seymore*, S Martinez, A Dare, I Hajizadeh, A Harpley, K Homann, M Price, M Morales Paliza, Vanderbilt University Medical Center, Nashville, TN

Purpose: To compare and evaluate the impactful dosimetric differences of three common treatment planning system algorithms longitudinally within the Ethos adaptive treatment workflow (EATW) and create practical expectations of each system. **Methods:** Dosimetric comparisons were analyzed across ten sessions of a prostate patient in an EATW at a satellite clinic with rotating physicians. Adaptive plans were created from contours segmented using artificial intelligence on a day of treatment CBCT. Initial calculations utilized the AcurosXB algorithm while simultaneously calculating externally with the Mobius3D-Collapsed Cone Convolution (CCC) algorithm. Plans were then exported offline to Varian Eclipse and recalculated using the Anisotropic Analytical Algorithm (AAA) 15.6.06 with preset monitor units and fluence parameters. Comparisons were made between the three algorithms using selected statistics and dose-volume histograms for each session. Additionally, longitudinal data was analyzed to evaluate trends over the course of the EATW. **Results:** Comparisons of DVH data between different algorithms indicate consistent differences in PTV coverage, as well as dose volume statistics in rectum and bladder organs-at-risk (OAR). AAA consistently resulted in the highest evaluation of dose volumes in each volume of interest, while CCC was consistently the lowest. AcurosXB is the clinically utilized dose algorithm, and in our analysis indicated a closer relationship with AAA. Longitudinal evaluations indicated minimal deviations in PTV coverage and only slight variations in OARs. Monitor units and structure volumes fluctuated between sessions accordingly, potentially related to different physician contouring criteria. **Conclusion:** As adaptive planning and treatment delivery grow more common with advancing technology, institutions may need to integrate new algorithms accordingly. This work establishes metrics for interpreting differences between three common treatment planning dose calculation algorithms in the Ethos workflow. This work establishes expected variations longitudinally and between algorithms that can be utilized by clinics new to adaptive workflows to develop confidence while incorporating unfamiliar processes.

PO-GePV-M-74

A Simple Adaptive Planning Workflow for MR-Guided Radiotherapy of Prostate Cancer

X Chen*, E Paulson, E Ahunbay, E Omari, W Hall, C Lawton, M Straza, X Li, Medical College of Wisconsin, Milwaukee, WI

Purpose: Two workflows, adaptive planning (adapt-to-shape, ATS) or repositioning (adapt-to-position, ATP) are used in MR-guided adaptive radiation therapy (MRgART) on a 1.5T MR-Linac. For MRgART of prostate cancer, ATP usually take 30 minutes, shorter than that for ATS (50 min), and is used for most fractions. However, ATP may not be sufficient if there is a large air-cavity in the rectum. We propose a simple adaptive workflow, Pseudo-ATS+, that can account for an air cavity change with a shorter time compared to ATS. **Methods:** The Pseudo-ATS+ workflow includes: (1) segmenting the air cavity and external contours on daily air scan specifically designed to image air, (2) populating the obtained air and external contours, along with the reference contours for other structures to the daily MRI, and (3) optimizing an adaptive plan on daily images. To evaluate the performance of Pseudo-ATS+, we performed standard ATP, reconstructed doses of the ATP and Pseudo-ATS+ plans on daily images with fully updated contours and compared the obtained doses with the ATS plans for selected daily MRI sets with the presence of an air cavity in the rectum. Various DVH parameters, e.g., minimum dose (Dmin) for the PTV and volume coverage of 63Gy (V63Gy) for rectum and bladder, were compared. **Results:** For Pseudo-ATS+, the differences in DVH parameters between the reconstructed dose and ATS plans were smaller than those for reconstructed ATP. The PTV Dmin of reconstructed Pseudo-ATS+ was 3.3% different from ATS, while the difference was 9.8% for reconstructed ATP from ATS for a case tested. Rectum V63Gy was within the planning goal for reconstructed Pseudo-ATS+ while reconstructed ATP plan dose was not. The Pseudo-ATS+ workflow required additional 5 minutes compared to ATP. **Conclusion:** This proposed simple adaptive workflow, Pseudo-ATS+, can properly account for rectal air cavities changes without significantly extending patient-on-couch time during MRgART for prostate cancer.

PO-GePV-M-75

Importance of Incorporating Rotational Setup Differences for QACT Dosimetric Evaluations

S Davis*, V Chaswal, R Tolakanahalli, Miami Cancer Institute, Miami, FL

Purpose: To develop an accurate method to incorporate rotational setup differences for QACT dosimetric evaluations using Eclipse and Precision treatment planning systems. **Methods:** Recalculation of the original treatment plan on a CBCT or updated fan-beam CT (QACT) is often used to provide the dosimetric impact of anatomical changes and to decide whether or not an adaptive plan is necessary. However, some existing technologies do not account for rotational differences (roll, pitch, and yaw) between the QACT and the planning CT. The VelocityAI software was used to resample the QACT to the planning CT frame-of-reference, to simulate rotational corrections that are applied at the treatment machines (up to 3° for TrueBeam and 5° for CyberKnife). Effect of omission of rotations on QACT dose estimates was studied on three pelvic treatment cases for TrueBeam/Eclipse with para-aortic and inguinal nodal targets and on an intracranial lesion treatment for CyberKnife/Precision. The original treatment plans were recalculated on the QACTs with and without rotational differences, to demonstrate the dosimetric sensitivity. **Results:** All three pelvic cases showed clinically unacceptable (<91% of prescription dose) minimum D0.03cc doses when rotational differences were not accounted for (63.5%-88.0%). Target coverage was acceptable when rotations were applied (minimum D0.03cc = 91.8%-95.8%). The CyberKnife case showed a small increase in optic nerve doses and a 16% increase in mean right cochlea dose when rotational differences were not taken into account. Dosimetric differences for OARs were negligible when rotations were applied. **Conclusion:** All four clinical examples presented would have triggered adaptive replanning if rotational differences in the patient CTs were not taken into account. Application of rotational corrections applied at the treatment machines is an important parameter when assessing the dosimetric impact of anatomical changes, and is a crucial component to adaptive RT workflows.

PO-GePV-M-76

Initial Experience with Online CT-Based Adaptive Radiotherapy in the Abdomen

A Price¹*, E Laugeman¹, B Cai², T Kim¹, Y Hao¹, O Green¹, H Gay¹, P Samson¹, H Kim¹, M Spraker¹, G Hugo¹, L Henke¹, (1) Washington University in St. Louis, St. Louis, MO, (2) UT Southwestern Medical Center, Dallas, TX

Purpose: CT-Based online adaptive radiotherapy using an integrated ring-gantry platform recently gained FDA clearance. This study describes our institution's early experience with abdominal CT-guided stereotactic adaptive radiotherapy (CT-STAR) to help guide other CT-based adopters. **Methods:** Our institution specifically targeted abdominal treatment sites with minimal tumor motion. We analyzed anatomical movement for both the target and OAR from the initial planning scans, determining the need for planning ITVs or motion planning risk volumes (mPRV). Patients were either treated at end-exhale breath hold or free breathing, which was determined by both patient compliance and tumor motion needs. Dosimetric indices from planning images, anatomy-of-the-day, and adapted anatomy were collected. Treatment times for each disease site were also collected. **Results:** Our institution treated two para-aortic lymph node (PA-

LN) and one anterior retroperitoneal lymph node (R-LN). Both PA-LN patients were scanned at end-exhale breath hold for adaptive contouring but treated at shallow free-breathing. The average tumor motion was 0.2cm and the average adjacent OAR motion was 0.4cm. In the R-LN patient, the patient was scanned and treated at end-exhale breath-hold. For the R-LN patient, the bowel dose was exceeded in all predicted plans. For the first PA-LN patient, the predicted plan exceeded small bowel constraints in all five fractions and exceeded the duodenum constraint in two of the five fractions. In the second PA-LN patient, the predicted plan exceeded small bowel constraints in all five fractions. For all three patients, adaptive treatment plans were within bowel tolerance. The average treatment times were 61.6min $\pm$ 23.6min (mini: 31min. max: 114min). **Conclusion:** Abdominal adaptive treatments with minimal motion were successfully treated in an acceptable time period. mPRVs can additionally account for predictable intra-fraction OAR motion in the absence of respiratory gating.

Longitudinal Review of Adaptive Therapy Planning Time for the Elekta Unity

D Dunkerley*, D Hyer, J Snyder, S Yaddanapudi, J St-Aubin, University of Iowa, Iowa City, IA

Purpose: The adaptive planning workflow on the Elekta Unity MR-Linac is a multi-step process for each treatment. These processes differ depending on whether the adapt-to-position (ATP) or adapt-to-shape (ATS) workflow has been selected. In the ATP workflow, a rigid registration is performed between the daily MR and the reference image and a warm-start gradient descent optimization is used. In the ATS workflow, deformable registration, re-contouring, and full objective-specific plan optimization is used. The time required for each step is dependent on the user's experience and is likely to improve with time. **Methods:** The total time required to complete online adaptive treatment planning and plan review was tracked at three separate time intervals, 18 days starting in December 2019 (146 fractions), 50 treatment days starting in March 2020 (133 fractions), and 26 treatment days starting in January 2021 for 125 fractions for ATP and ATS workflows. The distribution of time for each step in the planning process was recorded during treatment. The longitudinal mean and standard deviation of the times associated with each step in the planning process were calculated and a two tailed t-test was used to test if the time reductions were statistically significant. **Results:** Although changes in time were not statistically significant ($p>0.05$), a reduction in the mean time for certain planning steps was observed. The mean total time for ATP decreased from 15.7 to 14 minutes and decreased from 34.7 to 25.0 minutes for ATS over the three tracked time intervals. The detailed analysis of ATS planning times demonstrated a 40% decrease in the average registration (1.8 minutes) and contouring (3.9 minutes). **Conclusion:** Experience with the online adaptive RT planning tools and process is likely to decrease the time required for each treatment.

PO-GePV-M-78

Dose Accumulation of Daily Adaptive Plans Using MiM and RayStation for Elekta Unity MR-Linac

D Lee^{1*}, S Oh¹, D Pavord¹, A Colonias¹, R Fuhrer^{1,5}, J Sohn^{1,2}, (1) Allegheny Health Network, Pittsburgh, PA, (2) Drexel University College of Medicine, Philadelphia, PA

Purpose: This study aims to test the daily dose accumulation of online adaptive plans using commercially available MiM (MiM Software; Cleveland, OH) and RayStation (RaySearch; Stockholm, Sweden) for Elekta Unity MR-Linac. Dose accumulation is essential to validate delivered dose to tumor and surrounding organs, which can be a prerequisite for further re-planning and/or an additional fraction. **Methods:** This study utilized a CT and 5 daily MR datasets of a prostate cancer patient to develop a reference plan (37.5Gy in 5 fractions with 7-fields and a 7FFF Unity® beam) and simulate two plan adaptations using an offline MRL Monaco (v5.40.01). In the first and second simulations, (1) five adapt-to-position(s) (ATP), rigidly registering CT-to-MR(s), were performed and (2) three ATP(s) for Day1, Day3 and Day5 MR(s) and two adapt-to-shape(s) (ATS) for Day2 and Day4 MR(s), deformably registering CT-to-MR or MR-to-MR, were performed for composite doses. MiM (Ver 7.0.6) and RayStation (Ver 9A) were used for rigid and deformable image registration for composite doses. Composite doses were compared in mean dose and 3D gamma analysis using an in-house software. **Results:** We found a minimal difference of mean dose for ATP plans (MiM<0.1% and RayStation<0.3% for PTV (Prostate+SeminalVes+5mm margin)) and slightly higher for ATS plans (MiM<0.3% and RayStation<2.5% for PTV). The 3D gamma analysis resulted in 91.1% and 93.3% for ATP plans, and 90.6% and 89.9% for ATS plans across MiM and RayStation, respectively. **Conclusion:** This is the first that we demonstrated the dose accumulation of ATP and ATS using MiM and RayStation across rigid and deformable registration. In addition, generating a composite plan in adaptive radiation therapy process can be achievable to validate delivered cumulative doses. Further investigations will need to include an improvement of 3D dose accumulation and speed for real-time process whilst optimizing image registrations and adapting daily target organ contours.

PO-GePV-M-79

Comparison of the Efficacy of CT On Rails Versus In-Room CBCT for Online Daily Adaptive Proton Therapy

K Nesteruk*, M Bobic¹, A Lalonde¹, H Lee¹, G Sharp¹, J Verburg¹, B Winey¹, A Lomax², H Paganetti¹, (1) Massachusetts General Hospital and Harvard Medical School, Boston, MA, (2) Paul Scherrer Institute, Villigen, CH

Purpose: To compare the efficacy of CT on rails versus in-room CBCT for daily adaptive proton therapy. **Methods:** We analyze a cohort of head-and-neck patients with daily CBCT images to assess the influence of near-treatment-position imaging on the efficacy of daily adaptation. Virtual daily CT images were generated by deformable image registration of the planning CT to daily CBCT images. We identified the necessity of moving the patient after a CT scan to be the most significant difference in the adaptation workflow, leading to an increased treatment execution uncertainty σ . It is a combination of the isocenter-matching σ_i and random patient movements σ_m induced by the couch motion. The former should not exceed 1 mm. The latter depends on the treatment site and might be patient-specific. Accordingly, to mimic the adaptation workflow with CT, we introduced random offsets between Monte-Carlo based adaptation and delivery of the adapted plan. The offsets followed Gaussian distribution with σ corresponding to the total uncertainty in each axis posterior-anterior, left-right, and inferior-superior. We studied three different scenarios with $\sigma_m=1, 2$, and 3 mm. **Results:** Results showed no significant differences in accumulated DVHs and dose distributions for $\sigma=1.4$ mm and 2.3 mm. Offsets with $\sigma=3.2$ mm resulted in underdosage to high- and low-risk CTV, more hot spots of considerable volume, and noticeably higher doses to OARs. For high-risk CTV, the mean D_{98} was found to be 97.9%, 98.0%, 96.7% for $\sigma=1.4$ mm, 2.3 mm, 3.2 mm, respectively. **Conclusion:** If the total uncertainty due to imaging with CT on rails does not exceed 2 mm, the efficacy of daily adaptation would not be significantly affected. Given other advantages of fan-beam CT, such as lower whole-body dose and better image quality, CT on rails can be considered a good alternative to CBCT for adaptive proton therapy.

PO-GePV-M-80

Sun Nuclear DoseCHECK Vs Varian Mobius: Commissioning and Characterisation for Ethos Adaptive Independent Dose Calculations

R Brown^{1*}, R Bromley¹, C Stanton¹, B Zwan², J Booth¹, A Briggs¹, (1) Northern Sydney Cancer Centre, Royal North Shore Hospital, Sydney, AU, (2) Central Coast Cancer Centre, Gosford, AU

Purpose: To evaluate the accuracy and performance of DoseCHECK and Mobius as independent plan verification software for the purpose of pre-treatment quality assurance of Varian Ethos adaptive plans. **Methods:** DoseCHECK and Mobius were commissioned in accordance with international best practice documents on treatment planning system (TPS) commissioning and quality assurance, including: AAPM TG53, TG119, MPPG5a and IAEA TECDOC1583. All plans were sent to DoseCHECK and Mobius for independent dose calculation, and compared to measurement on the treatment delivery system (TDS). For end-to-end validation, Ethos clinical patient plans (n=50) were generated in the Ethos TPS encompassing a range of clinical sites and techniques (IMRT and VMAT), then sent to DoseCHECK and Mobius for independent dose calculation. Mean dose to the target and overall gamma pass rate were extracted and compared to phantom measurement on the TDS, with plan complexity defined as MU/Gy. **Results:** All results for commissioning test plans were within the published tolerances for DoseCHECK and Mobius when compared to the TPS and measurement. Higher degrees of uncertainty were noted for extreme cases, such as small field sizes, build-up region (surface dose) and heterogeneity. All patient plans were validated through measurement and in Mobius and DoseCHECK 3D gamma criteria of 3%/3mm (10% threshold, global normalisation) >95% points passing and mean dose to target difference within 3% was configured to achieve comparable results. The average gamma pass rate for both systems was >95% for all plans tested and mean dose to target difference <1%. In general, plans of higher complexity or significant heterogeneity contained higher uncertainty. **Conclusion:** DoseCHECK and Mobius were commissioned and found to be within tolerance of all tests recommended in international best-practice guidelines. Both systems were used to independently verify plan dose calculation for pre-treatment QA of Ethos adaptive plans.

NSCC has reference site agreements with Varian and SNC.

CBCT-Based Plan Adaptation for Chest Wall Intensity Modulated Proton Therapy

W Smith*, Y Hao, B Sun, A Darafsheh, T Mazur, T Zhang, S Perkins, T Zhao, Washington University School of Medicine, St. Louis, MO

Purpose: Cone-beam CT (CBCT) is an important imaging modality for precise positioning and monitoring gross anatomical changes. However, CBCT is not suitable for dose calculation in intensity-modulated proton therapy (IMPT), largely limited by the lack of accuracy in Hounsfield units. This work demonstrated a new workflow that utilizes CBCT for fractional dose verification as well as adaptation for chest wall IMPT. **Methods:** A small cohort of four chest wall patients (three ipsilateral and one bilateral) were included in this study. All had one simulation helical CT and at least one setup CBCT. Three had verification helical CTs at some points in their radiotherapy course. A synthetic CBCT was created by deforming the simulation helical CT to a setup CBCT in RayStation. Structures contoured on the simulation CT were also propagated to the synthetic CBCT through the same chain of deformable imaging registration. Dose to the targets and normal organs were reported and compared among the simulation helical CT, the synthetic CBCT, and verification helical CT. **Results:** V95% of PTV and V5Gy heart were consistent among planning CT, synthetic CBCT, and verification CT with less than 3% and 1% variation, respectively. Except for one who suffered from significant swelling of tumor stroma. In the latter case, the synthetic CBCT was able to predict the PTV re-contoured independently and the dose within 1% on a replanning helical CT triggered by the synthetic CBCT. **Conclusion:** This work supports the assertion that CBCT imaging can be used as an early warning system capable of detecting anatomy changes that warrants adaptive planning. The synthetic CBCT we developed in this study could be a powerful tool for fractional dose verification and quick plan adaptation in IMPT.

PO-GePV-M-82

Evaluation of AI-Driven Adaptive Workflow for High Quality Palliative Radiotherapy

A Kejda^{1,*}, S Wong¹, S Roderick¹, J Booth^{1,2}, T Eade^{1,3}, (1) Northern Sydney Cancer Centre, Royal North Shore Hospital, Sydney, AU, (2) University of Sydney, Sydney, New South Wales, AU, (3) Sydney Medical School, University of Sydney, Sydney New South Wales, AU

Purpose: Approximately one third of radiotherapy patients are treated with palliative intent. Varian's Ethos online adaption system utilises AI contouring on daily cone-beam CT (CBCT) to auto-generate a plan of the day. This work evaluated the Ethos adaptive workflow in palliative patients comparing clinician contours against Ethos AI segmentation, and corresponding adaptive plans against original (scheduled) plans. **Methods:** Ten palliative patients (27 fractions) were replanned with dynamic MLCs using Ethos TPS, then duplicated and sorted into two test arms. Adaptive treatment was simulated in a test environment using patient-specific CBCTs. In arm 1, clinicians edited all AI contours before an adaptive auto-plan was generated. In arm 2, no contour edits were made. The adaptive plans generated were compared using metrics assessed in original plans (PTV D95% and 100% conformity index). On a subset of six fractions, AI and clinician-modified structures were compared using the DICE similarity coefficient. **Results:** All adaptive plans passed the primary constraint PTV D95%>95%, while two scheduled fractions failed. Mean PTV D95% for adaptive and scheduled fractions were 102.4% and 104.0%, respectively, with no statistically significant difference found (t-test P=0.29). Mean conformity indices measured 0.97 and 0.85 for adaptive and scheduled plans, respectively, were found to be statistically different (t-test P=0.017). The DCEs for CTV, kidneys, liver, small bowel and stomach were 0.90±0.09, 0.930±0.05, 0.98±0.02, 0.928±0.04 and 0.70±0.11, respectively, indicating accurate AI segmentation of all contours except for the stomach. **Conclusion:** Ethos AI-driven adaption was shown to achieve better target coverage than scheduled plans, indicating the system could account for inter-fraction anatomy changes associated with palliative cohorts. Good agreement was shown between preliminary Ethos and clinician contours, except for the stomach, which was most likely impacted by the presence of gas causing image artefacts, impacting AI segmentation. Future work includes online adaption in diagnostic CT-enabled palliative planning.

Northern Sydney Cancer Centre has a funded collaborative research agreement with Varian

PO-GePV-M-83

Performance Characterization of a Real-Time Dose Reconstruction Algorithm for Prostate Stereotactic Radiotherapy Treatment

C Sengupta^{1,*}, S Skouboe², D Nguyen^{1,3,4}, T Ravkilde², P Poulsen², T Moodie², P Keall¹, (1) ACRF Image X Institute, The University of Sydney, Sydney, NSW, AU, (2) Department of Oncology, Aarhus University Hospital, DK, (3) University of Technology Sydney, Ultimo, NSW, AU, (4) North Sydney Cancer Centre, Royal North Shore Hospital, NSW, AU, (5) Crown Princess Mary Cancer Centre, Sydney, AU

Purpose: There is a growing awareness that the dose a patient receives in SBRT often differs from the planned dose due to tumor motion. To improve dose accuracy, dose reconstruction should ideally occur during treatment. To address this, a real-time dose reconstruction method, DoseTracker has been developed. In a critical step to its clinical deployment, we benchmark DoseTracker against a treatment planning system (TPS)-based dose reconstruction method for prostate SBRT treatments and hypothesize that the motion-induced dose-errors determined from these two methods should agree. **Methods:** Simulated real-time motion-inclusive dose reconstruction was performed using DoseTracker for nine prostate cancer patients who received IGRT with gating during five-fraction SBRT (7.25Gy/Fx) in the TROG-15.01 SPARK trial. Dose reconstruction was performed for both actual-gated (45 fractions) and simulated non-gated sessions (11 fractions). The motion-induced dose-errors were calculated as the difference between planned and motion-inclusive doses using DoseTracker and compared against the motion-induced dose-errors calculated using an iso-center shift method with a clinical TPS. The motion-induced dose-errors were computed for the clinical target volume (CTV), planning target volume (PTV), and two risk-organs, bladder and rectum. **Results:** The median computation time for each dose calculation of DoseTracker ranged from 110-320 ms for calculation volumes ranging from 287-691 cm³. The mean and standard deviation of the differences of the motion-induced dose-errors calculated using DoseTracker and the TPS were 0.02±0.01 Gy for CTV(ΔDmean), 0.02±0.01 Gy for PTV(ΔDmean), 0.04±0.07 Gy for CTV(ΔD100%), 0.03±0.06 Gy for PTV(ΔD95%), 0.02±0.02 Gy for bladder(ΔDmean) and 0.02±0.07 Gy for rectum(ΔDmean). The close agreement in motion-induced dose-errors supports the hypothesis that the performance of DoseTracker is comparable with the

TPS-based method for determining motion-induced dose deterioration. **Conclusion:** DoseTracker accurately determined motion-induced dose-errors in real-time for a lower pelvic tumor site. This study demonstrates that clinical implementation of real-time motion-inclusive dose reconstruction with DoseTracker is feasible.

A Dilated Convolution Neural Network to Predict Three-Dimensional Dose Distribution in IMRT Treatment of Cervical Carcinoma

Y Yang, Z Yuan*, University of Science and Technology of China, Hefei, Anhui, CN

Purpose: To implement a method for precise three-dimensional(3D) dose prediction in intensity-modulated radiation therapy(IMRT) using a dilated convolution deep convolutional neural network(CNN). **Methods:** Seventy-seven cases of patients with cervical carcinoma were retrospectively selected. Sixty-six cases were chosen randomly as the training set and the remaining as the test set. A deep convolutional neural network model named Deep-ResUnet101 was trained to predict 3D dose distribution. First, the dose distributions and all contours were converted to 3D matrix and 3D binary matrix respectively using in-house developed python programs. Second, the contours and dose distributions at voxel-level were fed to the dilated neural network. The model was trained from scratch with weights randomly initialized. The trained deep convolutional network was used to predict 3D dose distributions, and the accuracy was evaluated against the corresponding clinical dose distribution. **Results:** Our results demonstrate that the dilated neural network could predict 3D dose distribution precisely. For 11 tested cases, there was no significant difference between the predicted dose volume histograms (DVH) parameter values and the clinical ones. The mean absolute max dose differences and the mean absolute mean dose differences for PTV and OARs are within 2.2% and 2.8%, and nearly all the dosimetric indices for PTVs and OARs are within 0.1%. The average dice similarity coefficient (DSC) of different isodose volumes was 0.94-1. **Conclusion:** This study developed a new dilated convolutional neural network for voxelized 3D dose prediction, which can precisely predict the 3D dose distribution for cervical carcinoma IMRT patients. The predicted 3D dose distribution could be used to improve the design of IMRT plan, ensure the plan quality and consistency, and guide automatic IMRT treatment planning.

PO-GePV-M-85

Plan Quality and Feasibility of Adaptive CBCT-Guided Prostate and Nodal Volume SBRT

E Laugeman*, A Price, M Prusator, L Henke, B Baumann, Washington University in St. Louis, St. Louis, MO

Purpose: To investigate the clinical feasibility of utilizing a commercial CBCT-guided adaptive radiotherapy system (Ethos) for adaptive SBRT to the prostate and elective pelvic nodes. **Methods:** A template of clinical goals was created in Ethos to deliver 40Gy to prostate (P), 36.25Gy to P and proximal seminal vesicles (P+psV), and 25Gy to the pelvic nodes in 5 fractions with 3 full VMAT arcs, automatically optimized with an Intelligent Optimization Engine (IOE). The template was applied to five high-risk prostate patients without modification to simulate adaptive sessions, since anatomy can change but changes to Ethos planning goals are not editable during on-couch adaptive sessions. Plans were evaluated against NRG-GU009 & GU-010 constraints. Secondary calculations with Mobius3D and 3D gamma comparisons (3%/2mm criteria, 10% threshold) were evaluated. **Results:** Prostate volumes ranged from 42cc to 135cc. Rectum and bladder volumes ranged from 35cc to 149cc and 206cc to 507cc, respectively. For all 5 patient plans, IOE produced a plan that met all strict OAR constraints. All other constraints were at least within acceptable variation. The mean V100%Rx was 96.1%, 95.9%, and 99.5% for PTV_4000, PTV_3625, and PTV_2500, respectively. The minimum coverage of all PTVs by prescription dose was 93.9%; PTV coverage was sacrificed when necessary to spare overlapping organs-at-risk. Mean rectum max dose was 3837cGy [range: 3658-3911] (<4120 constraint) and mean bladder max dose was 4183cGy [range: 4163-4228] (<4350 constraint). MU ratios ranged from 4.0 to 6.1 (mean 4.9). All 3D gamma values with Mobius 3D dose calculation were greater than 99.6%. **Conclusion:** Clinically acceptable SBRT plans to P+psV and pelvic nodes were generated and feasibility to successfully create adaptive plans was demonstrated. Patient-specific optimization of the template could improve plan quality with confidence in on-couch adaptive plan fidelity.

PO-GePV-M-86

Comparison of Online Adaptation and Offline Re-Planning for Head and Neck Intensity-Modulated Proton Therapy

M Bobic^{1,2*}, A Lalonde¹, K Nesteruk¹, H Lee¹, J Verburg¹, G Sharp¹, B Winey¹, A Lomax^{2,3}, H Paganetti¹, (1) Massachusetts General Hospital and Harvard Medical School, Boston, MA, (2) ETH Zurich, Zurich, CH, (3) Paul Scherrer Institute, Villigen, CH

Purpose: To compare daily online plan adaptation with offline treatment re-planning for head and neck intensity-modulated proton therapy (IMPT). **Methods:** IMPT treatment plans are created for a retrospective cohort of eight head and neck cancer patients with daily cone-beam CT (CBCT) images (median=33 fractions) and a re-scan CT acquired during the course of treatment due to large anatomy changes. Treatment plans are created based on the nominal planning CT. Dose tracking of the IMPT treatment is performed for three different delivery scenarios: re-planning with a 3 mm planning margin (Re-PTV), re-planning without margins (Re-CTV), and online adaptation without margins (OA). Both re-planning scenarios are realized by delivering the initial plan until the re-scan CT was acquired, at which point a completely new plan is created that fulfills the same clinical goals. For OA, the initial CT plan is adapted at each fraction using an in-house developed online adaptation workflow based on Monte Carlo dose calculations on scatter-corrected CBCTs. Plan adaptation is achieved by tuning the weights of a subset of beamlets without changing their energies or positions. Planning contours are propagated from the CT to each daily CBCT using deformable image registration. The same propagated contours are employed for dose tracking and accumulation throughout the treatment. **Results:** In terms of target coverage, OA outperformed both re-planning scenarios. For the low-risk CTV, the mean D₉₅ for individual fractions was 91.6%, 94.3%, and 98.4% of the prescribed dose for Re-CTV, Re-PTV, and OA, respectively. For the high-risk CTV, 97.0%, 98.2%, and 98.3% were acquired for the same metrics. In terms of OAR sparing, OA kept the dose comparable to Re-CTV while reducing the dose compared to Re-PTV. **Conclusion:** This study demonstrates the superiority of online IMPT plan adaptation over offline treatment re-planning in the context of target coverage and OAR sparing.

PO-GePV-M-87

Comparison of Target Coverage Between Adapted and Non-Adapted Treatment Plans for Prostate Radiation Therapy

I Gallagher*, J Riess, C Coughlin, I Chetty, A Kretzler, S Vance, B Movsas, Henry Ford Health System, Detroit, MI

Purpose: To evaluate target coverage differences between adapted and non-adapted treatment plans for patients receiving adaptive radiation therapy to their prostate and proximal seminal vesicles. **Methods:** The D95 of the target structure was recorded for each session for both the adapted and non-adapted plans. All treatments were delivered on a Varian Ethos. For each treatment session contours were generated to reflect the anatomy on that day, including the target structures. The daily change in volume from baseline for the PTV, rectum, and bladder was also recorded. **Results:** Of the first 204 sessions delivered to 6 different patients, the average PTV D95 of the adapted plans was 99.7% of the prescription dose while the scheduled plans had an average D95 of 88.4%. Additionally, 198 of the 204 sessions had superior target coverage with the adaptive plan over the scheduled plan. The 6 sessions in which the scheduled plan provided better coverage were all from the same patient. During these 6 sessions the bladder was, on average, 63cc smaller than at the time of simulation while the rectum was 33cc larger. Comparatively, the bladder was 24cc underfilled and the rectum 12cc larger, on average, during all other sessions for this patient.

During these 6 sessions the adapted plan respected all specified normal tissue limits while the non-adapted plan exceeded the rectum and/or bowel limits. **Conclusion:** While adapted plans offered better target coverage in approximately 97% of treatment sessions there were instances in which the system intentionally under-covered the target in order to respect normal tissue limits as a result of variable bladder and rectum filling. This underscores the need to maintain a reproducible setup despite having adaptive capabilities.

PO-GePV-M-88

Developing On-Table ART with Conventional LINACs - TrueBeam

T Kim*, E Laugeman, F Reynoso, N Knutson, P Szentivanyi, M Schmidt, Washington University School of Medicine, St Louis, MO

Purpose: X-ray guided conventional LINAC-based RT is widely available and capable for ART, but currently lacks the ability to perform on-table adaptive procedures including adaptive CT and contour generation, and adaptive planning. In this project, we proposed a procedure for on-table adaptive radiotherapy on conventional LINACs (e.g., TrueBeam). **Methods:** Proposed on-table ART procedure consisted of 1) adaptive CT generation based on daily CBCT, 2) contour generation and 3) adaptive planning. We utilized offline adaptive feature of Velocity to generate adaptive CT and contours deformed from the planning CT and contours based on daily CBCT. The adaptive CT was then pushed into the treatment planning system (TPS) database where a collection of in-house scripts copied the beam's geometric parameters from the original plan and optimized dose for the adaptive CT using commercial KBP optimization. The feasibility of the proposed procedure was evaluated in terms of procedure time after daily CBCT and quality of three plans (prediction dose and two adaptive doses). **Results:** CTs and structures of head & neck cases were successfully generated based on daily CBCTs within 12 minutes. In addition to the predicted dose and two adaptive dose calculations within 5 minutes, the adaptive plan can be ready for delivery within 20 minutes. **Conclusion:** We demonstrated the clinical feasibility of on-table ART with conventional LINAC using a combined commercial solution with in-house planning scripts. The proposed approach can inspire on-table ART with conventional LINACs in community clinics.

PO-GePV-M-89

A Dosimetric Comparison of Stereotactic Body Radiation Therapy Delivery Techniques for Lung Cancer: Adaptive Versus Conventional

C Ding*, A Godley, K Westover, R Timmerman, J Park, The University of Texas Southwestern Medical Ctr, Indianapolis, IN

Purpose: To compare dosimetric effect of stereotactic body radiation therapy (SBRT) using adaptive and conventional techniques on the Ethos system. **Methods:** A comparison for a stage T3N0 lung cancer patient is presented. This patient was originally treated on a linac using SBRT with a prescription dose of 50Gy in 5 fractions covering at least 95% of PTV. Cone beam CT (CBCT) was performed to setup the patient each fraction. Retrospectively, an SBRT plan with the same dose prescription and similar target and normal tissue constraints was generated using the Ethos planning system (Varian, Palo Alto). Simulated dose deliveries were performed using the Ethos emulator based on the CBCTs of each clinical treatment. Two treatment delivery schemes were compared, Conventional: five regular treatments using the initial plan, Adaptive: five treatments adapted by Ethos to match the target on the clinical CBCTs. Delivered dose was deformed back to the planning CT to compare the distributions on target and normal tissue for these two schemes. **Results:** The PTV volume and shape changed during the 5 fractions SBRT treatment process. The volume started at 120.3cm³, which is close to the planning CT volume of 121.4cm³, then increased to 134.9cm³ at the second fraction, and dropped to 84.8cm³ at the fifth fraction. The delivered PTV coverage of prescription dose is 92.9% for adaptive delivery and 88.1% for conventional delivery. The lung receiving 12.5Gy or more is 121cm³ for both delivery schemes. The maximum dose to heart is 54.4Gy and 55.5Gy for adaptive and conventional delivery scheme respectively. **Conclusion:** The adaptive dose delivery managed to maintain planning target coverage, while keeping equivalent normal tissue sparing to the conventional dose delivery.

PO-GePV-M-90

Impact of Dynamic Intrafraction Air Cavity Changes During MR-Guided Adaptive Radiation Therapy for Abdominal Tumors

X Chen*, E Paulson, E Ahunbay, E Omari, W Hall, B Erickson, X Li, Medical College of Wisconsin, Milwaukee, WI

Purpose: The intrafraction anatomic change, especially the air cavity variability in the abdominal region, can be severe which can affect the accuracy of MR-guided adaptive radiation therapy (MRgART). The purpose of this study is to accurately quantify the intrafraction abdominal air cavity change using a dedicated MRI sequence and to study its dosimetric effect on MRgART. **Methods:** Abdominal air pockets were imaged using a dedicated, free-breathing air scan MRI sequence (3D FLASH, 1 msec echo time, 9 second scan time). A total of 21 air scans were acquired during pre-treatment imaging study sessions for 5 pancreatic cancer patients, each with 4 or 5 air scans separated by 2-5 minutes. Changes in all air cavities compared to the first air scan for each patient were quantified using the Dice similarity coefficient (DSC). An adaptive plan was generated on the first air scan and was re-calculated on subsequent air scans with the same beam settings. Changes of the dose to a 0.03cc volume (D0.03cc) for stomach, duodenum, colon and small bowel, and PTV coverage by 100% prescription (V100%) from the first air scan were calculated. **Results:** The volume of the air cavities ranged from 10cc to 50cc in the treatment field. Average DSC dropped to < 0.2 after 5 minutes. For two patients, the D0.03cc was increased by 15% to 20% in 2 to 5 minutes, while for the other three patients, the D0.03cc increment was < 4.7%. The PTV V100% dropped by 17% for one patient. **Conclusion:** Intrafraction changes in the position and shape abdominal air cavities during 20-25 minutes may be substantial, and can result in considerable dose increases to critical organs and/or decreases in target coverage. These data suggest the need for developing real-time adaptive planning solutions to account for dynamic intrafraction air cavities changes.

PO-GePV-M-91

Utilization of the QUART Phantom to Evaluate Imaging Stability of a CBCT-Based Online Adaptive Workflow

A Dare*, K Homann, M Morales Paliza, Vanderbilt University Medical Center, Nashville, TN

Purpose: To evaluate the quality of image sets within the Ethos adaptive treatment workflow (EATW) using a vendor-provided phantom. **Methods:** The QUART phantom (Varian GmbH, Switzerland) supplied with the Ethos linear accelerator is made of acrylic with a central module containing material inserts (air, Teflon, and polystyrene). The central module is sandwiched between two uniform background modules. Three image sets were used in the evaluation: planning CT (pCT), kV cone-beam-computed-tomography (CBCT) Head-iCBCT protocol scan taken during EATW, and synthetic CT (sCT) created using deformable registration of pCT and CBCT during EATW. The image quality tests of focus were CT Hounsfield Unit (HU) constancy, uniformity, and noise. HU constancy was tested by comparing average HU values in inserts on the center slice to pCT in corresponding regions of interest (ROIs). Uniformity was computed using maximum absolute HU difference of the mean HU in ROIs drawn in each cardinal direction and the center. Noise was taken as the maximum standard deviation from the uniformity ROIs, and SNR and CNR values were computed following the methodology described by the vendor. **Results:** In comparison with the pCT, the maximum HU difference was 46.9±44.4 HU for the CBCT and 0.48±17.4 HU for the sCT. The uniformity value was 4.3±18.4 HU for the pCT, 33.4±34.7 HU for the CBCT, and 4.5±18.6 HU for the sCT. The noise was 14.0 HU for the pCT, 31.2 HU for the CBCT, and 14.4 HU for the sCT. **Conclusion:** Across the tests performed, a consistent trend was observed that showed a recovery of the pCT image quality in the sCT. This comparability to pCT is important because the sCT is used for contouring, plan optimization, and dose calculation within the EATW. Future work includes an automated analysis quality assurance solution to incorporate a more comprehensive set of image quality tests.

PO-GePV-M-92

Evaluation of Online Planning Strategies for CBCT-Based Adaptive Radiotherapy for Locally Advanced Lung Cancer

J Kim*, W Mao, I Gallagher, J Riess, S Vance, B Movsas, J Chetty, A Kretzler, Henry Ford Health System, Detroit, MI

Purpose: For patients with locally-advanced lung cancer treated with fractionated RT (60-66 Gy), toxicities, such as radiation pneumonitis, are driven by volume-effect dose indices (e.g. V20). If, during ART, daily lung volumes are aligned to the reference CT, it is unlikely that a significant reduction in V20 or mean-lung-dose (MLD) will be realized since large discrepancies will require mismatch of large volumes of lung. Here, we investigated strategies beyond those used traditionally to minimize OAR dose to understand the potential benefit of daily ART. **Methods:** Retrospective data were evaluated from 10 locally-advanced, NSCLC patients previously treated on the Varian Halcyon. Adaptive workflow simulation was performed using an Ethos emulator on a virtual machine. Patients were originally planned using target and OAR criteria outlined in RTOG 1106. Separate plans were calculated for a set of pre-defined treatment geometries (IMRT or VMAT). Planning strategies compared in this study included use of standard RTOG 1106 optimization constraints (OPT_S) alone, and combined with ipsilateral lung constraints (OPT_IL) and ring constraints (OPT_RING). Plans were adapted for every fraction. **Results:** Target coverage was maintained within RTOG 1106 constraints. Reduction of $1.11 \pm 0.78\%$ ($p=0.03$) and $0.26 \pm 0.13\text{Gy}$ ($p=0.01$) was observed in V20 and MLD, respectively for OPT_IL relative to OPT_S. Corresponding reduction for OPT_RING was $0.45 \pm 0.54\%$ ($p=0.03$) and $0.14 \pm 0.19\text{Gy}$ ($p=0.05$) relative to OPT_S. One patient exceeded the V20 constraint for OPT_S but met constraints when using OPT_IL. Relative to OPT_S, significant but minor improvement was observed in heart V30 and V50 ($0.65 \pm 0.57\%$ ($p=0.01$) and $0.46 \pm 0.55\%$ ($p=0.03$), respectively) for OPT_RING and in esophagus D2cc ($-0.31 \pm 0.25\text{Gy}$, $p=0.05$) for OPT_IL. **Conclusion:** Results suggest that a planning strategy incorporating ipsilateral lung constraints may offer the best option for sparing normal lung tissue doses and glean the most benefit from daily ART for patients with locally advanced lung cancers.

Necessity of Plan Adaptation in Stereotactic MR-Guided Online Adaptive Radiotherapy

C L Williams*, Z Han, M Huynh, J E Leeman, L Singer, D N Cagney, R H Mak, E Huynh, Brigham & Women's Hospital and Dana-Farber Cancer Institute, Boston, MA

Purpose: Stereotactic MR-guided online adaptive radiotherapy (SMART) is a rapidly emerging technique in which new treatment plans are generated based on a patient's anatomy at each fraction. However, this process can also be time and resource intensive. The goal of this study is to determine which disease sites are most likely to meet criteria for the use of adaptive techniques. **Methods:** A total of 230 patients were treated with 5-fraction (or fewer) SMART treatments on MR-guided linear accelerator at our institution (1145 total fractions) between October 2019 and February 2021. At each fraction, the patient's anatomy was re-contoured by a physician and a treatment plan was re-calculated on the current anatomy to predict the dose that would have been delivered without adaptation. This prediction was compared to pre-specified prescription metrics, and adaptation was determined to be necessary if any critical organ at risk (OAR) metrics were exceeded, or if the target coverage was unacceptable. Patients were categorized by disease site (kidney/adrenal, liver, lymphoma, oligometastatic nodes, pancreas, prostate, spine and thoracic), and the timing of each adaptive fraction was recorded. **Results:** A total of 1038 of 1145 fractions (90.7%) showed indication for adaptation, with 734 due to OAR metrics being exceeded (64.1%) and 304 due to suboptimal target coverage (26.6%). The sites with the highest proportion of fractions meeting adaptive criteria were prostate (85/85, 100%) and pancreas (310/323, 96.0%), whereas the sites that least frequently met the criteria were kidney/adrenal (71/94, 75.5%) and oligometastatic nodes (345/395, 87.3%). The median time for plan adaptation was 31 minutes (range 11-68). **Conclusion:** There was a clinical benefit to plan adaptation for the majority of patients and fractions. However, adaptive need varied by disease site, with pancreas and prostate SBRT patients most likely to meet adaptive criteria.

AI-Based Online Adaptive Radiation Therapy for Lung Cancer Treatment

W Mao*, J Riess, J Kim, S Vance, P Parikh, H Li, B Zhao, B Movsas, I Chetty, A Kretzker, Henry Ford Health System, Detroit, MI

Purpose: Retrospective studies were performed to evaluate the accuracy of Varian Ethos AI-based automatically mapped structures and dosimetric consequences of daily adaptive radiation therapy (ART) for lung cancer treatment. **Methods:** Ten locally advanced non-small cell lung cancer patients (prescribed by 2Gyx30) with 297 fractions of treatment were selected for this retrospective study on an Ethos research emulator. All patient data were copied and simulated twice: AutomaticART – automatic contours were utilized without modification with the fully automatic workflow and SupervisedART – automatic contours were modified manually by physicians. All daily structure sets and doses were exported for dose accumulation and further analysis. Dosimetric results of scheduled plan, AutomaticART, and SupervisedART were compared as ratios of relative reference plan results and grouped as lower constraints for target coverage and upper constraint for sensitive structures and hot spots of targets. **Results:** 290 (of 297) fractions were successfully analyzed. Comparing target volumes between AutomaticART and SupervisedART, Dice similarity coefficient was 0.93 ± 0.05 , mean contour distance was 1.5 ± 1.2 mm, and Hausdorff distance was 4.0 ± 2.3 mm. AutomaticART and SupervisedART significantly improved minimum doses of planning treatment volumes by 4.85 ± 3.03 Gy and 4.46 ± 8.99 Gy, respectively, with a maximum increase of 22.62 Gy for one patient. For analysis over daily results of 290 fractions of treatment, average target dose coverages were improved from 0.96 ± 0.04 (scheduled plan) to 1.00 ± 0.02 and 1.02 ± 0.04 and average upper dose/volume constraints were lowered from 1.01 ± 0.11 to 0.94 ± 0.10 and 0.93 ± 0.12 for AutomaticART and SupervisedART, respectively. For cumulative dose comparison over 10 patients, target dose coverages were improved from 0.98 ± 0.02 (scheduled plan) to 1.01 ± 0.03 and 1.01 ± 0.02 , and upper dose/volume constraints were lowered from 0.99 ± 0.03 to 0.96 ± 0.02 and 0.96 ± 0.02 for AutomaticART and SupervisedART, respectively. **Conclusion:** Accuracy of Ethos AI-based automatic contouring is generally acceptable. The online adaptive radiation therapy improves target coverage and spares sensitive structures.

PO-GePV-M-95

Intentional Deep Overfit Learning (IDOL): An Application to CBCT-Based Auto-Contouring

J Chun^{1*}, X Liang², M Lin², D Nguyen², Y Zhang², J Wang², S Jiang², J Kim^{1*}, J Park², (1) Department of Radiation Oncology, Yonsei University College of Medicine, Seoul, KR, (2) Medical Artificial Intelligence and Automation (MAIA) Laboratory, Department of Radiation Oncology, University of Texas Southwestern Medical Center, Dallas, TX

Purpose: In cone-beam CT (CBCT)-guided adaptive radiotherapy (ART), deep learning (DL)-based automatic organ-at-risk (OAR) delineation can be an important time saving that enables an online ART workflow. However, there remain several barriers to the effective implementation of these approaches in a clinical setting, including severe image artifacts in CBCT images that hinder the delineation of critical structures and the difficulty of curating a training data set consisting of consistent manual annotations. We propose here a patient-specific auto-contouring approach utilizing the Intentional Deep Overfit Learning

(IDOL) framework that demonstrates a significant improvement in contouring accuracy using only a few training data sets. **Methods:** IDOL-based auto-contouring is an application of intentional overfitting that leverages patient-specific prior information. Training in the IDOL framework involves two stages: 1) conventional training of a generalized segmentation model with a training set of 30 CBCTs and manual contours, and 2) using the planning CT and contours of a 31st patient as prior information, the generalized model is trained further to achieve the IDOL model that is applied to the CBCT of the 31st patient. For testing, step 2 was repeated for patients 31-39 using the same generalized model as a starting point. **Results:** The proposed method was evaluated on a cohort of 9 head and neck cancer patients. The generalized model (step 1 training only) achieved Dice similarity coefficients (DSC) of 0.80 and 0.64 for the larynx and esophagus, respectively. By adopting the personalized IDOL model in each test case, the DSC improved to 0.89 (+0.09) and 0.74 (+0.10) for the same structures, showing a significant improvement in contouring accuracy. **Conclusion:** In this study, we have successfully applied the IDOL framework to the CBCT auto-contouring task. Our approach is widely applicable to common tasks in radiotherapy and can be utilized for CBCT or MRI-guided ART.

PO-GePV-M-96

Development of a Quality Assurance Process for Dose Accumulation in a CT-Guided Online Adaptive Radiotherapy System

B Maraghechi*, D Lam, T Mazur, G Hugo, B Cai, Washington University School of Medicine, St. Louis, MO

Purpose: The Varian ETHOS system provides the ability to adapt treatment based on daily changes in patient anatomy and also allows for dose accumulation. In this study, we develop a simple approach for routine quality assurance (QA) of dose accumulation. **Methods:** An electron density phantom was chosen for QA due to its wide availability in clinics. The inner section of the electron density phantom consists of nine cylindrical inserts. On a CT scan of the phantom one GTV (insert at 6 o'clock) and seven OARs (other inserts) were contoured in the treatment planning system (TPS). Two adapted sessions were then performed in which the GTV was re-contoured first at 7 o'clock and second at 5 o'clock. The accumulated dose was exported from the ETHOS TPS after delivery. Deformable vector fields were also exported to manually accumulate dose for comparison. Two approaches were considered to evaluate the dose accumulation. First, the mean dose in each structure was manually retrieved from each session, and then summed for comparison with the TPS-reported accumulated mean dose. In addition, manually-obtained and TPS-generated accumulates dose volumes were compared by Gamma analysis (2%/2mm). **Results:** The mean dose differences in the GTV was 0.2% and in the OAR1-7 were 38.3%, 16.0%, 0.8%, 0.7%, 0.3%, 1.0%, and 1.5%, respectively between the manually-summed dose and ETHOS-generated accumulated dose. Gamma passing rate between accumulated dose volumes was 99.4%. **Conclusion:** This study demonstrated strong agreement between manually obtained accumulated dose and the ETHOS dose accumulation in terms of structure mean dose values for the target and most OARs) and 3D dose distributions. Observed disagreement in the OAR1 and OAR2 is under further investigation and likely stems from the fact that these transformations (e.g. permutations in position) are not physically realistic.

Washington University receives research support from Siemens, Varian Medical Systems, and ViewRay. GDH reports personal fees from Varian Medical Systems outside the scope of the present work.

Identification of Morphological Changes in Head-And-Neck Patients Through In-Beam PET Monitoring in Proton Therapy

A C Kraan^{1*}, A Berti², A Retico¹, G Battistoni³, P Cerello⁴, D Del Sarto², V Ferrero⁴, E Fiorina^{4,5}, F Laruina², E Mazzoni¹, M Morrocchi^{2,1}, F Pennazio⁴, V Rosso^{2,1}, G Sportelli^{2,1}, V Vitolo⁵, G Bisogni^{2,1}, (1) Istituto Nazionale di Fisica Nucleare, Sezione di Pisa, Pisa, Italy, (2) University Of Pisa, Pisa, Italy, (3) Istituto Nazionale di Fisica Nucleare, Sezione di Milano, Milano, Italy (4) Istituto Nazionale di Fisica Nucleare, Sezione di Torino, Torino, Italy (5) Centro Nazionale di Adroterapia Oncologica, Pavia, Italy

Purpose: In-beam Positron Emission Tomography (PET) can be used for in-vivo non-invasive treatment monitoring in proton therapy. Although this modality has been frequently applied, no straightforward method exists to translate the PET images into easy to interpret information for clinical personnel. The purpose of this work is to propose an innovative statistical method for analyzing in-beam PET monitoring images to locate possible morphological changes occurring over the course of treatment, and to quantify and easily visualize them. **Methods:** We investigated the impact of anatomical changes on the in-beam PET signal of a patient with Squamous Cell Carcinoma, that presented sinonasal cavity emptying during the course of treatment. For this purpose, we artificially created a set of CT scans with various volume changes of the cavity region and performed a vast amount of Monte Carlo simulations of a proton therapy treatment to model PET signal, using the characteristics of a dual head in-beam PET system. We performed voxel-wise two-tailed statistical tests, resembling the Voxel-Based Morphometry (VBM) method commonly used in neuroimaging data analyses, to locate regions with significant morphological changes. **Results:** The VBM resembling method could be applied to the simulated in-beam PET images, despite the image artifacts and limited statistics. Three-dimensional probability maps were obtained, that allowed to locate and quantify interfractional morphological changes. The characteristic color patterns resulting from the method is appropriate to trigger alarms if morphological changes occur along the course of treatment, resulting in an under- and/or overdose exposure. **Conclusion:** Our method is promising to apply to in-beam PET monitoring data. Using simulated PET monitoring images, we showed that the method allowed to correctly identify the regions that changed, and to quantify and visualize them in a straightforward manner. This new approach is promising and possibly brings us a step closer to dose reconstruction.

PO-GePV-M-98

Clinical Assessment of Patient Variations Between Treatment and Simulation in Breast Deep-Inhalation Breath Hold (DIBH) Using Optical Surface Imaging and On-Board 2D Radiography

I Yan, G Li*, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: To guide surface-guided radiotherapy (SGRT) setup for breast DIBH patients and determine if the simulation CT surface reference should be used or treatment surface reference is needed through a retrospective assessment of 28 patients' daily setup data of both SGRT and 2DkV in 25-fraction DIBH treatments. **Methods:** Twenty-eight left-sided breast cancer patients treated with DIBH in 25 fractions were studied retrospectively. These patients had locally advanced breast cancer and no previous RT. Volumetric-modulated arc therapy (VMAT) technique was applied, targeting both the breast and local lymph nodes, and both daily AlignRT surface imaging and 2DkV were prescribed to ensure the accuracy. AlignRT was first applied to match the body contours of free-breathing and DIBH CTs, and then 2DkV was used to align the anterior bones at DIBH for final adjustment and then capture a new on-site surface reference for DIBH gating. Therefore, setup differences between the 2 imaging modalities were recorded and the vertical shifts were compared for all patients and all fractions. It was hypothesized that patients who had no previous RT experience may need time to adapt and achieve a consistent DIBH, and therefore, they were likely to go through changes before settling down with consistency. To test this, the average of vertical shifts in first 5 fractions was compared to that of the remaining 20 fractions. **Results:** Among 28 patients, 14 patients' vertical setup shifts support the hypothesis: 8 patients have smaller mean shifts in the first 5 fractions than remaining fractions by at least 50% while 4 patients' data show the opposite. The remaining 14 patients' data show no significant difference. **Conclusion:** This study has demonstrated that 50% patients experience substantial difference between the first 5 fractions and remaining 20 fractions. This suggests that SGRT reference surface may need to update during DIBH treatment.

PO-GePV-M-99

Comparison of Three Setup Methods of Skin Marker Alignment Using Diamond-Shaped Light Field for Prone Breast EBRT

H Xu*, S Cheston, A Gopal, S Chen, B Zhang, S Lee, S Dudley, University of Maryland School of Medicine, Baltimore, MD

Purpose: For the positioning of prone breast patients treated with tangential fields, a diamond-shaped light field(DSLF) is used daily at our institution to align with a corresponding skin marker besides IGRT. This study compares three different DSLF setups used in several hospitals to help standardize/optimize the clinical workflow. **Methods:** Sixty-one prone breast patients with daily kV tangential IGRT following DSLF were retrospectively categorized into three groups according to their DSLF setups in different hospitals: 1) field size(FS)=10x10cm² at central axis with direct lateral gantry(=90 or 270°), 2)Same as 1) except FS= 4x4cm², and 3) FS=4x4-6x8cm² at off-axis with tangential gantry as treatment beam (so that DSLF is approximately at the breast center). All the kV-based couch shifts in vertical and longitudinal directions were analyzed. The DSLF-only dose distribution was simulated by reversely shift the couch (to exclude IGRT) from the CT plan, which was assumed equivalent to the delivered dose when both DSLF and IGRT are used for patient alignment. The simulated DSLF-only dose to the target and OAR structures throughout the treatment course were calculated. **Results:** The mean daily couch shifts following DSLF No.1, 2, 3 are 0.64, 0.68, 0.8cm with standard deviation of 0.4, 0.3, 0.6cm respectively. The average target dose ratios of DSLF-only to DSLF-and-IGRT are 0.99, 0.99, 1 for three setups. Most planning objectives are still achieved for DSLF-only scenarios. The DSLF-only dose values to heart, chest wall and lung increases from setup No.1 to 2 to 3. Generally, Setup No.1 appears to spare OARs the best, whereas setup No.3 results in greater target coverage, and setup No.2 is in between No.1 and No.3. **Conclusion:** In general, the three DSLF setups are similar but yield different tradeoffs between target coverage and OAR dose sparing when daily IGRT is lacking. Our finding may help select DSLF setup.

PO-GePV-M-100

Evaluating Impact of Target Location on Intrafraction Target Motion for Lung SBRT

D Lack^{1*}, D To¹, J Liang², M Liu¹, I Xhaferllari¹, C Stevens², I Grills², T Guerrero², D Yan², (1) Beaumont Health System, Troy, MI, (2) Beaumont Health System, Royal Oak, MI

Purpose: To assess the impact of anatomical target location on intrafraction target motion for SBRT lung treatments. **Methods:** 4DCBCTs from 89 SBRT lung patients treated between 2018-2019 were analyzed retrospectively. Patients were grouped based on target location (50 upper lobe (UL), 8 middle lobe (ML), 31 lower lobe (LL)). GTV defined at phase-0 of planning CT was propagated to phase images of pre-delivery (with couch correction applied) and post-delivery 4DCBCTs using deformable image registration (Elekta/Admire). Target centroid was used to calculate motion amplitude and mean target position (averaged over 10-phases). Differences in amplitude and mean target position between pre-delivery and post-delivery 4DCBCT was used to assess intrafraction motion variation (IFV). Results were compared to institutional PTV margins of 5mm (anteroposterior, mediolateral) and 6mm (craniocaudal) and statistical significance evaluated with ANOVA. **Results:** Absolute intrafraction target motion amplitude differences in mediolateral and anteroposterior directions was similar between lobes. In the craniocaudal direction, significant differences were seen ($p < 0.005$) between lobes, with mean $\pm$ sd [range] of 1.15 $\pm$ 1.21 [0.0-6.0]mm, 0.75 $\pm$ 0.63 [0.0-2.6]mm, and 0.57 $\pm$ 0.52 [0.0-2.7]mm for LL, ML and UL. Absolute mean target position differences were statistically significant in mediolateral ($p = 0.03$) and craniocaudal ($p < 0.005$) directions, while anteroposterior was not ($p = 0.09$). In the craniocaudal direction mean $\pm$ sd [range] differences were 2.00 $\pm$ 1.78 [0.01-13.13]mm, 1.56 $\pm$ 1.32 [0.06-4.79]mm, and 1.35 $\pm$ 1.44 [0.01-8.77]mm for LL, ML, and UL. Comparison of mean target position differences to PTV margins found 0% of treatments had ≥ 5 mm difference in the mediolateral direction for all lobes, whereas 5.26%(LL), 3.13%(ML) and 0.42%(UL) had ≥ 5 mm difference in anteroposterior direction and 1.50%(LL), 0.0%(ML) and 1.26%(UL) had ≥ 6 mm difference in craniocaudal direction. **Conclusion:** Absolute IFV difference in target motion amplitude and mean target position were largest in the craniocaudal direction for LL lesions, with some lesions surpassing existing PTV margins. Further investigation is needed to determine the dosimetric impact of the IFV differences observed.

PO-GePV-M-101

Respiratory Traces Analysis in Left-Breast Irradiation with Deep Inspiration Breath Hold

M Langsen^{1,2*}, M Jermoumi^{2,3}, (1) Medical Physics Program, Jacobs School of Medicine and Biomedical Science, University at Buffalo (SUNY), Buffalo, NY, (2) Department of Radiation Oncology, Roswell Park Comprehensive Cancer Center, Buffalo, NY, (3) Department of Radiation Oncology, Jacobs School of Medicine & Biomedical Sciences, University at Buffalo (SUNY), Buffalo, NY

Purpose: The use of deep inspiration breath-hold (DIBH) for respiratory gating in radiotherapy targeting left-sided breast cancer has led to significant reduction of radiation dose to the heart and lungs. The aim of this study was to assess the DIBH respiratory traces. **Methods:** 45 left breast cancer patients with a mean age of 60.6 (SD 11.1) years were enrolled in this study. The patient was coached and asked to perform at least three breath-hold (BH). In total, 146 DIBH traces were acquired and collected during CT simulation using Varian Real-time Position Management (RPM) system. The DIBH respiratory traces stability and reproducibility within the gating window were assessed. The correlation between the DIBH stability/reproducibility and other parameters such as age, isocenter drift, and DIBH amplitude were analyzed. **Results:** The mean of DIBH stability and DIBH reproducibility were 0.4385 cm (SD 0.2233) and 0.3462 cm (SD 0.2905) respectively. 65% of patients had stability less than 0.5 cm and 80.0% of patients had reproducibility less than 0.5 cm. The difference between free-breathing and DIBH amplitude showed an average of 2.10 cm (SD 0.75). The optimal gating window was 0.70 cm (SD 0.52). The DIBH reproducibility showed significant correlation with isocenter drift ($r = 0.47$, $p = 0.0012$). Patients older than 60 years showed significant increased variability in DIBH stability ($F = 4.87$, $P = .0007$). **Conclusion:** We analyzed DIBH respiratory traces for left breast cancer patients, the optimal gating window was 0.7 cm. The range of 0 to 0.5 cm is advisable for DIBH reproducibility and stability. Additional coaching may be needed for patients older than 60 years. The finding of this work could be used as a metric tool to identify the potential candidate for the DIBH technique.

PO-GePV-M-102

Integrating Temporal Physical and Biological Dose Distribution Analysis in Imaged-Guided Hypofractionated Radiosurgery of High-Risk Brain Lesions

B Ziemer*, M Lafreniere, L Boretta, SE Braunstein, L Ma, University of California San Francisco Department of Radiation Oncology, San Francisco, CA

Purpose: High-risk brain lesions are large, located in eloquent brain region, and/or with aggressive histology. Online CBCT imaging guidance has primarily focused on daily patient setup without detailed analysis of dose accumulation effects along the full course of treatment. In this study, we aimed to develop a time series analysis approach by integrating temporal analysis with imaging guidance prior to the beam delivery for each treatment fraction in hypofractionated Gamma Knife radiosurgery of high-risk brain lesions. **Methods:** As a proof-of-concept, eight lesions (mean volume=17.4 $\pm$ 15.8 mL) from five patients treated to 30Gy in five fractions with online CBCT-guided hypofractionated SRS were retrospectively analyzed. CBCT scans were acquired at each fraction prior to delivery. 3D dose distributions were projected onto daily CBCT and compared to the planned treatment. The accumulated and biological equivalent dose over previously delivered treatment fractions were also computed to form a time series across all fractions. Comparison of 3D dose distribution against the original dose distributions for each treatment fraction was analyzed. **Results:** Examining the full treatment, a mean target dose deviation of -0.21Gy (-0.10Gy, -0.35Gy) was obtained averaging all cases/time points and represented an almost negligible deviation of <1.5% in target dosing. Further, a mean target EQD2 deviation of -0.42Gy (-0.2Gy, -0.7Gy) was also obtained, representing <3% deviation from the initial prescription. The largest dose deviation occurred with two lesions within 3cm. No systematic trend in the accumulated dose patterns was detected. **Conclusion:** Integrating temporal dose accumulation time series

analysis has been demonstrated for the first time to be best of our knowledge. Initial analysis on a small number of cases pointed to precision and robustness of CBCT image-guided hypofractionated SRS of high-risk intracranial targets. On-going analysis over a large number of cases treated across different modalities will lend more support to encouraging results already seen.

PO-GePV-M-103

Development of a Portable Body Surface Monitoring System Using Depth Camera

R Oshika^{1*}, S Mori², A Nomoto², Y Tachibana², K Yasui³, M Ichihara¹, S Kurata¹, N Hayashi³, (1)Graduate School of Health Sciences, Fujita Health University, Toyoake, Aichi, JP, (2)National Institute of Radiological Sciences, National Institutes of Quantum and Radiological Science and Technology, Inage, Chiba, JP(3)Fujita Health University, Tayoake, Aichi, JP

Purpose: Currently commercially available surface guided radiation therapy (SGRT) device is usually fixed on ceil or mounted on gantry. This has limited the lay-out and usability. On the other hand, a portable SGRT system allows SGRT to be performed from any camera angle and position. The purpose of this study is to develop a potable body surface monitoring system and to evaluate the system for clinical implementation. **Methods:** We developed a body surface monitoring system that was consisted of Kinect (Azure Kinect DK, Microsoft), which has RGB and depth camera, and software programmed by Python. Coordinate systems of our system and treatment room were aligned by the calibration using RGB images of chessboard. Depth map of the phantom captured by Kinect were converted into 3D point cloud. Finally, the phantom movement was calculated by the rigid registration using point-to-point iterative closest point (p2p-ICP) and point-to-plane ICP (p2pl-ICP) algorithms. The phantom movement were derived from the transformation matrix by two ICP algorithms. Positional detectability was evaluated using general head and neck phantom. The phantom was moved in the range of 10 to 20 mm in the x, y, and z directions, respectively, using the treatment couch (Imaging Couch, Brainlab). The detection accuracy was compared between two ICP algorithms. **Results:** As results of detectability evaluation, translational error of p2p-ICP was not satisfied the tolerance of 2 mm defined by AAPM TG-147 in 2 conditions. On the other hand, translational error of p2pl-ICP was satisfied the tolerance in all conditions. The largest error of p2p-ICP and p2pl-ICP were 2.8 mm in z direction and 1.4 mm in x direction, respectively. **Conclusion:** We developed the portable body surface monitoring system and evaluated the basic performance. These results show our system with p2pl-ICP algorithm has the potential for clinically implementation.

PO-GePV-M-104

Management of Urgent Sim-And-Treat Palliative Cases Via Halcyon KV-ICBCT Images

M Gei*, M Randall, D Pokhrel, University of Kentucky, Lexington, KY

Purpose: Halcyon O-ring Linac is equipped with large field of view (FOV) kV-CBCT imager for image-guided RT. 3D reconstruction potentially enables patient's CT simulation on Halcyon. We report the feasibility of using Halcyon's kV-iCBCT imaging for simulation in extenuation circumstances, e.g. CT simulator downtime. **Methods:** Halcyon's kV-iCBCT reconstruction algorithm was used to image RANDO body phantom for different palliative treatment sites and beam arrangements (whole brain RT, single-field c-spine, AP/PA thorax, 4-fields pelvis and 2-fields thigh). Pelvis iCBCT protocol was used regardless of treatment site due the available maximal FOV of 25cm in superior/inferior (S/I) and 50cm in right/left lateral (R/L) directions. Three-point BB's were placed on each phantom to replicate standard clinic workflow for isocenter-localization in treatment planning system (TPS). Palliative 3D-CRT treatment plans were created without heterogeneity correction in Eclipse TPS via AAA algorithm for a TrueBeam Linac for 6/18MV beams. Overall phantom set up and scanning time was <5min. Total MU/fraction and qualifiers of minimum/maximum point doses and V100 were used for plan evaluation. **Results:** In palliative care setting, all five RT plans for various treatment sites produced expected outcomes for total MU with 3D-CRT planning regardless of homogenous calculation. AP/PA thorax/mediastinum plan demonstrated slight increase in expected MU due to tissue-to-air heterogeneity within lung volumes that was not being accounted for in dose calculation, although it was clinically acceptable in the palliative setting. **Conclusion:** Halcyon's kV-iCBCT was tested for simulation of palliative patients. FOV enables full viewing to permit the use of treatment fields. Dose calculation without heterogeneity correction is reasonable in most or all palliative cases, with caution needed for beams passing through the lung. Generating an electron density curve for Halcyon kV-iCBCT is ongoing. Stitching multiple scans together (if needed) for >25 cm S/I anatomy is possible, and work in this area is underway.

PO-GePV-M-105

A Non-Image Based Mechanism to Detect Significant Patient Motion for a Frame-Based Radiosurgery Treatment Platform

J Brindle*, J Patrick, Z Saleh, Rhode Island Hospital / Warren Alpert Medical School of Brown University, Providence, RI

Purpose: Motion management is important while delivering high-dose radiation therapy. Image-based systems are often considered the gold standard; however some frame-based radiosurgery platforms lack the ability to perform imaging. This work assesses the ability of time-of-flight (ToF) distance sensors to monitor and detect gross patient motion in the absence of an image-based patient position verification system. **Methods:** Two low-cost distance sensors were assessed – VL53L1X and the TF MiniPlus. Both sensors operate on the time-of-flight (ToF) principle by emitting a laser beam and measuring its travel time to measure distance. Accuracy and precision were measured from 20cm to 90cm in 10cm increments. Fifteen readings were obtained at each position. The sensors were controlled by a microcontroller (Arduino Uno) and the readings were transferred to a computer through a serial port for further analysis. Additionally, both sensors were utilized in conjunction with a head phantom to assess stability over a 200s period and the ability to detect arbitrary movement induced by the operator. **Results:** The VL53L1X sensor produced more accurate results over the range of measurements performed while the TF MiniPlus produced more precise results. Over the measured range of distances, the TF MiniPlus sensor accuracy varied from 3% to 6% and the precision varied from 0.03% to 0.21%. The VL53L1X sensor accuracy varied by $\pm 2\%$ and the precision varied from 0.57% to 0.16%. When utilized with the head phantom, the sensors were able to detect an arbitrary induced movement of 5mm. **Conclusion:** These devices provide a mean to assess gross (> 4 mm) intrafraction patient motion in situations where image guidance or clear visual line of sight challenges may exist. This work serves as a proof of concept for industrial-grade sensors and/or multiple sensors which can be utilized to further reduce uncertainty and improve motion detection.

PO-GePV-M-106

A Case-Study Investigation of the Feasibility of PTV Expansion Reduction for Dose Escalation for Anal Cancer

A Yorke*, V Williams, E Kim, S Geneser, University of Washington Medical Center, Seattle, WA

Purpose: Several trials have investigated the impact of dose escalation on anal carcinoma and demonstrated increased colostomy-free survival. However, the high incident of treatment cessation due to acute toxicity may limit disease-free survival gains. ACCORD 03 and RTOG 0529 recommend PTV expansions of 3.0 and 3.5 cm, respectively. This study aims to assess the impact and feasibility of reducing these expansions. **Methods:** We assessed various PTV expansions (3.5, 3.0, 2.5, 2.0, and 1.5 cm) for a T3N1 locally advanced anal cancer patient treated with 54 Gy in 30 fractions. Daily CBCTs were registered to the planning CT using the treatment shift, and GTVs were contoured by a physician on each CBCT. GTV volumes ranging outside the PTVs were assessed and analyzed. **Results:** Daily GTVs remained well-within the 3.5 to 2.0 cm PTV expansions. GTVs were outside the 1.5 cm expansion PTV for 7 treatment days, with a maximum non-overlap volume of 1.1 cc and < 0.1 cc volume outside on two days. The patient's GTV volume on CBCT decreased markedly over the course of treatment, from 134.6 to 55.0 cc -- a reduction of 40.9%. **Conclusion:** In this case study, the daily GTVs remain well within the 2.0 cm expansion PTV with minimal volumes outside the 1.5 cm PTV expansion, indicating the feasibility to improve OAR sparing while retaining coverage. Given the 3.5 and 3.0 cm

PTV volumes are 1166.8 and 930.1 cc, respectively, compared with the initial planning GTV volume of 109.534.6 cc, the 2.0 cm PTV expansion resulting in 548.1 cc is reasonable. The GTV exhibited a substantial volume decrease, indicating it may be possible to monitor and safely further reduce the PTV expansion. This study demonstrates the feasibility of reducing PTV expansions for the purpose of anal cancer dose escalation.

PO-GePV-M-107

Target Motion Tracking with LLE-Based Features Using Surface Imaging Model

J Weng*, S Samant, University of Florida, Gainesville, FL

Purpose: We propose to identify the target location inside human body based on features acquired from simple surface imaging with 4DCT and LLE (Locally Linear Embedding). **Methods:** Our model is based on two 10-phase lung 4DCTs taken from the same patient within half-hour interval. We labeled targets in 4DCT, and then assigned 10 target positions initially corresponding to each phase of 4DCT. The first 4DCT is for training, and second is for testing. Firstly, a bounding box containing the anterior breast region of patient is contoured. Secondly, the outer skin surface of chest region is transformed into a mask, and the mask is extended into a single column vector with a high dimension. LLE (Locally Linear Embedding) is applied to generate features in lower 9-dimension space. Test images are also transformed into column vectors, embedded into lower dimension, and the corresponding distances are calculated between training and testing images based on features. **Results:** LLE is able to preserve the spatial relations of 4DCT from different phases to the lower dimension. LLE-based on features showed high correlation (0.9, p-value 10⁻⁴ in SI Direction) with target position. We also investigated location of target on the second 4DCT with LLE-based features. We achieved best result when the number of neighbors in LLE was 2, and the number of selected features was 2. There were approximately 2 position deviations (0.7cm) between prediction and the actual positions. **Conclusion:** LLE can estimate the location of target inside body with simple skin surface imaging during treatment. This could be used with surface tracking methods such as Align RT and C-Rad to reduce tracking uncertainties.

Fusion of Multi-Scale Feature Maps Improves Anisotropic Structure Detection from CT Images

Y Xie¹*, G Sharp², D Gierga³, T Hong⁴, T Bortfeld⁵, K Kang⁶, (1) Massachusetts General Hospital, Boston, MA, (6) Bio-tree System, Inc.

Purpose: Image guidance has been widely used in radiation therapy. Correctly identifying the bounding box that contains a region of interest (ROI), is an essential step in classical and deep learning image analysis. Unfortunately, not many anatomical structures have isotropic shapes. It is challenging to select feature maps from a single scale to detect an anisotropic structure. In this study, we improved our detection network architecture presented in AAPM2020 to achieve a better overall detection performance from CT images. **Methods:** We improved the network architecture by fusing the feature maps from multiple scales and letting data to decide how to combine them. To detect anisotropic shapes, this fusion was done independently in left-right, anterior-posterior and superior-inferior directions. We applied our network to two applications: 1) T12 detection for checking gross misalignments and 2) the prostate, bladder and rectum detection for adaptive therapy. The model of T12 detection was trained on thirty-five abdominal CT scans from the same imaging protocol and tested on fourteen CT scans. The model of the prostate, bladder and rectum detections was trained on thirty training CT data and tested on six testing datasets. In both applications, no test images were used during training. **Results:** Compared with the previous approach, our latest one reduces the box size uncertainty by 1/3 to 1/2; all mean box size errors are reduced, especially on T12 (11.07 mm to 5.33mm). The compromise of the center accuracy is negligible (<1mm). **Conclusion:** Our latest approach improves the reliability of accurately detecting structures with anisotropic shape in multiple sites for various applications. This can help to avoid major positioning errors in IGRT. Also the improved network demonstrated the ability to simultaneously detect multiple objects of a wide range of scales.

PO-GePV-M-109

X-Ray Imaging Practices in Radiation Therapy in the United States

S Gros¹*, W Small¹, C Martin², (1) Loyola University Chicago, Stritch School of Medicine, Department of Radiation Oncology, Maywood, IL, (2) University of Glasgow, Glasgow, GB

Purpose: To obtain a snapshot of X-ray imaging practices for Radiation Therapy (RT) in the United States. **Methods:** The ICRP TG-116 “Radiologic aspects of imaging in Radiation Therapy” developed a comprehensive survey to understand x-ray imaging practices in RT. Requests were sent to 72 physicists at US treatment centers. Responses were collected between August and October 2020. **Results:** Responses were received from 30 centers (57% were academic institutions) covering 143 linacs. The monthly patient loads (median:117 ranged between [20 – 380] patients per center. Reported imaging modalities for treatment planning include CT, MRI, PET, PET/CT, SPECT, angiograms, ultrasound, and optical systems. 92% of linacs are equipped with kV imaging, 70% of which are <10 years old. 80% of centers use IGRT for >75% patients, with planar kV-imaging and CBCT as standard modalities. All centers reported employing kV-CBCT routinely except for palliative patients. MV-MV pairs remain heavily used in public (tax-payer funded, not-for profit) centers and academic centers. The most frequently treated sites are lung, prostate and breast. The main imaging frequency is “daily” (>90%) except for breast (50% daily, 47% weekly, 3% T.I.W). Most cited reasons for optimizing imaging protocols were patient habitus and adjusting FOV to improve anatomical visualization. Reported imaging dose optimization methods included pediatric protocols for radiologic imaging, and employing Surface Guided RT (breast). Academic RT centers tend to spend more effort on imaging protocols optimization, facilitated by the easier access to local imaging physicists for consultation. Most centers perform monthly imaging QA, citing AAPM TG-142 as reference. However, only 63.3% of centers include imaging dose measurement as part of their QA protocols. **Conclusion:** IGRT has become the standard of care in the US. Most academic centers optimize their imaging protocols, but image quality is the main motivator rather than dose optimization, except for pediatric patients.

PO-GePV-M-110

Dosimetric Impact in Radiation Therapy When Using Dual-Energy CT Reconstructed Virtual Monoenergetic Images In Combination With Clinical Monoenergetic CT-Density Curves

B Broekhoven, W Godwin*, J Peng, D McDonald, M Maynard, K Fallon, G Owen, A Rapchak, Medical University of South Carolina, Charleston, SC

Purpose: The Dual Energy Monoenergetic Algorithm (DEMA) (Siemens AG) allows for the creation of virtual monoenergetic CT images (VMIs) from dual-energy CT (DECT) scans. VMI datasets produced for 40 keV through 150 keV were evaluated to determine the dosimetric impact associated with using a predetermined VMI dataset for radiation therapy treatment planning in concert with a standard 120 kVp CT-density curve. **Methods:** A Siemens SOMATOM Confidence RT Pro was used to scan an anthropomorphic phantom and a calibrated Gammex with materials ranging in density from 0.300 g cm⁻³ to 1.824 g cm⁻³. Scans were taken using a tube potential of 120 kVp. Additionally, two consecutive scans were collected for DECT with tube potentials of 80 and 140 kVp. 40 – 150 keV VMIs were created from the DECT scans. Mass density vs Hounsfield unit (HU) curves were analyzed for all Gammex scans. A VMAT treatment plan was created on the anthropomorphic phantom data sets and doses were computed and compared for the 80keV VMI and 120kVp scans. **Results:** The 80 keV VMIs agreed best with the standard 120 kVp CT-density curves. For mass densities ≤ 1.340 g cm⁻³, mean HU values differed by less than 5 HU. However, for mass densities ≥ 1.560 g cm⁻³, mean HU values differed by less than 35 HU. VMAT treatment plans computed on an anthropomorphic phantom demonstrated clinically equivalent dosimetry when computed on 80keV and 120kVp scans using a common CT-density curve. **Conclusion:** Dosimetric differences were found to be negligible when using an 80 keV VMI dataset for radiation therapy treatment planning with a standard 120 kVp CT-density curve.

It is feasible to implement DECT for clinical radiation therapy dose calculation while using a single common CT-density curve within a treatment planning system for all CT protocols.

PO-GePV-M-111

Liver Tumor Motion During SBRT with Different Motion Management and IGRT Strategies: A Systematic Review On Inter, Intra-Fraction and CT-Sim Motion

T Nano^{1*}, M Akkati¹, M Feng¹, M Milano², O Morin¹, M Sharma¹, (1) University of California, San Francisco, San Francisco, CA, (2) University of Rochester Medical Center

Purpose: There is large variability among clinics how ITV and PTV margins are defined for liver SBRT. In this work we evaluated via systematic review the inter, intra and CT-Sim/4DCT the liver motion during stereotactic body radiation treatment (SBRT) with various immobilization devices and image-guided radiation therapy (IGRT) techniques. **Methods:** PRISMA guidelines were followed for systematic review and meta-analysis. Studies reporting liver motion during SBRT, and using motion management techniques and IGRT were searched in PubMed and Embase databases. From an initial 533 studies published before July 2020 were identified; 43 met our selection criteria. The 43 studies were categorized into 29 free-breathing (FB; n=690 patients), 10 abdominal compression (AC; n=257 patients) and 4 breath-hold (BH; n=74 patients) studies. For each motion category, we recorded amplitude mean, standard deviation, range, systematic and random errors in superior-inferior (SI), left-right (LR) and anterior-posterior (AP) directions. Pooled weighted bubble-plots were generated on mean motion with 95% confidence interval in each direction and one-way ANOVA tests were performed on SI-LR, SI-AP and LR-AP directions. **Results:** For FB treatments, the pooled weighted mean and standard deviation in inter-fraction, intra-fraction and CT-Sim/4DCT motion (SI,LR,AP) were (4.8±4.0mm, 1.6±1.4mm, 2.3±2.6mm), (8.8±4.4mm, 4.6±2.6mm, 3.3±2.2mm) and (9.2±3.6mm, 1.9±1.5mm, 4.7±2.3mm), respectively. There was significantly higher intra-fraction motion in comparison to inter-fraction motion (p<0.01). For BH treatments, inter-fraction, intra-fraction and CT-Sim/4DCT motion were (1.0±7.0mm, 0.0±5.0mm, 1.0±3.0mm), (0.2±6.4mm, 0.4±4.1mm, 0.1±4.9mm) and (-0.1±1.2mm, 0.1±1.2mm, 0.1±1.3mm), respectively. For AC treatments, inter-fraction, intra-fraction and CT-Sim/4DCT motion were (-0.9mm, 0.1mm, 0.2mm), (1.0±1.2mm, 0.5±0.8mm, 0.7±0.7mm) and (6.7±4.0mm, 2.2±3.6mm, 3.1±2.7mm), respectively. **Conclusion:** The average inter- and intra-fraction liver motion during FB, BH and AC SBRT varies based on the motion management method. For FB treatment, significant motion necessitates use of an internal target volume and could be reduced with BH and AC. Further analysis will be presented on optimizing margin protocols.

PO-GePV-M-112

Evaluation of Larynx Displacements in Pre-Treatment CBCT Scans for a Population of Laryngeal Cancer Patients

A Antolak*, T Gray, N Woody, S Koyfman, P Xia, The Cleveland Clinic Foundation, Cleveland, OH

Purpose: The purpose of this work was to evaluate the daily alignment accuracy of pre-treatment cone-beam computed tomography (CBCT) scans for laryngeal cancer patients. **Methods:** CBCTs from the 1st, 11th, and 21st treatment fractions were exported to the MIM software package for 20 laryngeal cancer patients treated with VMAT. Each CBCT was rigidly registered to the treatment planning CT separately with respect to bony and soft tissue alignment. The displacement of the larynx was defined as the difference between the bony and soft tissue alignments, recorded for each of three orthogonal directions (right/left, anterior/posterior, and superior/inferior). In addition, the magnitude of the soft tissue-based registration shift from MIM was compared to the clinically recorded shifts from the patient's treatment to provide quality assurance (QA) of the therapist generated registration shifts. **Results:** The average larynx displacements in the R/L, A/P, and S/I directions were 0.0+/-1.0, -0.4+/-1.4, and 0.6+/-2.5 mm, respectively, with a maximum of 2.6, 5.5, and 8.9 mm. For each direction, 95% of all displacements were within 2.3, 3.0, and 5.8 mm. 4 out of the 20 patients recurred locally; however, there is no appearance of correlation of local recurrence with large larynx displacements (greater than 5 mm). When aligned to the larynx via soft tissue-based registration, the average difference between the registration performed in this work and the on-treatment applied registration shift based on soft tissue alignment was 1.1+/-1.2 mm, indicating excellent agreement with shifts generated during the patient's treatment. **Conclusion:** Despite being advised not to swallow during CBCT acquisition and during treatment, large S/I larynx displacements were observed, indicating the potential for swallowing to occur. In addition, the magnitude of the observed larynx displacements should be considered in the planning margin to account for potential swallowing during treatment.

PO-GePV-M-113

Dosimetric Validation of Surface Guided Patient Set-Up for Breast Radiotherapy

A Gopal*, G Lasio, B Zhang, H Xu, S Chen, S Mcavoy, C Decesaris, University of Maryland School of Medicine, Baltimore, MD

Purpose: To validate the dosimetric robustness of surface guided radiation therapy (SGRT) for breast radiotherapy using cone-beam CT (CBCT) dose calculations. **Methods:** A retrospective sample of 15 breast radiotherapy patients (40-50 Gy in 15-25 fractions) was selected for this analysis. All patients were set up using SGRT (VisionRT, London, UK) with weekly CBCT verification (chest wall alignment, 3DoF shifts, >75 CBCT datasets). The online matched CBCT images were imported into the treatment planning system (Raystation 8A) to compute CBCT fraction doses using a previously validated framework. Fraction doses with SGRT alone were simulated by repeating all CBCT dose calculations without any couch shifts. The differences between the doses calculated after CBCT and simulated SGRT alignments were evaluated to validate the dosimetric feasibility of using SGRT alone for setup. Observed trends between dose differences and CBCT shifts were assessed to determine minimum thresholds for CBCT shifts and SGRT monitoring. **Results:** The majority (>70%) of CBCT shifts were <5 mm. Minimal changes were observed between the CBCT and SGRT-aligned dose distributions (breast $\Delta D95 < 1\%$ for > 60% of fractions, < 3% for > 80% of fractions). **Conclusion:** The differences between the CBCT and SGRT-aligned doses increased with the magnitude of CBCT shifts and were minimal for small shifts (breast $\Delta D95 < 1\%$ for shifts <3 mm, <3% for shifts <5 mm), which supports the use of 3 mm thresholds for CBCT matching and SGRT monitoring. The use of SGRT alone was also found to be dosimetrically feasible for breast radiotherapy based on minimal degradation of delivered dose with SGRT alone (breast $D95 > 95\%$ or $\Delta D95 < 3\%$ for > 95% of fractions).

PO-GePV-M-114

Contrast Enhancement in Primary Oropharyngeal Tumors Through the Use of Split-Filter Dual Energy CT

M Lawless^{1*}, P Harari¹, A Burr¹, R Kimple¹, J Shah², J Miller¹, (1) University of Wisconsin-Madison, Madison, WI, (5) Siemens Healthineers, Cary, NC

Purpose: To investigate the ability of split-filter dual-energy computed tomography (DECT) to enhance oropharyngeal tumor contrast and contrast-to-noise ratio (CNR) for radiation therapy treatment planning. **Methods:** Split-filter DECT contrast enhanced images were acquired for twenty patients with oropharyngeal cancer. Virtual monoenergetic images (VMIs) were generated at energies of 40 keV and 50 keV and compared to virtual 120 kVp-equivalent images. Additional images were reconstructed with an iterative reconstruction technique (SAFIRE strength 3). Average contrast and contrast-to-noise ratios were calculated using ROIs placed in the gross-tumor volume (GTV) and the geniohyoid muscle. **Results:** The VMIs increased the average GTV contrast from 4.44±10.0 HU for the 120 kVp-equivalent image to 42.0±32.9 HU (p=1x10⁻⁶) and 25.6±22.3 (p=1x10⁻⁶) for the 40 keV and 50 keV images, respectively. The 40 keV and 50 keV VMIs also demonstrated an increase in noise by 93% (p=4x10⁻¹²) and 46% (p=4x10⁻¹¹), respectively, relative to the 120 kVp-equivalent image. The average CNR values increased from 0.54±1.16 for the 120 kVp-equivalent image to 2.51±1.88 (p=1x10⁻⁶) for the 40 keV image and 1.99±1.64 (p=3x10⁻⁷) for the 50 keV image. The iterative reconstruction algorithm decreased noise in the VMIs by 19% (p=2x10⁻⁷) and 23% (p=3x10⁻¹⁰), and improved

CNR by 26% ($p=5 \times 10^{-4}$) and 31% ($p=8 \times 10^{-5}$), in the 40 and 50 keV images, respectively. **Conclusion:** Primary oropharyngeal tumor contrast and CNR were significantly improved using VMIs reconstructed from the split-filter DECT technique, and the use of iterative reconstruction further improved the CNR by decreasing the noise in the image. This gain in tumor contrast has the potential to enable more accurate tumor vs normal tissue delineation for radiation therapy treatment planning.

PO-GePV-M-115

An Evaluation of Translational Set-Up Errors to Define An Institutional Protocol for Set-Up Margins in the Treatment of Cancer Cervix Using Image Guided Radiotherapy (IGRT)

G Rani, H Kaur*, J Ninan, P Chandrasenan, M Abdussameeh P, Artemis Hospitals, Gurugram, HRIN

Purpose: The primary aim of this study is to analyze the setup errors and thus defining an institutional protocol for the Clinical Target Volume(CTV) to Planning Target Volume(PTV) margins with three different methods in the patients of cancer cervix treated with Image Guided Radiotherapy(IGRT). **Methods:** A total of 37 patients with cancer cervix were selected for this retrospective study. Daily set-up errors were obtained by superimposing the planning CT as a reference image with the on-board Cone beam CT(CBCT) for each fraction delivered. The translational shifts in the Medio-Lateral(ML), Cranio-Caudal(CC), and Antero-Posterior(AP) directions given by CBCT were used for this study. Rotational shifts were found to be less than 0.1° and hence were not included. Further, these errors were analyzed to calculate systematic and random errors in each direction and the adequate CTV-PTV margins were estimated using Van Herk's, Stroom's, and ICRU 62 formulas. **Results:** Systematic errors were 0.13cm, 0.27cm and 0.14cm while random errors were 0.15cm, 0.43cm and 0.15cm in ML, CC and AP directions respectively. CTV to PTV margins calculated using Van- Herk's formula were 4.44mm in ML, 9.85mm in CC, and 4.48mm in AP directions. According to Stroom's formula, CTV-PTV margins were 3.77mm in ML, 8.48mm in CC, and 3.80mm in AP directions. Whereas based upon ICRU 62 formula CTV-PTV margins were 2.42mm in ML, 5.74mm in CC, and 2.43mm in AP directions. **Conclusion:** In order to maintain accuracy in the delivery of radiation, regular image verification is necessary. Although rigid immobilization is achieved, a significant variation in the day-to-day setup of patients still occurs. All the three formulas are satisfactory techniques for determining CTV to PTV margins. The suggested margins, based on the center's own experience, are calculated by the use of the Van Herk Formula.

PO-GePV-M-116

Head-To-Head Performance Comparison of Two Deep Learning Segmentation Algorithms for Radiotherapy Planning: A Study in Prostate

H Martinez^{1*}, B Rich², L Young³, F Yang², (1) Department of Biomedical Engineering, University Of Miami, Coral Gables, FL (2) Department Of Radiation Oncology, University Of Miami, Miami, FL (3) Department Of Radiation Oncology, University of Washington, Seattle, WA

Purpose: Deep learning (DL) based automated segmentation methods have demonstrated the potential to improve the radiotherapy (RT) treatment planning process by offering readily available, while consistent, anatomical contours. There is, however, a lack of knowledge of how reliable and valid these algorithms are for clinical use. This study aimed to evaluate performances of two marketed DL segmentation algorithms in a head-to-head study design. **Methods:** The algorithms being assessed included ProtégéAI (MIM Software Inc., Cleveland, OH) and AccuContour (Manteia Tech, Xiamen, China). Imaging data used consisted of CT simulation scans of 100 prostate cancer patients. The segmentation accuracy of each algorithm for prostate, bladder, femoral heads, rectum, and seminal vesicles was compared to the respective physician contour using metrics of Dice coefficient (DICE) and absolute volumetric difference (AVD) with differences being identified. **Results:** AccuContour significantly outperformed ProtégéAI in delineating bladder and right femoral head with mean DICE of 0.88 Vs. 0.74 (two-sided paired t-test; $p<0.001$) and 0.87 Vs. 0.82 ($p<0.001$) and mean AVD of 0.14 Vs. 0.25 ($p=0.007$) and 0.18 Vs. 0.36 ($p<0.001$); whereas the later excelled in delineating prostate and rectum with mean DICE of 0.83 Vs. 0.67 ($p<0.001$) and 0.83 Vs. 0.78 ($p<0.001$) and mean AVD of 0.17 Vs. 0.36 ($p<0.001$) and 0.13 Vs. 0.18 ($p=0.0149$). For seminal vesicle, ProtégéAI showed superior accuracy in terms of DICE (mean: 0.65 vs. 0.49; $p<0.001$) while no significant difference according to AVD (mean: 0.44 vs 0.54; $p=0.348$) in comparison to AccuContour. Regarding left femoral head, no significant difference was seen between the two algorithms regarding DICE (mean: 0.91 vs 0.90; $p=0.598$) or AVD (mean: 0.13 vs 0.10; $p=0.218$). **Conclusion:** Accuracy of DL-based segmentation varied based on algorithm and with anatomical location under evaluation. The findings from the current study indicate that caution should be exerted when implementing these algorithms into clinical workflow.

PO-GePV-M-117

Data-Driven Generation of CBCT-To-CT HU Mapping for Adaptive Radiotherapy in H&N Cancer

H Wang*, A Rea, J Xue, K Spuhler, T Qu, T Chen, D Barbee, K Hu, Department of Radiation Oncology, NYU Langone Health, New York University, New York, NY

Purpose: This study aims to develop a data-driven method to derive a patient-specific CBCT to CT HU mapping function and evaluate the method for dose calculation on CBCT in H&N cancer radiotherapy. **Methods:** Eleven patients receiving VMAT for oropharyngeal cancer in a dose de-escalation clinical trial were enrolled in this study. Daily CBCT and a mid-course CT for re-assessment were acquired. The study derived a CBCT-to-CT mapping from one pair of CT and its closest CBCT, and applied to CBCT in the other set for independent dose calculation evaluation. The mapping was created by spatially-constraint fuzzy c-mean clustering (FC) on (CBCT, CT) HU vectors in the regions of air, soft tissue and bone that were thresholded on CBCT. To generate pseudo-CT, the probabilities of a CBCT voxel belonging to subtypes were computed by clustering with the CBCT centroids, and a CT value was created from the CT centroids weighting with the probabilities. The methods of using a HU-density curve (HC) from Catphan phantom imaging and air-water-bone density assignment (DA) were also evaluated for CBCT-based dose calculations. Dose differences between the three methods and CT calculations were assessed. **Results:** Mean absolute differences of CT numbers in entire CBCT body of the patients are 110, 136 and 147 between FC, HC and DA method generated pseudo-CT and planning CTs, respectively. DVH differences between the three CBCT-based methods and CT calculated doses were within 3% for the PTV and related OARs. The percentage differences in parotid mean doses were $0.5 \pm 0.4\%$, $0.7 \pm 0.5\%$, $0.9 \pm 0.4\%$ for FC, HC, and DA methods, respectively. **Conclusion:** The fuzzy clustering on planning CT and 1st-day CBCT could generate a patient-specific CBCT-to-CT mapping for accurate dose calculation on patient CBCT in the subsequent fractions. The method may be used for CBCT-based daily dose assessment and adaptive replanning.

The work was supported partially by NIH grant UG3CA228699

PO-GePV-M-118

Quantitative Analysis of the Accuracy of CT to CBCT Deformable Image Registration for Contour Mapping for Prostate Cancer

R Schmidt*, N Dogan, J Ford, M Studenski, M Abramowitz, K Padgett, B Spieler, Y Xu, R Delgadillo, University of Miami, Miami, FL

Purpose: Deformable Image Registration (DIR) can automatically propagate planning CT (pCT) contours to daily cone-beam CT (CBCT) images to account for anatomical changes such as bladder and rectal filling. The accuracy of deformed contours depends on several factors, including DIR process, algorithm and image modality/quality. This study hypothesizes that auto-propagated prostate contours through the commercially available DIR applied to daily CBCT are sufficiently robust and accurate. **Methods:** 28 prostate cancer patients enrolled on an IRB-approved protocol, treated with VMAT and receiving daily CBCT images were selected. Following rigid registration shifts, the pCT was deformably registered to the daily CBCTs using an intensity-based DIR using a B-spline

algorithm to generate deformed (auto) prostate contours. Gold standard (reference) contours on CBCT images were manually drawn by an experienced radiation oncologist. DIR algorithm performance was evaluated by comparing the auto and manually-drawn prostate contours on daily CBCT images (1,010 fractions) via dice similarity (DSI), mean distance-to-agreement (MDA), change in center of mass position (Δ CM) and Jacobian. 42 radiomic texture features were extracted from both contours and there correlation was determined through Pearson's correlation (PCC) and Lin's concordance correlation (LCC). **Results:** The average DSI, MDA and Δ CM between the auto- and manually-drawn contours were found to be 0.90 ± 0.04 , 1.81 ± 0.47 mm and 2.17 ± 1.26 mm respectively. The average minimum and maximum of the Jacobian determinant were 0.77 ± 0.18 and 1.30 ± 0.23 respectively. 94.8% of all auto contours were within tolerance provided by TG-132. 34 radiomic texture features were robust to small changes in contours as seen through high PCC and LCC (>0.80), indicating that small contour differences do not significantly change the radiomic texture feature data. **Conclusion:** The use of small ROI improved the DIR accuracy for prostate contour propagation to be within tolerance recommendations of TG-132 and appears to be suitable for radiomic analysis and/or dose accumulation.

This work is supported by Varian Medical Systems. COI - honorarium from Varian.

PO-GePV-M-119

Improvement of MVCT Image Quality for Adaptive Helical Tomotherapy Using CycleGAN-Based Image Synthesis with Small Datasets

D Lee^{*1,3}, H Cho¹, Y Han^{2,3}, (1) Yonsei University, Wonju, KR, (2) Sungkyunkwan University, Seoul, KR (3) Samsung Medical Center, Seoul, KR

Purpose: Megavoltage computed tomography (MVCT) offers an opportunity for adaptive helical tomotherapy. However, high noise and a reduced contrast in the MVCT images resulted from a decrease in the imaging dose to patients limits the usability of MVCT. Therefore, we propose an algorithm to improve the image quality of MVCT with limited training data set. **Methods:** The proposed algorithm generates kilovoltage CT (kVCT)-like images from MVCT images using a deep learning-based image synthesis network. A total of 566 and 514 slices of CT images were prepared from 6 training and 5 test cases, respectively. Data augmentation using an affine transformation was used to produce the training data in order to overcome the lack of data diversity in the network training. The mean absolute error (MAE), root mean square error (RMSE), peak signal-to-noise ratio (PSNR), and structural similarity (SSIM) were used to quantify the correction accuracy of the images generated by the proposed algorithm. The proposed method was validated by comparing images generated with non-augmented datasets. **Results:** The average MAE, RMSE, PSNR, and SSIM values were 13.12 HU, 39.44 HU, 35.99 dB, and 0.96 in the proposed method, whereas the result with non-augmented data showed inferior outcomes (15.65 HU, 45.82 HU, 34.66 dB, 0.95). The voxel intensity of the image obtained by the proposed method also indicated similar distributions to those of the kVCT image. **Conclusion:** The proposed algorithm generates synthetic kVCT images from MVCT images using a deep learning network with small patient datasets. The image quality achieved by the proposed method was correspondingly improved to the level of a kVCT image while maintaining the anatomical structures of an MVCT image. With a further evaluation for clinical implementation, the proposed method can ensure an accurate treatment planning in adaptive radiation therapy.

Potential for Using Extracellular Volume Fraction Derived from Dual-Source DECT for Pancreatic Tumor Delineation

G Godfrey^{1*}, G Noid¹, J Shah², W Hall¹, B Erickson¹, X Li¹, (1) Medical College of Wisconsin, Milwaukee, WI, (2) Siemens Healthineers, Durham, NC

Purpose: Low extracellular volume fraction (ECVf) correlates with poor vasculature and possible necrosis in pancreatic adenocarcinoma. In this work we investigate the potential of using contrast enhanced dual-source dual-energy CT (DECT) to map out ECVf spatial distribution for pancreatic tumor delineation. **Methods:** Contrast enhanced DECT acquired using a dual-source DECT scanner (SOMATOM Drive, Siemens) at 80 and 140 kVp during standard radiotherapy (RT) simulation for one pancreatic cancer patient was analyzed. An ECVf map was generated from the low and high energy CT series acquired simultaneously during the late arterial contrast phase in the following steps: (1) calibrating DECT iodine contrast using a phantom with known iodine densities; (2) constructing the patient-specific iodine map based on the iodine calibration; and (3) computing the ECVf map using the patient-specific iodine map and the patient's hematocrit level measured on the day of simulation. A region of interest (ROI) of low ECVf was delineated using an ECVf threshold of 0 to 7% from the obtained ECVf map. The volume of the ECVf ROI was compared with the clinical gross tumor volume (GTV) using the Dice similarity coefficient (DSC), and the overlap of the corresponding contour pair of the GTV and ECVf ROI on each image slice was measured using distance to agreement (MDA) and Hausdorff distance (HD). **Results:** The low ECVf ROI reasonably correlated to the clinical GTV. The DSC, MDA and HD between the ECVf ROI and the clinical GTV were 0.6 ± 0.1 , 2.0 ± 1 mm, and 5.0 ± 0.8 mm, respectively. **Conclusion:** This work demonstrated the potential of using the extracellular volume fraction map, derived from contrast enhanced dual-source DECT, to help define the pancreatic GTV for RT planning. Further studies with more patient data are required to determine the sensitivity, specificity, and limitations of this ECVf technique.

Deep-Learning Based Auto-Classification of Anatomical Regions for IGRT Applications: Implementation and Explainability

J Cruz Bastida^{*}, S Li, E Pearson, H Al-Hallaq, The University of Chicago, Chicago, IL

Purpose: Anatomical classification from single x-ray projections could help automate the selection of scan and reconstruction parameters in cone-beam CT (CBCT) for image-guided radiotherapy (IGRT). Here, deep learning (DL) methods are used for classification and the results are interpreted with the aid of visual explainability tools. **Methods:** Projection data from 1055 patients with multiple CBCT scans were used to train and test a DL model. Each scan was manually classified into five categories using projections at 45° intervals: abdomen, head, neck, pelvis and thorax. The dataset was limited to no more than 2-10 scans per patient, such that anatomical classes were balanced. Data were distributed for training (75%), testing (12.5%), and evaluation (12.5%) with no overlap between patients among the 3 sets. A VGG-16 neural network (NN) with pre-trained weights (imageNET dataset) was used; NN weights were adjusted by re-training the model with projections of a given angle (0°, 90°, 180°, and 270°). The classification performance was quantified in terms of precision and accuracy. Gradient-weighted Class Activation Maps (Grad-CAM) were reviewed to identify strengths and limitations of the proposed DL model. **Results:** The highest performance was achieved using the anterior-posterior projection (90°), with 92% accuracy. Precision was high for head, neck and pelvis ($>97\%$) but low for abdomen and thorax (87% and 76%, respectively) classes. Thorax projections were commonly misclassified as abdomen, and vice versa. Manual review of Grad-CAM results suggested that abdomen/thorax misclassifications were due to either large or insufficient presence of lung tissue. For all other classes, Grad-CAM showed a clear emphasis on boney anatomical features (e.g., iliac crest, mandible). **Conclusion:** A DL model was proposed and validated for the auto-classification of anatomical regions from single x-ray projection images. By using Grad-CAM it was possible to identify possible sources of class confusion in order to improve future models.

Comparison of KV-CBCT Dose Measurement Techniques for Annual Linac QA

B Rudek, K Osterman*, J Xue, NYU Langone Health, New York, NY

Purpose: Modern linear accelerators (LINACs) are equipped with kV-imaging systems for 2D-images and 3D-cone-beam CT (CBCT). The delivered single kV-CBCT-dose is small compared to the treatment dose but can add up to a cumulative dose of 1-3% for multi-fraction courses according to TG180. Thus, TG142 recommends an annual assessment of the imaging dose. The purpose of this project was to review the current practice, compare approaches suggested in recent literature and standardize annual kV-CBCT dose measurements. **Methods:** Current institutional practice is to measure the CBCT dose with the 10cm-long RaySafe X2 pencil-ion-chamber inserted in the center position of a CIRS lung phantom. We introduced the PMMA-CTDI phantom in a satellite-location for all measurements. Dose was measured at 3/6/9/12 o'clock and center positions of a 32cm-wide CTDI phantom to determine max dose heterogeneity for a half-trajectory imaging protocol and at the 12 o'clock and center position of either the head or abdomen phantom for 11 protocols ranging from 80kVp/100mAs to 140kVp/1688mAs using the Raysafe X2, the Standard Imaging A101 pencil-ion-chamber, and the A12 Farmer-ion-chamber. Measurements were repeated with decreased kV-tube-collimator opening as suggested by Varian. **Results:** The dose discrepancy due to chamber position was largest between the 6 and 3 o'clock positions (10%) and the average was close to the peripheral measurement at 12 o'clock. All three detectors showed a linear dependency. Reducing CBCT beam collimation increased measurement complexity with only minimally improved agreement between measured and displayed CTDIw values. The standard deviation for dose measurements at different machines reduced from 22%/12% for the lung phantom to 7%/3% (max/mean) for the CTDI phantom. **Conclusion:** Dose measurements at 12 o'clock and center position of CTDI-phantom have been defined as our new standard using un-modified treatment imaging protocols; conversion factors for center-only or lung-phantom measurements have been provided.

PO-GePV-M-123

Abdominal 4DCT Image Quality/Visibility Between Iterative Model Reconstruction (IMR) and Iterative Reconstruction (iDose4)

S Shen*, R Sullivan, C Schneider, R Popple, R Jacob, University of Alabama Birmingham, Birmingham, AL

Purpose: IMR (Philips Healthcare) is widely used in diagnostic imaging. Use of IMR is not well documented in abdominal 4DCT for radiotherapy, where pixel counts are low. This study compared image quality and visibility between IMR and iDose4. **Methods:** A Gammex Model 467 tissue phantom was used for CT calibration. Contrast and resolution were evaluated using Philips QA CT phantom. Ten patients had 4DCT abdominal scans for treatment planning, with 160 mAs used for each phase image compared to 305 mAs used for conventional 3D imaging. Images were reconstructed using IMR and iDose4. The objective measurements included noise (pixel HU histogram), line profile crossing target (boundary gradient). Two independent observers provided subjective assessment on image quality and visibility for contouring target and organs. **Results:** For the tissue phantom, the mass density ranged 0 to 1.69 and HU ranged -1000 to 1170; the HU mean difference was -0.8 HU (STD 2.6 HU) between IMR(1) and iDose4(3). For the Philips QA phantom with multi plugs, HU ranged from 0 to 910 and, the HU mean difference was -0.9 HU (STD 0.8 HU) between IMR(1) and iDose4(3). There was no measurable difference in contrast and resolution using the Philips QA phantom, but IMR had less objective noise in rods and background compared to iDose4. For 4DCT in patients, there was no observable difference in target boundary gradient between IMR and iDose4. IMR had objective noise reduction (pixel histogram HU range) as much as 21% in targets and 29% in background tissue compared to that of iDose4. IMR had better image quality and visibility for contouring target and organ in all cases. **Conclusion:** For motion management in treatment planning, abdominal 4DCT has low pixel counts. We found IMR had better image quality and visibility when compared to that of iDose4.

PO-GePV-M-124

Comparison of CBCT Image Enhancement Using Patch-Based U-Net and GAN

Q Dou^{1*}, Q Chen², Y Rong³, X Feng⁴, (1) University of Virginia, Charlottesville, VA, (2) University of Kentucky, Lexington, KY, (3) Mayo Clinic Arizona, Phoenix, AZ, (4) Carina Medical LLC, Lexington, KY

Purpose: Cone-beam computed tomography (CBCT) is an important imaging method in current practice of adaptive radiation therapy (ART). However, the CBCT images suffer from the relatively poor image quality. In this study, we developed a pure image domain deep convolutional neural network (DCNN) based method to improve the CBCT image quality. **Methods:** Paired CBCT and standard CT from 50 head neck cancer patients were split into three sets: training (32), validation (8) and testing (10). Optimization in pre-processing and data quality control were applied to guarantee the quality of our training set. A 2D U-Net was used as our backbone network structure to perform CBCT enhancement. Experiments were conducted to validate the patch-based training strategy and investigate the optimal training patch size. In addition, combined L1 and conditional generative adversarial network (GAN) loss was applied to explore whether it could yield visually sharper images. The trained networks were finally applied to an external testing set to check their deployment performance. **Results:** The U-Net trained with a patch size of 128 × 128 achieved the best performance with the lowest mean absolute error of 34.78 HU (57.91 HU for input images) and the highest structural similarity of 0.8455 (0.7546 for input images). After fixing to the optimal patch size, the network trained with a combined L1 and conditional GAN loss was able to maintain a higher resolution, especially in the soft tissue regions. **Conclusion:** The proposed DCNN-based method can generate enhanced CBCT with significant quality improvement compared with input images. This potentially enables further CBCT applications in the ART workflow.

Characterization of Imaging Performance of a Novel Helical KVCT System for Use in Image-Guided and Adaptive Radiotherapy

R Tegtmeier*, W Ferris, J Bayouth, W Culberson, University of Wisconsin, Madison, WI

Purpose: To evaluate the imaging performance of a novel helical kVCT system, the Radixact ClearRT, for use in image-guided radiotherapy and dose calculation in adaptive radiotherapy and to compare this performance to existing systems used for these purposes. **Methods:** A commonly used CT image quality phantom was scanned across clinically-relevant acquisition modes for image quality characteristics including noise, uniformity, contrast, spatial resolution, and mean CT number and CT number linearity. These metrics were analyzed using ImageJ software and compared to those measured for the Radixact MVCT, TomoTherapy MVCT, Varian TrueBeam OBI CBCT, and the Siemens SOMATOM Definition Edge. Individual metric performance was compared relative to the image noise for each acquisition. **Results:** Similar noise levels were seen for ClearRT and Siemens, while noise for the other systems was 2-5 times higher on average. Uniformity was highest for Siemens. On average, ClearRT performed best for contrast, followed closely by Siemens and Varian. Spatial resolution was best for Varian, while ClearRT showed slightly worse resolution than Siemens and TomoTherapy. For CT number vs. electron density calibration curves for analogous protocols, ClearRT showed a similar linear fit to the Siemens system commonly used for dose calculation in planning images. Mean CT numbers were also similar for ClearRT and Siemens, especially for inserts mimicking fat and soft tissue. Scan times for Siemens were less than 20s and approximately 30-40s for ClearRT. Times for the other systems were 2-10 times higher on average. **Conclusion:** ClearRT performed well for metrics most important to IGRT – mainly contrast. For image characteristics most important to dose calculation - mean CT number and CT number linearity -

similar values were measured for ClearRT and Siemens. Thus, ClearRT appears capable of providing accurate images for adaptive treatments, which will be further evaluated with measurements on dose calculation accuracy.

PO-GePV-M-126

Estimation of Conversion Factors for CTDI_w Calculation in MVCBCT Acquisitions

M Myronakis^{1*}, M Jacobson^{2,3}, T Harris³, I Valencia Lozano^{2,3}, C Williams³, M Lehmann⁴, R Fueglistaller⁴, P Huber⁴, D Morf⁴, R Berbeco^{2,3}, (1), Heraklion, Crete, GR, (2) Dana Farber Cancer Institute, Natick, MA, (3) Brigham & Women's Hospital, Brookline, MA, (4) Varian Medical Systems, Baden, CH

Purpose: MVCBCT dosimetric performance using standardized dose indices can be used to optimize acquisition techniques in radiation therapy imaging. We propose a method to estimate CTDI_w for MVCBCT acquisitions directly from the delivered MU. This parameter will enable comparison with other x-ray based volumetric imaging (e.g. kVCBCT). **Methods:** An extended PMMA body phantom was modeled with a diameter and length of 32 cm and 30 cm, respectively. A 360-degree MVCBCT acquisition was simulated using the Varian MV imaging beam (2.5 MV) and field size equal to 26×26 cm² at isocenter. Correction factors for the large field size relative to the CTDI ion chamber length were calculated. Additional correction factors to account for dose distribution differences between MV and kV beams were calculated. The CTDI_w was calculated from the simulated dose distribution using the standard formula. A conversion coefficient to estimate CTDI_w from MU was derived. **Results:** Three-dimensional dose distributions were generated. Axial and radial dose profiles were produced to facilitate derivation of appropriate correction factors for center and peripheral CTDI locations. The correction factor for the wide field size was 2.45 for center and periphery. Correction factors for peripheral CTDI locations that fall outside the irradiated field ranged from 1.14 to 1.16. The conversion coefficient to estimate CTDI_w directly from delivered MU was equal to 0.212 cGy/MU. **Conclusion:** A method to directly estimate CTDI_w from delivered MU after an MVCBCT acquisition was proposed. The method relies on Monte Carlo simulations to produce correction factors for large field size and ion chamber location relative to the field size. The correction factors facilitate the derivation of conversion coefficients that allow direct calculation of CTDI_w from MU. The proposed method can be generalized for various field sizes and angles to provide a fast and reliable procedure for dose optimization of MVCBCT imaging techniques

PO-GePV-M-127

DeepDoseNet: A Deep Learning-Based Approach for 3D Dose Prediction

M H Soomro^{1*}, V Leandro Alves¹, H Nourzadeh², J Siebers¹, (1) University of Virginia Health System, Charlottesville, VA, (2) Thomas Jefferson University, Philadelphia, PA

Purpose: To develop an artificial intelligence—deep learning-based method for fully automated, accurate, and rapid prediction of optimized head-and-neck 3D dose distributions. **Methods:** The DeepDoseNet 3D dose prediction model is based on ResNet and Dilated DenseNet. The 340 head-and-neck datasets from the 2020 AAPM OpenKBP challenge were utilized, with 200 for training, 40 for validation, and 100 for testing. Structures include 56Gy, 63Gy, 70Gy PTVs, and brainstem, spinal cord, right parotid, left parotid, larynx, esophagus, and mandible OARs. Mean squared error (MSE) loss, mean absolute error (MAE) loss, and MAE plus domain-knowledge (DK)-based loss functions were investigated. Each model's performance was compared using a dose score, $\bar{S}(D)$, (mean absolute difference between ground truth and predicted 3D dose distributions) and a DVH score, $\bar{S}(DVH)$ (mean absolute difference between ground truth and predicted dose-volume metrics). **Results:** DeepDoseNet requires ~0.5 sec to predict the 3D dose distribution on NVIDIA Quadro RTX 8000 GPU with 48GB memory. The MAE+DK model had the lowest prediction error ($P < 0.0001$, Wilcoxon test) on validation and test datasets (validation: $\bar{S}(D)=2.3\text{Gy}$, $\bar{S}(DVH)=1.9\text{Gy}$; test: $\bar{S}(D)=2.0\text{Gy}$, $\bar{S}(DVH)=1.6\text{Gy}$) followed by the MAE model (validation: $\bar{S}(D)=3.6\text{Gy}$, $\bar{S}(DVH)=2.4\text{Gy}$; test: $\bar{S}(D)=3.5\text{Gy}$, $\bar{S}(DVH)=2.3\text{Gy}$). The MSE model had the highest prediction error (validation: $\bar{S}(D)=3.7\text{Gy}$, $\bar{S}(DVH)=3.2\text{Gy}$; test: $\bar{S}(D)=3.6\text{Gy}$, $\bar{S}(DVH)=3.0\text{Gy}$). **Conclusion:** The addition of the domain-knowledge reduced $\bar{S}(D)$ by ~60% and $\bar{S}(DVH)$ by ~70%. DeepDoseNet's optimized dose can be used to improve the efficiency of dose optimization algorithms by providing a good estimate of the final dose distribution. Because of DeepDoseNet's rapid and fully automated execution, it can be used in automated workflows to estimate the dosimetric relevance of delineated organs-at-risk (OARs).

A Case Study of the Effects of Bladder Filling for Treating Prostate and Nodes Using Online Adaptive Radiotherapy On Ethos

Y Hao*, B Baumann, L Henke, E Laugeman, A Price, D Yang, Washington University in St Louis, St Louis, MO

Purpose: In theory, image-guided online adaptive therapy (IGART) is a good choice for treating the prostate and the pelvic nodes by allowing the treatment plan to be adapted to account for daily changes in the OARs (bladder, rectum and bowel). However, present forms of the IGART process, including patient setup, imaging, contouring, reoptimizing, QA and re-imaging, have been shown to require 40-60minutes and bladder filling during this time could invalidate the potential dosimetric benefits offered by plan adaptation. The goal of this work is to evaluate the bladder-filling during IGART and its spatial effect on adjacent OARs. **Methods:** A single patient underwent twenty-five-CBCTs as part of 5-fraction-SBRT to the prostate and pelvic nodes. The first three-fractions of treatment were delivered without adaptation, and the last two were adapted based on daily CBCT. Additional CBCTs were acquired prior to each VMAT beam. The bladder and rectum were manually contoured on each CBCT. The relationship among the bladder volumes, the CBCT scan time, and the rectum anterior wall positions were studied. **Results:** Two out of three non-adapted fractions were delivered within a reasonable period (<15minutes). However, the patient's bladder filled quickly in all fractions (see supporting Fig.3), for example, from 200cc to 760cc in 50minutes. The patient had to discharge urine in 1 extended adaptive fraction (~70minutes). The position of the anterior rectal wall corresponded well with the bladder volume (Fig.4). The rectum anterior wall was pushed 1.9cm further posterior when the bladder was filled from 500cc to 900cc. **Conclusion:** In this study, bladder-filling was seen to affect the positioning of the rectum in a clinically meaningful way. For IGART to be effective, it is paramount to maximally reduce the total plan adaptation time, e.g. <20minutes, and carefully manage patients' liquid intake prior to treatment fractions to minimize intra-fraction bladder filling effects.

PO-GePV-M-129

Estimating Inconsistency in Deformable Image Registration-Based Dose Accumulation

K Kainz*, J Garcia Alvarez, H Zhong, A Tai, E Ahunbay, C Lawton, X Li, Medical College of Wisconsin, Milwaukee, WI

Purpose: To assess uncertainty in deformable image registration (DIR) based dose accumulation, we estimate the inverse consistency error (ICE) based on a DVH overlay method as applied to daily dose accumulation for prostate cancer cases. **Methods:** Dose accumulations of five fractions for ten prostate cancer cases treated with daily MVCT IGRT were performed by applying two commonly used DIR algorithms: a normalized correlation coefficient technique (NCC-DIR) and a free-form intensity-based registration (IB-DIR). Regions of interest (ROIs) included the PTV (prostate or prostate bed), bladder, and rectum. ICE was estimated using a DVH overlay technique, where a DIR applied between the plan CT and daily MVCT was used to forward-transfer the plan ROIs to the MVCT and inverse-transfer the daily dose to the plan CT. For the five summed daily doses, ICE was calculated as the weighted sum of the separation between the overlaid DVHs from the plan CT and daily MVCT for each fraction. **Results:** ICE for the PTV V(100%Rx) is similar for both algorithms, $1.6 \pm 1.6\%$ for IB-DIR and $1.2 \pm 0.6\%$ for NCC-DIR. For the bladder and rectum V(70%Rx), ICE is on average greater for IB-DIR (3.6% and 3.3%, respectively) than for NCC-

DIR (1.9% for both). Among all cases, the maximum value of ICE for PTV V(100%Rx) is 5.6% for IB-DIR and 2.1% for NCC-DIR; the maximum ICE for bladder V(70%Rx) was 6.3% for IB-DIR and 2.6% for NCC-DIR; and for rectum V(70%Rx) the maximum ICE was 6.3% for IB-DIR and 3.9% for NCC-DIR. **Conclusion:** We demonstrated that the inverse consistency error, a contributor to the overall uncertainty in DIR-based dose accumulation, can be estimated using the DVH overlay technique. The data obtained presently for prostate cancer cases indicate that caution should be exercised in using the dose accumulation for clinical decision making if ICE exceeds pre-defined thresholds.

PO-GePV-M-130

Accuracy of Pelvic CT-MR Deformable Image Registration: Comparison of Open-Source and Commercial Software

T Ishida*, N Kadoya, S Tanabe, H Ohashi, H Nemoto, S Dobashi, K Takeda, K Jingu, Tohoku University, Sendai, JP

Purpose: We evaluated the accuracy of deformable image registration (DIR) for the pelvic region between magnetic resonance (MR) and computed tomography (CT) images using two different software programs. **Methods:** This study used CT, T1-weighted (T1w) MR, and T2-weighted (T2w) MR images of the pelvic region of five male patients. DIRs were performed using Elastix, an open-source software, and Velocity AI, a commercial software. With Elastix, we used six patterns of cost functions with regularization weights $\lambda = 0.01, 0.1, 1, 10, 100$, and 200. For Velocity AI, we used a MR Corrected Deformable algorithm. The DIR accuracy was evaluated based on the Dice similarity coefficient (DSC) for prostate, bladder, rectum, and left and right femoral heads. **Results:** The mean DSCs from all structures in T1w images were 0.84 ± 0.08 (rigid, Elastix), 0.88 ± 0.05 (DIR, $\lambda = 0.1$), 0.86 ± 0.09 (DIR, $\lambda = 10$), 0.85 ± 0.08 (DIR, $\lambda = 200$), and 0.86 ± 0.07 (DIR, Velocity AI), respectively. For the T2w images, the mean DSCs were 0.85 ± 0.08 (rigid, Elastix), 0.85 ± 0.09 (DIR, $\lambda = 0.1$), 0.86 ± 0.09 (DIR, $\lambda = 10$), 0.85 ± 0.08 (DIR, $\lambda = 200$), and 0.85 ± 0.08 (DIR, Velocity AI), respectively. DIR accuracy in elastix was as good as Velocity AI when $\lambda = 0.1$ (10) between CT-T1w (CT-T2w) images. The λ at which the mean DSC was highest differed for each patient. **Conclusion:** The results suggested that DIR accuracy comparable to that of commercial DIR systems could be achieved by verifying the penalty weight for DIR between CT and MR images for each sequence and each facility.

This study was partially supported by the grant from the Japan Agency for Medical Research and Development.

PO-GePV-M-131

Estimation of Uncertainty in Deformable Image Registration Based Daily Dose Accumulation for Head and Neck Cancer

J Garcia Alvarez*, K Kainz, H Zhong, C Schultz, X Li, Medical College of Wisconsin, Milwaukee, WI

Purpose: Deformable image registration (DIR) based dose accumulation is essential for adaptive radiation therapy (ART) and can be subjective to errors. We accumulate daily doses based on DIR and estimate their uncertainties during RT for head and neck cancer (HNC). **Methods:** A commercial ART tool (PreciseART, Accuray, Inc.) was used to reconstruct daily doses and accumulate them via DIR for ten HNC patients treated with helical tomotherapy. The accuracy of dose accumulation was assessed through a consistency check that comprises: i) warping the structures defined in the planning kVCT to the daily MVCT, ii) mapping the dose calculated in the MVCT to the kVCT, iii) calculating and overlaying DVHs from both images. At a given volume level, the absolute difference between the doses computed in the DVH overlays was considered the leading uncertainty component of the assessed metric. By relating the evaluated dose/volume level in DVHs of both single fractions and cumulative distributions, daily uncertainties were propagated to estimate confidence intervals in the accumulated distribution. **Results:** Accumulated doses differed from planned values, e.g., the changes in PTV-D95%, larynx-D33%, esophagus-D50%, and ipsilateral parotid gland-D50% ranged from 97 to 101%, 90-111%, 63-106%, and 76-165%, respectively. For 87% of the regions-of-interest and metrics studied, uncertainties were less than 2% of the planned value, including all points of the PTV (D95%) and larynx (D33% and mean dose). For D50% in the esophagus and parotids, 24% of the points presented uncertainties from 3.5% to 5.5% of the accumulated dose; a maximum uncertainty of 20% was observed for the esophagus. **Conclusion:** The DIR-related dose reconstruction errors were estimated for HNC patients. Relative uncertainties can be greater than 5% for structures undergoing significant deformations during radiotherapy (around 20% volume change), e.g., the esophagus and parotids. In ART, both daily dose accumulation and its uncertainty should be considered.

PO-GePV-M-132

Improving Deformable Image Registration with Three Metrics for Postoperative Radiotherapy of Breast Cancer Patients

X Xie*, H Yan, J Dai, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Purpose: Deformable image registration (DIR) is increasingly used for target volume definition in radiotherapy. However, this kind of method is challenged by the situation of postoperative breast cancer patients due to the large deformations and non-correspondence caused by tumor resection and clip insertion. To deal with this situation, fiducials, region of interests (ROIs) and voxel intensities were jointly used for higher registration accuracy. **Methods:** Three metrics were combined to form the objective function of DIR algorithm. Fiducial-based metric minimizes the distance between 2 point sets with known correspondence. ROI-based metric utilized Kappa Statistic (KS) to maximize the overlap of corresponding ROIs. Intensity-based metric maximized mutual information (MI) between image intensities. Two sets of CT images before and after breast surgery were used for image registration. One set was the diagnostic CT image acquired before surgery, and another set was the planning CT image acquired after surgery for breast cancer radiotherapy. A total of 26 sets of CT images from 13 patients were collected retrospectively for the test. The registration accuracy of the proposed method was evaluated in terms of target registration error (TRE) and through visual assessment by the physician. **Results:** The difference of mean TRE between the proposed joint-metric method and the conventional intensity-based method was statistically significant for soft tissue (2.06 vs. 7.82, $P < 0.05$), rigid structure (3.02 vs. 3.34, $P < 0.05$) and boundary (3.70 vs. 6.93, $P < 0.05$). For visual assessment, the proposed method achieved better matching for soft tissue and boundary. **Conclusion:** The registration accuracy of the proposed method was higher than the conventional method based on the preliminary results. This method provides a feasible way for target volume definition in postoperative radiotherapy of breast cancer patients.

PO-GePV-M-133

Evaluation of Deformable Image Registration Accuracy for Liver Patients Using Contrast and Non-Contrast CT Images

C Allen^{1,2*}, A Yeo², N Hardcastle², R Franich¹, (1) RMIT University, Melbourne, Victoria, AU, (2) Peter MacCallum Cancer Centre, Melbourne, Victoria, AU

Purpose: Deformable image registration (DIR) facilitates cumulative dose estimation in re-irradiation of liver tumours. We quantify the accuracy of DIR in liver CT scans taken at multiple time points through use of contemporaneous intravenous contrast CTs. **Methods:** We selected patients who had undergone repeat courses of radiation therapy to liver tumours, who had contrast CTs (conCTs) acquired contemporaneously to non-contrast treatment planning CTs (non-ConCTs) for each course. Using VelocityAI (Varian Medical Systems, USA), rigid image registration (RIR) and DIR were performed between the two time-points based on either non-conCTs alone or conCTs alone. Deformable multipass (DMP), extended DMP (EDMP) and structure guided (SG) were evaluated. SG was based on liver contours or five random landmarks. Landmarks were identified on the conCTs and transferred to the contemporaneous nonConCTs via RIR and used to evaluate the accuracy of the RIR and DIR based on Target Registration Error (TRE). Landmarks used in SG registration were excluded from

TRE analysis of SG registration. **Results:** Mean RIR TRE was 5.8 mm for conCT and 6.0 mm for non-conCT registrations. The mean TRE was 3.9/6.0 mm for conCT/non-conCT, 4.3/5.9 mm for conCT/non-conCT for DMP and EDMP respectively. The mean TRE was 7.7/7.3 mm for conCT/non-conCT and 3.4/3.9 mm for conCT/non-conCT for SG based on liver contours or five landmarks respectively. **Conclusion:** SG DIR based on five landmarks achieved the lowest TRE, and SG DIR based on the liver contour the highest TRE. DIR based on contrast-CTs was more accurate than for non-contrast-CTs for DMP and EDMP DIR algorithms. For some landmarks, DIR increased the TRE compared to the RIR. Use of landmarks to guide the DIR improves accuracy of both contrast and non-contrast CT DIR.

Evaluation of Various Deformable Image Registration Algorithms for Abdomen Images with Biomechanically Modelled Deformations

Y Liu*, P Zhang, J Hong, G Mageras, W Lu, S Alam, J Deasy, L Cervino, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: Deformable image registration (DIR) is increasingly used in radiotherapy applications and provides basis for previous treatment evaluation and dose accumulation. We examine the accuracy of DIR algorithms available on commercial planning platforms and evaluate their clinical applicability for the abdominal site. **Methods:** Following the guideline of AAPM TG-132, we implemented a patient-specific QA process to evaluate the accuracy of DIR for the abdomen site using digital phantoms created via ImSimQA (Shrewsbury UK). To simulate the impact of respiratory motion, we deformed the planning CT image at the end of exhalation to the end of inhalation using the biomechanical model embedded in ImSimQA. Consequently, the respiratory deformations were transferred onto the GTV in pancreas in the abdominal region, and we obtained the deformation vector field (DVF) as ground truth. Subsequently, we exported the deformed CT to Eclipse and MiM, performed DIR, and derived DVF_Eclipse and DVF_MiM for evaluation. Quantitative differences between DVFs, such as mean, max, and the distribution were tabulated. Geometrically, dice coefficient between the DVF-propagated and ground truth tumor was calculated. We generated a comprehensive report to illustrate the performance for the patient of interest as QA record. **Results:** The biomechanical model-derived DVF covers an FOV from the mid lung to the inferiormost pancreas boundary, with displacements ranges from 0 to 6.8mm. Data analysis comparing DIRs using DVFs shows the mean $\pm$ standard deviation 3D discrepancy is 1.8 ± 0.8 mm for Eclipse, and -1.2 ± 0.9 mm for MIM, respectively. Discrepancies near the diaphragm are larger than the mid lung or the pancreas. MIM tends to underestimate while Eclipse tends to overestimate the effect of deformation. **Conclusion:** DIR performed by Eclipse and MIM are evaluated, with a realistic biomechanical model derived DVF serving as ground truth. Further investigations on the impact of DIRs on dose distribution for radiation therapy is warranted.

PO-GePV-M-135

Evaluation of Synthetic CT Images Generated by Deformable Image Registration of Outdated Planning CT to CBCT of Treatment Day

J Yoon*, I Yeo, University of Rochester, Rochester, NY

Purpose: Synthetic CT (sCT) generated by deformable image registration (DIR) of planning CT to CBCT was proposed for the delivered dose calculation in adaptive radiation therapy (ART). We aim to evaluate the registration accuracy when the acquisition times of the two images are different (patient anatomy has changed). **Methods:** A patient who had replanning CT in his abdomen due to significant weight loss during radiation treatment was chosen. Two sCT images were generated by deformable image registration (DIR) in Velocity using (1) initial planning CT ($\square$ sCT1) and (2) replanning CT ($\square$ sCT2), where planning CT images were deformed to CBCT that was taken on the same day of replanning CT. The DIR was performed using rigid and deformable multi pass option in the Velocity software system. After DIR, deformation vector and anatomical alignment were visually inspected. The deformed images were further analyzed for HU difference. **Results:** The magnitude of the difference between the two planning CT images was not fully realized between sCT1 and sCT2 due to the registration of initial CT to CBCT of a later day. A visual evaluation was satisfying except that the two sCT images showed a slight disagreement on external body contour and a more visible disagreement in the location of air in the internal organ. The two sCTs showed acceptable agreement in HU values as shown by the standard deviation of the HU difference of 54.5 HU centered around 0, across the entire voxels of the images. **Conclusion:** Using initial planning CT for sCT generation is acceptable when a patient's anatomy changes significantly in the abdomen. However, one should be aware of the possibility of losing the accuracy in the external outline and details of internal organs. Further dosimetry study is needed.

PO-GePV-M-136

Feasibility of Diagnostic Dose Fast-Helical Free Breathing CT Scan Protocol for Ventilation Measurement

M Lauria*, B Stiehl, L Naumann, A Santhanam, D O'Connell, K Singhrao, J Goldin, I Barjaktarevic, D Low, University of California, Los Angeles, Los Angeles, CA

Purpose: Free-Breathing Fast Helical CT (FBFHCT) has enabled physical modeling of the lungs, such as ventilation mapping and elastography, to guide radiation treatment planning. However, the nature of FBFHCT provides information useful for applications outside of radiation oncology, such as downstream modeling to guide surgery. To realize these applications, the dose must be reduced to the diagnostic range. The aim of this project is to assess the feasibility of diagnostic dose FBFHCT for ventilation measurements by quantifying the difference in measured ventilation between CT protocols matching radiation oncology and diagnostic dose levels. **Methods:** In this study, noise was injected into six 40mAs FBFHCT scans to simulate 20mAs images, correlating to total doses of 3.6mSv. The first image was arbitrarily selected to be the reference, and the other five were chosen based on simultaneous respiratory bellows signals that sufficiently sampled the range of breathing amplitudes, simulating prospective scanning. The images were registered to the reference image with the pTVreg algorithm. To assess the effect of the dose reduction on registration accuracy, the Jacobians and their fit to the breathing amplitudes (dJ/dA) were calculated for each voxel and compared between doses. **Results:** Among the patient datasets, the mean absolute difference in the voxel-specific Jacobians between 40mAs and 20mAs scan sets was 0.031. 86.8% of voxels had an absolute Jacobian difference of 0.05 or less. The mean difference in dJ/dA between doses was 0.04 Jacobian per breath, and 80.3% of voxels were within 0.05. **Conclusion:** We have measured the change in the Jacobians when reducing the image protocol dose to be acceptable, thus demonstrating that CTs in the diagnostic dose range can be used to correctly measure ventilation. This work opens the door to motion modeling, biomechanical modeling, and regional ventilation mapping outside of the radiotherapy domain.

PO-GePV-M-137

Usefulness of 4DCT-Based Elasticity Map for Function Preserving Liver Radiotherapy Treatment Planning

T Sera*, T Shiinoki, K Fujimoto, Y Yuasa, Y Kawazoe, H Tanaka, Yamaguchi UniversityUeJP

Purpose: Radiation-induced liver disease is the problem for liver radiotherapy. We have developed the 4DCT-based elasticity map and consider integrating the elasticity map into treatment planning. The purpose of this study is to evaluate the relationship between dosimetric metrics of functional liver based on the elasticity map and serum biomarkers of liver function. **Methods:** Twenty patients who underwent radiotherapy for liver were enrolled in this study. All patients were performed 4DCT scan for whole liver. Deformable image registration was performed using CT images at end-exhalation and end-inhalation and

deformable vector field (DVF) was acquired. Liver elasticity was calculated using DVF and finite element method. Functional liver regions were defined four categories using calculated liver elasticity (1) 5.00 kPa (2) 4.00 kPa (3) 2.93 kPa (4) whole liver. For all treatment planning, the prescribed dose was recalculated equivalent dose in 2 Gy fraction (EQD2). The relationships between dosimetric metrics (Mean, V5, V10, V20, V30Gy) for each functional liver, variation of aspartate aminotransferase to platelet ratio index (APRI) and fibrosis-4 index (FIB-4) were evaluated. **Results:** Functional liver regions could be classified based on the elasticity map. The mean functional liver volumes were 634.46, 274.77, and 120.00 cc for 5.00, 4.00 and 2.93 kPa, respectively. The means of the variation of APRI and FIB-4 were 0.49 and 2.85. For the anatomical liver region, all dosimetric parameters for functional liver were low or moderately correlated with APRI (R: 0.45-0.55) and FIB-4 (R: 0.36-0.54). For the functional liver region ≤ 2.93 kPa, all dosimetric parameters for functional liver were highly or moderately correlated with APRI (R: 0.66-0.81) and FIB-4 (R: 0.52-0.71). **Conclusion:** We have developed the loadmap to integrate the elasticity map based on the 4D-CT for radiotherapy treatment planning. That may be helpful for functional liver radiotherapy in clinical practice and deserves further analysis.

4DCT Based Ventilation Imaging Correlation to Pulmonary Function Test for SBRT Lung Patients

T Lin*, S Kumar, A Dayal, C Ma, Fox Chase Cancer Center, Philadelphia, PA

Purpose: Advances in early diagnosis in lung cancer have increased the interest in preserving post-radiotherapy lung function, especially with commonly used lung SBRT/SABR radiation treatment; therefore, lung function map is extra important for radiotherapy treatment planning. During treatment simulation for lung cancer radiation therapy, a CT scan with different phases/4DCT can be obtained for the evaluation of lung function. This project was to validate and utilize the new ventilation calculation prototype that Siemens provides in order to implement lung function sparing radiotherapy treatment planning. **Methods:** Patients with lung disease treated with SBRT (total 50-55Gy) at a single institution between 2011-2019 were retrospectively identified from a prospectively collected database. Pretreatment and post-treatment 10-phase 4DCT scans were included that are compatible with the Siemens E-Xamine software (Siemens Healthineers, Germany). We imported secondary data from these 4D scans to create a CT ventilation and aeration map using the E-Xamine software. The ventilation map calculated based on Hounsfield Unit changes with deformable registration was used in the E-Xamine. Pre-treatment CT with isodose levels, ventilation levels and tumor contours (GTV, ITV and PTV) and delivered doses (20Gy and 5Gy) were registered to post-treatment CT. The coefficient of ventilation (variance of the whole lung map) and lung V20 and V5 were correlated with pre and post pulmonary function test (PFT) results. **Results:** All 6 patients have pre/post PFTs within 5 months from the pre-treatment and post-treatment 4DCT scans. Relative changes in FEV1/FVC for V5Gy trended negatively with slope of -0.9 and r square value of 0.77. Relative changes in FVC for V20Gy trended positively with slope of 3.3 and r square = 0.61. **Conclusion:** E-Xamine calculated ventilation maps have a medium acceptable level respective to the PFT value changes.

PO-GePV-M-139

Multimodality Image Registration for Application in Brachytherapy Based On Automated Organ Segmentation

K Qing^{1*}, X Feng^{2,3}, S Glaser¹, W Watkins¹, D Du¹, Y Chen¹, C Han¹, J Liang¹, J Liu¹, B Liu³, Q Chen^{3,4}, A Liu¹, (1) City of Hope National Medical Center, Duarte, CA, (2) University of Virginia, Charlottesville, VA, (3) Carina Medical, Lexington, KY, (4) Rutgers Cancer Institute of New Jersey, New Brunswick, NJ, (5) University of Kentucky, Lexington, KY

Purpose: Treatment planning for modern brachytherapy requires imaging acquisitions such as computed tomography (CT) and magnetic resonance imaging (MRI). CT remains the first choice for treatment planning. MRI provides detailed information about treatment target delineation and soft tissue anatomy. Multimodality image registration is usually needed but often needs manual intervention. A novel automated multimodality image registration method based on automated organ segmentation is proposed and validated in this study, with the expectation to improve efficiency of treatment planning workflow for brachytherapy. **Methods:** CT and MRI images acquired on the same day from fourteen patients with locally advanced cervical cancer (stages IB3-III) treated with brachytherapy were used. A U-Net model was first trained to automatically segment the bladder in both CT and MRI. Data from eight patients were used for training, and data from the other six patients were used for validation. The Dice scores were used to evaluate segmentation accuracy. Rigid image registration was performed based on automated alignment of the contours. The average L2 differences between the translation vectors from the automatic registration and those from human were calculated to evaluate quality of registration. The proposed method was compared with conventional registration method based on mutual information provided by Advanced Normalization Tools (ANTs). **Results:** The Dice metrics for bladder segmentation in MRI and CT datasets were 0.89±0.04 and 0.80±0.06 respectively. Compared to ANTs using MRI and CT images directly (23.5±22.2mm, 3.5-52.3mm.), the U-Net-based registration significantly reduced the L2 distance error (5.9±4.0mm, 2.0-10.9mm) in the six testing patients against the ground truth. **Conclusion:** In this pilot study, a new multimodality image registration method based on automated organ segmentation is proposed and tested. Initial results showed a relatively high accuracy and robustness of this method with potential for future clinical applications.

A Study of 2D/3D with 3D/3D Registration Using KV/kV, KV/2.5X/6X

S Lin^{1*}, D Lovelock², S Lim², J Sillanpaa², D Wang², C Della-Biancia², S Berry², D Shasha^{1,2}, H Kuo^{1,2}, (1) Norwalk Hospital, Norwalk, CT, (2) Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: To validate the 2D/3D registrations by comparing the registration accuracy, image quality, and dose with the 3D/3D registrations. **Methods:** Cranial (CIRS STEEV) and body (BrainLab Pelvis) phantoms were used as an imaging target. Each phantom was placed near the treatment positions with deliberate small random translations and rotations. The 6D transformations were measured independently by seven techniques: 3D/3D match with CBCT, 2D/3D match with kV/kV on TrueBeam (kV/kV-T), kV/kV with ExacTrac (kV/kV-E), and kV/MV with four MV MU settings (2.5X-Hi, 2.5X-Lo, 6X-Hi, 6X-Lo). The 3D/3D registrations were used as the ground truth to evaluate the accuracy of the planar image group using 2D/3D registration. The difference between 3D/3D and 2D/3D was calculated and assessed with the Wilcoxon Rank-Sum Test (p-value<0.05). A Varian Las Vegas phantom was used to compare the image quality of different kV or MV to evaluate the impact of image quality at registration. 2 OSLD chips were placed at the surface, mid-plane, and exit of the phantoms to measure imaging doses. **Results:** From 23 measurements (cranial-11, body-12), the mean residual errors of each 2D/3D method in each translational and rotational dimension were small ($\leq 0.3\text{mm}/0.3^\circ$). kV/kV-E and kV-2.5X-Lo had the smallest standard deviations (SD) of 0.3mm/0.3° in all dimensions; kV/kV-T, kV-2.5X-Hi, and kV-6X-Hi showed SD of 0.5-0.7mm/0.3-0.5° at Lateral/Roll direction; kV-6X-Lo had the highest SD of 1mm/0.8° at Lateral/Roll direction. Compared to 3D/3D, 2D/3D registrations showed no significant difference (p-values: 0.13-1.00). 2.5X showed comparable contrast to kV. 6X contrast was worse than kV/2.5X. The maximum surface/mid-plane/exit doses (mGy) were 23.0/16.9/8.8, 24.8/28.9/19.7, 0.22/0.16/0.02, and 1.50/0.23/0.05 for 2.5X, 6X, 80/100kV-E, and 80/100kV-T, respectively. **Conclusion:** All 2D/3D registration methods in this study showed no significant difference to 3D/3D. 2.5X has comparable image quality to kV and lower doses than 6X. The MV imaging doses were 10 times higher than kV.

PO-GePV-M-141

Using Previously Registered CBCT Image to Facilitate Online HCT to CBCT Image Registration in Lung Stereotactic Body Radiation Therapy

J Liang*, D Yan, J Wloch, J Sliwinski, I Grills, C Stevens, T Guerrero, Q Liu, William Beaumont Hospital, Royal Oak, MI

Purpose: In our conventional image registration workflow, 4D-CBCT was directly registered to reference HCT using a dual registration approach in the Elekta XVI software. In this study, we proposed a new HCT-CBCT auto-registration strategy using previously registered CBCT as the reference image. **Methods:** From a previous CBCT session, the average 4D-CBCT was selected as CBCT0 and the registration vector of HCT-CBCT0 from clinician's registration was recorded as F0. In the new CBCT session, auto-registration was first performed between the new average 4D-CBCT (CBCT1) and CBCT0, and the registration vector of CBCT0-CBCT1 was recorded as F1. During this auto-registration step, the reference point in CBCT0 was shifted from its image center by F0, while the reference point in CBCT1 was kept at its original position. This operation would eliminate the uncertainty associated with rotation vectors. Combining F0 and F1 mathematically, the final registration matrix of HCT-CBCT1 was derived and 6 registration parameters were solved. The final registration parameters were compared with clinician's results (ground-truth) to evaluate its accuracy using a test dataset consisted of 32 challenging registration cases. **Results:** The uncertainty of the new auto-registration method was -0.1 ± 0.5 , -0.0 ± 1.0 and -0.2 ± 0.7 mm in 3 translational directions (lateral, longitudinal and vertical, respectively) and 0.0 ± 1.5 , 0.5 ± 1.7 and 0.5 ± 0.8 degree for rotations. Two patients (6.25%) had translational uncertainty >2 mm (max=2.5mm) and both occurred in the longitudinal direction. Meanwhile, the uncertainty of the conventional HCT-CBCT1 auto-registration was -0.4 ± 2.6 , -0.2 ± 7.4 , -1.4 ± 3.6 mm for translations and -0.3 ± 1.2 , 0.1 ± 1.5 and 0.0 ± 1.1 degree for rotations with eleven patients (34.4%) had translation uncertainty >2 mm (max=30mm) in at least one direction. Accuracy in translation was significantly improved with the new method while rotation accuracy stayed in the same order. **Conclusion:** By utilizing prior registration knowledge, the proposed auto-registration method provides a quick and reliable starting solution for online HCT-CBCT registration.

PO-GePV-M-142

Comparing Dose Summation Techniques for External Beam and LDR Brachytherapy for Combined Modality Prostate Cancer Treatment

A Cooney^{1,2*}, S To^{1,2}, D Guest², A Riegel^{1,2,3}, (1) Department of Radiation Medicine, Northwell Health, New Hyde Park, NY (2) Hofstra University, Hempstead, NY, (3) Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY

Purpose: To compare composite biological effective dose (BED) of prostate cancer patients from external beam radiation therapy (EBRT) and low dose rate (LDR) brachytherapy contributions through image-based rigid registration, fiducial-based rigid registration, b-spline deformable image registration (DIR), and dose volume histogram (DVH) parameter summing techniques. **Methods:** Ninety one (91) patients received intensity-modulated EBRT before ¹⁰³Pd-based LDR. Post-implant LDR plan CTs were registered to EBRT planning CTs via image-based rigid registration, fiducial-based rigid registration, and DIR. EBRT and LDR physical doses were converted to BED and summed via the 3 image registration techniques and scalar summation of select DVH parameters without registration. Results were compared to summed dose of 44 "control" patients whose post-implant and EBRT planning CTs were inherently registered via DICOM because they received LDR before EBRT. Prostate, urethra, bladder, and rectum dosimetric parameters were compared for statistically significant differences using ANOVA ($\alpha=0.05$). **Results:** Among the three image registration techniques, prostate D90 was higher for fiducial-based rigid registration (122.6 ± 19.6 GyBED) compared with image-based rigid and DIR (114.6 ± 18.4 GyBED, 116.1 ± 16.5 GyBED respectively), and all three were lower than the control group (130.1 ± 19.7 GyBED). Scalar summation of prostate D90 was significantly higher than all 3 image registration techniques and the control group (168.3 ± 17.2 GyBED), potentially due to interobserver variation in EBRT and LDR prostate contour. Composite urethra D10, rectum D2cc, and rectum D0.1cc from image-based rigid registration were significantly higher than the other registration techniques (3-7% for urethra, 16-20% for rectum D2cc, 26-30% for rectum D0.1cc.) **Conclusion:** Fiducial-based rigid registration and deformable registration yielded combined BED distributions that were closest (within 5-10%) to BED distributions from inherently-registered treatment plans. Scalar summation of DVH parameters may overestimate combined dosimetry, particularly with discrepancies in contour delineation between external beam and brachytherapy treatment plans.

PO-GePV-M-143

Evaluation of the Displacement of the Target Position Caused by Residual Setup Errors in Stereotactic Radiosurgery with Single-Isocenter Volumetric Modulated Arc Therapy for Multiple Brain Metastases

Y Tsuruta^{1,*}, M Nakamura², M Nakata¹, H Hirashima¹, D Zhou², T Fujimoto¹, K Takehana¹, M Uto¹, T Mizowaki¹, (1) Kyoto University Hospital, Kyoto-city, JP, (2) Kyoto University, Graduate School of Medicine, Kyoto, JP

Purpose: To evaluate the displacement of the target position caused by residual setup error (RSE) in stereotactic radiosurgery (SRS) with single-isocenter volumetric modulated arc therapy (SI-VMAT) for multiple brain metastases. **Methods:** A total number of 417 gross tumor volumes (GTVs) from 72 consecutive patients who underwent SRS with SI-VMAT between April 2017 and June 2019 were included. All patients were immobilized with a frameless mask. All treatment plans consisted of 3 or 5 arcs including non-coplanar arcs. Patient positioning was performed with ExacTrac X-ray system (ETX) (Brainlab) and a six-degree-of-freedom (6-DOF) robotic couch. Verification and correction of the patient position was performed until within tolerance values (0.7 mm/ 1.5°) for each arc. The RSEs were regarded as the values on the ETX obtained just before irradiation. The planned center positions of each GTV from treatment isocenter for all patients were calculated. Also, the distance between the planned center position of each GTV and treatment isocenter (d) was calculated. Then, the shifted center positions of each GTV caused by RSEs were calculated using in-house program. Finally, the distance between the planned center position and the shifted center position for all GTVs (Δd) was calculated, and the correlation of Δd and d was analyzed. **Results:** A total number of 7,270 shifted center positions were analyzed. All 1,185 RSEs were within the tolerance. The median of d was 49.5 mm (range: 4.9 – 95.0 mm). The frequency of Δd within 1 mm was 97.0%. No correlation was observed between Δd and d ($r=0.11$). The maximum value of Δd was 1.93 mm, which was observed in a tumor with d of 73.3 mm. **Conclusion:** The patient positioning with a frameless mask, ETX, and 6-DOF robotic couch is highly accurate in SRS with SI-VMAT for multiple brain metastases even when targets are far from treatment isocenter.

PO-GePV-M-144

A Quantitative Analysis of Lung Registration Error in a Clinically Used Deformable Image Registration Implementation Using Manually Identifiable Features in Fast Helical Free-Breathing CT Scans

L Naumann*, B Stiehl, M Lauria, K Singhrao, A Santhanam, D Low, University of California, Los Angeles, Los Angeles, CA

Purpose: Deformable image registration (DIR) of fast helical free-breathing CT (FBFHC) scans produces deformation vector fields (DVF) which describe the motion within the lung at the voxel level. The accuracy of these results are difficult to quantify and remain unverified. In this study, we aim to measure the error of a clinically used lung DIR implementation using identifiable landmark feature tracking. **Methods:** We developed a feature tracking algorithm of manually identified and selected structures within the deformably registered reference and target lung images. A set of 25 patient datasets (source-target image pair and associated DVFs) were retrospectively employed for this study. DVFs were generated using dense displacement sample (deeds) DIR. 50 manually identifiable structures were selected on each reference scan and the corresponding structures were then identified on the associated target scan. The algorithm accepts the input of a precise point (single voxel) on the identified feature selected by a user in the reference image. After displaying the corresponding deformed voxel location in accordance with the DVF, the algorithm accepts a true voxel location, which was selected based on the corresponding feature on the target image. The Euclidean distance and percent error between the deformed voxel location and the true voxel location was then calculated and reported by the

algorithm for each set of feature points. **Results:** The average distance/registration error measured across all features and datasets was 0.83mm (min: 0.28mm, max: 1.65mm, std: 0.37mm). The average percent error was observed to be 13.18% (min: 4.74%, max: 30.84%, std: 7.76%). **Conclusion:** This work employed a feature tracking tool to quantify the image registration accuracy of a clinically used DIR lung registration algorithm for FHFBC scans.

PO-GePV-M-145

A Method to Consider Dose Distribution and Dose Gradient in Evaluating Image Registration for Dose Accumulation

X Wu*, J Williamson, H Gach, H Li, D Yang, Washington University in St. Louis, St. Louis, MO

Purpose: Deformable dose-accumulation accuracy depends both on local spatial dose gradients of each treatment fraction and the accuracy of the underlying image registration. Conventional deformable registration evaluation methods focus only on the geometrical target registration error (TRE) without considering the dose-distribution characteristics. In this study, we propose a general procedure to incorporate dose distribution features in the registration evaluation process. It can support the selection of registration methods for patient-specific treatment planning and the estimation of dose accumulation uncertainty from the chosen registration methods. **Methods:** Our method generates a TRE tolerance map based on the dose distributions and the user-selected dose-error tolerance level in 4 steps: 1) Region of interest (ROI) are selected to excludes low-dose areas. 2) In a 15 mm radius neighborhood around each voxel in the ROI, the neighborhood voxels with doses that deviate from the center voxel dose by more than the dose-error tolerance (5% of the prescribed dose) are labeled. 3) For each voxel, the TRE tolerance vector is created that points to the nearest labelled voxel in its neighbor and has a magnitude equal to the distance between center and nearest labelled voxels. 4) The TRE tolerance map was composed by the TRE tolerance vectors for all voxels in the ROI. **Results:** We applied the proposed method to generate the dose-based TRE tolerance map for a SBRT case, and evaluated a Demons image registration method based on landmarks and the tolerance maps. The average landmark TRE was 2.7 mm and >90% of landmark pairs passed the TRE tolerance test. **Conclusion:** A procedure was developed to generate the dose-based TRE tolerance map, which could assist the selection of image registration method for subject-specific cases or the production of dose accumulation uncertainty from the registration methods.

The project described was partially supported by the Agency for Healthcare Research and Quality (AHRQ) grant number R01-HS022888, National Institute of Biomedical Imaging and Bioengineering (NIBIB) grant R03-EB028427 and National Heart, Lung, and Blood Institute (NHLBI) grant R01-HL148210.

PO-GePV-M-146

High-Resolution Spine Digital Reconstructed Radiograph (DRR) for Motion Tracking in Paraspinal Treatment

W Cai*, F Li, X He, P Zhang, X Li, T Li, Memorial Sloan Kettering Cancer Institute, New York, NY

Purpose: High quality DRR is essential to image-based motion tracking systems. In this work, we propose a method of creating high-resolution digital reconstructed radiograph (DRR) to facilitate image registration for a recently developed MV-KV imaging-based motion tracking system for paraspinal SBRT treatments. **Methods:** High-resolution spine-only DRRs were computed by incorporating planning CT information into high-resolution CBCT reconstructions. Varian's proprietary software iTools Reconstruction can reconstruct with an isotropic voxel size as small as 0.25mm, which is comparable to kV image resolution. A major challenge is to segment bones from CBCT because of its high noise level and numerous artifacts. Our strategy is to create a binary bone mask using planning CT images as they have much better image quality. The mask defines the volumes occupied by bones in CT, and in CBCT as well, provided that the patient is set up well against planning CT. Major steps of creating bone mask include: (1) Identify CBCT volume in CT; (2) Apply a soft threshold to extract cortical bones; and (3) Connect mask edges using convex hull. Bone volumes are segmented by multiply CBCT with the mask and are then projected to create bone-only DRRs from desired gantry angles using a detector pixel-driven approach. **Results:** The quality of DRRs indicated that high noise level and artifacts associated with high-resolution CBCT did not impact DRR quality. Compared to DRR created from CT sim, the high spatial resolution CBCT created DRRs sharper and show more anatomic details. High-resolution DRR profiles represent actual KV image profiles well. DRR-to-KV registration uncertainties are generally around 0.25mm. **Conclusion:** The proposed method is able to produce DRRs with a resolution and image quality comparable to kV images, which makes it possible for achieving sub-millimeter tracking accuracy for paraspinal SBRT.

The present study is partially supported by a research agreement with Varian Medical Systems.

PO-GePV-M-147

Automated Detection of IGRT Shift Errors Due to Mis-Registration

D Pittock^{1*}, A Kruger¹, D Fought¹, A Nelson¹, E Paulson², (1) MIM Software Inc., Cleveland, OH, (2) Medical College of Wisconsin, Milwaukee, WI

Purpose: Critical errors can result from incorrect shifts being applied during Image-Guided Radiation Therapy (IGRT). Incorrect shifts can result from mis-registering cone-beam CT (CBCT) images to reference images, or failing to move the linac couch by the intended shift. Once couch coordinates are captured, tolerance tables can be effective at identifying IGRT shift errors due to mis-registration. However, if the initial couch coordinates are captured incorrectly during verification simulation, a systematic error in the treatment could result. We demonstrate here an automated method to detect IGRT shift errors due to mis-registrations. **Methods:** Daily CBCT images and spatial registration object files containing actual IGRT shifts for six patients were transferred to MIM. Residual shifts were determined by the difference between actual IGRT shifts and an automated rigid registration performed by MIM ART Assist. To determine an action level for residual shift errors, treatment plans were recalculated on daily CBCT images with isocenter shifts of +/- 0.5, 1.0, 2.0, and 5.0 cm applied along the three cardinal directions using MIM SureCalc ART. Automated detection of residual shift errors was then implemented clinically in MIM ART Assist. **Results:** For shift errors of +/- 0.5 cm, no difference in target coverage was detected. For shift errors of +/- 1.0 cm, target coverage fell to 94% on average (range 92-97%). Beyond +/- 1.0 cm, target coverage fell below 80%. Based on these results, a residual shift error action level of +/- 1.0 cm was employed. During clinical use over 323 fractions, 8 fractions (3 chest, 1 abdomen, 4 pelvis patients) demonstrated residual shift errors exceeding +/- 1.0 cm that required further investigation. **Conclusion:** We have demonstrated an automated method to detect IGRT shift errors due to mis-registration. A residual shift error action level of +/- 1.0 cm may be appropriate to trigger further investigation.

PO-GePV-M-148

Intentional Deep Overfit Learning (IDOL) : An Application to Deep Learning Based MRI Super-Resolution

I Park^{1,2*}, J Chun¹, B Choi^{1,2}, S Olberg^{2,3}, T Kim⁴, B Cai², A Godley², A Pompos², P Medin², J Kim¹, S Jiang², J Park², (1) Department of Radiation Oncology, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea (2) Medical Artificial Intelligence and Automation (MAIA) Laboratory and Department of Radiation Oncology, University of Texas Southwestern Medical Center, Dallas, TX 75390, USA (3) Department of Biomedical Engineering, Washington University in St. Louis, St. Louis, MO (4) Department of Radiation Oncology, Washington University School of Medicine, St. Louis, MO

Purpose: Deep learning (DL)-based MRI super-resolution (SR) reconstruction has recently been receiving attention due to the significant improvement in spatial resolution compared to conventional SR techniques. However, there remain several barriers to the effective implementation of these approaches in a clinical setting. Low-resolution (LR) MRIs captured in the clinic contain complex tissues obfuscated by noise that are difficult for a simple DL framework to reconstruct. Moreover, training a robust SR network requires abundant, perfectly matched pairs of LR and high-resolution (HR) images that are often clinically

unavailable. We propose here a patient-specific SR approach utilizing the Intentional Deep Overfit Learning (IDOL) framework that demonstrates a significant improvement in SR MRI quality using only a few training data sets. **Methods:** IDOL-based SR is an intentional application of overfitting that leverages patient-specific prior information. Training in the IDOL framework involves two stages: 1) conventional training of a generalized SR model with a training set of LR and HR MRIs of 4 human volunteers, and 2) using the inhale respiratory phase of a 5th human subject as prior information, the generalized model is trained further to achieve the IDOL model that is applied to the exhale respiratory phase of the 5th subject. For testing, step2 was repeated for subjects 5-8 using the same generalized model as a starting point. **Results:** The proposed method was evaluated on a cohort of 4 volunteers. The generalized model (step1 training only) achieved a normalized mean absolute error (MAE) of 446.5 and peak signal-to-noise ratio (PSNR) of 31.33. By adopting the personalized IDOL model in each test case, the MAE and PSNR improved to 321.5 and 34.72, respectively. **Conclusion:** In this study, we have successfully applied the IDOL framework to the MRI super-resolution task. Our approach is widely applicable to common tasks in radiotherapy and can be utilized for MRI-guided ART.

PO-GePV-M-149

Left Ventricle Avoidance in Non-Small Cell Lung Cancer Radiotherapy: A Planning Comparison Study

O Chau^{1,2*}, S Gaede^{1,2}, (1) Western University, London, Ontario, CA, (2) London Regional Cancer Program, London, ON, CA

Purpose: To provide a dosimetric comparison among NSCLC treatment plans to determine whether minimizing dose to the left ventricle (LV) will significantly increase the dose to other organs at risk, while maintaining target coverage. **Methods:** Fifteen Stage III non-small cell lung cancer (NSCLC) patients who have received a standard 60Gy in 30 fraction volumetric-modulated arc therapy (VMAT) treatment and with a V20Gy = 20-30% were retrospectively replanned. The LV and left anterior descending artery (LAD) were additionally contoured on the end inhale and end exhale CT scans extracted from the clinical 4D-CT dataset and registered to the untaged average CT dataset that contained clinically defined targets and normal structures. The clinical treatment plans were retrospectively optimized with the goal of minimizing the mean(LV), and mean(heart) dose while maintaining the dose constraint of V20GyTotal Lung ≤ 30% and V95%PTV ≥ 95%. Dose-volume histograms and paired T-tests were used to compare the heart and lung dosimetric parameters, including mean heart, LV, and LAD doses, V5GyHeart, mean lung, V5GyLung and V20GyLung between the original and optimized treatment plans. **Results:** Significant reduction ($p \leq 0.044$) were observed in mean(LV), mean(heart), mean(LAD), max(LAD) dose and V5GyHeart in the re-optimized treatment plans compared to the clinically delivered plans. V20GyLung ≤ 30% and V95%PTV ≥ 95% were maintained and insignificant differences were determined for parameters of mean(Lung), V5GyLung and V20GyLung, mean(esophagus) and mean(cord). **Conclusion:** This study demonstrated that minimizing left ventricle dose in NSCLC treatment plans were achievable and dosimetrically advantageous in the heart while maintain dose constraints to normal lung and maximizing tumor control. Radiation dose reduction to cardiac substructures such as the left ventricle and LAD may decrease the risk of radiation-induced cardiac toxicity in this patient population.

PO-GePV-M-150

Comparison of a Commercial Calculation-Based and Offline Measurement-Based Systems for Online Adaptive Radiotherapy

A Quinn^{1*}, A Briggs², B Zwan³, J Booth⁴, (1) Royal North Shore Hospital, Sydney, NSW, AU, (2) Royal North Shore Hospital, Sydney, AU, (3) Gosford Hospital, Gosford, NSW, AU, (4) Royal North Shore Hospital, Sydney, NSW, AU

Purpose: Measurement-based patient-specific quality assurance (PSQA) is not possible for online adaptive radiotherapy (oART). The Varian Ethos CBCT-guided adaptive system utilises MobiusAdapt for online PSQA. This work compares MobiusAdapt and measurement-based PSQA for original and oART plans. **Methods:** Fifty-two clinical IMRT plans (17 original and 35 adapted) were generated with Ethos. A variety of treatment sites were selected to ensure the plan complexity range reflected that of typical clinical practice. MobiusAdapt calculations were performed pre-treatment for original, and pre-beam-on for oART plans. Post-treatment, phantom-based dose measurements were performed for all plans using Delta4+ for 2D dose verification and a homogenous CIRS phantom for point dose verification. Different analysis criteria were evaluated to aid the comparison. For MobiusAdapt, gamma analysis was performed with 95% pass-rate for 3%/2mm and 3%/3mm (department criteria). For Delta4+, gamma analysis was performed with 95% pass-rate for 2%/2mm, and 3%/2mm (department criteria). CIRS point dose deviations (DD) were evaluated with department criteria 3% and compared to MobiusAdapt target structure meanDD, and Delta4+ medianDD. Results were compared for each plan, and the pass-rates relative to plan complexity metric MU/Gy evaluated. **Results:** All plans passed department PSQA criteria. Average gamma pass-rates were 98.3% and 99.8% for MobiusAdapt 3%/2mm and 3%/3mm criteria, and 92.4% and 99.9% for Delta4+ 2%/2mm and 3%/2mm criteria. MobiusAdapt 3%/2mm pass-rates were on average 1% higher (range -2% to 3%) compared to Delta4+ 3%/2mm. Both CIRS point dose and Delta4+ medianDD measured on average 1% higher than Ethos, indicating agreement between measurement methods. Conversely, MobiusAdapt target meanDD was on average 1.4% lower than measurement. Greater plan complexity (MU/Gy) resulted in lower pass-rates for MobiusAdapt and Delta4+, and greater medianDD for Delta4+. **Conclusion:** Online calculation-based QA and post-treatment measurement-based QA was performed on Ethos IMRT plans of varying complexity. MobiusAdapt gamma pass-rates were comparable to Delta4+.

PO-GePV-M-151

Evaluation of Dosimetric Impact of Organ Variation on Daily Basis Using MIM Image Registration Software

R He*, H Soysal, M King, S Vijayakumar, C Yang, University of Mississippi Med. Center, Jackson, MS

Purpose: Evaluating the dosimetric impacts of the variations of organs during day to day delivery is a challenge. The aim of this study is to demonstrate a simple and efficient method to evaluate rectum and bladder dose volume histogram (DVH) on daily basis using MIM image registration software for prostate cancer radiotherapy. **Methods:** A prostate cancer patient with 76 Gy in 38 fractions was selected for this pilot study. The rectum and bladder contours were drawn on the daily CBCT images transferred in MIM. Each daily CBCT and original CT image data set was rigid-image-registered and the dose was transferred to the CBCT in MIM. The DVHs of bladder and rectum for each CBCT and the average of all fractions of DVH with one standard deviation (SD) generated in MIM were analyzed and graphed for the bladder and rectum. **Results:** Figure 1 displays the volume variations of bladder and rectum on daily CBCT. Figure 2 and 3 shows the DVH of bladder and rectum on CBCT. The variation of DVH on daily basis can be seen. Figure 4 and 5 compared the DVH of bladder and rectum between initial planning and the daily averaged DVH on CBCT. The dose parameters such as Maximum Dose and Vx are noticeable different. Table 1 lists the averaged dose parameters of maximum dose and Vx, e.g., V76, V70, V60, V50, and V40 of the bladder and rectum on CBCTs, and the corresponding dose parameters for the original planning CT. **Conclusion:** This study demonstrated the dosimetric impacts due to the changes of bladder and rectum as detected on daily CBCT during the course of prostate cancer radiotherapy. The comparison of dosimetric parameters and DVH between original treatment plan and day to day delivery on CBCT shows a noticeable difference due to the organ changes.

PO-GePV-M-152

Deep Learning Markerless Spine Tracking Using Intrafraction Motion Management (IMR) Images: A Feasibility Study for Paraspinal SBRT Motion Management

F Li*, W Cai, X He, P Zhang, L Cervino, X Li, T Li, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: To investigate the feasibility and accuracy of a deep-learning based spine tracking algorithm using on-treatment kV imaging. **Methods:** Varian's on-treatment IMR allows visual inspection of patient movement during treatment, it however does not provide quantitative information about the motion. In this

study, we trained a deep convolutional neural network to quantify the translational movement indicated by an IMR image. The proposed neural network registers an IMR to the corresponding spine-only DRR which is a pre-processed reference image representing the initial spine position established during patient setup. The neural network modifies Resnet101 to allow the input of a pair of images and regression for the relative translation (ΔX , ΔY) between them. The training and testing images were collected from nine patients treated for C-, T-, and L-spines, among which 390 images from eight patients were used for training and 41 images from the last patient were used for testing. To generate the full training data, we augmented the image set by randomly translating the IMR images to simulate patient movement. Each translated IMR is paired with the corresponding spine-only DRR to form an input sample, and the applied artificial translation is the training label. **Results:** The trained neural network were evaluated on the test dataset with simulated spine movements up to 5mm. The mean detection error was below 0.7mm. The performance was compared to mutual information (MI) based matching implemented by Matlab. We found that our model is significantly more accurate and robust at predicting spine movements larger than 2mm, in which case MI-based method were undermined by inherent soft tissue interference. **Conclusion:** The proposed deep convolutional neural network is capable of detecting spine motions with sub-millimeter accuracy for movements up to 5mm. Our results suggest that the proposed deep-learning approach is feasible for spine tracking during a SBRT treatment.

The present study is partially supported by a research agreement with Varian Medical Systems.

PO-GePV-M-153

Analysis of a Surface Imaging System Using a Six Degree of Freedom Couch

X Zhao*, E Covington, A Alexandrian, R Popple, University of Alabama at Birmingham, Birmingham, AL

Purpose: To compare surface imaging (SI) logs with MV images and linear accelerator trajectory logs to validate SI reported offsets on an anthropomorphic phantom for commissioning and routine quality assurance of a SI system used for stereotactic radiosurgery (SRS). **Methods:** An anthropomorphic Styrofoam phantom (Floracraft, Ludington, MI) with a radiopaque tungsten carbide ball bearing (BB) placed midline was tracked with SI with a region-of-interest (ROI) representative of a typical SRS ROI. Couch motion was programmed in developer mode and delivered on an Edge (Varian Medical Systems, Inc., Palo Alto, CA) linac. IDENTIFY (Varian Medical Systems, Inc., Palo Alto, CA) logs were synchronized with linac trajectory logs. Ten random couch positions were selected at couch rotations of 0, 45, 90, 270, 315° with MV images taken to account for couch walkout. The IDENTIFY residual error (ϵ), the difference between SI reported offset and MV or trajectory log position, was calculated. For lateral and longitudinal directions, ϵ was calculated from MV images. For vertical, and rotational ϵ , linac trajectory logs were used. **Results:** The median [range] of magnitude of translational ϵ was (0.17 [0.05, 0.27], 0.39 [0.21, 0.47], 0.43 [0.30, 0.53], 0.43 [0.33, 0.60], 0.46 [0.41, 0.63]) mm. The mean $\pm$ standard deviation (std) roll ϵ was (-0.01 $\pm$ 0.01, 0.28 $\pm$ 0.01, 0.55 $\pm$ 0.02, -0.30 $\pm$ 0.02, -0.26 $\pm$ 0.01) °; mean $\pm$ std pitch ϵ was (0.03 $\pm$ 0.01, 0.06 $\pm$ 0.01, 0.21 $\pm$ 0.01, 0.44 $\pm$ 0.02, 0.22 $\pm$ 0.01) °; mean $\pm$ std yaw ϵ was (0.02 $\pm$ 0.01, 0.08 $\pm$ 0.02, -0.02 $\pm$ 0.03, -0.08 $\pm$ 0.02, -0.02 $\pm$ 0.01) °, for couch rotations of 0, 45, 90, 270, 315°, respectively. **Conclusion:** SI system and linear accelerator trajectory log analysis can be used to assess SI system performance with automated couch motion to validate accuracy for systems used for SRS.

Impact of Various Noise Reduction Techniques on Markerless Tumor Tracking in Dual Energy Imaging

M Kaur^{1*}, P Wagstaff¹, H Mostafavi², M Lehmann², D Morf², L Cortes², L Zhu², H Kang¹, M Harkenrider¹, J Roeske¹, (1) Loyola University, Chicago, IL, (2) Varian Medical Systems, Palo Alto, CA

Purpose: This study aims to quantitatively evaluate the performance of various noise reduction algorithms on markerless tumor tracking using dual-energy (DE) imaging. **Methods:** DE images were obtained using the fast-kV switching capabilities of the on-board imager (OBI) of a commercial linear accelerator with alternating acquisitions at 60 and 120 kVp. Weighted log-subtraction was then used on paired 60/120 kVp images to generate soft tissue images. Both the anti-correlated noise reduction (ACNR) technique, and 2D-median filter were applied to subsequent DE images. Additionally, the adaptive histogram equalization (AHE) algorithm was also evaluated for comparison. The tumor motion on DE-unfiltered and DE-filtered image sequences was tracked using a template-based matching algorithm. Ground truth positions from the DE-unfiltered and DE-filtered images were estimated using Bayesian inference. **Results:** A total of 1145 DE-unfiltered and DE-filtered image frames were evaluated for 5 patients. The DE-filtered images showed slight variation in tracking results vs. DE-unfiltered images, with reduced tracking error > 0.1 mm in 30.2% (346/1145), 13.8% (159/1145), 12.5% (144/1145) of image frames using median filter, ACNR, and AHE methods respectively. However, DE-filtered images only showed improved results for tracking error > 1.0 mm in 1.57% (18/1145), 1.57% (18/1145), 2.18% (25/1145) image frames, with median filter, ACNR, and AHE techniques respectively. **Conclusion:** These noise reduction techniques do not significantly affect tumor tracking on DE images. Thus, DE images are suitable to track the tumor without using any additional post-processing. This is advantageous since the addition of noise reduction techniques increases image processing times and affects system latency.

Feasibility Study of An InBore Real-Time Surface Monitoring System

G Kim^{1*}, (1) University of California, San Diego, La Jolla, CA

Purpose: To evaluate the performance of the InBore real-time monitoring system (Vision RT Ltd., London, UK) on the Halcyon and Ethos-type linacs. **Methods:** The study was designed with 14 test sets to evaluate the InBore camera system safety and accuracy. The Catphan phantom was used to test the InBore camera system's impact on beam delivery for typical clinical cases using different IGRT techniques. The InBore camera system's physical stability was tested for the potential collision risk between the treatment couch and treatment accessories as well as access for Halcyon service. The monitoring accuracy was measured with the VisionRT Cube phantom, static head phantom, thorax phantom, and the breathing thorax phantom. **Results:** There was no dosimetric difference between the pre-and post-InBore camera system installation for multiple plans and several disease sites. The InBore camera system does not obscure the beam delivery pathway and no impact was observed on the image quality on the Halcyon IGRT techniques. The result of the monitoring accuracy for static phantoms (> 20 min monitoring) was < 0.4 mm in any direction and < 0.1 degree in any rotation axis. The result of geometric accuracy using the known translational shifts (1, 3, 5, 10, and 20 mm) in each direction, the average deviation was 0.08 mm, and maximum deviation was 0.5 mm. The monitoring range of the InBore camera system was ± 10 cm Vert, ± 7 cm Lat, ± 5 cm Lng direction. **Conclusion:** The InBore camera system on the Halcyon linac is appropriate for clinical use and active patient monitoring. It is likely that this system will be applicable for cases such as SRS, SBRT, DIBH, and adaptive cases. This monitoring technique may be useful for the adaptive therapy workflow to monitor the patient while waiting for the plan to adapt to the patient's anatomy of the day.

UC San Diego received research funding from VisionRT in partial support of this project.

PO-GePV-M-156

An iOS Surface Audiovisual Biofeedback Smartphone Application for Respiratory Monitoring in Radiation Oncology

T Nano¹, E Hirata¹, E Blomain², L Skinner², N Prionas¹, B Loo², D Capaldi^{2*}, (1) University of California, San Francisco, San Francisco, CA, (2) Stanford University, Stanford, CA

Purpose: Radiation dose delivered to a target located near the upper abdomen or thorax is significantly affected by respiratory motion, necessitating large margins and limiting dose escalation. Currently, normal tissue sparing can be improved by using motion monitoring systems. The amalgamation of these systems with audiovisual biofeedback can further improve the quality and delivery of radiation as the patient is able to see their breathing pattern and correct for variations leading to consistent and more predictable target motion. Alternative to current solutions, we have developed and evaluated the feasibility of an audiovisual feedback system that leverages depth information from the depth sensor onboard iOS devices to provide visual coaching to improve patient compliance and reduce treatment delivery time. **Methods:** The iOS application, coined iOS Surface Audiovisual Biofeedback (iSAVB), was developed in Swift (Apple Inc.) and implemented on an iPhone® with the TrueDepth camera system. Validation was performed using the QUASAR™ Respiratory Motion Phantom (Modus Medical Devices); previously recorded motion traces during free-breathing and breath-hold treatments were programmed into the motion platform and played while recording depth information using iSAVB. iSAVB measurement of displacement was compared to the input signal trace using linear regressions and Bland-Altman analysis. **Results:** Free-breathing and breath-hold traces show excellent agreement between the input signal trace from the motion phantom and iSAVB. iSAVB and QUASAR™ motion phantom traces were significantly related (free-breathing: $r=0.999$, $p<0.0001$; bias= 0.00 ± 0.04 cm, 95%-confidence-interval= -0.07 cm, 0.07 cm; breath-hold: $r=0.991$, $p<0.0001$; bias= 0.00 ± 0.08 cm, 95%-confidence-interval= -0.16 cm, 0.16 cm). **Conclusion:** Feasibility of an iOS application to provide depth information for real-time respiratory motion monitoring is demonstrated. With the ubiquity of smartphone devices, this work has the potential to provide audiovisual biofeedback to patients in a low-cost platform that will improve the efficacy of radiation therapy.

PO-GePV-M-157

Towards Real-Time Markerless Prostate IGRT During VMAT Treatment

A Mylonas^{1,2*}, M Mueller^{1,2}, P Keall¹, J Booth³, D Nguyen^{1,2,3}, (1) ACRF Image X Institute, Faculty of Medicine and Health, The University of Sydney, Sydney, NSW, AU, (2) School of Biomedical Engineering, University of Technology Sydney, Sydney, NSW, AU, (3) Northern Sydney Cancer Centre, Royal North Shore Hospital, Sydney, NSW, AU

Purpose: Image-guided radiation therapy (IGRT) and real-time IGRT for prostate cancer typically relies on markers to determine the target location in kilovoltage (kV) images. However, the placement of markers is an additional procedure that introduces costs and side effects. We present a novel deep learning method for markerless prostate IGRT. **Methods:** A real-time tracking system using a conditional generative adversarial network (cGAN) was developed. A base model was trained on an imaging database of prostate cancer patients in the TROG 15.01 SPARK trial and was fine-tuned individually on unseen patients. The base model was trained using 17,000 kV images from 34 fractions of 17 patients. A patient-specific model was then trained for five different patients using 3,600 digitally reconstructed radiographs (DRR) per patient generated over 360 degrees. The DRRs were produced using the planning CTs and clinical target volume contours. The system was evaluated on 1,000 kV images/patient from two fractions. The implanted markers were used as the ground truth and were masked out for training and testing. The centroid geometric error was defined as the cGAN segmentation versus the ground truth and the Dice similarity coefficient (DSC) was calculated to gauge the similarity of the segmentations. **Results:** On patient images, the mean error was 0.2 ± 1.9 mm and -0.2 ± 1.5 mm in the lateral/anterior-posterior and superior-inferior directions, respectively. The [2.5th, 97.5th] percentiles of the error were [-3.4, 3.9]mm in the lateral/anterior-posterior direction, and [-2.6, 2.2]mm in the superior-inferior direction. The mean DSC was 0.92 ± 0.03 . **Conclusion:** The first algorithm for markerless prostate segmentation during an arc treatment was developed and evaluated on patient kV images. The results demonstrate that real-time markerless prostate IGRT is achievable to a high degree of accuracy using deep learning. This solution could enable more patients access to real-time IGRT without the costs, time and side effects for marker placement.

PO-GePV-M-158

Enhancing Cherenkov Photon Yield by Gold Implants

K Okazaki^{1*}, E Brost², Y Watanabe¹, (1) University of Minnesota, Minneapolis, MN, (2) Mayo Clinic, Rochester, MN

Purpose: To study how much Cherenkov photons are generated with and without a gold implant/marker in a water phantom for utilizing the Cherenkov photons in radiation therapy. **Methods:** The Geant4-based Monte Carlo code, GAMOS, was employed for simulating the number of Cherenkov photons produced with and without a gold marker implanted in a homogeneous water phantom under photon beam irradiation. A $10 \times 10 \times 10$ cm³ phantom was modeled. A thin gold plate with a 10 mm diameter and 1.0 mm thickness was placed at the center of the phantom. 6, 10, and 15 MV photon beams with a 5×5 cm² field size directed towards the phantom. The integrated dose and the number of Cherenkov photons produced within 5 mm above and below the gold plate, designated as ROI1 and ROI2, were calculated. Those quantities with the gold were compared with those without the gold. **Results:** The integrated dose in the ROI1 increased by 28.0, 27.2, and 24.4% for 6, 10, and 15 MV beams, respectively. The dose difference in the ROI2 increased as the photon energy increased. The differences in the numbers of the Cherenkov photons in ROI1 between with and without the gold were 23.2, 11.8, and -19.2% for the 6, 10, and 15 MV beam, respectively, whereas the difference was -0.06, 7.71, and -6.04% in the ROI2. **Conclusion:** Monte Carlo simulations showed the increase of the dose in the ROI1; thus, resulting in an enhancement of the Cherenkov photon yield by a gold marker. The difference in the Cherenkov photon yield between with and without the gold marker in the ROI1 was significant for 6 and 10 MV beams. A potential application of this phenomenon includes a non-invasive real-time identification of the marker location implanted in a tumor for motion tracking.

PO-GePV-M-159

Towards Faster and More Accurate Target Localization on Intrafraction X-Ray Fluoroscopy for Lung Radiotherapy Using Modified YoloV3 Detector

L Deng^{1*}, Z Dai², X Liang^{1,3}, Y Xie¹, (1) Shenzhen Institutes of Advanced Technology, Shenzhen, 44, CN, (2) Guangdong Provincial Hospital of Chinese Medicine, Guangzhou, 44, CN, (3) Stanford University School of Medicine, Stanford, CA

Purpose: Recently, there has been renewed interest in using object detection algorithms to localize the treatment target on X-ray Fluoroscopy to overcome the time-consuming shortage of template matching. However, the major obstacle of deep-learning-based object detection is that the accuracy drops severely when the target is blocked by vertebral bodies. In this study, we set out to verify the usefulness of a modified YoloV3 framework combined with training data augmentation strategies to mitigate this problem. **Methods:** To compare with the previous study applying the Faster-RCNN framework, we repeated the experiments with the dynamic thorax phantom (CIRS), in which a tumor surrogate was programmed to move independently from the chest. Besides, we verified the reproducibility of the proposed method using datasets provided by The Markerless Lung Target Tracking Challenge (MATCH). The datasets consist of CT and X-ray imaging files of a 3D-printed anthropomorphic phantom and files recording 3D trajectories of the complex phantom motion. In both experiments,

the programmed 3D positions were mapped to 2D X-ray images to serve as the ground truth. **Results:** For the CIRS phantom, the mislocalization problem was addressed when the surrogate size was 18mm or 27mm. But when it decreased to 12mm, the localization failure rate(LFR) dropped to 16% compared with the result of 41% for Faster-RCNN. In MATCH datasets, for target1, targets in all frames were successfully detected and errors of 86% results were less than 1mm with an average error of (0.58±1.7mm, -0.35±2.4mm). For target2, the LFR was 7% and errors of 72% results were less than 1mm with an average error of (0.74±1.9mm, 1.32±1.47mm). The overall end-to-end processing time of an image is less than 60ms(~16.7FPS). **Conclusion:** The proposed method is obviously improved, considering the trade-off between accuracy and localization latency. It nearly addresses the mislocalization problem while further approaching real-time operation.

PO-GePV-M-160

Quantitative Interpretation of Data Acquired During Intrafraction Motion Review Imaging

G Graeper*, A Cetnar, A Ayan, M Weldon, Ohio State Univ, Columbus, OH

Purpose: The current clinical interface for Varian's Intrafraction Motion Review is limited, providing only qualitative data for review at the treatment console. This study provides ways of extracting and interpreting data from combined log files for quantitative evaluation offline. **Methods:** Combined log files acquired during patient treatment were exported for analysis. We developed a parsing code in C# to scan the combined file looking for unique identifiers pertaining to the data of interest. Data was saved as a comma separated .txt file that could easily be opened with spreadsheet software for further analysis. We used a time-based system to correlate treatment arcs time to specific patient treatments. **Results:** We were able to extract clinically relevant parameters from the log files including: date and time, gantry angle, expected marker position, found marker position, pixel size, and detection result. Detection result is the written classification of the color-coded results seen on the console during treatment. The stored data does not record found versus expected seed position difference, but only the X and Y positions and the detection result (ie. within or outside tolerance). Such numerical detection positional differences need to be calculated externally. **Conclusion:** The current data available for clinical decision-making is limited when using IMR. However, data is recorded in the combined log files, which can be utilized to better understand motion during patient treatment. Understanding data recorded during treatment within the combined log files can be helpful for retrospectively reviewing motion during treatment to continue to improve patient care.

PO-GePV-M-161

Clinical Performance of a New Commercial Surface Imaging System for Frameless Stereotactic Radiosurgery

E Covington*, D Stanley, J Fiveash, R Popple, University of Alabama-Birmingham, Birmingham, AL

Purpose: To assess the performance of a new commercial surface imaging (SI) system by analyzing intrafraction motion from the initial cohort of patients treated with frameless stereotactic radiosurgery. Aggregate data was used to analyze system performance at non-zero couch angles and when camera pods are blocked by gantry motion. **Methods:** Patients were immobilized with an open face thermoplastic Encompass™ (Qfix, Avondale, PA) mask. The SI region of interest (ROI) was contoured in the treatment planning system (TPS) and exported to the SI system. Patients were aligned by kV followed with CBCT then the SI reference was captured. After treatment, linear accelerator trajectory logs were synchronized with SI logs to correlate SI reported offsets with couch and gantry positions. **Results:** 58 fractions from 25 patients were monitored on an Edge linear accelerator (Varian Medical Systems, Palo Alto, CA) with IDENTIFY (Varian Medical Systems, Palo Alto, CA). The median magnitude of translational SI reported offsets at the end of treatment was 0.31 mm. The median magnitude before beam-on at non-zero couch angles was 0.57 mm. SI reported offsets were shown to increase when camera pods are blocked by the gantry with larger increases seen at non-zero couch angles. **Conclusion:** SI and linear accelerator trajectory logs were used to analyze intrafraction motion during frameless stereotactic radiosurgery and evaluate SI system performance. Performance is comparable to other commercially available surface imaging systems where offsets are shown to increase at non-zero couch angles and during camera pod blockage.

This work was funded by Varian Medical Systems.

PO-GePV-M-162

Comparing Patient Setup Techniques Between Optical Surface Guidance and Conventional Tattoo/Laser Alignment Using Cherenkov Image Consistency Metrics

R Hachadorian^{1*}, D Alexander¹, E Chen², D Gladstone^{1,3}, M Jermyn^{1,4}, G Gill³, R Zhang^{1,3}, P Bruza^{1,4}, L Jarvis^{1,3}, B Pogue^{1,4}, (1) Dartmouth College, Hanover, NH, (2) Cheshire Medical Center, Keene, NH, (3) Dartmouth-Hitchcock Med. Ctr., Lebanon, NH, (4) DoseOptics LLC, Lebanon, NH

Purpose: For breast radiation therapy treatments, the standard of care is traditionally to mark the patient with small tattoos which are used for alignment each day, though in over 1,700 oncology centers worldwide, optical surface guidance (SG) systems are used for patient positioning prior to receiving radiation. In this study, Cherenkov imaging metrics were analyzed in a clinic that utilizes SGRT for pre-treatment patient alignment (site 1) and compared to the metrics from a clinic that practices conventional tattoo/alignment (site 2). This was done to determine whether setup techniques were more consistent using one technique over the other. **Methods:** Free-breathing breast treatments were recorded with Cherenkov imaging each day for n = 15 patients, (fx = 134 fractions) at site 1, and for n = 5 patients, (fx = 54 fractions) at site 2. A two-tailed t-test of unequal variance was carried out to determine significance for comparison of DICE analytics (% similarity) and MDC (Mean Distance to Conformity). **Results:** MDC and DICE t-test results reveal that the null hypothesis could not be rejected, indicating that the setup techniques yield no significant difference (DICE, p = 0.432; MDC, p = 0.094). The p-value describing MDC comparison was smaller, however, possibly indicating that this may be the analytical metric more sensitive to changes in beam shape. **Conclusion:** While SGRT may be a less invasive technique via the negation of tattoos and possibly a faster setup technique, ultimately, the Cherenkov data acquired in our two clinics showed no significant difference between the surface-guidance setup technique and the conventional skin marks/laser technique. In the two clinics studied, the quality or accuracy of patient setup was not compromised by using one setup technique over the other. Cherenkov imaging for clinical real-time monitoring was shown to provide a useful tool for this analysis.

Authors Prof. Brian Pogue, Prof. M Jermyn, Prof. P. Bruza, and Dr. Lesley Jarvis M.D. have competing interests with DoseOptics LLC, a company that manufactures Cherenkov cameras used to monitor radiation therapy.

Clinical Detectability of MR Suitable Prostate Fiducial Markers Utilizing the TrueBeam Advanced Imaging Package During VMAT Prostate Treatment in Phantom

M Klem*, K Jones, J Turian, Rush University Medical Center, Chicago, IL

Purpose: We study the detection of MR suitable fiducial markers (FM) in an anthropomorphic phantom. We report the clinical detection rate, angular dependence, and optimized detection algorithm choice for fiducial marker tracking during VMAT prostate treatment on the Varian TrueBeam. **Methods:** A Rando phantom, holding a beefsteak prostate phantom seeded with 1, Platinum-coil (0.35x10mm) and 2, Platinum-coil (0.35x20mm) FM's, was used. The phantom received a (VMAT) treatment utilizing on-board kV imaging and our clinical FM SOP. In each image, the Varian software found and located each

marker within a 3mm radius of its planned location. Treatment was repeated 22 times using all available marker detection settings (MDS), collecting 913 images. **Results:** The “GoldSeed_1_3x3_3” MDS was optimal for identifying the platinum-coil (0.35x10mm) marker, finding it in 100% of the projection images. The platinum-coil (0.35x20mm) marker was much more robust to MDS selection, where eight different settings each identified the marker in 100% of the projection images. Little projection-angle dependence was observed, with an association only appearing when the worst performing MDS's were selected. The mean and standard deviation of the distance from the recognized marker position to the expected position in the projection images was found to be 1.25mm and 0.2mm respectively for the (0.35x20mm) marker and 1.5mm and 1.2mm respectively for the (0.35x10mm) marker using optimized MDS's. **Conclusion:** The TrueBeam Advanced Imaging Package was used during a VMAT treatment of a prostate phantom housed in an anthropomorphic pelvis phantom. The clinical detectability of two MR suitable FM's was assessed. The longer platinum markers show improved detectability. Currently, marker detection accuracy is being studied and will be compared to prior measurements of markers from the same and different vendors.

Auto-Segmentation of Organs at Risk for CT Thoracic Cases: A Single Institution's Experience

D Darkow^{1*}, B Lee¹, J Seger-Paisley², R Woods², U Duong², A Houser², J Paisley^{2,3}, M Butler¹, A Kruzer¹, A Nelson¹, (1) MIM Software Inc. (2) New Hanover Regional Medical Center (3) Coastal Carolina Radiation Oncology

Purpose: The purpose of this experiment is to examine one institution's experience with a 3D Convolutional Neural Network (CNN) based automated contouring method. **Methods:** A CNN trained on 658 expert-segmented images from multiple institutions was used to provide baseline contours for 129 patients undergoing thoracic radiation therapy. Five structures were included: heart, left/right lungs, esophagus, and spinal cord. Six dosimetrists edited those baseline contours to match their institutional standards. The Dice score (DSC) and Hausdorff distance (HD, mean/maximum) were calculated for each edited contour compared to the CNN contour. For each patient, the dosimetrists provided a self-reported scale of the edits required for each structure, choosing from “Minimal Edits”, “Moderate Edits”, “Not Usable”, and “N/A”. The “N/A” option was chosen if the structure was not required for the treatment plan or an automatically generated segmentation was not considered for use. **Results:** The following average statistics were calculated for each structure (DSC, mean HD, maximum HD): Heart (0.92, 2.17, 14.89), Left Lung (0.98, 0.58, 12.61), Right Lung (0.98, 0.56, 13.16), Esophagus (0.76, 10.11, 44.79), Spinal Cord (0.86, 5.50, 35.71). Of the 292 structures for which the amount of edits were reported, 83% required minimal edits, 11% required moderate edits, and 6% were redrawn. **Conclusion:** The CNN contours required minimal edits to yield clinically acceptable results, as demonstrated by the DSC, HD, and self-reported editing amounts. The esophagus and spinal cord yielded lower DSC and higher HD, (mean and standard deviation) due to variability in the superior/inferior extent of the structure that was contoured when using the CNN versus manual editing. In the future, we plan to investigate solutions to stylistic differences to improve the CNN performance with structures with variable extents.

PO-GePV-M-165

Deep Learning-Based Auto-Segmentation of Glioblastoma in Brain Cancer Radiotherapy

S Sadeghi*, S Gholami

Purpose: Contouring is a potential source of uncertainties in radiotherapy treatment planning that could affect treatment outcomes. It is important to reduce contouring uncertainties in terms of inter-and intra-observer variation. In this study, we review the most recent researches and introduce an automatic brain tumor segmentation method. Our method is able to predict multiple brain tumor regions using the Brats 2019 dataset; We evaluate and report the dosimetric impact of automatic segmentation for treatment planning. **Methods:** Two contouring methods are compared. We use manual contours as the gold standard against our deep-learning-based auto-contour. In each method, Gross Tumor Volume (GTV) was generated on 15 patients with glioblastoma cancer. Workflows were compared according to contour similarity, and dosimetric evaluation. Different treatment plans were compared using gamma index analyses were performed with 1%/1 mm, 3%/3 mm. **Results:** The GTV segmentation network achieved a DSC of 0.88 ± 0.04 on the test set. The proposed network achieved a HD of 1.27 ± 0.39 mm for the GTV. The automatically generated contours met the dose coverage constraints using gamma analyses in all of the cases for GTV. Gamma index measurements for 1%/1 mm and 3%/3 mm were achieved at 97.92% and 99.375% respectively. **Conclusion:** The proposed deep-learning-based auto-contour is fast, reliable, and achieved an acceptable agreement between the ground truth and predicted contours in relation to similarity and dosimetry. This method can provide a useful tool for automatic segmentation of the brain tumor and improve the reproducibility of contouring in the radiotherapy workflow.

PO-GePV-M-166

Clinical Evaluation of Deep Learning Based Auto Segmentation (DLAS) of Organs at Risk in the Head and Neck Region

S Huang*, C Ackerman, C Johnson, P Tsai, L Hu, W Xiong, C Apinorasethkul, G Yu, H Zhai, RH Press, H Lin, New York Proton Center, New York, NY

Purpose: To clinically evaluate the accuracy of DLAS of organs in computed tomography (CT) images in head and neck region utilizing deep-learning based and commercially available software. **Methods:** 9 organs at risk (brainstem, esophagus, eyes, larynx, mandible, optic nerves, oral cavity, parotids and spinal cord) in 16 head-and-neck planning CT images were firstly segmented by skilled clinicians as the ground truth. For comparison, auto-segmentation was conducted by AccuContour (Version 3.0, Manteia) using both the vendor's default and customized models. The customized model was generated by Manteia AccuLearning AI model training platform using 20 training cases following the vendor's minimum recommendations. Segmentation accuracy of both the default and customized model was assessed using Dice similarity coefficient (DSC) and mean distance metrics. **Results:** The average time to auto segment all 9 structures was 1 min/patient. DLAS with default model performed well, with an average DSC and mean distance of 0.90 and 0.46mm for mandible, 0.86 and 0.8mm for brainstem, 0.84 and 0.7mm for eyes, 0.77 and 2.0mm for esophagus, 0.77 and 3.3 mm for spinal cord, 0.77 and 3.3 mm for oral cavity, 0.74 and 7.2mm for parotids, 0.58 and 0.6mm for optic nerves, and 0.41 and 2.9mm for larynx. Significant improvement ($P=0.034$) of DLAS accuracy using a customized model was observed for all OARs except for optic nerves, with DSC and mean distance increased by 0.10 and 0.96mm respectively. The largest difference was found for larynx (DSC=0.85, distance mean=1.2mm). **Conclusion:** AccuContour DLAS of computed tomography images proved to be a useful tool in the rapid delineation of normal tissues. AccuLearning training platform can build customized models to further improve DLAS accuracy for an individual clinic with a small training cohort.

PO-GePV-M-167

PTV Auto Contouring for Prostate and Nodes Utilizing Deep Learning Artificial Intelligence

H Yao*, J Chang, J Baker, Northwell Health and Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Lake Success, New York

Purpose: Create a 3D deep learning model capable of generating a Planning Target Volume (PTV) on the prostate and nodes volume with CT input images for radiotherapy treatment planning. **Methods:** We anonymized and exported 265 CT images and PTV_4500 volumes of prostate cancer patients for this project. PTVs with 45 Gy were contoured by 7 MDs and reviewed to be clinically acceptable. Two groups were formed from 212 cases for training and 53 for testing. We developed a Pixel-Deconvolutional Network (PDN) model by tweaking the weighting parameters to minimize the dice loss function using the training cases. The performance of the auto-segmentation was analyzed through the similarity DICE and Average Hausdorff Distance (AHD) between manual (gold-standard) and auto segmented PTV_4500 (predicted). Given the restrictions of computing resources, all images required resizing to lower resolution initially as input for the network. **Results:** The mean DICE/AHD scores with standard deviation (SD) for the testing set were (0.716±0.076) and (2.061±1.749 cm) for the CT image modality. If excluding one testing case with AHD > 10 cm, the mean and SD were (0.723±0.062) and (1.885±1.209 cm). The computation time for training was about 222 minutes. **Conclusion:** A deep-learning network was developed to contour the PTV for radiotherapy of prostate with nodes to 45 Gy with simulation CT images. The predicted contours have a reasonable dice score and AHD value compared with the manual contouring. We believe increased contouring accuracy is possible through more curating of the training data.

PO-GePV-M-168

Synthetic Lung MRI for Auto-Segmentation Using Unet Training: Supervised Cross-Domain Adaptation from CT to MRI

Y Liu*, J Jiang, N Tyagi, H Veeraraghavan, G Li, J Deasy, L Cervino, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: Magnetic resonance imaging (MRI) has become an emerging tool in radiation therapy. It improves treatment accuracy over conventional CT-based radiotherapy due to superior soft-tissue contrast. While dose calculation is usually performed with CT images, MRI contrast can be critical for accurate tumor and organ delineation and segmentation. Therefore, we developed a supervised cross-domain adaptation based deep learning method to generate synthetic MR from CT datasets, facilitating tumor and organ auto-segmentation. **Methods:** Current deep learning approach achieves reasonably accurate tumor segmentation from limited MRI data by leveraging large CT datasets. This method helps to preserve tumors on synthesized MRIs produced from CT images. We present a supervised cross-domain adaptation-based deep learning approach to generate synthetic MR from registered CT and T2-weighted MRI datasets. This approach was implemented following the steps: (1) performed image registration of CT and MRI on 15 lung cancer patients (IRB approved); (2) paired CT and MR data from 15 cancer patients was used for Unet training to generate training model for adaption; (3) a CT image from the 16th patient served as the test image for the training model, to generate synthetic MRI. The test CT image also served as the reference for image quality evaluation. Mutual information was calculated for the synthetic MRI and the test CT, and it was used as an evaluator of the trained model. This method was subsequently evaluated by comparing supervised cross-domain adaptation model with unsupervised cross-domain adaptation. **Results:** Mutual information of the synthetic MRI and reference CT calculated from supervised cross-domain adaptation is 1.41; with unsupervised cross-domain adaptation it is 1.18, lower than the former. **Conclusion:** The novel supervised cross-domain adaptation based deep learning approach showed promising results, achieving more accurate image features on synthetic MRIs, compared with unsupervised cross-domain adaptation based deep learning approach.

PO-GePV-M-169

Prior Information Guided Auto-Contouring of Breast Tumor Bed for Post-Operative Breast Cancer Radiotherapy

X Xie*, H Yan, J Dai, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CN

Purpose: Contouring of breast tumor bed in planning CT is important to post-operative radiotherapy of patients after breast conserving surgery (BCS). However, this contouring is highly uncertain due to specimen volume, seroma size, clarity, surgical clips, inter-observer variability, and other factors. To alleviate this issue, prior information was introduced in a 3D U-Net model to predict the contour of breast tumor bed automatically. **Methods:** The pre-operative CT was first aligned to the planning CT via intensity-based B-splines registration. Then the contour of breast tumor expansion in pre-operative CT was transformed to planning CT accordingly. This transformed contour indicates the approximate area of breast tumor bed in planning CT and would be valuable prior information in searching for more accurate contour. Next, the transformed contour with CT images were fed into a 3D U-Net model to predict the fine contour of breast tumor bed. 110 sets of CT images (each including pre-operative CT and planning CT) and the corresponding label images were used for model training with five-fold cross-validation. The dice similarity coefficient (DSC) and Hausdorff distance (HD) were used to evaluate the accuracy of 3D U-Net model. **Results:** The average DSC and HD of prediction model were 0.685±0.065 and 20.816±14.565 for breast tumor bed without the input of prior information, while the average values were 0.795±0.038 and 13.896±8.737 with the input of prior information. The differences were statistically significant (0.685 vs. 0.795, $P = 0.0014 < 0.05$; 20.816 vs. 13.896, $P = 0.002 < 0.05$). **Conclusion:** The introduction of prior information improved the prediction accuracy of breast tumor bed contour. This method provides an automatic way to contour breast tumor bed more accurately in CT image and will be useful in other image modalities.

PO-GePV-M-170

The Physics of Cellular Self-Assembly to Investigate Cancer Migration in Interface with Healthy Tissues

A Shafiee¹, J Kassir², E Ghadiri³, (1) Medical Physics Program, George W. Woodruff School of Mechanical Engineering, Georgia Institute of Technology, Atlanta, GA, (2) Wake Forest School of Medicine, Winston Salem, NC, (3) Department of Chemistry, Wake Forest University, Winston Salem, NC, (4) Comprehensive Cancer Center, Wake Forest School of Medicine, Winston Salem, NC

Purpose: A more precise understanding of cancerous biological systems may help devise novel treatments in oncology. To that end, the underlying physics of the dynamics of multicellular systems may provide valuable insight into the process of oncogenesis and consequently develop remedies to halt or decelerate cancer progression. One avenue of exploration is the physics of cellular self-assembly that may shed more light onto the biology of tumor invasion into healthy tissues. **Methods:** A model based on the physics of tissue engineering, which investigates tissue migration microscopically and is known as "Zipper CAMs", was modified to enable its application to the cellular interactions at the interface between cancerous and healthy tissues. The kinetics of cell adhesion molecules in the surfaces of individual cells were investigated to predict and control the final tissue location. Statistical mechanics was used to calculate the force involved in this cellular self-assembly. **Results:** The model successfully predicted the speed of cancerous tissue invasion into healthy tissues. The data show that the migration procedure must abide by some physical principles including tissue surface tension (ATST), and that the biomechanical properties of both tissues types play a critical role in both the invasion and its speed. The ATST represent the strength of adhesion molecules that drive the invasion and provide the energy and force for migration. Such physical parameters may therefore provide important information to oncologists on how to prevent or decelerate the process. **Conclusion:** The physics of cellular self-assembly has been used over the past 10 years in tissue engineering to fabricate healthy human tissues and organs. However, the application of physics in the interaction between cancerous and healthy tissues is barely explored. Here, we introduce a mathematical and microscopic model based on the physical principles of the dynamics of multicellular systems to comprehend and control cancer invasion.

PO-GePV-M-171

Apparent Diffusion Coefficient Calculation On a 0.35T MR-Linac System

B Lewis^{1*}, J Shin^{1,2}, J Kim², H Gach¹, T Kim¹, (1) Washington University in St. Louis, Saint Louis, MO, (2) Yonsei University College of Medicine, Seoul, KR

Purpose: Diagnostic radiology techniques continue to be utilized for improving patient outcome in radiotherapy, including diffusion weighted imaging (DWI) for tumor staging and monitoring. MR-guided radiotherapy (MRgRT) has become a highly desirable treatment modality and provides the capability for daily DWI. This study assesses apparent diffusion coefficients (ADC) from EPI and TSE sequences with a NIST traceable phantom on 0.35T MR-linac. **Methods:** DWI acquisitions of a NIST traceable diffusion phantom with 13 vials of aqueous polyvinylpyrrolidone (PVP), concentrations from 0% to 50%, were performed on a 0.35T MR-linac. DWI-EPI acquisitions were performed with b-values of 0, 200, 500, and 800 s/mm², diffusion prepared (DP)-TSE acquisitions utilized b-values of 0, 300, 500, and 800 s/mm². Acquisitions were performed with pre-scan normalization on and off, along with noise fields. Additionally, signal averages (NSA) of 1, 4, 16, and 32 were acquired. ADC values were calculated using nonlinear least-squares fitting of all b-values for original and denoised images. Two denoising methods were used including quadratic background subtraction and noise field subtraction. **Results:** EPI acquisitions with noise field subtraction had the lowest ADC error of -7.3% and 4.4% from reference for 0% and 40% PVP, NSA=1. ADC values from initial EPI-DWI acquisitions had an ADC error of -14.2% and -9.8% from reference for 0% and 40% PVP, NSA=1. Initial TSE images had an error of -6.9% and -57.6% from reference for 0% and 40% PVP with NSA=1. ADC values were significantly greater than reference value for 50% PVP on all scans and postprocessing methods but is outside the physiological range in humans. **Conclusion:** EPI and TSE had similar ADC accuracy but were not equivalent to reference values. However, TSE acquisitions had reduced geometric distortion and greater consistency across NSA values. Further correction is required for accurate ADC calculation on low field MRgRT systems.

PO-GePV-M-172

Automated Analysis of QA Images Acquired with Low-Field MRgRT

R Moskwa¹*, B Paliwal², I Tanumiharjo², P Yadav², (1) Medical Physics, University of Wisconsin-Madison, Madison, WI, (2) School of Medicine and Public Health, University of Wisconsin-Madison, Madison, WI

Purpose: Test the accuracy and reproducibility of Magphan(R) phantom, designed for quality assurance (QA) needs of MRI-guided radiotherapy. It allows automated measurements for image analysis and acquisition of important imaging parameters. **Methods:** QA was performed weekly. Magphan(R) RT phantom in a low-field MR-LINAC system was scanned over a period of 10 months. At least 35 measurements for each imaging parameter were acquired. Three MRI sequences were used for QA: TRUFI, T1, and T2. DICOM files were used to calculate the following imaging parameters: geometric distortion, uniformity, resolution, signal-to-noise ratio (SNR), and laser alignment. Point spread function and edge spread function are also calculated for resolution analysis. All data was collected and analyzed for accuracy and reproducibility. Mean, median, standard deviation, maximum and minimum values were used in combination with plots to check for data consistency over the 10-month period. **Results:** Data showed small standard deviation and high consistency for each tested imaging parameter with each MRI sequence. Highest variability in data was seen with the TRUFI sequence, which was expected because of low resolution and short scan time (25sec). Point spread function, edge spread function, signal uniformity and SNR measurements remained consistent over 10 months. Laser alignment traditional offsets and angular deviation remained consistent over 10 months, except for one day where phantom was misaligned. Distortion analysis, performed for two different phantom fiducial diameters per imaging sequence, remained consistent for both diameters. **Conclusion:** The Magphan(R) RT phantom showed to be both reliable, reproducible, and easy to use. Imaging parameters that are not available with the current accepted low-field LINAC QA phantom, such as laser alignment and geometric distortion, were found to be both important and relevant. These results show promise for a more streamlined, time-saving, and less error-prone low-field MR-LINAC QA workflow when compared to current practices.

PO-GePV-M-173

Investigation of Unity MR-Linac Adaptive Planning On Prostate SBRT Plan Quality

J St-Aubin*, J Snyder, D Dunkerley, S Yaddanapudi, D Hyer, University of Iowa, Iowa City, IA

Purpose: The Elekta Unity MR-Linac utilizes 1.5 T magnetic resonance (MR) images and software tools to create an adaptive plan prior to each patient treatment. This study aims to investigate the impact of adaptive planning on SBRT prostate treatments. **Methods:** In this preliminary retrospective planning study, two adaptive planning methods were investigated for a single prostate patient following the PACE-B SBRT protocol (3,625 cGy delivered in 5 Fractions). The first method mimicked the time constraints of online adaptive planning and allowed only a single optimization attempt. The second method mimicked an offline planning approach and allowed for multiple optimization runs in an attempt to maximize the treatment plan quality. Both adaptive planning methods were then compared to a Versa HD VMAT plan calculated on the daily MRI. All dose calculations on MRI used bulk density overrides, and all fractions were added using a DVH addition technique to determine final DVH metrics. **Results:** All organ-at-risk DVH metrics met the PACE protocol requirements for all planning methods evaluated, but PTV coverage was determined to be 76% in the VMAT plan which was not modified for anatomical changes. Prostate and proximal seminal vesicle coverage was 95% and 92% respectively for the VMAT plan but was 99.9% for both adaptive planning methods with PTV coverage normalized to 95% for both adaptive planning approaches. It was found that the offline adaptive plan approach yielded additional OAR sparing for the rectum and bladder compared to the online plan approach. **Conclusion:** PTV coverage was significantly improved with an adaptive planning strategy, as were the prostate and proximal seminal vesicle coverage. Both the adaptive and non-adaptive VMAT plan met all OAR constraints of the PACE-B protocol, but it was found that the time constraints related to online adaptive planning may lead to sub-optimal OAR sparing.

PO-GePV-M-174

The Dosimetric Impact of Magnetic Field on Lung Cancer Treatment When Using MR-Linac

C Ding*, A Godley, K Westover, R Timmerman, J Park, The University of Texas Southwestern Medical Ctr, Indianapolis, IN

Purpose: To compare dose distribution of stereotactic body radiation therapy (SBRT) treatment for lung cancer with or without the presence of magnetic field on 3D and IMRT plans using MR-Linac. **Methods:** A comparison for a stage T3N0 lung cancer patient, which was originally treated on a conventional linac using SBRT with a prescription dose of 50Gy in 5 fractions covering at least 95% of PTV, is presented in this study. Retrospectively, 3D and IMRT based SBRT plans with the same PTV dose prescription were generated using the Monaco planning system for Unity MR-Linac (Elekta, Stockholm, Sweden) without magnetic field correction. Those plans were re-calculated using magnetic field corrected beam data to represent the presence of magnetic field during treatment. Dose distributions with and without magnetic field in exactly same beams were compared on 3D and IMRT plans. Thereafter, the IMRT plan was re-optimized using magnetic field corrected beam data with the same target and normal tissue dose constraints. Dose distribution of IMRT plans optimized with and without magnetic field were also compared. **Results:** The dose on lung side of lung-target interface was reduced with the presence of magnetic field for both 3D and IMRT plans. Therefore, the target coverage was compromised by the presence of magnetic field if the planning system ignored the effects of the field. After re-optimization, the IMRT plan can compensate for the reduced coverage of the target while keep sparing of the normal tissue. **Conclusion:** The presence of magnetic field changes the dose distribution of lung treatment and the lung target interface. Re-optimization is required for IMRT plans with magnetic field corrected beam data.

PO-GePV-M-175

Dosimetric Evaluation for MR-Linac Online Adaptive Planning Approaches: A Case Study of Recurrent Adrenocortical Carcinoma

J Niedzielski*, A Koong, A Sobremonte, P Castillo, B Lee, J Yang, UT MD Anderson Cancer Center, Houston, TX

Purpose: Elekta Unity MR-Linac provides two online plan adaptation approaches: daily plan re-optimization with isocenter adaptation (i.e., adapt-to-position, ATP) and daily re-planning considering anatomical changes (adapt-to-shape, ATS). We aimed to analyze the dosimetric differences between these two approaches for a patient treated with ATS in order to shed a light for optimizing online plan adaptation strategy. **Methods:** A 77 year-old female, whom was diagnosed with recurrent adrenocortical carcinoma, was treated with hypofractionated radiotherapy for a metastatic pelvic sidewall tumor that was located proximal to the large bowel. The patient was treated with the Elekta Unity system, with a prescription of 60 Gy delivered in 10 fractions. The ATS workflow was applied to each fraction for online plan adaptation, including re-contouring of the GTV and normal tissues (large bowel, rectum, bladder, and small bowel). Retrospectively, the ATP workflow was applied by re-planning based on the isocenter shift on each daily MR scan. Accumulated dose for each of the two plan adaptation methods was calculated by summation of the absolute DVH of each structure. **Results:** The tumor volume did not show significant changes during treatment, but the proximity of large bowel to tumor varied from day to day. The clinical goal of GTV D90%>60Gy was achieved using both methods (60.5Gy vs. 60.1Gy, ATP vs. ATS). However, there were significantly higher doses using the ATP method for large bowel, bladder, rectum, and small bowel ($p=0.0001$, 0.0001 , 0.02 , 0.0002 , respectively), with the large bowel violated the $D_{max}<40\text{Gy}$ constraint using the ATP approach (46.1Gy vs. 39.4Gy, ATP vs. ATS). Additionally, the maximum doses of large bowel had a larger variance on the ATP workflow, as compared to the ATS (stdev=3.6Gy vs. 0.9Gy). **Conclusion:** ATS approach may offer higher precision than ATP approach in treating tumors proximal to radiosensitive normal tissues, without sacrificing target coverage.

PO-GePV-M-176

Urethra Inter-Fractional Geometric Variations of Prostate Cancer Patients: A Study Using an On-Board MRI

J Pham*, R Savjani, S Yoon, Y Gao, M Cao, P Hu, K Sheng, D Low, M Steinberg, A Kishan, Y Yang, UCLA School of Medicine, Los Angeles, CA

Purpose: Urethral injury plays a significant role in genitourinary (GU) toxicities for prostate cancer patients receiving radiation therapy (RT). However, urethra sparing has been challenging due to non-trivial urethra delineation with conventional RT technologies. MRI provides strong soft tissue contrast and potentially high urethra visibility. Moreover, MR-guided online adaptive RT (MRgART) based on patient's daily MRI shows the potential of improved organ-at-risk (OAR) sparing. In this study, we used MR-guided radiation therapy (MRgRT) on-board MRI to retrospectively analyze inter-fractional urethra localization and geometric variation for a cohort of prostate cancer patients and evaluated the value of MRgART for urethra sparing. **Methods:** Eleven prostate cancer patients were scanned on a 0.35T MRgRT system using a urethra-specific T2-weighted 3D HASTE sequence at two different timepoints between simulation and the final fraction. The average time between urethral imaging pair was 19.8 days. A resident radiation oncologist retrospectively contoured the prostatic urethra for all patient images. Additionally, the oncologist qualitatively scored the prostatic urethra visibility. For each patient, the urethra imaging pairs were rigidly registered based on the prostate gland and urethra inter-fractional geometric variation was evaluated using 95th percentile Hausdorff distance (HD95), mean-distance-to-agreement (MDA), and DICE coefficient. **Results:** Qualitatively, 3D HASTE provided good conspicuity and the urethra could be identified clearly for the majority of the patient scans. The average length and diameter of the prostatic urethra was $3.54\pm0.52\text{cm}$ and $0.78\pm0.12\text{cm}$. The average HD95, MDA, and DICE between urethra imaging pairs was $0.26\pm0.10\text{cm}$, $0.11\pm0.04\text{cm}$, and 0.58 ± 0.14 . The majority of urethral inter-fractional shifts were observed in the anterior-posterior and superior-inferior direction. **Conclusion:** Urethral inter-fractional geometric variation is significant, with respect to the urethra diameter, when shifts are introduced in the anterior-posterior direction. MRgART workflow with optimal on-board imaging may improve urethra sparing throughout treatment.

PO-GePV-M-177

Feasibility of Adapt-To-Position Treatment of Prostate Patients Undergoing Ultra-Hypofractionated MR-Guided Adaptive Radiotherapy

S Burleson*, V Brennan, M Zelefsky, N Tyagi, Memorial Sloan-Kettering Cancer Center, New York, NY

Purpose: To investigate the feasibility and dosimetric outcome of performing adapt-to-position (ATP) workflow on prostate cases undergoing ultra-hypofractionated radiotherapy with boost to dominant intraprostatic lesion (DIL). **Methods:** 10 prostate patients were treated on Unity MR-Linac using a five-fraction regimen with 40Gy to prostate and 45Gy simultaneous-integrated-boost to DIL. All patients were treated clinically using adapt-to-shape (ATS) workflow with full re-plan and contour adjustments. Retrospectively, an ATP plan was generated on the original planning CT (pCT) to account for daily prostate shifts based on soft tissue match. The ATP plan was also re-calculated on the daily MR (dMR) with the adjusted contours-of-the-day to see the realistic impact of performing ATP. Dosimetric data to OAR's (bladder, rectum, bowel) and targets (PTV_Prost, PTV_DIL) were compared between the treated ATS (ATS_txt), ATP (ATP), and the ATP plan recalculated on dMR (ATP_recalc). Volume and positional/center of mass (COM) changes for targets were compared between pCT and dMR's. **Results:** PTV_Prost and PTV_DIL coverage decreased more than 10% on ATP_recalc compared to the ATS_txt in 20% and 28% of fractions respectively. This coverage drop was not seen on any of the ATP plans. The average volume change of the PTV_DIL contour on dMR compared to pCT for the course of treatment ranged from 0.5-10 cc indicating during treatment changes. The difference in relative distance between the PTV_Prost COM and the PTV_DIL COM between the pCT and dMR's ranged from 0.3-1.42 cm. Certain OAR constraints were violated on ATP_recalc but were met on ATP. **Conclusion:** The decrease in target coverage and change in relative COM highlights that ATP planning is not an optimal approach for MR-guided adaptive prostate radiotherapy when boosting the DIL since ATP does not reflect daily variation in position and deformation of soft tissue anatomy and may result in OAR dosimetric parameters being exceeded.

PO-GePV-M-178

Dosimetric Effects of Air Cavities for MRI-Guided Online Adaptive Radiation Therapy (MRgART) of Prostate Bed After Radical Prostatectomy

J Pham*, M Cao, A Kishan, Y Yang, UCLA School of Medicine, Los Angeles, CA

Purpose: To evaluate the dosimetric impact of air cavity electron density correction for MR-guided Online Adaptive Radiation Therapy (MRgART) of prostate bed patients after radical prostatectomy. **Methods:** Five prostate bed patients treated on a 0.35T MR Linac following institutional bladder and rectum filling protocol were retrospectively included to simulate the MRgART workflow. For two fractions of each patient, workflow1 'Recalc': the initial clinical plan was calculated on the daily setup MRI with electron density directly obtained from simulation CT deformably registered to daily MRI; and workflow2 'Override': the initial clinical plan was calculated with one additional step, air cavities were manually contoured with bulky air density assignment based on daily MRI anatomy. Dosimetric metrics for targets and OAR were compared between the calculated dose with and without air cavity electron density correction and its impact on clinical decision for the necessity of adaptive planning was evaluated for each fraction. **Results:** The average air cavity change between simulation CT and daily MRI was $8.15\pm9.16\text{cc}$. Clinical dosimetric endpoints between the 'Recalc' and 'Override' workflow showed little clinical dosimetric differences, with the maximum deviations being 3.47% and 2.82% for the rectum (V27.5Gy) and bladder (V32.5Gy). Furthermore, the dosimetric difference did not lead to change in clinical decision for adaptive planning except for only one fraction, where the dose calculation with air cavity density correction indicated that the bladder D_{max} dose exceeded the constraint while the calculated dose without correction showed acceptable dose, although the absolute difference was only 0.4Gy. **Conclusion:** With strict bladder and rectum filling protocol, air cavity changes between simulation and daily treatment did not result in large dosimetric changes on our 0.35T MRgRT system. However, caution may need to be paid for potential large air cavity variations or under higher magnetic fields.

Dr. Yang has received honoraria and consulting fees from ViewRay. Dr. Kishan has received honoraria and research funding from ViewRay.

PO-GePV-M-179

Assessment of Dose Accuracy of Bulk Synthetic CT in MR-Guided Online Adaptive Radiotherapy for Nasopharyngeal Carcinoma

S Ding*, H Liu, B Wang, Y Li, B Liu, X HUANG, Sun Yat-sen University Cancer Center, Guangzhou, CN

Purpose: This study aims to evaluate the dose accuracy of bulk relative electron density (rED) assignment approach to generate synthetic CT (sCT) for application in 1.5T MR-Linac, to assess the reliability of this approach in the case of online adaptive MR-guided radiotherapy for Nasopharyngeal Carcinoma (NPC) patients. **Methods:** The original CT and MRI T2 were acquired for 10 NPC patients. All region of interests (ROIs) were delineated on CT in Monaco system (v5.40.02). Each patient's MRI/CT image pair was aligned using a rigid registration algorithm and ROIs were copied to MRI from CT. The sCT was generated in MRI using bulk rED assignment approach, based on the rED values of the ROIs. Three sCT images were generated: The sCT(ICRU) uses the rED values recommended by ICRU46, the sCT(tailor) uses the patient-specific mean rED values, and the sCT(Homogeneity) was created using water equivalent value for entire patient data set. The same treatment plan was calculated on three sCTs and original CT. Dose calculation accuracy was evaluated by gamma analysis, point dose comparison and dose volume histogram (DVH) parameters. **Results:** For both criteria, 1%/1mm and 2%/2mm gamma passing rate results of plans on sCT(tailor) were always higher than plans on sCT(ICRU) and sCT(Homogeneity) when compared with original CT based plans ($p = 0.005$). The difference on point dose in PTVnx for each case calculated on sCT(tailor) ($-0.14\% \pm 1.44\%$) was smaller if compared to those calculated on sCT(ICRU) ($-8.77\% \pm 2.33\%$) and sCT(Homogeneity) ($1.65\% \pm 2.57\%$). The DVH differences for plan based on sCT(tailor) were much smaller than sCT(ICRU) and sCT(Homogeneity). **Conclusion:** The sCT generated with bulk rED assignment approach guarantees an acceptable level of dose accuracy for NPC patients with 1.5T MR-Linac, making this approach suitable to online adaptive MR-guided radiotherapy. The accuracy can be improved by using patient-specific rED values.

PO-GePV-M-180

Superparamagnetic Iron Oxide Enhanced MRI for Elekta Unity MR-Linac: A Pre-Clinical Phantom Study

D Lee*, P Klepchick¹, H Lee¹, D Pavord¹, S Oh¹, J Sohn^{1,2}, A Kirichenko¹, (1) Allegheny Health Network, Pittsburgh, PA, (2) Drexel University College of Medicine, Philadelphia, PA

Purpose: This study aims to sufficiently visualize Super-Paramagnetic-Iron-Oxide enhanced MR images for Elekta Unity MR-Linac (Elekta; Stockholm, Sweden). Once IV of Ferumoxytol (Feraheme, AMAG Pharmaceuticals, Waltham, MA) injected as an alternative contrast media, it is prolonged hepatic blood pool phase and delayed intracellular uptake in liver Kupffer cells over a month. Then, it alters MR signals due to susceptibility effect. Hence, we performed a pre-clinical phantom study to investigate the sensitivity of Feraheme on MR images of Unity. **Methods:** Varying concentrations of Feraheme and Gadobutrol (Gd, Gadavist, Bayer HealthCare) were diluted in water into clinically relevant concentrations and poured into cylindrical containers: (1) 10 μ g/mL, (2) 15 μ g/mL and (3) 30 μ g/mL of Feraheme, (4) 0.1mmol/kg Gd, and (5) distilled water only and an identical set with the same concentrations with 1% w/w agarose. The varying concentrations were imaged using CT and MRI (Siemens and Unity) with T1-Weighted, T2, Proton Density (PD) and T2* sequences. All MR images were visually inspected to evaluate signal enhancements. **Results:** Feraheme successfully enhanced MR images but not for CT. Feraheme especially enhanced T1-Weighted (TR<8.0ms/TE<5ms) images brighter than Gd. Feraheme negatively enhanced T2 (TR/TE=1000.0/100.0ms) images but it is insufficient to differentiate the three Feraheme concentrations of contrast agents. Feraheme also negatively enhanced PD (TR/TE=1400.0/30.0ms) images, similar to the T2 images but it slightly differentiate them. In addition, Feraheme enhanced T2* (TR/TE=1074.7/5.8ms) images of Siemens but negatively-minimally enhanced T2* (TR/TE=1457.7/18.4ms) images of Unity. The 1% agarose resulted in signal reduction on only T2 images. **Conclusion:** This study utilized a clinical range of concentrations of Feraheme to enhance MR images with positive or negative signal changes on T1, T2, PD and T2* images whilst compared to the ground truth of diagnostic images. It is evident that Feraheme can be applicable for Unity and clinical trials for investigations liver functional imaging.

PO-GePV-M-181

Evaluation of Cranial FSRT Plan Quality on a Magnetic Resonance Image Guided Linear Accelerator

K Snyder*, J Kim, J Dolan, Y Huang, A Doemer, N Wen, I Chetty, P Parikh, M Shah, S Siddiqui, Henry Ford Health System, Detroit, MI

Purpose: To investigate treatment plan quality for intracranial post-operative tumor beds treated with fractionated stereotactic radiotherapy (FSRT) for delivery on a Magnetic Resonance Image Guided Linear Accelerator (MR-Linac). **Methods:** Ten intracranial FSRT patients were replanned on a Monte Carlo-based commercial treatment planning system (TPS), MRIdian v5.4.0.97 (ViewRay, Mountain View CA). The MR-linac system combines a 0.345T magnet and a 6MV flattening filter free (FFF) treatment beam. Plans were generated using a step-and-shoot IMRT technique, generated with a double-stacked MLC with an equivalent leaf width of 4.15mm. Eleven beams were utilized, spaced 20-35 degrees apart. Target volumes were prescribed to 24-30Gy in 3 fractions (8-10Gy per fraction) and normalized so that 95% of the target volume received prescription dose. Plans were optimized to achieve AAPM TG 101 organ at risk tolerances and sharp dose fall off. Dose fall off parameters were evaluated including conformality index (CI), gradient index (GI), volume of Normal Brain (Brain-Target volume) receiving 12Gy (NormBrainV12Gy), 18Gy (NormBrainV18Gy), and 24Gy (NormBrainV24Gy) as well as maximum dose to the target volume (MaxTargetD0.03cc). Deliverability of five of the ten cases was verified with ion chamber and film measurements. **Results:** The average target volume was 26.20cc (range: 10.57cc-59.36cc), with several planned with a simultaneous integrated boost (SIB). The average MaxTargetD0.03cc normalized to the SIB dose was 120% (range: 112%-126%). The corresponding CI and GI were 1.15 and 3.69, respectively. Average volumes to NormBrainV12Gy, NormBrainV18Gy, NormBrainV24Gy were 65.87cc, 22.09cc, and 5.38cc, respectively. Average delivery time was 12.2 minutes. Average ion chamber point dose difference from planned values was -1.92% and average gamma pass rate utilizing 3%/1mm criteria was 97.94%. **Conclusion:** This study demonstrates the feasibility of planning intracranial FSRT on an MR-Linac. Delivery was verified and dose distributions were deemed clinically acceptable and accomplished without sacrificing maximum target dose.

PO-GePV-M-182

Synthetic CT Generation from MRI for Stereotactic Radiosurgery

S Hsu*, D Mynampati, W Tome, Montefiore Medical Center, Bronx, NY

Purpose: To evaluate the accuracy of synthetic CT from MRI using a conditional generative adversarial network (cGAN) for stereotactic radiosurgery (SRS). **Methods:** A method to generate synthetic CT was developed using an image-to-image translation cGAN with a loss function including a least-square adversarial term, mean-absolute-error (MAE) regularization and mutual information. Training datasets included 25 pairs of CT-sim images and diagnostic T1-weighted MRI with gadolinium contrast acquired for SRS planning. Before training, non-uniformity corrections and image normalization using z-score were applied to MR images. Synthetic CT images were compared with true CT images for 5 cases (brain metastases, arteriovenous malformation and vestibular schwannoma) in terms of image quality and dosimetric accuracy. To evaluate the dosimetric accuracy, clinical plans were recalculated on synthetic CT images with the fixed MUs in an Eclipse treatment planning system. Dose volume histograms (DVHs) and 3D gamma analyses (1%/1mm) were compared between

synthetic CT (with and without density corrections) and true CT datasets. **Results:** For the test datasets, CT number MAEs for air, soft tissues and bone were 456, 53 and 320 respectively. The peak signal-to-noise ratios (PSNR) were in the range of 23.2-25.2 and the structural index similarity measures (SSIM) were in the range of 0.905-0.92. The 3D gamma analyses ($\gamma < 1$) for true CT data against synthetic CT data with and without density corrections were 98%-100% and 87%-95%, respectively. Compared to DVHs for the true CT data, D99.5% for synthetic CT data with and without density corrections was $-0.4\% \pm 0.7\%$ and $1.2\% \pm 1.9\%$, respectively, while D2% for the data with and without corrections was $-0.2\% \pm 0.6\%$ and $2.2\% \pm 0.5\%$. **Conclusion:** Our study demonstrated the potential of using synthetic CT from MRI for SRS treatment planning. Our future work will validate our method on more cases and also investigate the accuracy of synthetic CT for SRS position verification.

PO-GePV-M-183

CINE Viewer in Eclipse for Tumor Motion Evaluation in MRgRT

T Kim^{1*}, Y Wu², N Knutson³, M Schmidt⁴, (1) Washington University in St. Louis, Saint Louis, MO, (2) Washington University, St. Louis, MO, (3) Washington University School of Medicine, St Louis, MO, (4) Washington University School of Medicine in St. Louis, Saint Louis, MO

Purpose: 4D MRI has been limitedly utilized in clinic unlike 4D CT for tumor motion evaluation. In contrast, 2D CINE MRI has been actively used in MRgRT through MRI vendors' display tools, resulting in limited access from Radiation Oncology practice. In the study, we investigated the feasibility of utilizing CINE MRI through a treatment planning system. **Methods:** We developed CINE viewer in Eclipse using Varian Eclipse Scripting Application Programming Interface (ESAPI). It consisted of 1) single/orthogonal viewer, 2) display controller,s and 3) measurement tools for tumor motion evaluation. **Results:** In Eclipse, CINE viewer loaded 1) CINE MRIs from 1.5T Philips Ingenia MRI which were DICOM imported to Eclipse database and 2) CINE MRIs from ViewRay 0.35T MR-LINAC which were saved to a local database from ViewRay TPS as a movie file. CINE viewer handled two display modes (single plane or orthogonal planes) depending on acquisition planes. Multiple measuring markers were placed on tumor at various respiratory phases, which provided tumor motion ranges in x-, y-axis of CINE images among the respiratory phases. **Conclusion:** We demonstrated the clinical feasibility of tumor motion evaluation using CINE viewer in Eclipse for MRI simulation and MRgRT review. The proposed approach streamlines tumor motion evaluation using CINE MRI using Eclipse in MRgRT procedures.

PO-GePV-M-184

Evaluate the Jointly Model-Based Reconstruction Method to Correct MRI Images Geometrical Distortion for Precise MRI-Based Brain Stereotactic Radiosurgery Planning: Using Pari QC Head Phantom

M Hosseini¹, SMR Aghamiri², A Fatemi^{3, 4*}, SM Bagherimofidi⁵, (1) Shahid Beheshti University, Tehran, IR, (2) Shahid Beheshti University, Tehran, IR, (3) University of Mississippi Medical Center, Jackson, MS, (4) SpinTexc. LLC, Jackson, MS, (5) University of Mississippi Medical Center, Jackson, MS

Purpose: The main problem of using MRI images for radiotherapy planning is its geometrical distortion. The primary source of sequence-dependent MRI image geometrical distortion changes in magnetic susceptibilities. The conventional B0 field-mapping method is not accurate. This work aims to improve the distortion correction method and evaluate the alternative approach using the jointly model-based reconstruction. **Methods:** MRI and CT images of customized QC head phantom "Pari head phantom," by Spintecx.LLC, which includes air cavities and internal tissue mimicking structures, were acquired. We used multi echo-GRE MRI pulse sequence to generate magnitude images at different TEs and derive field map. The k-space data obtained using a 3D T1-MPRAGE sequence. The Cartesian k-space trajectory modeled as a regularized least-square cost function to estimate the undistorted field-map and corrected image. To generate the field map, the quadratic regularizer parameter was set to 2^{-3} , and for the image, the non-quadratic edge preserving regularizer parameter was set to 2^3 by cross-validation. We minimized this cost function by using the CG-NUFFT algorithm in MATLAB. Convergence criterion met by an iterative process. Finally, both corrected images using a field map and our proposed method compared with MRI image register with CT images. **Results:** We estimate NRMSE error of the corrected and uncorrected MRI images by registering to CT images. Maximum improvement in NRMSE error was 47% and 19.48% for jointly model-based reconstruction and correction by distorted field-map. The most-distorted areas were around air cavities. **Conclusion:** MRI image's geometrical distortion close to air cavities is considerably large. Using the "Pari QC head phantom" lets us simulate the MRI image's geometrical distortion close to air-cavities. And Our method shows better results than the conventional B0 field map method to correct MRI images more effectively and faster. This method will improve and facilitate using MRI images for precise SRS planning.

PO-GePV-M-185

Application of Super-Resolution Reconstruction to Prostate 0.35T MRI Scans

J Charters^{1*}, A Kishan¹, J Lamb¹, (1) Dept. of Radiation Oncology, UCLA, Los Angeles, CA

Purpose: Super-resolution (SR) is a technique to combine multiple low-resolution images acquired with sub-voxel frame shifts into a single high-resolution image by inverting a linear image acquisition model, which may be used to address resolution limitations arising from subject motion and hardware. In this study we evaluate the performance of SR on 0.35T magnetic resonance imaging (MRI) prostate scans towards an application of low-field MRI-guided focal therapy. **Methods:** Balanced steady-state free precession (bSSFP) multi-slice images of an American College of Radiology (ACR) MRI accreditation phantom and one prostate patient were acquired on a 0.35T MRI-guided radiotherapy machine. All images had a pixel spacing of 1.5mm x 1.5mm. Couch translations of 0.5mm and 1.0mm were applied in both in-plane directions, for a total of five acquisitions per object. Registrations were performed using Elastix. We used a maximum a posteriori (MAP) based SR algorithm to reconstruct the reference object by a factor of 2 in each dimension. We assumed uniform Gaussian blurring in the SR forward model from high-resolution to low-resolution and a Gaussian noise prior. The resulting images were compared to bilinear upsampling and an upsampled average of the registered images. Example edges in the patient image were chosen to extract line profiles, which were then fit to a sigmoid function. The sigmoid widths quantified spatial resolution of the object. **Results:** In the ACR phantom high-contrast spatial resolution slice, the SR image showed improvement in the visibility of the hole-array pairs. Similarly, greater detail was present in the prostate patient SR reconstruction. Sigmoid curve fitting demonstrated smaller widths for SR over single image and average image interpolation. **Conclusion:** MAP-based SR is a feasible method to improve 0.35T MR prostate image resolution. Additional improvements, such as incorporating a measured imager point-spread function, may be beneficial.

PO-GePV-M-186

Automated Detection of Freiburg Flap Applicator Catheters for Surface Brachytherapy on PETRA MR Images

E Kaza*, CY Lee, R Cormack, PM Devlin, I Buzurovic, Brigham and Women's Hospital, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Purpose: MR-only treatment planning for skin High Dose Rate surface applicator brachytherapy (SABT) relies on accurate depiction of applicator channels on MR images. This work presents automatic detection of empty Freiburg Flap (FF) applicator catheters on optimized Pointwise Encoding Time Reduction with Radial Acquisition (PETRA) images, where catheters exhibit positive contrast. **Methods:** An FF applicator (12 catheters with 24 spheres of 10mm diameter) was sandwiched between two plexiglass blocks and placed on a MagPhan TMR008 phantom in a 3T Siemens Vida. Coronal 0.8mm isotropic resolution 3D PETRA images (TR/TE/TI 3.3/0.07/100 ms, FOV 306x306mm², BW 407Hz/px) were acquired using UltraFlexLarge18 and Spine32 coils. A ROI encompassing a visible catheter and its surrounding beads on axial slices was drawn in MATLAB. After manual definition of the center column of the first sphere, the center and width of the following spheres was derived using known dimensions. Normalized signal intensity column profiles and their numerical

gradients were computed. Profile mean and standard deviation (PM, SD) and gradient mean (GM) over the 13 columns width of each sphere was extracted. Locations of maximum PM found within 2 pixels of minima of SD and of GM were catheter position candidates for a sphere. A catheter was reconstructed by selecting the candidate position of a sphere within 1 pixel from its preceding one. **Results:** Since FF catheters appeared as bright lines with dark borders inside bright circles, the characteristics of signal intensity profiles perpendicular to the catheters revealed accurately catheter position. The presented algorithm detected successfully all 12 catheters inside their 24 surrounding spheres. Six catheters were reconstructed as completely straight lines, five presented 0.8mm and one 1.6mm maximum deviation from a straight line. **Conclusion:** Automated detection of empty catheters in FF applicators for skin SBT was feasible, based on their signal intensity properties on PETRA MRI.

PO-GePV-M-187

MRI-Based Prostate SBRT Treatment Planning Using Synthetic CT

J Scholey¹*, T Nano², X Miao³, P Larson⁴, M Descovich⁵, (1) University of California San Francisco, San Francisco, CA, (2) University of California San Francisco, San Francisco, CA, (3) Siemens Medical Solutions USA Inc., Boston, MA (4) University of California San Francisco, San Francisco, CA, (5) University of California San Francisco, San Francisco, CA

Purpose: To evaluate the feasibility of using a commercial MRI-derived synthetic CT (sCT) protocol for CyberKnife- and VMAT-based treatment planning for prostate SBRT. **Methods:** Same-day CT and MRI simulations in the treatment position were performed on ten patients who were prospectively enrolled into this IRB-approved study and treated with SBRT to the prostate (40Gy in 5 fractions). Dixon in-phase and out-of-phase MRIs were acquired on a 3T scanner (MAGNETOM Vida, Siemens Healthcare) using a 3D T1-weighted gradient echo sequence (TE1/TE2/TR=1.23/2.46/4ms, readout bandwidth=1090 Hz/pixel, 1x1x1.5mm³, scan time=5mins) to generate sCT datasets with a bulk-assignment algorithm based on in-phase, out-of-phase, fat-only, and water-only MRIs. CT and sCT datasets were co-registered and HU values compared using mean absolute error (MAE). CyberKnife and VMAT treatment plans were generated on each patient CT and recomputed onto corresponding sCTs using the same plan parameters and CT HU calibration curve. Dose distributions were compared using 3%/3mm local gamma criteria and dose-volume-histograms. **Results:** Relative electron density values computed from CT datasets and assigned to sCT datasets were 1.04, 0.95, 1.1, and 1.7g/cc for soft tissue, adipose, inner bone, and cortical bone, respectively. The proposed sCT protocol produced total MAE of 94±20HU. As expected, disagreement could be seen in instances of variable bowel/rectal gas filling, fiducials or calcifications appearing in the CT but not the sCT, and/or bone distribution differences, a common challenge in mapping sCT from MRI. Gamma criteria values were 98.9±0.9% (97.1-100%) and 97.7±1.3% (95.3-99.3%) for VMAT and CyberKnife plans, respectively. Dose delivered to 95% PTV volume in sCT plans was 100.5±0.8% (99.8-102.5%) and 97.0±6.0% (81.9-103.0%) of the prescription dose in the CT plans for VMAT and CyberKnife plans, respectively. **Conclusion:** MRI-derived sCT using the proposed approach shows excellent dosimetry agreement with conventional CT simulation, demonstrating the feasibility of using MRI-derived sCT for prostate SBRT treatment planning.

PO-GePV-M-188

Geometric Accuracy of Spiral FLAIR for Treatment Planning in Stereotactic Radiosurgery: A Preliminary Study

Z Li¹*, S Srivastava², J Karis¹, (1) Barrow Neurological Institute, Phoenix, AZ, (2) Dignity Health, Phoenix, AZ

Purpose: Recently a spiral FLAIR MRI technique has been developed for treatment planning in stereotactic radiosurgery of trigeminal neuralgia, providing good delineation of the nerve root, adequate suppression of CSF, improved contrast, and insensitivity to field disturbance due to the metal frame. This study aims to determine the geometric accuracy of spiral FLAIR for treatment planning. **Methods:** A CIRS MR distortion and image fusion head phantom 603A was used. CT images were acquired as reference. The phantom was scanned on a 3T research MRI scanner with a metal frame using SPGR, FIESTA, and the proposed spiral FLAIR (only available on the 3T research scanner), and on a 1.5T clinical MRI scanner without the metal frame using SPGR and conventional FLAIR. To measure the geometric accuracy, all MRI images were registered to CT images in Leksell GammaPlan. The coordinates of 13 points were measured from CT and all MRI images, 4 corner markers and 1 center marker at the middle slice, 4 corners at a superior and an inferior slice, respectively. The point-to-point deviation in each coordinate direction and corresponding distance between CT and each MRI data set were computed. Mean error in each direction, and mean and standard deviation of distance, are derived. **Results:** Mean errors in (X, Y) (mm) at 3T are (0.19, 0.32), (0.37, 0.40), (0.68, 0.56) for SPGR, FIESTA, spiral FLAIR, respectively, (0.60, 0.24) and (0.56, 0.18) at 1.5T for SPGR and conventional FLAIR, respectively. Mean and standard deviation of distance at 3T are (0.40±0.26), (0.59±0.25), (0.98±0.56), for SPGR, FIESTA, spiral FLAIR, respectively, (0.66±0.38) and (0.61±0.25) at 1.5T for SPGR and conventional FLAIR, respectively. The error in Z is 0 in all measurements. **Conclusion:** This study demonstrated that spiral FLAIR achieves good geometric accuracy, providing a potential tool for stereotactic radiosurgery treatment planning of trigeminal neuralgia.

Barrow Neurological Institute has a master research agreement with Philips Healthcare.

PO-GePV-M-189

Feasibility of Lung Stereotactic Body Radiation Therapy (SBRT) Treatment with MR-Image Guided Linear Accelerator (MRI-Linac)

S Hoffman*, T Refaat, B Lee, J Roeske, A Sethi, Loyola University Medical Center, Naperville, IL

Purpose: MR image guided radiation therapy (MRigRT) offers real time imaging of tumor motion to monitor lung lesions and gate treatments for high dose schemes like lung stereotactic body radiation therapy (SBRT). The feasibility of performing lung SBRT on MR guided linear accelerator was investigated and compared to conventional C-arm linac-based treatment. **Methods:** Six patients had their clinically optimized treatment plans completed on one system and replanned on the other. Target definitions included GTV for MR-linac gated plans (3mm expansion for PTV) and ITV (5mm expanded PTV) for C-arm linac non-gated plans. Organs at risk (OAR) were defined as per RTOG 0813. Target doses were 50-55Gy delivered with 6 MV FFF X-rays using either VMAT (C-arm linac) or step-and-shoot IMRT (MR-linac). Plans were normalized to give identical PTV coverage (V_{95%}). Target dose, dose conformity index (CI), dose gradient index (GI) and OAR volume dose constraints were compared between both modalities. The CI was compared as a function of target motion amplitude as measured by 4DCT. **Results:** Compared to C-arm linac, plans delivered on the MR-linac gave an average higher median OAR dose of 0.4±0.6Gy and a higher maximum OAR dose of 1.0±0.8% with no difference in PTV and GTV/ITV coverage. For targets with motion amplitude ≤5mm, MR-linac based plans had a worse CI (1.31±0.17 vs. 1.08±0.07, p=0.046) compared to C-arm linacs. For larger motion amplitude (>10mm), the CI was similar (1.12±0.09 vs. 1.13±0.07, p=0.913). MR-linac had a lesser GI (7.4±2.1 vs 4.9±1.2, p=0.084) and comparable GI (4.5±0.9 and 4.3±0.6, p=0.818) compared to C-arm linac for targets with motion amplitude ≤5 mm and ≥10 mm, respectively. **Conclusion:** MR-linac based IMRT plans gave similar dosimetric results compared to C-arm linac VMAT plans for lung SBRT for targets that had motion amplitude >10mm and slightly higher doses for targets with motion amplitude <5mm.

PO-GePV-M-190

Dosimetric Evaluation of Compressed Sensing Respiratory Gating in MRI-Guided Radiotherapy

J Charters¹*, Y Abdulkadir¹, D O'Connell¹, Y Yang¹, J Lamb¹, (1) University of California, Los Angeles, Los Angeles, CA

Purpose: A commercial 0.35T magnetic resonance imaging (MRI)-guided radiotherapy vendor recently introduced upgraded real-time imaging frame rate based on compressed-sensing techniques. Furthermore, changes to motion tracking algorithms were introduced. Compressed sensing can be used to increase

image frame rate, but may also compromise image quality. In order to assess the impact of this upgrade on respiratory gating accuracy, we evaluated gated dose distributions pre- and post-upgrade using a motion phantom and radiochromic film. **Methods:** Five motion traces were used to drive an MRI-compatible motion phantom, including two artificial waveforms with 4 and 6 second periods, and two free-breathing and one breath-hold breathing traces acquired from previously treated patients. A treatment plan was developed to deliver a 3 cm diameter spherical dose distribution typical of a stereotactic body radiotherapy plan. Gating was performed using 4 frames-per-second (fps) imaging pre-upgrade, and 8 fps post-upgrading using two different motion tracking algorithms, namely “small mobile targets” (SMT) and “large deformable targets” (LDT). Radiochromic film was placed in a moving insert within the phantom to measure dose. Triple-channel film dosimetry was performed and the planned and delivered dose distributions were compared using gamma with 3%/3mm criteria. One-tailed Wilcoxon signed-rank tests compared gamma indices between 4 fps and two algorithms at 8 fps. **Results:** Gamma pass rates ranged from 63–93% over the 15 combinations of breathing trace and gating conditions examined. At a significance level of 0.05, median gamma indices for 4 fps and 8 fps SMT each exceeded that for 8 fps LDT. Median gamma indices between 4 fps and 8 fps SMT were not statistically distinguishable. **Conclusion:** Respiratory gating at 8 fps provides dose distributions similar to that at 4 fps. The particular algorithm selected for motion tracking in the real-time images measurably influences gated dose distributions and should be chosen deliberately.

PO-GePV-M-191

Evaluating a Daily QA RT to MRI Isocentricity Test for an MR-Guided Linear Accelerator

M Mistro*, J Belardo, A Copeland, T Tyson, A Kubli, K Mooney, C Ainsley, Thomas Jefferson University, Philadelphia, PA

Purpose: To evaluate a proposed daily isocentricity test for MRI and RT coincidence for an MR-guided linear accelerator **Methods:** An MR-compatible A28 PTW chamber, inserted into a holder bored along the central axis of a cylindrical water phantom, was aligned under MR image guidance such that the center of its sensitive volume was located at the MRI isocenter of our MR-guided linear accelerator. A 0.60 cm x 0.83 cm field (comparable to the detector's dimensions) was irradiated at each of the four cardinal angles, and the charge measured in each case was normalized to the charge measured for a 10.04 x 9.96 cm field (to eliminate sensitivity of the readings to temperature, pressure, and the machine's output). A series of known shifts to the phantom position along each of the cardinal axes was then introduced, and the same sequence of measurements was repeated in order to establish a relationship between the detector's response and its offset from MRI isocenter. The relationship in each direction was fitted by a second order polynomial function, from which a global three-dimensional fitting function was derived. It is proposed that daily measurement of the five fields above with the detector aligned to the MRI isocenter, coupled with this three-dimensional fitting function, can be used to reconstruct, and thereby assess, the offset of radiation isocenter from MRI isocenter as part of a daily quality assurance program. **Results:** The detector's response is proven to be highly sensitive to displacements between radiation isocenter and MRI isocenter on the desired millimeter scale, and is well described by a three-dimensional second order polynomial function. **Conclusion:** The method shows promise as a daily QA test of the congruence between radiation and imaging isocenters, although it cannot quantify it absolutely, being sensitive also to daily variations in the field-bounding leaf positions.

PO-GePV-M-192

Dosimetric Evaluation of Irradiation Geometry and Potential Air-Gaps in An Acrylic Miniphantom Used for External Audit of Absolute Dose Calibration for a Hybrid 1.5T MR-Linac (MRL) System

N Tyagi*, E Subashi, D Lovelock, S Lim, Memorial Sloan-Kettering Cancer Center, New York, NY

Purpose: To investigate the impact of partial lateral scatter (LS), back scatter (BS) and presence of airgaps on OSLD measurements in a standard IROC acrylic miniphantom on the Unity MRL. **Methods:** The following irradiation geometries were investigated using OSLDs, A26MR/A12MR ion-chamber (IC) and Monaco Monte Carlo system: (a) IC/OSLD in IROC miniphantom (partial LS, partial BS) (b) IC/OSLD in a miniphantom placed on a solid water (SW) stack at a depth of 1.5cm (partial LS, full BS) (c) IC/OSLD placed at a depth of 1.5cm inside a 3cm slab of SW/buildup (full LS, partial BS) (d) IC/OSLD centered inside a 3 cm slab of SW/buildup at a depth of 1.5cm placed on top of a SW stack (full LS, full BS). Average of two irradiated OSLDs with and without water was used at each setup. An airgap of 1mm and 2mm, mimicking presence of potential airgap around the OSLDs in the IROC geometry was also simulated. The calibration condition of the machine was 1cGy/MU at SAD=143.5cm, d=5cm, G90, and 10x10cm². **Results:** The expected dose at d=1.5cm was 110cGy. The Monaco calculation (0.5% uncertainty and 1.0mm voxel-size) for the 4 setups were 108.2, 108.1, 109.4 and 110.0 cGy. The corresponding IC measurements were 109.0±0.03, 109.5±0.06, 110.2±0.02 and 109.8±0.03 cGy. Without water, OSLDs measurements were ~10% higher than the expected. With added water to minimize airgaps, the measurements were significantly improved to within 2.2%. The dosimetric impacts of 1mm and 2mm airgaps were also verified with Monaco to be 13.3% and 27.9% higher respectively due to the electron-return-effect. **Conclusion:** IROC MP geometry with partial LS and BS did not have any impact at the measurement depth. A minimal amount of air around or within the OSLDs can cause measurement discrepancies of 10% or higher when placed in a high b-field Unity MRL.

PO-GePV-M-193

Assessment of Inter- and Intrafraction Organs Motion with Online MRI for Cervical Cancer Patients Treated On a 1.5T MR-Linac

S Ding*, H Liu, B Wang, Y Li, B Liu, Y Ouyang, X HUANG, Sun Yat-sen University Cancer Center, Guangzhou, CN

Purpose: Internal bladder and rectum motion occur during radiotherapy for cervix cancer. IMRT planning studies have shown that the quality of radiation delivery is influenced by these anatomical changes. The study is to evaluate bladder and rectum inter- and intrafraction motion using MRI during the full course of MR-Linac radiotherapy fractions, in preparation of MR-guided online adaptive radiotherapy. **Methods:** Five stage II A - III B cervix cancer patients were treated with 25×1.8 Gy fractions on a 1.5T MR-Linac. Each fraction, pre-treatment MRI scans were obtained at the start of every treatment session, and post-treatment MRI scans were obtained at the end of every treatment session. The bladder and rectum were delineated on each MRI by the same radiation oncologist. Inter-fraction and intrafraction variability were evaluated with the Dice similarity coefficient (DSC), the Hausdorff distance (HD), mean distance to agreement (MDA), volume (V) and dose volume parameters. **Results:** Large inter-fraction motion was found for bladder and rectum due to their filling variation (Bladder: DSC: 0.68±0.17, HD: 30.58±15.32, MDA: 7.77±4.65, V: -23.02%±13.13%, Dmean: 2.23%±7.10; Rectum: DSC: 0.69±0.04, HD: 22.98±4.02, MDA: 3.45±0.63, V: 13.57%±18.09%, Dmean: 0.4%±0.7%). Median in-room treatment time pre fraction was 35 min which was much longer than conventional treatment time. The intrafraction motion for bladder was obvious that was explained by the bladder filling variation due to prolonged in-room treatment time per fraction (DSC: 0.88±0.07, HD: 14.66±8.48, MDA: 1.89±1.15, V: 13.06%±15.66%, Dmean: -0.89%±2.45%). The intrafraction rectum motion was much smaller. **Conclusion:** Considerable inter-fraction bladder and rectum motion is observed and intrafraction bladder motion which caused by longer treatment time is also obvious in cervical cancer patients on 1.5T MR-Linac. Intrafraction MR-guided online adaptive radiotherapy may potentially further correct this motion.

PO-GePV-M-194

Optimizing the Accuracy and Training Speed of An Artificial Neural Network for Three-Dimensional Tumour Trajectory Prediction in Linac-MR Image-Guided Radiation Therapy

N W Johnson^{1*}, B G Fallone^{1,2}, J Yun^{1,2}, (1) University of Alberta, Edmonton, AB, CA, (2) Cross Cancer Institute, Edmonton, AB, CA

Purpose: To predict 3D tumor trajectories during respiratory motion using an artificial neural network (ANN) for applications to real-time IGRT using a hybrid linac-MR, and to improve the accuracy and training speed of the ANN through hyperparameter optimization, adaptive learning, data augmentation, ensemble learning and GPU acceleration. **Methods:** External surrogate estimates of 3D internal thoracoabdominal tumor trajectories during normal respiration are obtained from Suh et al. (Phys. Med. Biol. 53 3623 (2008)). Long short-term memory recurrent neural networks (LSTM-RNNs) with a range of structures and hyperparameter selections are trained on a 30s subset of data obtained at the start of each fraction, and their accuracy in predicting the tumor position at a forecasting delay of 200ms is evaluated for the following 450s of motion. **Results:** Preliminary results indicate that shallow, narrow LSTM-RNNs can perform as well as or better than the larger LSTM-RNNs employed previously in this work, significantly reducing computational expense and training time. Across all fractions, the mean absolute error at a 200ms forecasting time is found to be 0.40 mm, increasing by a factor of 1.5 between 0-30s post-training and 420-450s post-training. Early experiments with ensemble learning indicates that improvements up to 30% are attainable when the output of 5 randomly initialized models are averaged, and since the individual networks are small, large ensembles may be trained simultaneously on a single GPU. **Conclusion:** Sub-mm mean absolute error (30s training, 450s testing, 240ms input intervals, 200ms forecasting interval) is achievable with small LSTM-RNNs when applied to a dataset of 3D thoracoabdominal tumor trajectories during normal respiratory motion. This suggests that computationally inexpensive, patient- and fraction-specific ANNs may be practically trained on-demand prior to each fraction of IGRT on a linac-MR.

Implementation of a 3D Printing Program in a Radiation Oncology Clinic: A Case for Simple Custom Breast Bolus Fabrication

M Lafreniere*, J Cunha, M Descovich, C Park, N Prionas, M Sharma, UC San Francisco, San Francisco, CA

Purpose: Customized bolus is an important tool in modulating radiotherapy treatment planning in post-mastectomy (+/- reconstruction) patients. Three-dimensional printing of boluses can streamline custom bolus fabrication in radiotherapy. We present guidelines for implementing a 3D printing program specifically tailored for the production of custom breast boluses in the context of a radiation oncology clinic. **Methods:** We considered 10 different printers having a large enough footprint to produce breast boluses in one piece, and a fast-printing speed to allow timely clinical production of breast boluses. We selected the one with the fastest printing speed (Ultimaker S5) to conduct our evaluation. We compared cost, fabrication time, dosimetric properties and geometric accuracy of wax bolus versus 3D printed bolus. The absorbed dose was measured with OLSDs for 20 different bolus thicknesses and materials (wax, thermoplastic, PLA and TPU), and with a field size of 10 cm by 10 cm, 200 MUs at 6 MV, and 100 SAD. **Results:** The conventional wax bolus fabrication method used at our institution takes about 5.5 hours. The 3D printed bolus fabrication process can save about 5 hours of work for each bolus made since about 30 minutes is required to supervise the 3D printing process. Moreover, custom bolus production cost can be cut down significantly once the 3D printer is purchased, since 1 kg of wax costs about \$60, and 1 kg of PLA costs about \$20. A layer height of 0.4 mm enables both sufficient thickness precision and efficient printing speed. Using 3D printing allow to decrease the bolus thickness uncertainty associated with the manual bolus fabrication process. There are no significant dosimetric differences between the wax boluses and the 3D printed boluses. **Conclusion:** Our results show that 3D printing is an efficient, cost-effective and accurate method to produce breast boluses.

PO-GePV-M-196

X-Ray Imaging Properties of Tissue Equivalent Materials

R Gao¹, D Ma^{2*}, M Li³, J Qiu⁴, (1) Taishan Sanatorium of Shandong Province, Taian, 37, CN, (2) Shandong First Medical University & Shandong Academy Of Medical Sciences, Taian, 37, CN, (3) , Taian, 37, CN, (4) Shandong First Medical University & Shandong Academy Of Medical Sciences, Tai'an, CN

Purpose: Tissue equivalent materials have been widely used in medical imaging phantom. For radiologic image simulation, imaging characteristics and physical properties of phantom should be similar to real tissue they replicate. The mechanical properties of materials have been reported. However, medical imaging properties of materials, that are essential for phantom production, are not provided by the manufacturer. This work would be studied in detail the X-ray imaging properties of a selected number of tissue equivalent materials. **Methods:** A variety of tissue equivalent materials were evaluated included several formulations of polylactic acid (PLA), acrylonitrile butadiene styrene (ABS), light curing resin (LCR), epoxide resin, polyethylene (PE), silica gel and hydrogel (n = 9). All of these materials were fabricated using instructions of manufacturer recommended. X-ray attenuation coefficient (μ) was tested on a digital radiography (CXDI-55G, Canon, Japan) with dosimeter at tube voltage from 40-120 kV and 100 mA tube current. CT image data were acquired on a CT scan (Lightspeed, GE, USA) at 120 kV and 100 mA. **Results:** These tissue equivalent materials had different μ (Fig.1). The CT numbers at 120 kV of these materials were also different, ranging from -42-630 HU (Table1). CT number of ABS was negative value, indicating that X-ray attenuation of ABS was weaker than that of water. Other materials had positive CT numbers and stronger X-ray attenuation than water. Several factors affect X-ray attenuation. Some are related to the x-ray beam and the others to properties of the material. The properties of material include the density (ρ) and the effective atomic number (Zeff). In general, substance with higher Zeff or ρ will absorb more X-rays, resulting in more X-ray attenuation. **Conclusion:** These results would make us more familiar with tissue equivalent materials, as well as providing clear guidance in selecting materials suitable as real tissue.

PO-GePV-M-197

Evaluation of 3D Filaments for Creating Patient-Specific Radiotherapeutic Phantoms

J Adamovics^{1*}, F Li², O Dona³, Y Wang⁴, A Adamovics⁵, C Wu⁶, (1) Rider University., Lawrenceville, NJ, (2) Columbia University, New York, NY, (3) Columbia University, New York, NY, (4) New York Presbyterian/Columbia University Irving Medical Center, New York, NY, (5) HEURIS INC., Skillman, NJ(6) New York Presbyterian/Columbia University Irving Medical Center, New York, NY

Purpose: To evaluate the radiodensity of modified 3D filaments for creating patient specific anthropomorphic head and neck radiotherapeutic phantoms. **Methods:** A DICOM file of a head and neck phantom was downloaded from the NIH cancer imaging archive. Using Vesalius 3 software the file was segmented to bone (226-2071 HU) and skin (-718 to -177 HU) converted to STL files and then to g-code using the 3D slicer Cura. 3D filaments with various potentially varying radio densities were prepared by melting polylactic acid (PLA) pellets at 180°C and mixing with the mineral powders listed in the Table (Filabot EX2, Barre VT, 05641). The resulting filaments were 3D printed with either the Ender3 or CR10 models (Creality). The resulting 3D prints were imaged on a CT scanner (Siemens) with scan parameters of 140 kV and 300mA. **Results:** The measured HU values ranged from -185 for PLA without additive to 2800 for PLA containing 60% steel. PLA containing 20% Bronze (20% in-fill) had an HU result of 840 while 5% bismuth trioxide (85% in-fill) was higher at 1100. PLA containing calcium silicate was 355 (85% in fill) while human skull measured at 1500 HU. **Conclusion:** The HU results for the two controls, PLA filament

without additives and human skull, are consistent with prior reported values. The 20% Bronze and 5% bismuth trioxide fall within the HU range of bone. The HU result for the PLA filament is consistent with that of skin. Additional fine adjustments of the HU values can be made by varying the % of mineral content and the % in-fill density in the Cura slicer before 3D printing.

PO-GePV-M-198

Development and Performance Evaluation of a Portable Respiratory Self-Training System Using Patch Type Magnetic Sensor

H Kang, J Kim, D Kim*, Yonsei Cancer Center, Seoul, 41KR

Purpose: Respiratory training to patients has been recommended to deliver planned radiation accurately to tumors that are moved by respiration in the thorax and abdomen. However, it is difficult to provide respiratory training to all patients because it requires additional space, time, and professional human resources. We developed portable self-respiratory training system that is based on patch type magnetic sensor; and evaluated the system for basic performance and clinical applicability. **Methods:** The system, which is used with a sensor attached to the chest and a magnet to the back, is designed to monitor the patient's respiration by measuring changes of magnetic field strength according to movements of the chest surface. It consists of a micro-electro-mechanical-system (MEMS) based patch type magnetic sensor capable of wireless communication, magnet for measurement, and mobile application. To evaluate the performance of the system, we measured the level of systemic noise, the precision of a sensor for various breathing patterns, signals change for varying distances, and effects of the presence or absence of intermediate substances between the sensor and the magnet. Various respiration patterns were produced by the QUASAR respiratory motion phantom, and the data were analyzed by fitting method and peak value method. **Results:** The sensor had a noise ratio <0.54% of the signal; average errors of signal amplitude and period for breathing patterns were 78.87 μ m and 72 ms, respectively. The signal could be measured consistently when the sensor-magnet distance was 15-20 cm. The signal difference was 1.89% for the presence or absence of a material, indicating that its influence on the measurement signal is relatively small. **Conclusion:** The potential of the respiratory self-training system was confirmed by performance tests and clinical usability evaluation. In the future, we believe that the system could provide precise respiratory training to various patients through clinical trials.

PO-GePV-M-199

Developing and Testing a Real-Time Collision Avoidance System for Couch and Gantry of a Linear Accelerator (LINAC)

Z Saleh^{1,2*}, J Patrick^{1,2}, E Klein^{1,2}, (1) Rhode Island Hospital, Providence, RI, (2) Warren Alpert Medical School of Brown University, Providence, RI

Purpose: Linear accelerators are equipped with safety mechanisms to avoid collision within the patient zone. However, they lack the safety features to detect collision between gantry and couch with the surrounding environment inside the treatment room. In this study, we present a low-cost solution for collision avoidance using commercially available sensors. **Methods:** Two types of sensors were considered for this study. A low-cost ultrasonic distance sensor (HC-SR04) that provides a non-contact measurement for distances between 2 cm and 400 cm. A thin film pressure sensor (ZD10-100) for contact-based force-sensing measurement, which is rated at 500 grams. The pressure sensor was covered with a 5 mm layer of foam tape to transmit applied pressure to the force-sensitive resistor embedded inside the sensor. For testing purposes, the sensors were mounted at the base of the couch. The distance and force measurements were monitored in real-time (every 250 ms) by a micro-controller (Arduino Uno). The micro-controller was programmed to activate a trigger when the distance dropped below 3 cm or when a force was detected simulating a hard stop. **Results:** The ultrasound sensor underestimated the distance over the measured range (3-50 cm) with an accuracy of 3-9 mm. The pressure sensor demonstrated high sensitivity when a small force was applied. The micro-controller successfully activated the trigger signal when an object was detected within 3 cm range or when an object came in contact with the pressure sensor. **Conclusion:** We have demonstrated the feasibility of constructing a collision avoidance system using distance and force sensitive sensors. These sensors can be arranged in different configurations along the base of the couch and various locations along the gantry to achieve optimal performance. An industrial grade ultrasonic sensor is recommended for better stability and accuracy.

PO-GePV-M-200

The Feasibility Study of In-Vivo Detection of Retained Gadolinium in Brain and Bone Using Magnetic Resonance Imaging (MRI) and K X-Ray Fluorescence (K-XRF) Systems

F Mostafaei^{1*}, A Arbab¹, J Barrett¹, H Nie², A Maghsoodpour¹, A Bosomtwi¹, A Al-Basheer¹, (1) Augusta University, Department of Radiation Oncology, Augusta, GA, (2) Purdue Univ, West Lafayette, IN

Purpose: Gadolinium-based Contrast Agents (GBCAs) have been used in MRI for a long time. Gd is cleared from the body via glomerular filtration within hours. However, latest researches indicated that Gd could accumulate in organs such as brain and bone as a long-term deposit. A non-invasive technique to measure retained Gd in the body would allow investigation of the potential negative health effects. Gd retention was only thought to be a concern for those with impaired renal function. Nevertheless, new studies have been pointing to the retention of Gd in the brain of individuals with healthy renal function, raises new questions and concerns regarding the safety of the widely used GBCAs. **Methods:** In a small animal study, Gd concentration in the brain was measured by a 7T animal MRI at different time intervals after contrast injection (1 hour, 24 hours & 7 days). The mice bones were extracted and Gd deposit was assessed by the 109Cd γ -ray induced K-XRF system. The correlation between Gd concentration in bone and brain will be investigated. **Results:** The minimum detection limit of Gd in a bare bone phantom using K-XRF was calculated based on μ g Gd per gram phantom and found to be 0.8 ppm. The average brain Gd concentration using MRI relaxivity (R1) mode was measured to be 0.00022 Mol/L for left and right caudoputamen, an hour post-contrast injection. The Gd concentration of 24-hour and 7-day post-contrast injection for both regions of interest was 0.00021 Mol/L, indicating no substantial reduction of Gd retention in brain. **Conclusion:** MRI and XRF systems can be used to quantify Gd retention in the brain and bone. There was no significant decrease of Gd deposit in brain at different time intervals post-contrast injection. Accurate assessment of Gd deposit is crucial for investigating potential toxicity.

PO-GePV-M-201

An Indoor Real-Time Location System (RTLS) to Improve Patient Safety and Clinical Workflow of Radiation Therapy

Y Yan*, G Tang, E Chambers, J Gillespie, C Wallace, T Chiu, A Pompos, A Godley, D Sher, K Westover, H Choy, R Timmerman, S Jiang, UT Southwestern Medical Center, Dallas, TX

Purpose: To present the infrastructure and technologies of an indoor RTLS system and its applications in a radiation therapy facility to improve patient safety and clinical workflow. **Methods:** Bluetooth Low Energy (BLE) technology was utilized as the foundation of the RTLS system. As sensors 384 Raspberry Pis were installed throughout our 136,000 sf facility which is divided into 363 zones. BLE beacons carried by subjects (patients, staff and devices) transmit BLE signals that are detected by nearby sensors. Variations in received signal strength due to distance and building structure form a unique pattern that is classified by an artificial intelligence based algorithm to tell a beacon's location. Based on the location engine infrastructure, a suite of RTLS applications were developed to improve clinical operations. **Results:** Through iterations of R&D, the RTLS system achieved a 99.9% location accuracy at zone level after it was trained. To meet clinical needs for better practice, eight applications were developed: 1) the beacon registration and asset management tool; 2) the Live Map that indicates live locations of subjects on floor maps; 3) the location search engine; 4) the electronic checklist that locates and verifies patients and accessories; 5) the MR safety surveillance system; 6) the attendance logging; 7) the timing tool for improvement of workflow efficiency and patient experience; 8) a set of data analytics and reporting tools. Since deployed in 2018, RTLS has made it more efficient to locate and verify patients and devices, and reduced wrong or

missing treatment device errors from 63 in 2018 to 23 in 2020. **Conclusion:** BLE RTLS system is proven to be an effective tool at low cost for care teams to boost patient safety, experience and operation efficiency in radiation therapy clinics, and could be easily adapted to other hospital settings.

PO-GePV-M-202

Total-Body Potassium in Rats Determined by Compact in Vivo Neutron Activation Analysis Assembly

S Tabbassum^{1*}, C Pinjing², F Yanko³, R Balachandran⁴, M Aschner⁵, A Bowman⁶, H Nie⁷, (1) Purdue University, W Lafayette, IN, (2) Purdue University, W Lafayette, IN (3) Purdue University, W Lafayette, IN (4) Purdue University, W Lafayette, IN (5) Department of Molecular Pharmacology, Albert Einstein College of Medicine, Bronx, NY, (6) Purdue University, W Lafayette, IN (7) Purdue University, West Lafayette, IN

Purpose: This study aimed to evaluate the feasibility of a compact neutron generator-based in-vivo measurement system to quantify total body potassium in small animals using rat carcasses. **Methods:** A cohort of thirty-nine rats (n= 20 males and 19 females, average weight 255±15 and 163±7 gram), which were part of a manganese exposure study, were sacrificed and inserted in polyethylene bottles. These rats were then placed and irradiated in a carefully designed irradiation cave built beside the neutron generator with an optimized thermal neutron flux and radiation dose ratio. The irradiation time was 10 minutes, followed by a 10-minute decay and 2-hour measurement using the high purity germanium detector. **Results:** The average K concentration in male and female rats was significantly different (3546±473 vs. 2258±/-281µg/g). There was a significant correlation between potassium concentration and weight in both male and female groups (for male r(20) =.48, P=0.03, for female r(19)=.59, P=.007). We evaluated the impact of manganese exposure on potassium, and potassium concentration was not affected by manganese exposure. **Conclusion:** This work shows that in-vivo neutron activation analysis can be a potential way to explore in-vivo potassium storage and metabolism.

PO-GePV-M-203

Correlation Analysis Between the Kyoto Gastritis Classification and Early Gastric Cancer

Y Gao^{1*}, R Zhang², W Zhang³, W Bai⁴, (1) Hebei General Hospital, Shijiazhuang, CN, (2) The 4th Hospital of Hebei Medical University, Shijiazhuang, Hebei, CN, (3) Shijin Irrigation District Affairs Center, Hebei Province, CN, (4) The Fourth Hospital of Hebei Medical University, Shijiazhuang, CN

Purpose: To explore the value of Endoscopic performance score for risk of gastric cancer. **Methods:** 578 patients with chronic atrophic gastritis were selected as the study subjects. We selected endoscopic appearance and background mucosal appearance, biopsy pathology, and Helicobacter Pylori examination, to analyze the relationship between Endoscopic performance score and gastric carcinoma. **Results:** In 578 patients with chronic atrophic gastritis, 156 cases LGIN and 86 cases HGIN were detected. The detection rate of HGIN in male patients was 22.3% (57/256) and that of female patients was 9.0 % (29/322). The difference was statistically significant (P<0.001). There are Kyoto gastritis score less than 3 points 213 cases, score 4-6 points 198 cases, score 7-8 points 167 cases. The scoring grade was significantly correlated with the occurrence and degree of intraepithelial neoplasia (R=0.260, P < 0.001). The total score of patients with gastric cancer in the fundus of the stomach and cardia was significantly increased (P<0.01). In univariate analysis, the risk factor for gastric cancer is intestinal metaplasia, with an OR value of 4.811(95% CI 2.905-7.967, P<0.01). **Conclusion:** Endoscopic performance score has a good predictive value for the risk of gastric cancer.

PO-GePV-M-204

Detection of Cell Apoptosis with Gaussian Markov Random Field Algorithm

J Feng^{1,2,*}, Y Sa², (1) Tianjin Huanhu Hospital, Tianjin, CN, (2) Department of Biomedical Engineering Tianjin University, Tianjin, CN

Purpose: Cell apoptosis plays critical roles in cancer research and treatments. Flow cytometry (FCM) in combination with cell staining is commonly used for detecting cell apoptosis, which is of higher cost and time consuming. We developed a new machine learning based stain-free method for the detection and study of cell apoptosis. **Methods:** Suspension-cultured K562 cells were stained with Annexin V and nuclear dyes after apoptosis induction and then sorted by fluorescence-activated cell sorting (FACS) to obtain the cell samples in different stages. Texture features of diffraction images of the cells acquired with our polarization diffraction imaging flow cytometry (p-DIFC) system were extracted with a Gaussian Markov Random Field (GMRF) algorithm. The data were separated into training and test groups. Four classifiers were chosen to explore the model and to obtain the best performance on the data. **Results:** The new method could achieve a high precision of 92% in the classification of cells in different status during apoptosis on independent test datasets of the cell line. The chosen classifiers performed well in the classification. And the results also showed that the detection precision of the model on the independent test datasets was stable. **Conclusion:** The new method constituted by a GMRF algorithm for feature extraction and a SVM for classification has advantages in the apoptosis measurements with alive cells to keep their structure and function integrity for further experimental studies.

PO-GePV-M-205

Carbon Nanotubes Role in KV X-Rays: Enhancement or Diminution?

S Ashmeg*, R Lalonde, UPMC, Pittsburgh, PA

Purpose: To experimentally ascertain the impact of carbon nanotube (CNT) on deposited energy in solid water by keV x-rays. In our previous work, we have found that adding CNTs to water enhances the measured dose deposited by x-ray beams in the MeV range. **Methods:** The radiation dose from 80,100,120,140 kVp x-rays was measured using an ion chamber at 1 cm depth in a solid water phantom. In an area of 5 cm x 5 cm, a layer of carbon nanotubes in two forms (foil and powder) was placed on the surface of the phantom, at 99 cm SSD. The pinpoint-type ion chamber is at 100 cm SAD, a centimeter below the carbon nanotubes. The measured dose enhancement ratio (DER) is the ratio of the dose to solid water + CNTs / dose to solid water only. **Results:** With CNTs in tape form, the measured DERs are 1.089, 1.083, 1.020 and 1.016 for 80 kVp, 100 kVp, 120 kVp and 140 kVp, respectively. When the tape CNTs is replaced by 650 mg of powder form CNTs, the measured DER is 1.089, 1.083, 1.051 and 1.048 for 80 kVp, 100 kVp, 120 kVp and 140 kVp, respectively. **Conclusion:** For all measured energies, the dose was enhanced when carbon nanotubes were added to the beam path. The dose increase is as high as 9% for 80 kVp and as low as 2% for 140 kVp.

PO-GePV-M-206

Virtual Collision Checks with a Laser Scanning and Depth Sensing Camera

B Posehn^{1*}, H Clark², (1) University Of British Columbia, Vancouver, BC, CA, (2) British Columbia Cancer Agency, Surrey, BC, CA

Purpose: Radiotherapy with non-coplanar beams typically require patients to attend a mock treatment ('collision check') wherein the motions of a radiotherapy plan are performed with the patient immobilized, but without radiation delivery. Treatment staff observe clearance throughout the simulation. Collision checks require LINAC time, staff time, and patient travel. Alternatively, plans and support structures can be conservatively designed to avoid the need for collision checks, but this can limit available beam orientations and patient setups (e.g., arms up) and result in sub-optimal plans. In this work we demonstrate that virtual simulation of collision checks are possible using a low-cost hand-held laser scanning and depth sensing (LiDAR) camera. **Methods:** An inexpensive (\$500 USD) camera was built using a Raspberry Pi, an Intel RealSense L515 LiDAR camera module, and a 3D-printed housing. Models of a General Electric CT

scanner and Varian TrueBeam LINAC, including couches, were captured. Models were spatially registered, and the LINAC model was rigged for virtual motion. An anthropomorphic phantom placed on the CT couch was LiDAR scanned, registered to the base CT model, and a 3D mesh model was extracted. It was then virtually transferred to the LINAC. LINAC rotational motion was simulated via a Minkowski product and intersection tests were performed to identify intentionally-created collision scenarios. **Results:** Spatial errors in the LiDAR-scanned surfaces were dependent on the material, ranging from the LINAC exterior (± 0.7 mm) to glossy carbon fibre (± 2.1 mm). In the absence of other positional uncertainties (e.g., support structures), couch-LINAC collisions due to couch translation could be predicted virtually within approximately 2.2 mm. **Conclusion:** Virtual collision checks have the potential to reduce resource usage for plans with non-coplanar beams, atypical patient setups, and bulky support structures. By allowing radiotherapy planners to simulate collision checks as part of the planning stage, additional treatment options are possible.

PO-GePV-M-207

Introduction of Automation in Radiation Treatment Plan Assignment and Daily Monitoring

J Beaudry, E Pinto, C Czmielewski, N Stein, B Leong, S Shen, C Della-Biancia, G Niyazov, L Cervino, A Damato*, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: To report on the development of ROSS (Radiation Oncology Smart Scheduling), an automated tool to assist with assignment of radiation therapy plans to planners and daily monitoring for a busy medical physics department with treatments administered over 8 locations and centralized treatment planning (71 planners, 31 linacs, 12 simulators). **Methods:** Plan scheduling assigns plans associated to completed simulations at the end of each business day and monitors the assigned plans for unexpected conflicts (start date change, planner absence, etc). ROSS uses constraint programming to generate assignments with no violations (staff credentialing, time-off, clinical conflicts) and optimizes the schedule for equitable distribution of workload among planners. ROSS accesses databases with assigned plans and new simulations to extract relevant information (required credentialing, technique, dates, etc.) and staff schedules. ROSS monitors the databases daily to flag violations (e.g., changes in start dates, new staff conflicts). Constraints and objectives were continuously adjusted and analyzed during the limited clinical rollout since fall 2020 to determine sufficient and optimal choices. Flagged violations were analyzed for a one-month period and divided into high-impact (likely clinical impact) and low-impact (clerical). **Results:** Adjustments to ROSS included constraints: limits on the number of plans due daily and in total, ramp-up/down near vacation periods, sufficient availability during planning/fusions, number of new assignments, multi-sites assigned to one planner. Development objectives inserted included: minimizing cross-campus planning, number of fusions assigned, reaching a dynamic target goal in number of plans (defined by clinical duties such as MR linac, same day SRS program, brachytherapy). ROSS' daily checks flagged 62 (14 high-priority and 48 low-priority) violations. ROSS produces assignments with a clinically feasible schedule that contains 0 violations in scheduling, with average runtimes of 244 seconds. **Conclusion:** ROSS demonstrates that automation can meaningfully assist in scheduling and provides early detection of emergent plan assignment issues.

PO-GePV-M-208

A Supplementary Management System for Personalized Ultra-Fractionated Stereotactic Adaptive Radiotherapy (PULSAR)

J Lin*, A Godley, R Timmerman, D Sher, J Wu, G Tang, Y Yan, The University of Texas Southwestern Medical Ctr, Dallas, TX

Purpose: Personalized ultra-fractionated stereotactic adaptive radiotherapy (PULSAR) is a promising radiation therapy paradigm taking advantage of the clinically proven effectiveness of stereotactic ablative radiotherapy (SABR) and the opportunity to adapt more effectively with long intervals (weeks to months) between individual SABR treatments (pulses). However, the long time between consecutive pulses creates a management challenge to the care team. A specialized whiteboard application was developed to oversee the process of PULSAR treatments to ensure patient treatment is completed correctly. **Methods:** The web-based whiteboard application was designed to track the whole process of treatment planning and delivery throughout the entire course of PULSAR. When the prescription and timing is defined, tasks for the entire course will be automatically scheduled. Responsible parties will be reminded of upcoming work via email and page based on the due dates. The patient's progress is visually presented to optimize effectiveness and ease of use. The whiteboard application is connected to databases of clinical information systems for automatic data acquisition. **Results:** A whiteboard application was developed in the ecosystem of our in-house applications. It is drastically different from any in-house or commercial system in a) visually presenting the progress of the entire patient treatment and within each pulse; b) automatically laying out schedules of the entire course; c) automatically updating some of the statuses and sending reminders to responsible parties. Functions for access control and audits are also embedded in this application to ensure safety and a smooth workflow. **Conclusion:** The PULSAR whiteboard application is a feasible means to organize and track PULSAR treatments. It helps the care team carry out non-conventional adaptive radiation therapy treatments on schedule. Profession-sensitive whiteboards and analytics tools can also be added for higher efficiency and better workflows.

PO-GePV-M-209

Analysis of the Dose Enhancement Factor in the Presence of Gold Nanoparticles in Clinical Radiotherapy Beams

P Monteiro¹*, A Quevedo², H Trombini¹, T Pianosci¹, (1) Federal University of Health Sciences of Porto Alegre, Porto Alegre, RS, BR, (2) University of Sao Paulo, Ribeirao Preto, SP, BR

Purpose: Radiotherapy aims to realize tumor control using ionizing radiation sources, preserving adjacent healthy tissues. Recent studies aim to deliver the dose in a more conformed way to tumor tissues. Among new strategies to enhance dose in tumor volume, the use of high-Z materials combined with radiotherapy emerged as a proposal for this. Thus, the combination of radiotherapy with gold nanoparticles as an alternative to maximize the efficiency of the treatment, aiming to reduce the toxicity. Therefore, this work analyzed the increase in dose deposition resulting from the effects of the interaction between gold nanoparticles and radiation from different clinical radiotherapy beams, using Monte Carlo Simulation with PENELOPE code. **Methods:** A homogeneous model of gold incorporation in water was used to quantify the interaction effect of gold with ionizing radiation (Ir-192; photon beam - 6 MV; electron beam - 6 MeV). The Dose Enhancement Factor (DEF) was calculated for all simulated conditions. **Results:** The results showed that DEF increases according to the increase in gold concentration, being also dependent on the spectrum of primary radiation used. The DEF values using the highest concentration studied for the 192Ir, 6 MV, e 6 MeV were 2.82 ± 0.09 , 1.41 ± 0.08 and 1.0297 ± 0.0002 , respectively. Thus, the work showed that the use of gold nanoparticles for electron beams does not result in a significant DEF value. **Conclusion:** The use of gold nanoparticles can provide a more effective tumor control, minimizing toxicity in adjacent healthy tissues, increasing the dose around the gold nanoparticles. This is a preliminary study with a simplified model for a previous analysis of DEFs in different types of radiation. Studies with more realistic cell models are needed to estimate an increase in local dose at different energies and beams.

PO-GePV-M-210

Measuring Distribution of An I-125 Labeled Elastin-Like Polypeptide (ELP) Nanoparticle Within Mice Tumors for Consideration as a Novel Technique of Delivering Brachytherapy

H Song¹*, J Milligan¹, K Lafata¹, G Kelly¹, A Chilkoti¹, J Cai², F Yin¹, (1) Duke University, Durham, NC, (2) Hong Kong Polytechnic University, Hong Kong, China

Purpose: An elastin-like polypeptide (ELP) nanoparticle labeled with I-131 has been demonstrated to deliver curative radiation doses to xenografted tumors

in mice. The ELP conjugate is soluble below body temperature and undergoes a thermally triggered phase transition to become an insoluble coacervate at body temperature, establishing a stable radioactive intratumoral depot. This work is to quantify activity distribution for the purpose of calculating radiation dose distribution. **Methods:** Human pancreatic adenocarcinoma cells (BxPc3-luc2) were subcutaneously injected in 5 male nu/nu mice. When tumors grew to about 500 mm³, each mouse was injected with 300 uCi of ELP labeled with the X-ray emitter I-125 (instead of beta emitter I-131) for SPECT imaging. With ELP stabilized within tumor at 24 hours, the mice were sacrificed. The excised tumor was fixed in agarose in a plastic holder that was designed to allow for biopsy at two known locations. The tumor was then imaged with micro-SPECT/CT. After SPECT/CT imaging, small biopsy punches were taken. The absolute radioactivity of each biopsy sample was measured in a gamma counter and was used to convert the SPECT image intensity to absolute distribution of I-125 within the tumor. **Results:** SPECT images show that ELP distribution within the tumor is inhomogeneous and an-isotropic. The intensity decays quickly with distance from the injection depot but not monotonously. Local hot spots were observed outside of the injection depot. For quantitative analysis, inconsistencies between SPECT intensity and radioactivity measured at the two biopsy points were observed, preventing reliable conversion of SPECT intensity to radioactivity. **Conclusion:** If ELP intratumoral delivery is engineered for improved homogeneity within tumors, especially within larger tumors, ELPs have the potential to become a novel technique for delivering brachytherapy to the whole tumor volume. Inhomogeneous patterns of ELP diffusion in inhomogeneous tissue poses challenges to quantify its distribution.

Generating Voxel-Based Dose from Activity Distribution for Radionuclide Therapy by Deep Learning Method

H Lin¹, J Jing¹, L Xu¹, (1) Hefei University of Technology Hefei, AH, CN

Purpose: To provide a potential approach to automatically generate a voxel-based dose for radionuclide therapy from activity distribution by Generative Adversarial Nets (GANs) for visualizing process, guiding treatment strategies or calculating cumulative dose etc.. **Methods:** The activity-density superposition image is input into the Generator (G) as the referred image to generate the pseudo dose image, then it is identified by the Discriminator (D) via mixing with the true dose image (i.e. GT). If the pseudo dose image is identified, the information is fed back and the G will re-generate a pseudo dose image, until the D falls to obtain the 'false for true' dose image. As a feasibility study, dose distributions based on CT-based Zubal phantom with various source organs and activity distributions were trained and tested. The dose distribution was calculated by a voxel-based Monte Carlo dose algorithm. The activity source was assumed to be 1, 2, 3, 4 or 7 blocks of subsources, and the 3-subsource model was as test dataset and the others were as training dataset. The activity distribution at the subsource scale was assumed to be homogeneous or heterogeneous (i.e. Gaussian diffusion with sigma 0.0, 0.3 or 0.6). The differences were compared by whole body-based or organ-based, and evaluated by Gamma analysis. **Results:** The dose of different activity heterogeneous degrees could be well predicted by its same or quasi-heterogeneous degree model. The whole body-based conversion is suitable for activity homogeneous distribution, whereas the organ-based conversion is suitable for activity highly heterogeneous distribution (e.g. sigma 0.6). Although the 1-source model has been trained via very few dataset, it shows the best balance in precision and training efficiency. There are offsets in the mean dose prediction, but they show high Gamma pass ratio (> 93%). **Conclusion:** Deep learning method is explored to automatic generation of radionuclide dose.

This study was supported by the Fundamental Research Funds for the Central Universities (108-4115100092) and the university student innovation project of Hefei University of Technology (2020CXCYS209).

Prediction of Dose Discrepancies Using Differences in Plan Normalization Values of Head-And-Neck VMAT Plans

M Sasaki^{1*}, H Ikushima², S Kobuchi³, K Kuwahara⁴, A Kajino⁵, D Sato⁶, W Sugimoto⁷, M Oita⁸, (1) Department of Therapeutic Radiology, Institute of Biomedical Sciences, Tokushima University Graduate School, Tokushima, JP (2) Department of Therapeutic Radiology, Institute of Biomedical Sciences, Tokushima University Graduate School, Tokushima, JP (3) Graduate School of Health Sciences, Tokushima University, Tokushima, JP (4) Graduate School of Health Sciences, Tokushima University, Tokushima, JP (5) Graduate School of Health Sciences, Tokushima University, Tokushima, JP (6) Graduate School of Health Sciences, Tokushima University, Tokushima, JP (7) Department of Radiological Technology, Tokushima Prefectural Central Hospital, Tokushima, JP (8) Okayama University Graduate School of Interdisciplinary Science and Engineering in Health Systems, Okayama, JP

Purpose: This study evaluated whether plan normalization value (PNV) differences could be used as predictors of potential discrepancies between planned and delivered doses. **Methods:** Forty-five patients who underwent volumetric-modulated arc therapy (VMAT) for head-and-neck cancer at our institution were included. The absolute dose and dose distribution were verified using ionization chamber and a GafChromic film and Delta4 PT, respectively. The VMAT plan to change the PNV used computed-tomography images and a simulated head-and-neck radiotherapy structure-set provided by the American Association of Physicists in Medicine Task Group (TG) 119. Seven treatment plans with varying PNVs were selected: 95%, 97%, 99%, 100%, 101%, 103%, and 105% PNV. For dose distribution verification, we used Delta4 PT in clinical cases. **Results:** PNV ranged from 98% to 102% in 38 (84.4%) of the 45 cases of head-and-neck VMAT. Further, PNVs ranged from 98% to 102% with 14 measurement locations exceeding $\pm 2.0\%$, and five measurement locations exceeded $\pm 3\%$. All GafChromic film and Delta4 PT gamma analysis (GA) results were above 90%, regardless of the PNV range. There was no apparent difference between the results of PNV and dose verification for 45 cases of head-and-neck VMAT. The 2 mm/2% result for GA in TG119 showed a trend of decreasing GA pass rates as the PNV moved away from 100%. **Conclusion:** The linear accelerator beam did not hold in the 95–105% PNV range, and the delivery was accurate with little effect on the accuracy of the planned and delivered doses.

PO-GePV-M-213

Effect of VMAT Improvement Before and After Referring to Radiation Therapy Planning QA Software

M Sasaki^{1*}, Y Nakaguchi², T Kamomae³, S Kobuchi⁴, K Kuwahara⁵, A Kajino⁶, D Sato⁷, H Ikushima⁸, (1) Department of Therapeutic Radiology, Institute of Biomedical Sciences, Tokushima University Graduate School, Tokushima, JP, (2) TOYO-MEDIC Co., Ltd, Shinjuku-ku, 13, JP, (3) Nagoya University Graduate School of Medicine, Nagoya, JP, (4) Graduate School of Health Sciences, Tokushima University, Tokushima, Kyoto, JP, (5) Graduate School of Health Sciences, Tokushima University, Tokushima, Tokushima, JP, (6) Graduate School of Health Sciences, Tokushima University, Tokushima, Tokushima, JP, (7) Graduate School of Health Sciences, Tokushima University, Tokushima, Tokushima, JP, (8) Department of Therapeutic Radiology, Institute of Biomedical Sciences, Tokushima University Graduate School, Tokushima, JP

Purpose: Software that evaluates the quality of treatment plans (PlanIQ™) has become commercially available in recent years. It includes a feasibility assessment tool that provides the ideal dose volume histogram (DVH) for each organ at risk, based on the ideal dose falloff from the prescribed dose at the target boundary. It is important to investigate whether the PlanIQ™ assessment tool (Feasibility DVH™) can assist treatment planners who are not experienced in treatment planning. Therefore, the present study aimed to evaluate the usefulness of this tool for improving the quality of treatment plans. **Methods:** This study included five participants with prostate cancer. Volumetric-modulated arc therapy (VMAT) planning data obtained before and after using the Feasibility DVH™ were scored with PlanIQ™. The impact of the feasibility assessment tool on the quality of the VMAT plans was evaluated for different patients and treatment planners. The treatment planners include two graduate students, two undergraduate students, and one clinical planner. **Results:** Four out of five cases showed improved treatment planning by referring to the Feasibility DVH™. In addition, four of five treatment planners showed improvement in treatment

planning by referring to the Feasibility DVH™. **Conclusion:** The present findings suggest that referring to the Feasibility DVH™ tool may improve the quality of treatment plans for different types of planners and patients. However, planners at any level of experience should be trained to check the dose distribution in addition to checking the DVH.

Geometric and Dosimetric Impact of 3D Generative Adversarial network-Based Metal Artifact Reduction Algorithm On VMAT and IMPT for the Head and Neck Region

M Nakamura^{1*}, M Nakao², K Imanishi³, H Hirashima¹, Y Tsuruta^{1,4}, (1) Graduate School of Medicine, Kyoto University, (2) Graduate School of Informatics, Kyoto University, (3) e-Growth Co., Ltd., (4) Kyoto University Hospital

Purpose: We investigated the geometric and dosimetric impact of 3D generative adversarial network (GAN)-based metal artifact reduction (MAR) algorithms on VMAT and IMPT for the head and neck region, based on artifact-free CT volumes with dental fillings. **Methods:** Two different CT volumes, one with four (m4) and the other with eight (m8) pseudo-dental fillings with a CT value of 4,000 HU, were created as ground truths for each case from thirteen metal-free CT volumes of the head and neck region (Reference). CT volumes with metal artifacts were then generated from the Reference CT volumes (Artifacts). On the Artifacts CT volumes, metal artifacts were manually corrected for using the water density override method with a value of 1.0 g/cm³ (Water). By contrast, the CT volumes with reduced metal artifacts using 3D GAN were also generated (GAN-MAR). The structural similarity (SSIM) index within the target were calculated between the Reference CT volumes and other volumes. After creating VMAT and IMPT plans on the Reference CT volumes, the original plans were recalculated for the remaining CT volumes. **Results:** The calculation time required to generate a single GAN-MAR CT volume was approximately 30 seconds. The median PTV volume was 133.6 ml (range, 98.7–169.1 ml), and median overlap ratio of the artifact corrected volume to the PTV volume was 7.5% (range, 0.0–18.5%) in the m4 group and 14.3% (range, 0.0–22.8%) in the m8 group. The SSIM showed that the GAN-MAR CT volumes were more similar to the Reference CT volumes than Water and Artifacts. The median dosimetric differences from the original plans were within 3% for VMAT and IMPT. **Conclusion:** GAN-MAR yielded identical CT volumes with the Reference CT volumes. The observed dosimetric difference compared to the original plan were clinically acceptable.

PO-GePV-M-215

Physical and Dosimetric Characteristic Properties of BeO OSL for Clinical Dosimetric Measurements

E Kara*, A Hicsonmez, ONKO Ankara Oncology Center, Ankara, TR

Purpose: The study aims to figure out the physical and the dosimetric characteristics of the Beryllium Oxide (BeO) optically stimulated luminescence dosimeters (OSLDs) system and to investigate the ability to use OSLDs for machine quality assurance measurements by using necessary factors as mentioned in AAPM 191 for dose calculation. **Methods:** OSLs were irradiated with 6 MV, 10 MV, and 15 MV photon beams using Elekta Versa HD linear accelerator. The measurements were taken by placing BeO OSLs at the maximum dose depth and ion chamber at the reference depth for each energy at the source surface distance (SSD) at 100 cm. For the angular/directional dependence test, the setup for the cylindrical phantom was the same as the slab phantom, but a SAD of 100 cm was set to the isocenter of the phantom and center of the OSL dosimeter. The tests performed were reproducibility/sensitivity, dose-response linearity, energy dependence, angular dependence, field size dependence, and SSD dependence. As a result of the tests, correction factors were obtained, and the OSL measurement accuracy was increased by using these factors. **Results:** Reproducibility/sensitivity and angular dependence are smaller than %2, dose-response linearity and energy dependence are smaller than %1. After making SSD corrections as recommended in IAEA Human Health Reports No:8, the dependency of SSD is %3 for SSD 80cm and smaller than %2 for other SSDs. Field size dependence is larger than %2. k(L), for linearity, k(Q) for beam quality, k(Θ) for angular dependence, k(SSD) for SSD correction, k(Field) for field correction are obtained for all energies. **Conclusion:** It is possible to increase the accuracy of measurements with OSLDs when all factors are obtained and added to the measurement results. Using BeO OSLD in radiotherapy measurements is promising with further studies like percentage depth dose measurements.

BeO dosimeters used in the study were provided by RADKOR Personal Dosimeter Measurement and Assessment Laboratory company.

Head and Neck Multi-Organ Segmentation on Dual-Energy CT Using Dual Pyramid Convolutional Neural Networks

T Wang*, Y Lei, J Roper, B Ghavidel, J Beitler, M McDonald, J Bradley, T Liu, X Yang, Emory University, Atlanta, GA

Purpose: Organ delineation is crucial to diagnosis and therapy, while is also labor-intensive and observer-dependent. Dual energy CT (DECT) provides additional image contrast than conventional single energy CT (SECT), which may facilitate automatic organ segmentation. This work aims to develop an automatic multi-organ segmentation approach using deep learning for head-and-neck region on DECT. **Methods:** We proposed a Mask scoring regional convolutional neural network (R-CNN) where comprehensive features are firstly learnt from two independent pyramid networks and are then combined via deep attention strategy to highlight the informative ones extracted from both two channels of low and high energy CT. To perform multi-organ segmentation and avoid misclassification, a mask scoring subnetwork was integrated into the Mask R-CNN framework to build the correlation between the class of potential detected organ's volume of interest (VOI) and the shape of that organ's segmentation within that VOI. We trained and tested our model on DECT images from 66 head-and-neck cancer patients with manual contours of 19 organs as training target and ground truth. **Results:** For large- and mid-sized organs such as brain and parotid, the proposed method successfully achieved average Dice similarity coefficient (DSC) larger than 0.8. For small-sized organs with very low contrast such as chiasm, cochlea, lens and optic nerves, the DSCs ranged between 0.5 and 0.8. With the propose method, using DECT images outperforms using SECT in all 19 organs with statistical significance in DSC ($p < 0.05$). Meanwhile, by using the DECT, the proposed method is also significantly superior to a recently developed CNN-based method in most of organs. **Conclusion:** Quantitative results demonstrated the feasibility of the proposed method, the superiority of using DECT to SECT, and the advantage of the proposed R-CNN over CNN. The proposed segmentation tool has the potential to facilitate the current radiation therapy workflow in treatment planning.

PO-GePV-M-217

Foreign Bodies Detection in Pediatrics with Low Dose CT

M Aljallad^{1*}, (1) West County Radiology, St. Louis, MO

Purpose: To develop a reasonable image quality CT protocol to detect the foreign bodies (FBs) in the respiratory tract of pediatrics with both a minimum patient radiation dose and an equivalent radiation risk to a conventional radiograph chest exam. **Methods:** CT Data were collected on a Siemens CT system (SOMATOM Flash). The imaging techniques of the child CT chest protocol were optimized, and vendor dose optimization features were utilized to further lower the dose and maintain good image quality. Twenty CT exams using the modified CT protocol were performed with different FBs distributions in a five years old size anthropomorphic phantom (LUNGBODY) shown in Figure(1). The FBs included small size radiopaque bodies such as fish bones, peanuts, LEGO

toys, etc. The exams were then presented randomly to the radiologist team to interpret the images and report the results. The CT effective and organ doses were calculated by Radimetrics™ software using Monte Carlo (MC) simulations. For dose comparison purposes, we used the routine chest radiograph exam to image the LUNGBODY phantom. The chest radiograph's organ dose is calculated using MC PCXC2.0 software for five years of phantom's lung, heart, and liver. **Results:** The effective dose of the original protocol was 3 mSv, while the dose of the modified protocol was only 0.26 mSv. The reduction in dose by one order of magnitude was mainly caused by the kVp and mAs reduction. The reported effective doses of the LUNGBODY for the modified CT using MC simulations and the chest radiograph using MC PCXC2.0 software and ICRP 103 weighting factors are listed in table(1). **Conclusion:** Low-dose CT protocols can be very reliable for FB detection with high image quality and low patient dose, especially in pediatric patients where the aspiration of FBs is a frequent and severe cause of respiratory problems in children.

PO-GePV-M-218

Magnetic Particle Spectrometer for Diagnosis of Magnetic Nanoparticles

M Irfan¹, N Dogan¹, A Bingolbali^{2*}, (1) Gebze Technical University, Gebze/Kocaeli, TR, (2) Yildiz Technical University, Istanbul, TR

Purpose: Magnetic particle imaging (MPI) is an emerging medical imaging technique that only relies on superparamagnetic iron oxide nanoparticles (SPIONs) as tracer agents. Magnetic particle spectrometer and relaxometer are used as diagnostic tools for evaluation and selection of the best magnetic nanoparticles for MPI usage. In this study, a magnetic particle spectrometer (MPS) is designed at 9.9 kHz to measure the 5th/3rd harmonic ratio, full width at half maximum (FWHM) of the point spread function, and relaxation time of the nanoparticles at 15 mT excitation field. **Methods:** Hardware components of the MPS were simulated in COMSOL Multiphysics 5.4. Drive and receive coils were enclosed in cylindrical copper shielding to eliminate the environmental noise disturbance. The direct feedthrough effect of the fundamental harmonics was minimized with the optimized gradiometric design of the receive coil. A highly homogenous excitation field of 15 mT was targeted at the sample position (midpoint of the setup). The setup of the MPS was implemented based on simulated parameters to achieve optimum results. **Results:** Commercially available SPIONs (Vivotrax, Perimag) were first tested with home-built MPS. Mn_{0.75}Fe_{2.25}O₄ coated with citric acid and Mn_{0.75}Fe_{2.25}O₄ coated with polyacrylic acid were characterized at 9.9 kHz with 15 mT (peak amplitude) excitation field, and then compared with the commercial nanoparticles. Mn_{0.75}Fe_{2.25}O₄ has a 0.49 (5th/3rd) ratio, 7.60 mT FWHM, and 4.09 μs relaxation time. These results are in good agreement with Perimag. Similarly, Mn_{0.75}Fe_{2.25}O₄ has a 0.46 (5th/3rd) ratio, 8.95 mT FWHM, and 4.259 μs relaxation time. The effect of different coatings on the same iron core was analyzed as well. **Conclusion:** The home-made MPS provides an opportunity to diagnose magnetic nanoparticles and helps to mark the best tracer agent for MPI scanning. The expected resolution of MPI scanners for specific SPIONs can be estimated from FWHM (mT) of MPS.

An Multi-Stage Explainable System for Lobe Injury Diagnosis

D Qian^{1*}, S Xu², S Wu³, R Wang¹, (1) Perception Vision Medical Technology, Guangzhou, Guangdong, 44, CN, (2) Sun Yat-sen University, Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center of Cancer Medicine, Guangzhou, Guangdong 44, CN, (3) Sun Yat-Sen University, Guangzhou, Guangdong, 44, CN

Purpose: To develop an accurate and explainable diagnosis system for lobe injury of Magnetic Resonance Imaging(MRI) image. **Methods:** A multi-stage explainable system(MSES) was constructed to make an accurate and explainable diagnosis for lobe injury on MRI images. MSES adopted a two-stage strategy. At the first stage, a 2.5D multi-task and multi-depth group UNet(MMGU) was constructed, which concatenated upper current and lower slices as inputs to supply context information and merged two segmentation branches, a positive branch pre-trained on positive slices with multi-depth paths, features at different levels of decoder fused to enhance feature's semantic information, a negative branch, structure same as the positive part, pre-trained on slices with positive and negative sample ratio of 1:4. Multi-task including region and boundary segmentation was proposed to enhance the lobe injury boundary effect. At the second stage, during the training step, the segmentation result of MMGU was used to form ROI patches to fine-tune a resnet-18 model as a false patch discrimination model(FPDM). During the case prediction stage, a similar process was performed to the training step to predict ROI patch probabilities, then the maximum was selected as the case probability. The Dice's coefficient(DSC) was used to evaluate the accuracy of MMGU, while the receiver operating characteristic(ROC) curves were used to evaluate the performance of the MSES. **Results:** On the testing data set, MMGU achieved superior segmentation performance with a mean DSC of 0.7865. the MSES gained superior diagnosis performance with an AUC of 0.98. **Conclusion:** The quantitative and visualization evaluation results demonstrates the effectiveness of the MSES, which also has a good diagnosis explanation, for it affords the lobe jury probability of interest patches on MRI images, which befits clinicians to make further analysis and decision.

Develop a Rotational Robust Optimized Spot-Scanning Proton Arc (SPArc) Algorithm

S Chang*, G Liu, L Zhao, W Zheng, A Qin, D Yan, X Li, X Ding, Beaumont Health System, Royal Oak, Michigan

Purpose: Develop a new rotational robust optimization SPArc algorithm (SPArcrot) to mitigate the dosimetric impact from patient's rotational setup error. **Methods:** The SPArcrot incorporates a multi-CT robust optimization framework. Compared to the standard SPArc optimization algorithm, the SPArcrot takes into account two more CT image sets by rotating +5°, and -5° of the planning CT. Five cases from different disease sites such as brain, lung, head neck (HN), prostate, and liver cancer were selected to evaluate the effectiveness of SPArcrot. Both SPArc and SPArcrot plans were generated using the same translational robust optimization parameters. Then, both SPArc and SPArcrot plans were recalculated using a series of pseudo-CT introducing different rotational setup errors (±1°, ±2°, ±3°, and ±5°). Dosimetric metrics such as D98%, D95% of CTV, and 3D gamma analysis were used to assess the dose distribution changes inside the target and patient bodies. **Results:** The magnitudes of dosimetric perturbation in the targets due to rotational errors were significantly reduced by the SPArcrot in all the cases (Figure 1, 2). The max dose uncertainties to brainstem, optic nerves, spinal cord, and esophagus were reduced using SPArcrot for brain and lung cases, respectively(Figure 1). The uncertainties of the mean dose to the OARs such as the liver and oral cavity, parotid is comparable between the two planning techniques. The gamma pass-rate (3%/3mm) was significantly improved for CTV of all the disease sites in SPArcrot plan group (Table 1). **Conclusion:** SPArcrot could effectively mitigate the max dose perturbations in the adjunct OARs which is critical to the series organ. This new algorithm could be implemented through the multi-CT robust optimization framework using the existing commercial TPS.

The research project in part was supported by Ion Beam Application research grant.

Inverse Shielding for Super High-Frequency (SHF) Microwaves to Ensure Contemporary PET Imaging Quality

K Wang^{1*}, M Huq², (1) UPMC Hillman Cancer Center, Pittsburgh, PA, (2) UPMC Hillman Cancer Center and University of Pittsburgh School of Medicine, Pittsburgh, PA

Purpose: Prevalent PET imaging reconstructs 2γ photon pairs from electron-positron annihilations. Due to QED, ~60% of annihilations occur directly and 40% occur through positronium (Ps) process. The ratio of triplet Ps (3S1, ortho-Ps, decaying to 3γ) to singlet Ps (1S0, para-Ps, decaying to 2γ) is 3:1 in vacuum. Although 3S1 to 1S0 transitions are forbidden, most ortho-Ps convert to para-Ps through "Pick-off process", hence 2γ events predominated. The energy difference between 3S1 and 1S0 (hyperfine splitting or HFS) is 203.4GH at ground state and 25.4GHz at first excited state. With magnetic fields, excited energy levels are split (Zeeman Effect), hence transitions between 23S1 to 21S0 become possible. Human body provided such conditions through biological tuning. Absorbing 25.4GHz microwave, many 23S1 converts to 21S0 and decays to 3γ rather than 2γ . This downgrades imaging quality because contemporary PET imaging rejects 3γ events. Such loss of para-Ps becomes crucial in PET-guided radiotherapy since minimal tracer was administered. Hence shielding against 25.4GHz source is necessary. **Methods:** Typical PET facility shielding is to protect area outside imaging room, this microwave shielding is inverse shielding because it tends to isolate patient against external microwave radiations. Microwaves could penetrate through 2-3 feet concrete walls, but will be stopped at thin metal layer, e.g., aluminum of 1-2mm thickness. For this reason, a metal layer should be always put into PET facility shielding in all directions of the vault, since pure concrete shielding is insufficient. **Results:** Microwaves of HFS energy 25.4GHz (or other higher excited states) drop PET imaging quality significantly. **Conclusion:** In PET-guided radiotherapy, PET imaging at a fractional basis serves for target localization rather than diagnosis, thus minimal injected dose is administered to reduce exposures. Losing para-Ps is unaffordable because image quality might downgrade to unacceptable level. Hence shielding microwaves of HFS energy levels are necessary.

Direct Proton Dosimetry for Fractionated Radiotherapy: Dose Invariance Features and Mono-Endpoints

K Wang^{1*}, R Beatty², (1) UPMC Hillman Cancer Center, Pittsburgh, PA, (2) M.S. Hershey Medical Center, Hershey, PA

Purpose: Proton radiotherapy has been booming since the new millennium. Contemporary proton dosimetry is to use Relative Biological Effectiveness (RBE=1.1) factor to convert reference photon dose to perspective proton dose regardless treatment strategies. This shortcut simplifies proton dosimetry into an add-on to the existing photon dosimetry, causing dose uncertainties in fractionated strategies. As a direct-ionization modality, protons essentially differ from X-rays/ γ -rays in cell-killing mechanism. In this study, we intended to establish direct proton dosimetry for fractionated treatment strategies. **Methods:** Unlike X-rays/ γ -rays, the cellular survival percentage for proton is a straight line in logarithm scale against dose, hence escalation doses remain a straight line. Different fractional strategies are mathematically equivalent if they have the same escalated doses, regardless of number of fractions or fractional dose in each strategy. This dose invariance feature is essential for fractionation themes in proton dosimetry. In X-rays/ γ -rays dosimetry, biological effective dose (BED) is used to compare 2 conventional fractionation (CF) themes, but the endpoints are different due to approximation with LQ modeling. In proton dosimetry, the endpoint is identical (mono-endpoint), and no approximation is needed. **Results:** We evaluated dose uncertainties and deviation of endpoint of using fixed RBE=1.1 in all fractionated themes, referencing to direct proton dosimetry. For CF the dose uncertainties are minimal. For hyper-fractionation, the real RBE>1.1, hence using fixed RBE will overdose. For hypo-fractionation, SBRT and SRS, the real RBE<1.1, hence using fixed RBE will be under-dosed, and the uncertainties increase with decrease of number of fractions for same endpoint. **Conclusion:** We established an independent proton dosimetry with high precision based on radiobiological nature, in which dose invariance and mono-endpoint are 2 essential features. We evaluate dose uncertainties for all fractionated themes using fixed RBE=1.1. For its accuracy, proton dosimetry could be used as the primary reference in radiotherapy, rather than vice versa.

PO-GePV-M-223

Respiratory Motion Management from MD Consultation to Radiotherapy

Z Ji, M Schmidt, N Knutson, T Kim*, Washington University School of Medicine, St Louis, MO

Purpose: Respiratory motion management is a key component in thoracic and abdominal radiotherapy. In this project, we developed a respiratory motion management program from MD consultation to treatment including respiratory trace acquisition, respiratory motion evaluation and visual-guided radiotherapy. **Methods:** MRI/CT-compatible respiratory sensor and corresponding software were developed in our departmental respiratory motion management program. Respiratory trace can be acquired at MD consultation by clinical staff, analyzed and reported by Physics team, and visually utilized during CT/MRI simulation and treatment (visual guidance). **Results:** Hardware includes an air pressure sensor (Venier Barometer), placed on patient abdomen using a Velcro belt. The Barometer measures the pressure changes from patient abdominal displacement against the velcro belt. An USB device (Venier Go!Link) interfaces with the air pressure sensor for data-collection via developed software. Software has two components. 1) Real-time data collection and display, which can be switched between wave mode and bar mode. Wave mode shows the breath signal as a continuous wave, while the bar mode displays a horizontal bar moving up down corresponding to the patient's breath cycle. The real-time data collection part also includes a breath-holding timer function to guide the patient during breath-holding period. 2) Breathing pattern analyzer. Analysis for breath includes selections of breath time range and automatic breath period detection. Parameters such as Global Amplitude Variation (GAV), Period Variation (PV) are calculated. Local Amplitude Variation (LAV) is calculated using an adjustable window, suggesting a range of the gating window. Breath-holding analysis also includes time range selection. An adjustable window is also laid on the breath-holding analysis plot to calculate AV. **Conclusion:** We successfully developed the respiratory motion management from MD consultation to Radiotherapy. It is an efficient clinical solution for patient respiratory trace acquisition, patient training, breathing pattern analysis and corresponding respiratory motion management determination for radiotherapy.

PO-GePV-M-224

Dosimetric Properties of An HDR Ir-192 Source

X Cui, X Cui*, An hui Province Key Laboratory of Medical Physics and Technology, Institute of Health and Medical technology, Hefei Institutes of Physical Science, Chinese Academy of Sciences, Hefei, 34CN

Purpose: We simulated the dose rate distributions around domestically produced HDR Ir-192 source by means of the Monte Carlo technique using the MCNP4c code. **Methods:** Based on the dose rate calculation equation in the TG43 protocol, we established the Ir-192 source model with the MCNP4c code. We simulated and calculated the spatial dose distribution of this model, and obtained and analyzed the radial dose function and anisotropy function of the Ir-192 source. **Results:** The simulated anisotropy function was in line with and within the allowed error range of published results. At short radial distance, the simulated radial dose function was more in line with published results; at long radial distance, the simulated radial dose function was more in line with some published results, but showed bigger discrepancy with other published results. **Conclusion:** The dosimetric properties of a domestically produced HDR Ir-192 source can be better studied and simulated with the Monte Carlo technique based on the MCNP4c code. The study results lay a theoretical foundation for further exploration of factors that impact the dose distribution of after-loading radiotherapy.

PO-GePV-M-225

An Incremental-Based Model for Organ at Risk in Multi-Scene Cervical Cancer Radiotherapy

Z Zhang¹, R Zhou¹, S Wu^{2*}, d qian³, R Wang³, S Wang¹, Z Yang¹, (1) Xiangya Hospital Central South of University, Changsha, Hunan, CN, (2) Sun Yat-Sen University, Guangzhou, Guangdong, CN, (3) Perception Vision Medical Technology, Guangzhou, Guangdong, CN

Purpose: Accurate delineation of organs at risk(OARs) is the key to protect the organs during radiotherapy. There exists multiple scenes in cervical cancer radiotherapy, such as after-loading and external irradiation, which have huge differences in the image domain and organ form. Using multiple independent models delineate organ at risk for each scene is inefficient and fails to use information between scenes. Therefore, an incremental-based segmentation model(IBSM) for OARs in multi-scene radiotherapy for cervical cancer was put forward. **Methods:** IBSM adopted a three-branch structure, the after-loading branch pre-trained on the positive slices of after-loading Computed Tomography (CT) images with object organs of rectum, bladder, and sigmoid, the external irradiation branch, structure same as the after-loading branch, pre-trained on the positive slices of irradiation CT images with object organs of rectum and bladder, the fusion branch merging the after-loading and irradiation branch as feature extract module trained on full data including after-loading and external irradiation CT images with full object organs above. During training, IBSM accepted after-loading and external irradiation data as inputs alternately. Dynamic weighted multi-task loss function among multiple organs and samples was proposed to guide the model to focus more on the hard samples and organs. The Dice's coefficient(DSC) was used to evaluate the accuracy of IBSM. **Results:** On the testing data set, IBSM achieved superior performance on most organs, with the mean DSC of 76.5(±6.18)% on the rectum, 89.6(±1.92)% on the bladder, 63.9(±1.3)% on sigmoid of after-loading CT images, 47.2(±30.769)% on the rectum, 84.5(±6.47)% on the bladder of external irradiation CT images. The IBSM gained consistent good delineation result on most organs. **Conclusion:** This work indicates the potential and effectiveness of ensemble and incremental-based model in multiple scene radiotherapy with a distinct data source and task.

PO-GePV-M-226

Determination of the Phantom Surface Dose Using a Diode Detector for Diagnostic X-Ray Beams

R Tanabe*

Purpose: To determine the surface dose for diagnostic kilovoltage x-ray beams from the air kerma and a half-value layer (HVL, mm Al) measured using a diode detector. **Methods:** A kV/dose multi-sensor (AGMS-DM+ detector, Radcal Co. USA) was used as a diode detector, and calibrated in terms of the air kerma measured with a PTW 30013 Farmer-type ionization chamber. The air kerma was measured for 20 x-ray beams with tube voltages of 50-140 kVp and HVL of 2.2-9.7 mm Al for a quality index (QI) of 0.4, 0.5 and 0.6, which is specified by the ratio of the effective energy to maximum energy corresponding to the tube voltage. The air kerma was converted into the phantom surface dose using the backscatter factor and the ratio of mass-energy absorption coefficient for water to air. Finally, the air kerma measured by the AGMS-DM+ detector was expressed as a ratio of the surface dose for 10 × 10 and 20 × 20 cm² fields. The ratio of both was represented as a function of HVL for the given QI values and verified by comparing it with that calculated using the Monte Carlo method. **Results:** The air kerma calibration factor for the AGMS-DM+ detector ranged from 0.986 to 1.016 (0.9% in k = 1), and was almost independent of the x-ray fluence spectra for the given QI values. The ratio of the surface dose to the air kerma determined by the PTW 30013 chamber and the AGMS-DM+ detector was less than 1.8% for the values calculated using the Monte Carlo method, showed a good correlation with HVL for the given QI values. **Conclusion:** It is possible to determine the surface dose from the air kerma and HVL measured by a diode detector for the given QI values for diagnostic kilovoltage x-ray beams.

The diode detector, AGMS-DM+ detector used in this study were provided by Toyo Medic Co. in Japan.

PO-GePV-M-227

A New Intracavitary Applicator Design: Dosimetric Characterization of Shielded Multichannel Applicator for High Dose Rate 60Co Brachytherapy Gynecological Cancer Treatment

h aloraibi^{1*}, S Gholami², (1) Bint Al Hoda Hospital, Al-nasrayah, IQ, (2) Cancer institute-Imam Khomeini hospital-TUMS, Tehran, IR

Purpose: The present study aims to construct a flexible multichannel applicator with several channels placed along the periphery of a cylinder and a rigid cylinder with interchangeable shields and evaluate dosimetric properties of this novel intracavitary applicator using MCNPX Monte Carlo code in terms of modulating between full dose to the target and minimum dose to the mucosa and non-involved parts of the cervix wall and rectum using HDR 60Co radioisotope. **Methods:** In this report, TG43 report and MC was used as reference tools, and then the comparison of dose distribution using both MC of both the new applicator was calculated shielded and unshielded cylinder applicators. **Results:** MCNPX Monte Carlo calculation shows that shielded multichannel applicator designs reduce the dose by 66% and 59%, but 66% and 63%, and 79 and 76% between 1.8 cm and 3 cm for 5channels, 3 channels, and 3 channels applicators with a thickness of 1.35 cm, 1.5cm and 2.1 cm from the applicator surface in desired regions. Furthermore, the dose rate in front of the shield and shielding ability is closely independent of the size of the shield thickness when calculated from the applicator surface, and dose rate in more distant volumes will to some extent be not influenced by shield thickness. **Conclusion:** Shielded multichannel applicator considerably spares OARs, but it needs to significantly compromise the treatment plan in cancerous regions. Therefore, further optimization of shielding design that compromises the treatment plan in parts that need the full dose.

PO-GePV-M-228

Quantification of Spinal Bone Marrow Fat Fraction Using Three-Material Decomposition Technique on Dual-Energy CT: A Feasibility Study

B Li*, N Hua, J Li, V Andreu-arasa, C Lebedis, S Anderson, Boston University Medical Center, Boston, MA

Purpose: Two-material decomposition is insufficient to quantify the fat fraction of spinal bone marrow, which is comprised of a mixture of bone minerals, water, and yellow marrow (fat). To develop a three-material decomposition-based bone marrow fat fraction (FF3MD) quantification technique using dual-energy CT, and investigate its feasibility to characterize osteoporotic and pathologic spinal fractures in adults. **Methods:** Bone marrow edema phantoms containing trabecular bone minerals, water, and fat were constructed using fat fractions and bone mineral density values matching those expected in healthy and edematous bone, and scanned on a commercial dual-energy CT. Fat quantified by FF3MD were compared to MRI fat fraction FF_(MRI) and conventional two-material-decomposition-based fat fraction FF_(2MD). Subsequently, FF(3MD) was applied in a retrospective case study including seven adults (four male and three female; average age: 60.4 y.o.; range: 23-89 y.o.) with 10 spinal fractures (six acute osteoporotic, two hemangiomas, and two metastases) imaged at the time of admission. Findings were compared to MRI or pathology. **Results:** FF_(3MD) demonstrated an excellent correlation with FF_(MRI) (r=0.97, R2=0.96) in the phantom, significantly more accurate than FF_(2MD) when confounding bone minerals are present (50 mg/cm3: r=1.02, R2=0.95 vs. r=0.65, R2=0.79 (p<0.01); 100 mg/cm3: r=0.81, R2=0.47 vs. r=0.21, R2=0.21 (p<0.05)). The fat fractions of the 6/6 acute osteoporotic fractures were significantly lower than the healthy anatomical counterparts (p=0.0377). The fat fractions of the 2/2 vertebral hemangiomas and the 2/2 metastatic lesions were increased and decreased, respectively, when compared to healthy anatomical counterparts. These findings correlated well with T1-/T2-weighted MRI or pathology findings. **Conclusion:** FF_(3MD) accurately quantified bone marrow fat fraction, comparing with FFMRI, in the phantom. Three-material decomposition-based findings correlated well with MRI or pathology in the case study to characterize osteoporotic and pathologic fractures.

B Li, V Andreu-Arasa, C LeBedis, S Anderson received a research grant from GE Healthcare on dual-energy CT clinical applications.

PO-GePV-M-229

The First Investigation of Spot-Scanning Proton Arc (SPArc) Delivery Time and Accuracy with Different Delivery Tolerance Window Settings

G Liu^{1,2*}, L Zhao¹, D Yan¹, G Janssens³, X Li¹, X Ding¹, (1) Beaumont Health System, Royal Oak, MI, USA (2) Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China (3) Ion Beam Applications SA

Purpose: The tolerance window has been playing a critical role in the arc treatment delivery in the photon treatment. However, there is no study has been done on the proton arc delivery module yet. This is the first investigation of Spot-scanning proton arc (SPArc) treatment delivery time and accuracy with various delivery tolerance window settings. **Methods:** SPArc plans were generated for four representative disease sites (lung, brain, head neck, liver cancer) with an angle sampling frequency of 2.5 degrees. An in-house dynamic arc controller was used as a simulator mimicking the arc treatment delivery with various tolerance windows (± 0.25 , ± 0.5 , ± 1 , and ± 1.25 degrees). The controller generates machine mechanical and irradiation information (logfilesimulation) with one degree of sampling frequency during the arc delivery simulation, such as gantry speed, acceleration and deceleration, spot position, and delivery sequence similar to the actual machine logfiles. The logfilesimulation was then imported to the treatment planning system (TPS) to reconstruct the delivered dose distribution and compared to the initial SPArc plan. A three-dimensional gamma index with criteria 3mm/3% was used to assess delivery accuracy quantitatively. Total treatment delivery time and relative lost time (dynamic arc delivery time – fix beam delivery time) / fix beam delivery time $\times 100$ were reported. **Results:** The 3D gamma pass ratio was great than 97% for all the cases. The total delivery time for dynamic arc delivery increased with the decreasing of delivery tolerance windows length. The average delivery time and the relative lost time (%) were 1024 ± 516 s (235% ± 31 %), 527 ± 262 s (73% ± 13 %), 375 ± 185 s (23% ± 7 %), 322 ± 149 s (7% ± 1 %), 311 ± 141 s (5% ± 2 %) for tolerance windows as ± 0.25 , ± 0.5 , ± 1 , and ± 1.25 degrees respectively. **Conclusion:** This is the first investigation of SPArc delivery time and accuracy with different delivery tolerance window settings. The simulated result indicated that the SPArc plan with 2.5degrees sampling frequency can be delivered efficiently and accurately with ± 1 or ± 1.25 degrees tolerance window.

This study was supported by the research fundings from Ion Beam Application Inc.(IBA) and Beaumont Health Herb and Betty Fisher Research Seed Grant Award. Xuanfeng Ding, Xiaoqiang Li, and Di Yan have a patent related to the Particle Arc Therapy (WO2017156419).The patent has been licensed to Ion Beam Application, Belgium.

MRI Characterization of 3D Printed Anatomic Models Using a Dual-Echo Ultrashort TE (UTE) Sequence

N Wake*, Q Peng, Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY

Purpose: Three-dimensional printing (3DP) has been used increasingly in medicine over the past several years for various applications such as surgical planning, trainee education, and patient education. 3DP allows for the creation of comprehensive patient-specific models or models with complex geometries that otherwise may not be achievable. Although many different printing materials are available for 3DP, most materials are hard plastics or based on powders which generally have very short transverse relaxation time (< 1 ms), therefore are not readily visualized using conventional MRI techniques. The purpose of this study was to use an UTE MRI sequence to visualize a 3DP anatomic model with complex geometry and evaluate the volume accuracy of the MRI acquisition method. **Methods:** A patient-specific 3DP renal mass model was created from volumetric medical imaging data using binder jetting (CJP 660 Pro, 3D Systems). The printed model was immersed in saline water and scanned at 3T using a dual-echo ultrashort TE sequence with isotropic (0.6mm)³ spatial resolution and TR/TE1/TE2/FA=7.8ms/50 μ s/2.2ms/7°. 3D MR datasets from two echoes were subtracted to improve contrast before model segmentation. MR images were evaluated for image quality and the accuracy of the MR technique was evaluated. **Results:** The first echo with TE=50 μ s had positive MR signal from the 3DP model, while the second echo had negligible MR signal with TE=2.2ms. High positive contrast between 3DP model and background was achieved after image subtraction, leading to easy 3DP model segmentation. Renal mass volumes were 82523.12mm², 79247.75mm³, 75906.68mm³ for the 3D printed design from the patient-specific imaging data, the MRI of the model, and the CT of the model respectively, with DICE correlation coefficients of 0.98 for the MRI and 0.96 for the CT. **Conclusion:** 3D dual-echo UTE MRI can be utilized to generate positive MR contrast images from 3DP anatomic models to accurately determine geometrical volume.

Feasibility of Federated Learning for Head and Neck (HN) Tumor Segmentation in PET/CT

Y Yuan*, S Adabi, Y Lo, J Junn, R Bakst, The Mount Sinai Hospital, New York, NY

Purpose: Generalization of deep-learning-based medical image segmentation strongly relies on the number and the diversity of training cases; however, it is practically challenging to aggregate data from different institutions due to various technical, legal, privacy, and data ownership barriers. This study aims to investigate the feasibility of employing federated learning to collaboratively train an auto-segmentation model for HN tumor segmentation in PET/CT from multi-institutional cases without data sharing. **Methods:** We used 200 training cases from the HECKTOR challenge in MICCAI 2020. These cases were collected from four institutions, including 55 from CHGJ, 18 from CHMR, 55 from CHUM and 72 cases from CHUS. We randomly selected 20% cases from each institution to form a testing dataset of 40 cases, and the rest of them were used for training. The segmentation was based on scale-attention-network (SA-Net) that we recently developed and achieved the 4th place in the HECKTOR challenge. We implemented FedAvg where the weights from each local model were aggregated in the server to form a global model that was re-distributed to each client for further training. The performance of the FedAvg model was compared with the baseline models that were trained exclusively on the local data within each institution. **Results:** The average DSC on the testing dataset was 0.716, 0.434, 0.680 and 0.738 when applying the baseline model from CHGJ, CHMR, CHUM and CHUS respectively. The FedAvg model yielded an average DSC of 0.752, which achieved 97% performance of the pooled model (DSC: 0.775) that was trained by pooling all the data across institutions. **Conclusion:** Our experiments show that the segmentation performance of the baseline models was restricted by the limited local data. Despite the significant imbalance in numbers of cases per institution, federated learning has potential to train a better model across collaborating institutions without sharing their data.

PO-GePV-M-232

Clinical Evaluation Study of Image Guided Radiotherapy (IGRT) for Prostate Cancer Comparing Kv Imaging of Fiducial Markers and Cone Beam Computed Tomography (CBCT) Using SpaceOAR-View as a Matching Structure

R Mghari*, I Pataki, K Keene, Cape Fear Valley Medical Center, Holly Springs, NC

Purpose: To study the effectiveness of Space OAR-View gel as volume to match to during the Cone Beam CT acquisition as part of image guidance and comparing the matching to fiducial markers for patients with prostate cancer. **Methods:** From September 2020 we selected 12 patients with the following criteria: Age < 80 years; P.S. 0-1; Stage T1a – T2b; Gleason Score 3+3 with PSA ≤15 ng/ml. The patients selected did not undergo prior radiation therapy or surgery to the pelvis area. Space OAR-View by Boston Scientific was placed between anterior rectal wall and posterior prostate and 4 fiducial markers were implanted using a trans perineal approach. Each patient was immobilized in a supine position and simulated with 2.5mm CT scan with empty bladder. Contours of critical structures included the Space-OAR-View gel. Image guided radiation therapy using both cone beam CT (CBCT) and KV/KV fiducial markers match were used daily to assess the correlation and comparison between the Space-OAR-View contoured structure with respect to the Markers. Gel volume was also evaluated for the duration of the treatments. **Results:** Review of our preliminary data suggests that the use of Space OAR-View gel as structure to match to after cone beam CT is a valid and accurate methodology that helps the users during the fusion; it presents benefits over matching to other structures such as anterior rectal wall due to day to day variations and changes; it correlated well with a comparison to the fiducial markers match. We have also noticed a small variation in the Space OAR-View volume and more data is needed to validate our observations. **Conclusion:** Our study procedural imaging prostate patients with CBCT and matching to the gel findings may benefit patients with prostate fossa whom don't get fiducial markers and CBCT can be used with the gel.

PO-GePV-M-233

A Knowledge-Based Automatic Lung IMRT Planning Method for Partial Heart Sparing

L Yuan*, J Sohn, R Singh, E Weiss, S Kim, Virginia Commonwealth University, Richmond, VA

Purpose: Recent findings suggest that sparing of cardiac sub-volumes might be critical to maintain normal organ function. However, a lack of established dose constraints and planning experience hinder the clinical adaptation of cardiac substructure sparing in IMRT planning. This study was to establish clinically achievable cardiac substructure dose constraints based on prior plans and investigate their correlation with patient anatomy. An automatic lung IMRT planning method was developed to incorporate patient specific normal tissue dose constraints. **Methods:** Seventeen locally-advanced lung cancer patients who were treated with fixed-field IMRT were included in this study. The cardiac-substructures and the right heart sub-volume were contoured. Knowledge models were trained to predict the OARs and cardiac-substructure dose metrics utilized a step-wise regression method to quickly build models with good generalizability using only limited dataset. The predicted dose metrics were compared with the actual dose in clinical plans and a leave-one-out cross-validation method was used to evaluate the prediction accuracy of the dose metrics. The optimization objectives for automatic planning were determined based on model prediction. The creation of the objectives and plan optimization were all handled by a computer script interfacing with the treatment planning system with no human intervention. The dose metrics obtained by the automatic plans are compared with the clinical plans by paired signed-rank tests. **Results:** Knowledge models showed good predictive accuracy: the determination coefficients (R^2) for the dose metrics range between 0.3-0.9. Eight of the twelve predicted dose metrics had $R^2 > 0.5$. In particular, R^2 was 0.81 for right sub-volume of heart. Automatic plans improved all heart dose metrics and esophagus V60Gy and were comparable for all other dose metrics. **Conclusion:** Knowledge models can be utilized to determine patient-specific dose constraints for heart sub-volume and other OARs. Automatic planning can achieve comparable or better plan quality than clinical plans.

Real-Time Volumetric Image Guidance Via Deep Learning

X Liang^{1*}, L Xing¹, (1) Stanford University, Stanford, CA

Purpose: Volumetric image guidance (VIG) requires X-ray computed tomography (CT) image and the corresponding multi-target segmentation. However, a large number of projection views from different angular positions are needed for CT reconstruction. The notorious multi-target segmentation then relies on the preceding CT. The time-consuming processes, including the multiple projection views acquisition, reconstruction, and segmentation, make the real-time VIG infeasible. **Methods:** Here, we develop a Deep Learning (DL) method to generate fully high-fidelity volumetric CT images and the multi-target segmentation simultaneously in real-time from a single-view X-ray projection. **Results:** We demonstrate the feasibility of the approach with a dynamic thorax phantom and more than twenty patients. **Conclusion:** Real-time VIG via deep learning allows on-the-fly visualization and dramatically reduces the imaging dose for patients, which could be useful in image-guided interventional procedures. It might help simplify the hardware of tomographic imaging systems.

This work was partially supported by NIH (1R01 CA176553 and R01CA227713). Lei Xing serves as the principal investigator of a master research agreement between Stanford University and Varian Medical System.

A Site Agnostic 3D Dose Distribution Prediction Model for Radiation Therapy with Deep Neural Networks

m mashayekhi^{1*}, A Balagopal¹, I Tapia², X Zhong¹, S Jiang¹, D Nguyen¹, (1) The University of Texas Southwestern Medical Ctr, Dallas, TX, (2) University Of Texas At Dallas

Purpose: Radiotherapy data is hard to collect. Normally we can only get a couple hundred patient's data to train the model on. Current dose prediction models are site specific, and need to be trained on the limited data available, this can reduce the overall potential performance. We propose a site agnostic model that can leverage data from any treatment site thus increasing total data available to train the model with. **Methods:** The input to our proposed model is the patient's 3D anatomical information and physician imposed tradeoff preferences to predict the 3D-dose prediction. Our supervised convolutional neural network, is based on 3D-U-net model. Data preprocessing includes mapping dose to voxels based on their distance ranks to PTV. The dataset contains 70 prostate cancer IMRT plans (source data) and 38 head and neck cancer VMAT plans (target data). We tested the generalizability of the model to different treatment sites via transfer learning technique. We have tested the performance of model with quantitative dose-volume-histogram (DVH) metrics for planning target volume (PTV) and organs-at-risk (OARs). We also tested the dependence of the model performance on the training data size to ensure the efficiency gain. **Results:** We implemented a deep neural network for volumetric dose prediction that is independent of the number of OARs and the treatment site. We tested the performance benefit by leveraging data from 2 different sites: prostate and head and neck. The model trained on one treatment site, efficiently performed high quality predictions on the second site even with small training sizes. **Conclusion:** Our proposed model is independent of the number of input OARs and the treatment site. Our model is able to make accurate predictions with limited training data

PO-GePV-M-236

Optimization of a FLASH Proton Beam Using a Track-Repeating Algorithm

Q Wang^{1*}, U Titt², R Mohan³, F Guan⁴, P Yepes⁵, (1) Rice University, Houston, TX, (2) MD Anderson Cancer Center, Houston, TX, (3) UT MD Anderson Cancer Center, Houston, TX, (4) The University of Texas, MD Anderson Cancer Center, Houston, TX, (5) Rice University, Houston, TX

Purpose: We optimize characteristics of a 86.4 MeV proton beam for FLASH experiments using the Fast Dose Calculator (FDC), a track-repeating Monte Carlo algorithm. **Methods:** A phase space file located at 383 mm upstream of the isocenter is generated through tuning parameters to match FDC results with measured integrated dose distribution in water and MCNPX simulated lateral dose files in air. To spread out the Bragg Peak, widen the beam and reduce the penumbra, we insert a Ridge Filter, a high-density material Scatterer and a Collimator in the beam path and optimize their shapes, sizes and positions. The FDC calculations are validated by comparing Geant4 simulations. In addition, an algorithm to automatically choose the optimal dimension and position of the beam shaping elements is developed and tested using the same beam. **Results:** The optimized beam had a 10.5 mm SOBP (from 80% to 80% of the maximum dose), 13.5 and 12.5 mm lateral width with dose above 80% and 90% respectively and a 2.5 mm penumbra from 80% to 20% in the lateral profile. The FDC calculations had passing rates above 99% using 3mm/3% as gamma-index criterion comparing with Geant4 simulations. The automatic algorithm can choose the proper radius of high-density Scatterer within 20 minutes. **Conclusion:** The 86.4 MeV FLASH proton beam can be optimized by inserting proper high-density material Scatterer, Ridge Filter and Collimator. The track-repeating Monte Carlo algorithm FDC can accurately predict dose distribution when beam shaping elements are included. The automatic algorithm works efficiently in choosing dimensions for high-density Scatterer.

Interpretable Artificial Intelligence-Based Extracapsular Extension Prediction in Head and Neck Cancer Analysis

Y Wang¹, W Duggar^{2*}, T Thomas², P Roberts², R Gatewood², L Bian¹, H Wang¹, (1) Mississippi State University, (2) University of Mississippi Med. Center

Purpose: In medical image-based computer-aided diagnosis, various artificial intelligence (AI)-based models have been proposed and demonstrated high performance. However, there is still a gap between the human's understanding and how these models learned, which influence how we understand and trust these AI algorithms. Therefore, the interpretability of AI model is essential. Our objective is to automatically perform Extracapsular Extension (ECE) detection with an interpretable deep learning technique. ECE is a decisive indication for treatment planning of patients with head and neck squamous cell carcinoma (HNSCC). Current detection practice often requires the visual identification of professionals and ultimately pathologic confirmation. We investigate AI techniques to assist with human identification. **Methods:** In this research, we propose a deep learning method to detect ECE from 3D computed tomography (CT) scans. The proposed model has multi-input that captures information with different scales. The deep convolutional neural network (DCNN) structure has been implemented. To check the explainability of the model, 3D possibility map is utilized to highlight the possible ECE region. Then, the results can be compared with the locations of lymph node region. **Results:** The experimental results have demonstrated that our model can identify ECE and non-ECE patients. Specifically, we have achieved the ECE detection with 96.92% accuracy, and 98.84% AUC. In addition, ECE probability maps are generated for patients, and ECE high potential regions are shown, which is able to enhance the interpretability of the model. **Conclusion:** The research demonstrates the capability to use artificial intelligence for ECE detection. By introducing the possibility map, we can identify where ECE has possibly occurred. Therefore, this will contribute to the explainability of the proposed model. The outcome of this study is expected to promote the implementation of interpretable artificial intelligence-assist ECE detection.

PO-GePV-M-238

Using Deep Learning Auto-Planning for Evaluating the Dosimetric Impact of Deep Learning Auto-Segmentation Without Human Intervention Over Multiple Dose Escalation Schemes for Lung SBRT Treatment Planning

M Holmstrom^{1*}, E Samuelsson¹, Y Wang², (1) RaySearch Laboratories, Stockholm, Sweden, (2) Department of Radiation Oncology, Massachusetts General Hospital, Harvard Medical School, Boston, MA

Purpose: This work presents an integrated solution for automatic segmentation and planning for lung SBRT. Running auto-planning with multiple dose escalation schemes allowed the dosimetric impact of auto-segmentation to be evaluated. **Methods:** The DL planning model was trained in RayStation 10B, using 99 lung SBRT plans delivering 50 Gy in five fractions. The DL segmentation model originated from an official RaySearch model for heart, spinal cord, esophagus, and both lungs. This was extended with a sub-model for chest wall, trained in RayStation 10B using the same lung SBRT patients. The planning model was previously validated, allowing it to be used as a virtual planner. It generates three types of auto-plans, following different dose escalation schemes (110%, 115%, and 120%) to an ITV-4mm heater in the center of the lesion. For 15 test patients, auto-planning was run based on manual and DL ROIs, separately. The former was evaluated on manual ROIs only, while the latter was evaluated on both manual and DL ROIs. PTV, CTV, and heater were always manually delineated. **Results:** When evaluating on manual ROIs, auto-planning based on manual and DL ROIs resulted in similar lung V20 dose, heart mean dose, and spinal cord maximum dose for all test patients and all dose escalation schemes. Studying target coverage and chest wall sparing, however, only 12/15 patients had adequate coverage in the DL ROI-based plans. The remaining three patients had lesions abutting the chest wall, for which the lesion was subtracted from the chest wall in the manual contours. This behavior was not captured by the DL segmentation model. **Conclusion:** Generally, auto-planning based on DL ROIs instead of manual ROIs did not have significant dosimetric effects, except for some patients with lesions abutting the chest wall. Further, the choice of dose escalation scheme had no effect in these dosimetric analyses.

Mats Holmstrom and Elin Samuelsson are employees of RaySearch Laboratories, Stockholm, Sweden.

Validation of a Track-Repeating Monte Carlo Method for Isotopes Calculation

Q Wang^{1*}, Y Li², Z Shen³, M Moyers⁴, C Zhu⁵, D Yu⁶, X Bai⁷, A Adair⁸, H Chen⁹, J Li¹⁰, J Lin¹¹, P Yepes¹², (1) Rice University, Houston, TX, (2) Shanghai Proton And Heavy Center, (3), Shanghai, 31, CN, (4) Shanghai Proton and Heavy Ion Center, Colton, CA, (5) UT MD Anderson Cancer Center, Houston, TX, (6) Shanghai Proton and heavy ion center, Shanghai, CN, (7) University of Houston, Houston, (8) UT MD Anderson Cancer Center, Houston, TX, (9) Shanghai Proton And Heavy Ion Center, (10) Shanghai Proton And Heavy Ion Center, (11) Shanghai Proton And Heavy Ion Center, (12) Rice University, Houston, TX

Purpose: A small amount of positron-emitting isotopes, such as 10C, 11C, 14O, 15O, 13N, 30P and 38K, are produced in a patient body during carbon treatment. This phenomenon can be used to estimate the dose range through PET scan. When the scan is performed after the treatment, most of these generated isotopes will not be detected due to their fast decay, except for 11C. We implemented positron-emitting isotope production in Fast Dose Calculator (FDC), a track-repeating Monte Carlo method. The purpose of this work is to validate the accuracy of FDC isotopes simulation for dose range estimates. **Methods:** During the carbon trajectories simulation by FDC, we save stopped isotopes mentioned above. The same calculation is performed by Geant4 with physics list QSGP_BIC_AIHHP. The FDC isotopes simulation is validated by comparing the ranges of isotope distribution from FDC and Geant4 after blur, decay and body washout processed. We used a cohort of ten patients treated with carbon therapy with the following cases: 4 Thorax, 4 Pelvis and 2 Head & Neck. In addition, six databases with different tissues including water, muscle, adipose, breast, brain and cartilage were generated for FDC. **Results:** The mean range

difference between FDC and Geant4 of 1008 range estimates are -0.4539, -0.09474, -0.180, -0.2257, -0.3993 and -0.3859 mm with FDC database of water, muscle, adipose, breast, brain and cartilage respectively. The standard deviation of the range difference for the 1008 channels is around 4 for different databases. The speed of FDC is thousands of times faster than Geant4. **Conclusion:** FDC isotope distribution calculation is validated. Using muscle database, FDC can give more accurate average range compared with databases using other tissues.

Dual-Energy Subtraction Efficiency: Development of An Objective Quality Metric for Tissue-Subtraction Radiography

S Lopez Maurino^{1*}, K Karim², (1) KA Imaging Inc, Waterloo, ON, CA, (2) University of Waterloo, Waterloo, ON, CA

Purpose: To develop a figure of merit for the objective evaluation and comparison of tissue-selective images generated from dual-energy (DE) radiography systems. **Methods:** The requirements for a successful metric are identified and a metric is proposed based on the spectral transfer of noise, contrast, and resolution properties from the captured (or primary) DE image data to the generated (or secondary) tissue-subtracted images. It combines the relative noise and resolution properties of the tissue-subtracted images with respect to the primary data with the measured quantity and quality of tissue cancellation. An experimental method and an imaging phantom are presented for the capturing all the necessary primary data. Lastly, an analytical method for computing this metric is detailed and verified in a variety of scenarios through first-order X-ray imaging simulations. **Results:** The proposed Dual-Energy Subtraction Efficiency (DSE) metric adequately describes a multitude of image properties for all simulated image scenarios, indicating its ability to accurately and objectively evaluate image quality. It is even possible to identify the particulars of the image deficiencies by studying the DSE spectral shape. **Conclusion:** The DSE and its measurement method described can become a tool to characterize dual-energy radiographic image quality objectively and quantitatively, allowing for improved system comparison, development, and optimization. We conclude that, alongside quality metrics dedicated to conventional radiography such as detective quantum efficiency, it is now possible to extend objective X-ray system evaluation to include dual-energy subtraction radiography.

A Multi-Modal Deep Learning-Based Decision Support System for Individualized Radiotherapy of Non-Small Cell Lung Cancer

A Niciakowski^{1*}, S Gupta², G Suarez³, H Chen⁴, F Guo⁵, J Kim⁶, J Deng⁷, (1)University of Minnesota-Twin Cities, MN (2) Delhi Technological University, Delhi, India, (3) University of Puerto Rico, Mayaguez, PR, (4) Yale New Haven Hospital, New Haven, CT, (5) Yale New Haven Hospital, New Haven, CT, (6) Yale New Haven Hospital, New Haven, CT, (7) Yale University School of Medicine, New Haven, CT

Purpose: There have been rapidly growing applications of artificial intelligence in precision radiotherapy, particularly involving deep learning, which often outperform physicians by utilizing big data in the clinic. The goal of this study is to develop a multi-modal deep learning-based decision support system to help physicians in individualizing radiotherapy for their non-small cell lung cancer patients. **Methods:** With IRB approval, data of 200 non-small cell lung cancer patients was obtained, which included treatment planning data, images, and clinical notes. Factors extracted from treatment planning system were focused on clinical, demographic, and dose-volume indexes. Radiomics features were extracted by a convolutional neural network from imaging data, while the clinical notes were analyzed using natural language processing to cluster phrases into predictive features. The toxicities of each patient were ranked on a RTOG scale of 0-5 on radiation pneumonitis. Initial optimization was performed on individual sub-models, the results of which were normalized and input into a deep neural network to make a final prediction. For each model, the data was split into training and testing data, while a variety of Python tools such as Tensorflow and PyDicom were used to optimize the number of hidden layers and weights for the final predictions. Missing data was imputed using open source packages. **Results:** The accuracy of the individual models was in the 75% range depending on the parameters. Our study indicated that additions beyond three hidden layers had diminishing returns. The final model ended up predicting patient's radiation pneumonitis with an accuracy of 83%. **Conclusion:** Our work indicates that there is statistical validity in adopting a multi-modality-based decision support system for radiation therapy, particularly in predicting radiation-induced toxicity. More work will be needed on determining predictive model calibration and creating a data infrastructure for streamlined integration of structured and unstructured data in radiotherapy.

PO-GePV-M-242

Decreasing NTCP Toxicity in Lung Cancer RT by Reducing PTV Margins Using a Combined Deep Learning Auto-Segmentation and Automated Treatment Planning Approach

M Thor^{*}, H Veeraraghavan, J Jiang, M Zarepisheh, A Rimner, J Deasy, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: Large planning target volumes (PTVs) in locally-advanced non-small cell lung cancer (LA-NSCLC) frequently result in high doses to nearby normal tissues that can consequently lead to severe complications. We reduced current PTV margins and studied the impact on normal tissue complication probabilities (NTCPs). Tumors and considered normal tissues were derived from deep learning (DL) auto-segmentation and treatment was simulated using automated planning with the ambition of using an overall unbiased approach. **Methods:** The cord, esophagus, heart, lungs and tumors (GTV) of 8 randomly selected patients with LA-NSCLC previously treated with definitive concurrent chemo-radiation to 60 Gy in 30 fractions were segmented using a multiple residual network DL auto-segmentation algorithm. The CTV was created via an added 7mm isotropic margin. Another 2mm and 5mm isotropic margin were used to generate a study-specific small PTV (PTVS) and a clinical practice large PTV (PTVL), respectively. One PTVS plan and one PTVL plan was generated for all patients using automated hierarchical optimization applying all currently used dose-volume criteria. Plans were compared by means of NTCP using published models (Esophagus: Esophagitis; Lung: Pneumonitis) and by clinically relevant dose metrics: max dose (cord), mean dose (heart) and D95% (PTV). **Results:** For all patients, PTV coverage was similar in the PTVS and in the PTVL plans (D95%=60Gy in all plans) while dose to all normal tissues was systematically lower in the PTVS plans: The risk of esophagitis was on average reduced from 60% to 57%, the risk of pneumonitis from 8% to 6%, cord max dose from 24Gy to 17Gy and heart mean dose from 9Gy to 8Gy. **Conclusion:** This modestly reduced PTV margin study has demonstrated considerable dose sparing for the key normal tissues in lung cancer RT by means of an unbiased automated segmentation and automated planning approach.

Multi-Scale Deep Learning CT Liver and Spleen Segmentation Network for Radiation-Induced Toxicity Outcomes Analysis

R Haq^{*}, I Onochie, A Apte, M Thor, J Deasy, Memorial Sloan-Kettering Cancer Center, New York, NY

Purpose: Dose toxicity to immune-related organs-at-risk during radiation therapy (RT) may contribute to lymphopenia and radiation-induced liver disease. Our goal is to provide an open-source tool to automatically segment the liver and spleen from clinical contours to enable maximal tissue sparing and perform clinical outcomes analysis. To facilitate this, we built and validated a Deep Learning Segmentation (DLS) framework for consistent and robust auto-

segmentations. **Methods:** The DLS framework leveraged contextual information from 182 contrast and non-contrast enhanced Computed Tomography (CT) scans with well-curated clinical contours of patients previously treated with thoracic/abdominal RT. The DLS model was trained on a nested deep neural network architecture, Unet++, for multi-label segmentation (learning rate: 0.1; batch size: 8 images for 70 epochs) using 90% of the CT scans. The multi-scale, deep-supervision enabled network learned representations from dense skip-connections on entire CT body scans. The remaining 10% of the scans were used for quantitative evaluation of the final model vs. reference contours using Dice Similarity Coefficients (DSC), 95th percentile of Hausdorff Distances (HD95) and the mean dose. Statistical comparison was performed using the Wilcoxon signed-rank test and Spearman's correlation coefficient tests. **Results:** The DLS model reduced segmentation time per patient from about half an hour of manual segmentation to 40 seconds. The liver and spleen achieved accuracy of (median DSC=(0.94(0.93-0.95), 0.92(0.89-0.93)) and HD95=(7.5mm(5.3mm-8.4mm), 3.7mm(3.3mm-6.2mm)). No statistically significant difference was observed between the calculated mean dose for the auto-generated and the expert contours for both structures (p-value>=0.4). **Conclusion:** The model was robust against variability in image characteristics and large image background, including the presence/absence of contrast. The segmentation accuracy is considered adequate for extracting dose-volume histograms to use in outcomes analyses. The abdominal DLS model is distributed as a part of CERR's Model Implementations library.

This research is partially supported by NCI R01 CA198121.

Performance Evaluation and Validation of Knowledge-Based Treatment Planning of VMAT for Post-Mastectomy Loco-Regional Radiotherapy Involving Internal Mammary Chain

R Phurailatpam*, M Sah, J Jain, T Wadasadawala, K Joshi, J Swamidass, ACTREC, Navi Mumbai, MHIN

Purpose: Clinical implementation of knowledge-based treatment planning for Volumetric Modulated Arc Radiotherapy for post-mastectomy loco-regional radiotherapy. **Methods:** A knowledge-based treatment planning (KBP) model was built (Rapid-Plan v13.5.35, Eclipse v13.5, Varian Medical System) using 73 left-sided patients who had undergone irradiation of the ipsilateral chest wall with internal mammary nodes (IMN) and supra-clavicular fossa (SCF) with prescribed dose of 26 Gy/5 fractions. All the clinical were generated using 6MV photon beams with two tangential partial arcs with isocentre located in the centre of PTV chest wall (Eclipse v13.5). For the validation, automatic plans(KBP) were generated for 13 patient datasets in a single optimization step without any manual intervention. Various dose volume parameters were compared and analysed using paired t-test and Wilcoxon signed rank test. P<0.05 was considered significant. **Results:** Mean $\pm$ Standard deviation (SD) between clinical plans and KBP for various DVH parameters have been analysed and comparisons are given as :D 95[%] of PTV for CW, IMN and SCF were 93.2 $\pm$ 2.4vs 93.2 $\pm$ 3.1 (p=0.95), 89.48 $\pm$ 2.94 vs 91.21 $\pm$ 2.49 (p=0.17) and 94.95 $\pm$ 1.4 vs 97.27 $\pm$ 1.7 (p=0.00) respectively. For OARs, mean dose (Gy) $\pm$ SD to heart, contralateral breast, ipsilateral lung was 2.92 $\pm$ 0.54 vs 2.79 $\pm$ 0.55 (p=0.06), 2.14 $\pm$ 0.34 vs 2.27 $\pm$ 0.24 (p=0.162) and 6.67 $\pm$ 0.71vs 7.48 $\pm$ 0.39 (p<0.001) respectively. For contralateral lung, mean dose (Gy) with (IQR) was 2.46 (2.21,2.51) vs 2.2 (1.97,2.28) with (p =0.012). Maximum dose to left anterior descending artery (LAD) was 15.1 $\pm$ 3.1 vs 13.16 $\pm$ 2.43 (p=0.001). Homogeneity index (HI) and Conformation Number (CN) of total PTV for clinical and KBP were 0.12 $\pm$ 0.02 vs 0.12 $\pm$ 0.02 (p=0.39) and 0.93 $\pm$ 0.02vs 0.93 $\pm$ 0.03 (p=0.47). Mean $\pm$ SD of MU for clinical and rapid plan were 1994 $\pm$ 275.3 vs 1704 $\pm$ 315.3 (p=0.002). **Conclusion:** The KBP were either better or comparable to the clinically acceptable plans generated by experienced physicist for various Dosimetric parameters analysed. Hence KBP can be used for clinical implementation.

PO-GePV-M-245

Benchmarking of Three Spatial Fractionated Radiation Therapy Techniques for Multiple Treatment Sites

J Zavala Bojorquez^{1*}, (1) Cleveland Clinic, Cleveland, OH

Purpose: To benchmark three techniques for Spatial Fractionated Radiation Therapy (SFRT) and evaluate their dosimetric performance in multiple treatment sites. **Methods:** Five patients (multiple sites) who underwent conventional single-field GridBlock therapy were replanned using GridBlock, MLC-based, and Lattice-based SFRT (15Gy/1fraction, 6 MV). The GridBlock consisted of a hexagonal pattern of divergent holes (hole diameter=1.43cm, center-to-center spacing=2.11cm). The MLC-based grid was generated by converting a static beam to a step and shoot beam delivering grid pattern (square aperture=1cm, open-to-closed ratio=0.375/0.625). The Lattice-based grid was generated by placing cylinders with 1.5cm diameter and 3cm center-to-center spacing within the GTV to mimic conventional GridBlock therapy. The quality of the plans was evaluated using different dosimetric parameters (Valley-to-Peak Ratio (VPR=D10valley/D90peak), mean GTV dose, equivalent uniform doses (EUD) for both GTV and Normal Tissue, delivery time). **Results:** The VPR is the major postulated contributor of the bystander and abscopal effects in SFRT. The lattice technique achieved a better mean VPR (54.03 $\pm$ 15%) when compared to those of the Grid-Block (19.09 $\pm$ 4%) and MLC (19.40 $\pm$ 16%) techniques. For dose coverage of the GTV, the lattice technique also achieved a better dose coverage (D=9Gy $\pm$ 3Gy) compared to Grid-Block (D=5.8Gy $\pm$ 1Gy) and MLC (D=4Gy $\pm$ 1Gy). The EUD predicts the effectiveness of tumor control and normal tissue toxicity and the lattice technique predicted better tumor control and normal tissue toxicity (mean EUD_tumor =7.97Gy, mean EUD_normal=5.87Gy) than the GridBlock (mean EUD_tumor=1.08Gy, mean EUD_normal=6.91Gy) and MLC (mean EUD_tumor=1.67Gy, mean EUD_normal=5.45Gy). The beam-delivery time was clinical acceptable for all the techniques (mean T_lattice=8.1min, mean T_GridBlock=2.83min, mean T_MLC=7.3min). **Conclusion:** When available, the lattice technique should be preferred above the GridBlock and MLC techniques because it produces better quality plans. It achieves better VPRs and coverage of the GTV. It gives better predictions of the tumor control and normal tissue toxicity, and its delivery times are clinical acceptable.

A Motion Phantom Study on RefleXion X1: The Dosimetric Impacts of Stereotactic Radiation Therapy Delivery Technique and Motion

D Capaldi^{1,2*}, E Simiele^{1a}, M Owens², B Han¹, M Surucu¹, L Xing¹, L Vitzthum¹, D Chang¹, N Kovalchuk¹, (1) Stanford University, Stanford, CA, (2) RefleXion Medical, Hayward, CA

Purpose: RefleXionTM X1 is a novel therapy machine designed to support both biology-guided radiotherapy (BgRT) and SBRT. To determine the dosimetric effects of motion during RefleXion SBRT treatment delivery, a lung phantom film dosimetry study was performed under multiple motion conditions using the first clinical installation of RefleXion X1. **Methods:** CIRS Dynamic Thorax Motion Phantom with a 3.0cm diameter spherical tumor film insert was used to program respiratory waveforms with varying peak-to-peak amplitude (A) and period (T). 4DCT scans were acquired for the following 3 dynamic conditions: A=0.6cm with T=5s, A=1.2cm with T=4s, and A=2cm with T=6s to simulate human respiratory motion of lung tumours. Phase-based binning was performed, and GTVs were contoured on each respiratory-phase. ITVs were then generated, and PTVs were created with 2mm and 5mm expansions. To determine the effects of different motion and delivery parameters, treatment plans were created for both PTVs using 1 and 2cm jaw sizes with a prescription of $\geq$ 95% coverage of PTV with 5.0Gy. Plans were delivered to a phantom under planned dynamic conditions. Two-dimensional dose was measured using Gafchromic EBT-3 film along the sagittal plane of the target center. The film measurements were used to calculate the 2D cumulative DVH, percentage of ITV receiving the prescription dose, and the minimum dose received by 95% of the ITV. **Results:** The larger motion amplitude resulted in more under-dosing of the ITV, and this effect was greater for 1cm-jaw plans. The 2cm-jaw plans provided adequate coverage to the ITV for smaller amplitudes of motion (i.e., 0.6cm/1.2cm) with ITV-to-PTV margins of 2mm or 5mm. **Conclusion:** The interplay of RefleXion SBRT delivery and target motion was measured for several clinically-relevant lung cases. Clinically acceptable ITV coverage was obtained for smaller amplitudes of motion with 2cm-jaws whereas significant under-dosing was

observed for larger motion amplitudes with 1cm-jaws.

PO-GePV-M-247

Tattooless Patient Setup with 3D Optical Surface Imaging For Paraspinal Radiation Therapy

Wang-Chia Ko¹, Yulin Song^{1*}, Hao-Yun Hsu², Boris A. Mueller³, David Guttmann³, Luke Pike³, Paul Tamas³, Miao Zhang², Josh Yamada³, (1) Department of Biostatistics, MSPH, Columbia University, NY, (2) Department of Medical Physics, Memorial Sloan Kettering Cancer Center, NY (3) Department of Radiation Oncology, Memorial Sloan Kettering Cancer Center, NY

Purpose: Permanent skin tattoos have been part of standard care for paraspinal patients undergoing EBRT. In this study, we prospectively evaluated tattooless setup with 3D surface imaging and compared it with the skin tattoo-based approach. **Methods:** Patients receiving paraspinal radiation therapy underwent a standard tattoo-based setup, alternating daily with a tattooless setup by surface imaging. Following the initial setup, the patient position was verified by daily CBCT imaging, with matching on the bone or surgical hardware to represent ground truth. Translational and rotational shifts determined by CBCT imaging were recorded, as were setup time duration and total in-room time duration. Statistical analysis was performed using the non-parametric Wilcoxon Rank-Sum test and F-test for Equality of Two Variances. **Results:** We evaluated 57 individual treatments from 14 paraspinal patients, 22 treated under surface imaging, and 35 under a traditional tattoo-based setup. The distributions of entire in-room time duration and set up time duration are right-skewed in both cohorts and are not normally distributed. The median entire in-room time duration and set up time duration in the surface imaging cohort are indifferent from those of the traditional skin tattoo cohort ($p = 0.417$ and 0.597 , respectively). The variance of position shift in LNG direction in the 3D surface imaging cohort is significantly different from that of the traditional skin tattoo cohort ($p = 0.0069$). There is insufficient evidence ($p > 0.05$) to indicate a difference in variance or mean between the two cohorts in other directions. **Conclusion:** Our preliminary results suggest that a tattooless setup approach to paraspinal radiotherapy with surface imaging may be sufficiently accurate for initial patient setup. Further analyses among large cohorts and including delivered dosimetry will determine whether standard tattoo-based approaches can be replaced by 3D surface imaging.

PO-GePV-M-248

A Medical Image Challenge Infrastructure

K Farahani^{1*}, J Kalpathy-Cramer², B Bearce³, U Wagner⁴, (1) National Cancer Institute, Bethesda, MD, (2) Boston, MA, (3) No institution provided (4) Frederick National Lab, Frederick, MD

Purpose: To develop an infrastructure for benchmarking the performance of task-specific software tools in medical imaging challenge competitions. **Methods:** The open-source challenge platform, CodaLab, has become a popular tool for benchmarking scientific competitions. We customized an instance of CodaLab for use in medical imaging applications, by adding capabilities to accept challenge proposals, provide guidelines, and distribute data from public image repositories such as The Cancer Imaging Archive, or from a private server. Additional developments include allowing docker submissions, a documentation site, and a helpdesk to assist users. **Results:** The National Cancer Institute's Medical Imaging Challenge Infrastructure (MedICI - <https://github.com/QTIM-Lab/MedICI>) can be deployed locally or in a public cloud. It allows for challenge design submissions. Organizers are able to use scripts and codes from public libraries in R, Python, Javascript, etc to evaluate the results based on previously defined metrics. To date, over 20 medical imaging challenges, with applications in cancer have been conducted through MedICI, either independently or in conjunction with scientific conferences. These have included challenges in benchmarking tools for image-based detection, diagnosis, classification of cancers, and prediction of response to radiotherapy. Many of the tools developed in response to challenges on MedICI have deployed innovative approaches to machine learning and deep learning in medical imaging. **Conclusion:** Challenges provide a robust way to promote open data science by assessing the performance of software tools in addressing practical technical or clinical tasks in medical imaging. They facilitate a head-to-head assessment of innovative tools for diagnosis and treatment of disease using standardized datasets and high-quality ground truth data. As a resource, MedICI provides a comprehensive platform for the implementation of challenges in medical imaging. It will continue to evolve and be a valuable resource to the community by serving challenges to scientific organizations, including the AAPM.

Automatic Segmentation of Head and Neck Tumors During Treatment: Can We Remove the Mask Yet?

M Gardner^{1*}, A Mylonas^{1,2}, M Mueller¹, Y Ben Bouchta¹, J Sykes³, P Keall¹, D Nguyen^{1,2}, (1) ACRF Image X Institute, Sydney, NSW, AU, (2) University of Technology Sydney, Ultimo, NSW, AU (3) Blacktown Hospital, Blacktown, NSW, AU

Purpose: To investigate the feasibility of automatic segmentation of head and neck (H&N) tumors in kV images using simulated projections. Success will lead to the ability to track tumor motion during H&N radiotherapy with the goal of removing the need for the thermoplastic mask for radiotherapy. **Methods:** CT scans of two patients were used from the HNSCC database from the Cancer Imaging Archive. For each patient, 3600 evenly spaced digitally reconstructed radiographs (DRRs) were generated (0.1° projection angle difference) from the CT scan. For each DRR the ground truth tumor location was forward projected from the planning CT and corresponding structures file. A Cycle Generation Adversarial Network (cGAN) was trained to detect the tumour location in each DRR. The testing data consisted of 360 DRRs from a rigidly transformed copy of the CT volume, with the projection angles of the DRRs being taken from a typical CBCT scan for H&N patients. The CT scan was rotated by 3° and then translated by 3mm in the AP, LR and SI directions. The estimated tumor location from the cGAN was compared with the ground truth for each patient by measuring the centroid error and the DICE similarity coefficient (DSC). **Results:** The mean($\pm$ Standard deviation) DSC coefficients for patients 1 and 2 were 0.89 ± 0.02 , 0.90 ± 0.02 , and for all patients the DSC was 0.89 ± 0.02 . The mean($\pm$ Standard deviation) absolute centroid error for patients 1 and 2 were 1.43 ± 0.76 mm and 1.54 ± 0.88 mm, and for all patients was 1.49 ± 0.82 mm. **Conclusion:** The results in this study demonstrate potential for tracking the tumor location for head and neck cancers in silico. Further development of this technology will pave the way for the removal of the need for thermoplastic masks for treating head and neck cancers during radiotherapy.

This project received funding support from Cancer Australia

Efficient and Stable Evaluation of Image Registration Using Deep Learning

B Yang^{*}, X Chen, J Zhu, K Men, J Dai, Cancer hospital Chinese academy of medical sciences, Beijing, 11CN

Purpose: The alignment of the region of interest is of primary concern in radiotherapy. Although quantitative assessment can be obtained by manually contouring the same structures on both fixed and moving images, this process is time-consuming and observer-dependent. Here, we established an efficient and stable evaluation tool using deep learning to evaluate the accuracy of image registration quantitatively and objectively. **Methods:** Ten patients with head and neck tumors were enrolled. Two sets of CT images for each patient were acquired in different time, and then were registered with rigid and deformable methods, respectively. Eight OARs were segmented by oncologists and the deep learning method in each image, named as Manual-fixed, Manual-moving, Auto-fixed and Auto-moving respectively. Then, both Manual-moving and Auto-moving were introduced to the transformation matrices to get Manual-moving-trans and Auto-moving-trans. The similarities between Manual-fixed and Manual-moving-trans were quantified by the geometric index, including Dice similarity coefficient (DSC) and mean distance to agreement (MDA), which was set as the ground truth (GT) in this study. The same analysis was applied to

Auto-fixed and Auto-moving-trans, obtaining the value of DSC and MDA. Finally, it was compared with the GT to verify its reliability. The paired t-test was performed for statistical analysis. A p-value less than 0.05 was statistically significant. **Results:** For the rigid registration, Δ DSC for all OARs were smaller than 0.012%, and all Δ MDA less than 0.2mm. There were no significant differences between GT and evaluation tool. In the deformable case, Δ DSC for all OARs were within 0.02%, and Δ MDA were always less than 0.09mm. There were no significant except for the spinal cord and the mandible. **Conclusion:** The proposed deep learning-based evaluation tool could substitute the conventional evaluation method with the quantitative measurement, reflecting the accuracy of registration stably and efficiently in the interested region.

PO-GePV-M-251

A Generalizable Target Contour Validation Method Using Radiomics Based Regression Analysis

Z Lin^{1*}, C Chen³, Z Fei³, Q Zhou², z li² (1) Xiamen University, (2) Manteia Medical Technologies, Xiamen, (3) CN, Department of Radiotherapy, Fujian Cancer Hospital, Fujian Medical University

Purpose: To analyze the changing trend of radiomics features of the targeted volumes, especially those with fuzzy edges, on the boundary area in CT images of nasopharyngeal carcinoma patients, and to explore this approach as a method to evaluate the quality of automatic or manual delineation of GTVs and organ at risks (OARs) with low contrast boundaries. **Methods:** Contours of GTVs and OARs in CT images of nasopharyngeal carcinoma patients were expanded and retracted by 1 mm, 2 mm and 3 mm respectively. Next, extract the radiomics features of the original image, the expanded images and the shrunk images. Then, the difference of adjacent features is calculated to get the feature differences. Regression model is built on features extracted using decision tree algorithm. The error of the model in the test set is calculated and analyzed. Performance was assessed on a separate test dataset. **Results:** We conducted sufficient experiments on 2 datasets of nasopharyngeal cancer patients. One set of the data was used as the ground truth for model training, and the other data set was used for model testing. We used the mean square error as the evaluation index of the model, and the error is 0.02. We compared the results of the model prediction to doctor's judgment, and found that our model can distinguish and gives evaluation on these situations very well: incomplete delineation of the area, delineation area is too large, and delineation is of good quality. **Conclusion:** We found that there are changing trend of radiomics features in the boundary area of targeted volumes with fuzzy edges in CT images of nasopharyngeal carcinoma patients. By exploring this characteristic change using regression models, we can evaluate the quality of the target area delineation automatically to accelerate quality assurance procedure in clinical practice.

PO-GePV-M-252

Monte Carlo Simulation of Varian Linac Using PRIMO

Y Li^{*}, X Sun, C Liu, National Clinical Research Center for Cancer/Cancer Hospital & Shenzhen Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Shenzhen, Guangzhou, CN

Purpose: PRIMO is a new Monte-Carlo program and has a user-friendly graphical interface. A commissioned PRIMO program can be used in quality assurance. **Methods:** A VitalBeam with 6X and 6X FFF equipped with the 120 Millennium MLC was simulated by PRIMO. We adjusted four parameters(initial energy, energy full width at half maximum(FWHM), focal spot FWHM, and beam divergence) to match the measurements in the water-tank. PTW BEAMSCANTM water-tank and Semiflex 3D 0.07cm³ ion-chamber were used in the measurement. Percentage depth dose(PDD) and off-axis ratio(OAR) were evaluated with gamma passing rate. PDDs were matched at different widths of standard square fields(3cm, 4cm, 6cm, 8cm, 10cm, 15cm, 20cm, 30cm and 40cm) in central axis. OARs were matched at five depths(1.5cm, 5cm, 10cm, 20cm and 30cm) in cross-field direction. Dose leaf gap (DLG) was measured by an electronic portal imaging device(EPID) using a sweeping gap method with SDD=105cm. **Results:** Gamma passing rate of PDD and OAR showed a high level of agreement between Monte Carlo calculations and measurements. For the criterion of 2%/2mm, 1%/2mm, and 1%/1mm, the gamma passing rate(GIPR) of 6X PDD were 99.33%~100%, 99%~100%, 99%~100%, respectively. The GIPR of 6X FFF PDD were 99.33%~100%, 98.99%~99.66%, 97.64~98.99, respectively. The GIPR of 6X OAR were 96.4%~100%, 90.99%~100%, 85.12%~98.62%, respectively. The GIPR of 6X FFF OAR were 95.15%~100%, 89.32%~100%, and 87.02%~99.74%, respectively. The calculated DLG matched well with the measured DLG(6X: 1.36mm vs. 1.45mm; 6X FFF: 1.05mm vs 1.35mm, calculation vs measurement). The transmission factors were also similar(6X: 1.25% vs 1.39%; 6X FFF: 0.8% vs 1.15%, calculation vs measurement). **Conclusion:** The calculated PDD, OAR, and DLG were all in good agreement with measurements. As an independent and accurate Monte Carlo tool, PRIMO can be used in beam configuration, quality assurance, and treatment plan verification.

PO-GePV-M-253

Translating Predictive Models Into Treatment Planning Guidelines for Use in Clinical Practice: The Example of the Cardiopulmonary Dose Model for Overall Survival in RTOG 0617

M Thor^{*}, L Sun, P Patel, C Lee, A Apte, L Santanam, N Shaverdian, A Shepherd, A Rimner, J Deasy, Memorial Sloan Kettering Cancer Center, NY, NY

Purpose: New knowledge on normal tissue response requires updated NTCP models. Based on accumulated experience translating such models into treatment planning optimization goals, this study derived evidence-based dose-volume criteria from the recently published RTOG 0617 overall survival (OS) model. **Methods:** The published model included Atria D45%, Mean Lung Dose (MLD), Pericardium MOH55%, and Ventricles MOH55%. This study focused on reducing Pericardium MOH55% since MLD is already constrained internally (MLD<20Gy), Atria and Ventricles are included in the Pericardium, and the strongest association with OS was observed with Pericardium dose. Objective function input in commercial treatment planning systems is limited to Dx and Vx. Hence, MOH55% was most strongly represented by a combination of D15 and pericardium mean dose (PMD, Spearman's rho: 0.93, 0.99). These two variables were also among the best OS predictors in RTOG 0617. Dose-volume goals were D15<6Gy and PMD<5Gy, which represented low risk in the OS model. Nine of 105 randomly selected internal patients previously treated to 60Gy in 30 fractions with concurrent chemo-radiation and durvalumab were re-planned incorporating D15 and PMD goals using standard planning practice. Pericardium was generated from our open-source deep-learning algorithm. **Results:** Compared to the original plans, D15 was on average reduced from 43Gy to 29Gy; PMD was reduced from 20Gy to 13Gy; the normalized relative reduction ranged between 6-72% and 7-64%, respectively. Only 2/9 patients met D15<6Gy and PMD<5Gy; the majority (7/9 patients) were reduced to an intermediate-moderate risk (D15<49Gy and PMD<20Gy). Pericardium sparing was less in patients with a larger (>8%) Pericardium-PTV overlap; median relative reduction: 18% vs. 58% for D15 and 20% vs. 48% for PMD. **Conclusion:** This study has demonstrated a practical treatment planning-based approach to translate a published NTCP model that included multiple and new organs and novel dose parameterizations to form dose-volume criteria for use in treatment planning.

Image Quality Assessment of Low CT Dose for Foreign Bodies Detection

M Aljallad^{1*}, (1) West County Radiology, St. Louis, MO

Purpose: To develop a suitable image quality CT protocol to detect the foreign bodies (FBs) in the respiratory tract of pediatrics with both a minimum patient radiation dose and an equivalent radiation risk to a conventional radiograph chest exam. **Methods:** CT Data were collected on a Siemens Flash. The

modification to the protocol included setting the reference kVp to 80, which lowered the CTDI value by 58%, the reference mAs to 9 mAs which reduced the CTDI by an additional 90%, using X-CARE and Adaptive Dose Shield, SAFIRE was set to order 4. Twenty CT exams using the modified CT protocol were performed with different FBs distributions in a five years old size anthropomorphic phantom (LUNGBODY) shown in Figure (1). The FBs included small size radiopaque bodies such as fish bones, peanuts, LEGO toys, etc. The exams were then presented randomly to the radiologist team to interpret the images and report the results. The GE QC phantom (Figure a) was used to measure the modulation transfer function (MTF). The ACR CT phantom (Figure 2) used to measure the (CNR). Image quality metric (Q) is calculated to characterize and to compare the different CT protocols in terms of dose, spatial resolution, and noise using: $Q = c \cdot (p(10\%)^4) / (\sigma \cdot D)$. **Results:** The CNR is reduced by 20% due to the decrease in mAs. The images were reconstructed with kernel I30, the limiting spatial resolution at 10% MTF was improved. The Q-factor was increased, indicating improvement in image quality, due to the decrease in the CTDI and the increase in the MTF. The results are summarized in table(1) **Conclusion:** Low-dose CT protocols can be very reliable for FB detection with high image quality and low patient dose, especially in pediatric patients where the aspiration of FBs is a frequent and severe cause of respiratory problems in children.

PO-GePV-M-255

Ventilation Measurements from Free-Breathing CT

D Low^{1*}, D O'Connell¹, M Lauria¹, B Stiehl¹, L Naumann¹, P Lee², J Hegde¹, I Barjaktarevic¹, J Goldin¹, A Santhanam¹, (1) UCLA, Los Angeles, CA, (2) M.D. Anderson Cancer Center, Houston, TX

Purpose: To develop methods for measuring free-breathing ventilation using free-breathing CT scans **Methods:** A multi-scan free-breathing CT protocol was used to scan ten patients. The CT scans were acquired with a simultaneous breathing surrogate (abdominal pneumatic bellows). To reduce calculation time, the image registration was conducted on regions-of-interest (ROIs) from the upper right lungs. The ROIs were first registered using a published registration technique (pTV), which was followed up with a secondary registration that used a two-term objective function; a ventilation-adjusted Hounsfield Unit difference and a conservation-of-mass term labeled $\Delta\Gamma$ that denoted the difference between the deformation Jacobian and the tissue density ratio. The ventilations were calculated voxel-by-voxel as the slope of a first-order fit of the Jacobian as a function of the breathing amplitude. **Results:** The ventilation patterns showed different patterns and magnitudes. The mean ventilations calculated from the DVFs of the pTV and secondary registration were nearly identical, but the standard deviations of the voxel-to-voxel differences were approximately 0.1. The mean of the 90th percentile values of $\Delta\Gamma$ were reduced from 0.153 to 0.079, implying first that the secondary registration improved the conservation-of-mass criterion by almost 50% and that on average the correspondence between the Jacobian and density ratios were less than 0.1. This improvement occurred in spite of the average of the 90th percentile changes in the DVF magnitudes being only 0.58 mm. **Conclusion:** This work introduces the use of multiple free-breathing CT scans for free-breathing ventilation measurements. The approach has some benefits over the traditional use of 4DCT or breath-hold scans, including not having sorting artifacts. The benefits over breath-hold scans include the relatively small motion induced by quiet respiration versus deep-inspiration breath hold and the potential for characterizing dynamic breathing processes that disappear during breath hold.

PO-GePV-M-256

Investigation of Light-Transparent Bolus for Potential Breast SGRT Applications

Yulin Song¹, Hao-Yun Hsu^{1*}, Wang-Chia Ko², Paul Tamas⁴, Miao Zhang⁵, Boris A. Mueller⁶, David Guttman⁷, Lior Z. Braunstein⁸, (1) Department of Medical Physics, Memorial Sloan Kettering Cancer Center, NY, (2) Department of Biostatistics, MSPH, Columbia University, NY, (3) Department of Radiation Oncology, Memorial Sloan Kettering Cancer Center, NY

Purpose: Standard light-opaque bolus is suboptimal for radiotherapy (RT) patient setup because it obscures surface skin marks. ClearSight bolus is a transparent polymer gel bolus designed for enhanced patient setup with surface visibility. We evaluated the clinical characteristics of ClearSight bolus to determine its suitability for breast SGRT applications. **Methods:** Room-light transparency was evaluated by placing bolus (30 cm x 30 cm x 3 mm) on an AlignRT calibration plate. The visibility, deformation, and sharpness of the black blobs were examined. Radiation attenuation was measured by placing bolus on a 15-cm stack of solid water, with ion chamber at d5 for 6x, 6xFFF, 15x, d3 for 6E, 9E, and d4 for 12E, 16E, and 20E. The readings were compared with those obtained from an equivalent thickness of solid water. Bolus-to-skin conformity was evaluated by placing bolus over surfaces with various curvatures and examining the air gap between the two. Effects on 3D optical surface imaging tracking were assessed by placing bolus on various surfaces and measuring 6D shifts using AlignRT Advance. **Results:** ClearSight bolus had good room-light transparency. The black blobs and crosshair on the calibration board were easily visible through the bolus. The mean attenuation ratio between bolus and solid water was 1.0010 ± 0.0006 for photon energies and 1.0499 ± 0.0682 for electron energies. Bolus-to-skin conformity was good for flat and cylindrical surfaces, but inadequate for hemispherical surfaces. ClearSight bolus was not entirely transparent to the structured light from AlignRT Advance: it induced a modest translational shift (range -1.0 to 1.5mm) and rotational shift (range -1.5° to 1.5°) depending on surface topography. **Conclusion:** ClearSight bolus is suitable for breast SGRT applications. When using AlignRT Advance, capturing a new reference surface is necessary after bolus placement and, for some patients, larger than usual bolus may be required.

PO-GePV-M-257

A Deep Learning-Based Physician-Specific OAR Segmentation Framework for Radiotherapy Treatment Planning

Y Chen^{*}, L Xing, L Yu, N Panjwani, J Obeid, M Gensheimer, H Bagshaw, M Buyyounouski, N Kovalchuk, B Han, Stanford University School of Medicine, Stanford, CA

Purpose: To assist the organ contouring in current treatment planning procedures, we developed a deep learning-based framework to automatize the whole contouring process contributing to the clinical practice. **Methods:** This framework was designed for the auto-segmentation of organs at risk (OARs) in head and neck, and pelvis sites, which consisted of a pre-processing module, a deep learning-based segmentation module, and a post-processing module. In the pre-processing module, the original image data was extracted from the clinical DICOM Image file, and then processed for the segmentation network learning. A U-Net like network was designed in the segmentation module, in which three input branches for three consecutive image slices were designed to consider the contour consistency among adjacent image slices, and a deep supervision strategy was integrated to speed up the convergence of the network. The segmentation results would be converted to a DCIOM Structure file in the post-processing module for treatment planning. Moreover, this framework is being developed toward physician-specific to comply with the contour style of each radiation oncologist separately. **Results:** The organ-averaged Dice similarity coefficient (DSC) performance of this auto-segmentation framework is 0.71 and 0.74 for 16 head and neck and 11 pelvis OARs, respectively. Once a clinical DICOM Image data is input to the framework, a corresponding DICOM Structure file would be automatically generated containing the OAR segmentation results. The overall operation takes about 1-2 min per case without the need for additional manual interference. **Conclusion:** A deep learning-based framework was developed for the auto-segmentation of head and neck, and pelvis OARs with promising contouring accuracy and operation time. This framework is ready to be applied in our clinical practice to improve the efficiency of current treatment planning procedures.

This research was supported by a grant from Varian Medical Systems (Palo Alto, CA).

Decision On SBRT, regular Or Less Fractions RT with a Simple TCP and EQD2 Calculation

S Li*, B Wang, T Giaddui, B Micaily, C Miyamoto, Temple University Hospital, Philadelphia, PA

Purpose: The determination to use SBRT or fractionated RT for none-small lung cancer (NSCLC) are typically determined by tumor size and location without patient specific TCP and EQD2 calculations. A method is proposed here to quickly assess the patient cancer and tissue cell distributions, TCP and EQD2. **Methods:** Physician-defined CTV (or GTV) is decomposed into small ROIs, that are defined by intersections of radiopacity on an average of 4DCT scans and SUV of FDG PET images for an apparent cancer cell density. Nearby OARs are prioritized according to the patient conditions. Clinical SBRT plans with GTV < 22 cc and IMRT plans with CTVs > 500 cc are retrospectively analyzed. A unified multi-activation (UMA) model for cell survival of squamous cell lung carcinoma (SW1573, n=12, Do=1.1-Gy), adenocarcinoma of Lung (HX144, n=4.0, Do=2.2-Gy), (normal epithelial cell lines, n = 9.0, Do=1.1-Gy) and tumor cell density of 10⁵/gram are used for TCP and EQD2 calculations. **Results:** Plans of standard SBRT in five 10-Gy fractions have approximately 100%TCP for most density levels of the cancer cells. A low density volume at the periphery of an adenocarcinoma with a GTV of 10 cc has the lowest 98%TCP and a high but acceptable EQD2 of 90-Gy to a 25-cc of the surrounding lung. TCP and EQD2 to the treatment in options of: (1) 1.8-Gyx37, (2) 3-Gyx22, or (3) 13.2-Gyx5 of a 750-cc squamous cell lung cancer, 0.1-cc spinal cord, 25-cc lungs, 5-cc heart, and 2-cc esophagus are (1) 33%, 36, 65, 40, 58-Gy, (2) 98%, 37, 99, 43, 75-Gy, and (3) 100%, 46, 227,73, 248-Gy, respectively, favor of the option (2). **Conclusion:** The new method can quickly calculate TCP and EQD2 with apparent cell density and dose distribution which may help clinicians make accurate treatment decisions.

PO-GePV-M-259

Penalized Entropy Loss Function with High Quality Uncertainty Estimation for Pneumonia Diagnosis in Pediatric Patients

D Feng¹, X Chen^{1*}, K Wang², Z Zhou³, (1) Xi'an Jiaotong University, Xi'an, 61, CN, (2) UT Southwestern Medical Center, Dallas, TX, (3) University of Central Missouri, Warrensburg, MO

Purpose: In the uncertainty-informed decision system, models may make wrong predictions with high certainty which leads to omission of false predictions. Therefore, we propose to set up a model which could make correct prediction with low uncertainty and wrong prediction with high uncertainty. **Methods:** From accuracy and certainty perspective, we categorized the predictions into four kinds, correct and certain (CC), correct and uncertain (CU), wrong and certain (WC), wrong and uncertain (WU). The desirable model is that almost all predictions belong to CC or WU and fewer WC cases. Therefore, we integrated uncertainty estimation into training phase and proposed penalized entropy (PE) loss. PE has two terms, accuracy related and certainty related terms. Accuracy related term is cross entropy. Certainty related term is penalizing WC predictions and is the multiplication of negative likelihood (NLL) and certainty, where certainty is calculated by Monte Carlo dropout. High NLL and high certainty will result in high certainty-related loss which means wrong and certain decision. A hyper-parameter is used for relative weighting of certainty-related term with respect to accuracy-related term. **Results:** Validating on the Chest X-ray dataset, we achieved higher quality of uncertainty estimation that accuracy vs. uncertainty (AvU) is 0.89 which outperformed state-of-the-art losses. Furthermore, PE can produce more accurate predictions with accuracy of 0.90 and AUC of 0.96. **Conclusion:** In this study, we proposed a penalized entropy loss function in a prediction model for pneumonia diagnosis in pediatric patients. This model achieves better uncertainty estimation that makes correct predictions with high certainty, wrong predictions with high uncertainty, especially avoiding wrong but certain results. Compared to state-of-the-art loss functions, this loss can not only give higher quality uncertainty estimation but also more accurate results. Therefore, model trained with this novel loss function can be used in clinical for precise and comprehensive diagnosis.

PO-GePV-M-260

LiteUnet : A Lightweight 2DUnet Combine GRU for Cardiac Substructures Segmentation

J Jiang¹, R Zhou², Z Zhang², Z Qian³, S Wu^{1*}, Y Lu¹, (1) School of Computer Science and Engineering, Sun Yat-Sen University, Guangzhou, Guangdong, CN, (2) Xiangya Hospital Central South of University, Changsha, Hunan, CN, (3) Perception Vision Medical Technology, Guangzhou, CN

Purpose: To propose a lightweight and universality two-dimensional convolution neural network for whole heart segmentation of CT data on few-shot learning. And explore what kind of deep learning model architecture is more suitable for CT data that is three-dimensional and less training data. **Methods:** Every case in our CT data is 512*512*n (n for CT slice, depending on the actual case). Firstly, we use 2D UNet to roughly cut out the region of the heart, then we can obtain data that is 192*192*48 and contains the entire heart. Secondly, we use 2D UNet combine bidirectional-GRU and attention mechanism on 3D heart CT to segment out 14 cardiac substructures. **Results:** Our model has few parameters and is easy to train, but performance is equal to or even exceed some models of three-dimensional convolution. **Conclusion:** This work indicates the advantage of the model of two-dimensional convolution combine some time-series processing methods like RNN when we use three-dimensional CT dataset on few-shot learning.

PO-GePV-M-261

Predicting Lymph Node Metastasis Through Automated and Reliable Multi-Objective Model in Head & Neck Cancer

Z Zhou^{1*}, L Chen², M Dohopolski³, D Sher⁴, J Wang⁵, (1) University Of Central Missouri, Warrensburg, MO, (2) UT Southwestern Medical Center, Allen, TX, (3) UT Southwestern Medical Center, Dallas, TX, (4) UT Southwestern Moncrief Cancer Ctr, Fort Worth, TX, (5) UT Southwestern Medical Center, Dallas, TX

Purpose: Accurate diagnosis of lymph node metastasis (LNM) is critical in treatment management for patients with head & neck (H&N) cancer. We aim to develop an automated and reliable multi-objective model (ARMO) for reliable LNM prediction. **Methods:** Totally 129 surgical H&N cancer patients with pathology-confirmed LNs status are used and there are 130 malignant nodes and 413 benign nodes. Two hundred and fifty-six hand-crafted feature are extracted from PET and CT images, respectively. To obtain balanced outcome between sensitivity and specificity, a multi-objective model is developed to obtain Pareto-optimal model set in the training stage. In addition, to obtain calibrated confidence, which aims at maximizing the output probability with correct prediction label and minimizing the probability with incorrect prediction label, a weight that measures the relative importance of each Pareto-optimal model is calculated in training stage. Meanwhile, the individual reliability which measures how reliable of each Pareto-optimal model output is estimated in testing stage. Furthermore, an analytic evidential reasoning rule is used to combine the output of each Pareto-optimal model. Finally, the overall reliability of the model output is obtained by averaging the individual reliability to estimate the model uncertainty, which can be used to alter clinicians on model outputs with high uncertainty. Accuracy (ACC), AUC, sensitivity (SEN) and specificity (SPE) are used to measure the model performance, whilst expected calibration error (ECE) and maximum calibration error (MCE) are used to measure the confidence of calibration, where both ECE and MCE of a perfectly calibrated model are 0. **Results:** The mean $\pm$ standard deviation of AUC, ACC, SEN and SPE for ARMO are 0.97 $\pm$ 0.00, 0.93 $\pm$ 0.00, 0.88 $\pm$ 0.01, 0.94 $\pm$ 0.00, respectively. Meanwhile, the ECE is 0.0085 $\pm$ 0.0018 and MCE is 0.4483 $\pm$ 0.0336. **Conclusion:** We developed a reliable LNM prediction model, which can not only obtain promising performance, but also better calibrated confidence and uncertainty estimation.

PO-GePV-M-262

Development of Markerless Pancreatic Tumor Tracking Realized by Deep Learning

D Zhou^{1*}, M Nakamura¹, N Mukumoto¹, M Yoshimura², T Mizowaki², (1) Kyoto University, Graduate School of Medicine, Kyoto, JP, (2) Kyoto University Hospital, Kyoto, JP

Purpose: To realize markerless pancreatic tumor tracking by using a deep learning model to detect the contour of the clinical target volume (CTV) on the orthogonal X-ray images acquired by the on-board imagers of the gimbaled linac system. **Methods:** The input of the model was either the digitally reconstructed radiograph (DRR) image or the X-ray image acquired by the on-board imagers. The output was the image with the contour of the CTV. After the four-dimensional computer tomography was acquired, a data augmentation procedure contains interpolation between respiratory phases and tilt of gantry and ring angle was conducted to generated sufficient images to train the deep learning model. For one patient, a total of 2500 DRR images were generated for one X-ray tube angle. Two-thousand images were used to fine-tune the pre-trained model and the remaining images were used to evaluate the accuracy of the model. The contour of CTV was extracted from CTV-only DRR and then set as the ground truth of contour prediction. The dice similarity coefficient (DSC) and the centroid difference of contour at the isocenter level were used to evaluate the accuracy of prediction. **Results:** We initially performed markerless pancreatic tumor contour prediction on the DRR images of one patient from orthogonal X-ray tube angles, 45° and 135°. The mean DSC between prediction and ground truth were 0.91 and 0.82 for 45° and 135°, respectively. The mean centroid differences were 2.10 mm and 5.25 mm, respectively. Running on a single NVIDIA GV100 graphics processing unit, the mean calculation time on an image was 172 ms. **Conclusion:** This work demonstrates the success of the current workflow and adaption of the deep learning model on markerless tumor tracking for pancreatic cancer. The prediction accuracy and calculation time also indicate a bright future in clinical practice.

PO-GePV-M-263

Using New Feature Extraction Framework to Predict Heart Toxicity in Breast Cancer

B Choi^{1*}, S Yoo¹, J Moon¹, J Kim¹, J Chang¹, H Kim¹, (1) Department of Radiation Oncology, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul

Purpose: Radiation-induced cardiac toxicity such as acute coronary event (ACE) is a key issue of breast radiotherapy. As it has been mostly discussed in mean heart dose, however, there are few studies about cardiac substructures and ACE after radiotherapy. This work proposes a new heart toxicity prediction model by a new feature extraction and processing framework with cardiac sub-structure and dose distribution. **Methods:** The patient cohort consists of 29 toxicity and 16 non-toxicity cases after breast radiotherapy. A recent study demonstrated that the feature extraction from segmenting target volume followed by feature selection produced better prediction accuracy in survival prediction after lung SBRT than radiomics and conventional deep neural network (convolution/fully-connected layers). We applied the framework for toxicity prediction. It compared three types of prediction models: a) radiomics, b) conventional deep neural network, and c) feature extraction and processing model with CT image and dose information as input, and heart segmentation as output. The output of the auto-segmentation model in (c) was varied from entire heart to 6 sub-structures and 3 sub-structures (left-ventricle, right-ventricle, and left-anterior descending artery). The relationship between the features and prediction was visualized by a method, called Grad-CAM. The network training and testing was conducted with 4-fold cross-validation. **Results:** The conventional deep neural network (50-60% accuracy) performed worst. The proposed model led to higher prediction accuracy (over 78%) than radiomics (69%). Impressively, the predictive model with 6 and 3 sub-structures (81%) outperformed that with entire heart structure (78%). The model with 3 sub-structures showed greater specificity and sensitivity than that with 6-substructures, though both having the same accuracy. When visualized by Grad-CAM, the hot-spots were generated around left-ventricle region in most cases. **Conclusion:** Our proposed prediction model characterized by 1) new feature extraction/processing process and 2) cardiac sub-structure dose/structure information enhanced the prediction accuracy.

PO-GePV-M-264

Local Temperature as a Surrogate of Inflammatory State Induced by Skin Irritant

R Culcasi^{1,2*}, M Snyder², (1) Beaumont Hospital, Royal Oak, MI, (2) Wayne State University, Detroit, MI

Purpose: To visualize changes in microcirculation of irritated skin through Eulerian amplification of high-resolution monochrome videos correlated to known detected temperature differences by a thermal camera as a control. **Methods:** MATLAB code was written to implement Eulerian amplification, a technique developed by the M.I.T. Media Lab, to exaggerate changes in skin color to make them more discernable in video sequences. In an investigator self-monitoring feasibility trial, a monochrome machine vision camera (model Edmund Optics EO-2323) with detector resolution of 1920 x 1200 pixels and frame rate of 180 fps was used to collect high-resolution video of a region of interest (ROI) undergoing circulatory changes induced by a cold compress. Heart rate was extracted from subtle color changes, then the video was amplified by a factor of 100 with a bandwidth of 0.1 Hz encompassing the heart rate. A thermal camera (model FLIR A325sc) with detector resolution of 320 x 240 pixels was used to collect static thermal images to monitor temperature changes over time to act as a standard against which the visualization of changes in blood flow by the monochrome camera could be correlated. **Results:** Following removal of a cold compress, blood flow increased to the region of interest as a result of vasodilation and was noted by the increase in amplitude of non-visible skin color changes in the magnified video as time increased. These increases in amplitude were correlated to increases in temperature observed by the thermal camera. **Conclusion:** The thermal camera temperature differences were mapped to blood flow changes and demonstrated the monochrome camera's ability to detect non-visible changes in microcirculation based on amplification of subtle skin color changes. This technique was evaluated for application in radiotherapy to assess skin changes throughout treatment and detect erythema before clinical manifestation in patients at risk for skin reactions.

A Nomogram to Estimate Required Ci-S in Prostate HDR Brachytherapy

J Nasehi Tehrani^{1*}, G Lasio¹, B Libby², N Lamichhane¹, K Jiang¹, M MacFarlane¹, M Guerrero¹, (1) University of Maryland, Bel Air, MD, (2) University of Virginia, Charlottesville, VA

Purpose: To improve patient safety by providing an independent mathematical model to estimate Curie seconds in prostate HDR brachytherapy. **Methods:** HDR prostate brachytherapy, particularly for boost treatment with a single fraction of 15Gy, has become a regular procedure in recent years. For a given source activity, the time needed to deliver the prescribed dose is correlated with the target volume (TV). We calculate the Curie seconds (Ci-s) for each patient plan by multiplying the Iridium-192 source activity in Curies and the total treatment time in seconds. We create a nomogram (Ci-s vs. TV) based on a training dataset of 90 HDR prostate cases with a treatment volume of 15cc to 70cc. Three different curve-fitting models are used in this study (power, polynomial, and logarithmic). We test the models in a validation dataset of 11 additional patients from a different institution and different HDR afterloader vendor. **Results:** The coefficient of determination (R²) for the models are 90.45% (power), 90.29% (Polynomial), and 89.68% (logarithmic). The average absolute percentage errors for 11 patients are 4.4% (power), 4.6% (polynomial), and 9.2% (logarithmic). The power curve fit shows the smallest estimation error on 11 patients with a maximum error of 12.4% for 6.84CC and a minimum error of 0.5% for 14.8CC TV. The power curve model for the estimation of Ci-s is

$704.39x(TV)^{0.5342}$. The polynomial model parameters are $A2=-0.8245$, $A1=133.66$, $A0=1115.7$, and the logarithmic model is $2433.2x\ln(TV)-3839$. **Conclusion:** This method can be used clinically as a sanity check by physicists. The power curve fitting shows the best performance for typical prostate volumes (25-40cc). More extensive clinical tests will finalize the determination of the model for clinical use. Future work will incorporate more variables into the training data to improve the predictive power. We are also going to increase more training data for TV less than 10cc.

PO-GePV-T-02

Independent Determination of Absorbed Dose to Water Depth-Dose Curves for Ru-106 Ophthalmic Plaques Traceable to the Primary Standards of External Beam Radiotherapy

V Kaveckyte^{1,2*}, S Dahlander², A Carlsson Tedgren^{1,2}, (1) Department of Health, Medicine and Caring Sciences, Linköping University, SE-58185 Linköping, Sweden (2) Department of Medical Radiation Physics and Nuclear Medicine, Karolinska University Hospital, SE-17176 Stockholm, Sweden

Purpose: To propose an approach for independent determination of the absorbed dose to water ($D(water)$) depth-dose curves traceable to the external beam primary standards of absorbed dose to water for the dosimetry of ophthalmic ^{106}Ru plaques used in brachytherapy. **Methods:** A microSilicon diode was cross-calibrated against a reference air ionization chamber in terms of the $D(water)$ in a 6 MeV external electron beam. The diode and a high precision setup equipment was used to determine the $D(water)$ depth-dose curves for ^{106}Ru CCB-type plaques manufactured in 2018 and 2019. Detector blueprints were available and a Monte Carlo (MC) code system PENELOPE-2018 was used to correct for the absorbed-dose energy dependence of the detector between calibration and measurement beam qualities (from 2 to 10 mm distance from the plaque surface). The results were compared with the $D(water)$ depth-dose curves calculated with MC in the absence of the detector and with those determined by the vendor with a plastic scintillator with other traceability. Further analysis was made to determine possible reasons of the discrepancies. **Results:** Differences between experimentally determined $D(water)$ depth-dose curves using the microSilicon diode and those provided by the vendor were from -5 % at the reference depth of 2 mm to nearly 20 % at 10 mm depth. The MC-calculated $D(water)$ depth-dose curves in the absence of the detector differed systematically from the vendor values but agreed within their provided uncertainties with the values obtained using the microSilicon detector. **Conclusion:** We show that a detector calibration in external beam allows for accurate and independent dosimetry of ^{106}Ru CCB plaques with lower uncertainties than following an existing method of plaque calibration.

PO-GePV-T-03

HDR Ring Applicator Commissioning: Eliminating the Need for Film-Processors to Generate Autoradiographs

J Kilian-Meneghin*, S Thompson, J Khan, B Liu, N Yue, L Hathout, I Vergalaso, Rutgers, Cancer Institute of New Jersey, New Brunswick, NJ

Purpose: Commissioning of HDR applicators requires dwell position verification. This is particularly challenging for ring applicators, which are known to have unreliable offsets of the distal dwell due to the sharp curvature of the ring channel. Historically, this verification was performed via autoradiograph: first by imaging the applicator with an inserted dummy source of nominal dwell positions and then by delivering an HDR plan at the same expected dwell positions to radiographic film. This required the use of film processors, which have since become largely extinct in radiation oncology departments. Therefore, this work aims to investigate a novel and accessible method to generate an autoradiograph with a linac in order to commission a ring applicator. **Methods:** Varian 450 plastic and titanium ring applicators were affixed to Gafchromic EBT3 radiochromic film and secured using a clamping device. In order to determine the optimal energy/MU settings, it was irradiated with 6, 12, and 18 MeV electrons at MU=100, 500, 1000 and 1500 using a 10x10 cone and SSD=106cm. The applicator/film geometry was then carefully transferred for HDR plan delivery with 10s per dwell for plastic and 15s for titanium, respectively. Films were qualitatively assessed for resolution and quantitatively analyzed for contrast. **Results:** Plastic and titanium applicator image resolution improved with increasing energy and contrast increased with MU. For the titanium applicator contrast/MU plateaued above 1000MU and showed no further improvement (1000MU: 0.07, 1500MU: 0.07). **Conclusion:** The method presented demonstrates a novel and efficient approach to generate an autoradiograph, thereby enabling accurate dwell position verification during applicator commissioning. It was evident that appropriate energy/MU selection will vary with applicator material/thickness and is the subject of future investigation.

PO-GePV-T-04

Quantifying Risk Associated with Physics Errors in HDR Prostate Brachytherapy Using Automated Simulations

M Trager, J Beaudry, D Aramburu Nunez, G Cohen, L Dauer, D Gorovets, N Hassan Rezaeian, M Kollmeier, B Leong, P McCann, M Williamson, M Zelefsky, A Damato*, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: To quantitatively evaluate clinical significance of potential HDR prostate brachytherapy (HDRPB) physics errors through automated simulations. **Methods:** Three idealized HDRPB geometries with rectum, urethra and different sized prostate contours were generated in BrachyVision. High and low dwell-time modulated plans using clinical constraints were created per geometry. Based on FMEA analysis, four high-impact errors applicable to HDRPB were selected for quantitative analysis. Plans were exported, and error simulations and dose calculations were performed using MATLAB and Python routines: single ($N=1,722$) and systematic ($N=126$) catheter shifts (cranio-caudal; -1cm:1cm); single catheter digitization errors (tip and connector needle-tips displaced independently in random directions; 0.1cm:0.5cm; $N=44,318$); and swaps (two catheters swapped during digitization or connection; $N=528$). The deviations due to each error on Prostate_D_90%, Urethra_D_20% and Rectum_D_1cc were analyzed using two thresholds considered for clinical significance: 5-20% (possible clinical impact [PCI]) and >20% (likely clinical impact [LCI]). **Results:** Single catheter shifts resulted in a PCI for <6% of simulations for small geometry with large shifts (≥ 0.8 cm), and no LCI. Systematic catheter shifts had the largest clinical impact on Prostate_D_90% with 100% of simulations resulting in a PCI for shifts ≥ 0.5 cm and LCI for shifts ≥ 0.8 cm. Systematic shifts had no clinical impact on Urethra_D_20%; for Rectum_D_1cc PCI occurred in 25% of shifts ≥ 0.5 cm with no LCI. Digitization errors resulted in PCI for all structures but LCIs only for Urethra_D_20cc. As prostate size and modulation decreased, impact on prostate and rectum increased while urethra decreased. Swaps had PCI 14%, 21% and 9% of the time for Prostate_D_90%, Urethra_D_20% and Rectum_D_1cc, respectively. **Conclusion:** Prostate_D_90% and Rectum_D_1cc had the highest chance of PCI from systematic catheter shifts, while Urethra_D_20% was from swaps. LCI was uncommon for all combinations, besides systematic catheter shift's impact on Prostate_D_90%. Digitization errors most consistently caused PCI for all scenarios.

PO-GePV-T-05

Error Detection in HDR Prostate Brachytherapy with Plan-Specific Optimization of In-Vivo Dosimetry (IVD) Parameters

D Aramburu Nunez, M Collier, J Beaudry, G Cohen, A Damato*, Memorial Sloan-Kettering Cancer Center, New York City, NY

Purpose: To demonstrate that plan-specific optimization of IVD detector position increases the specificity and sensitivity of error detection. **Methods:** 19 HDR prostate plans were used to generate virtual simulation of treatment delivery with virtual errors introduced in the plan and virtual IVD monitoring using 4 detectors with realistic characteristics (noise, etc). An algorithm was created to optimize detector position and signal threshold based on plan. Three schemes were investigated: using the algorithm (optimized), using a standard positioning [unoptimized], and positioned at random [random]. A comparison of theoretical use of different detectors (Plastic scintillators, MOSFET, and semiconductor diodes) was performed. **Results:** For plastic scintillator detectors, sensitivity and specificity for the optimized scheme (average $\pm$ SD) were (0.88 ± 0.06) , and (0.98 ± 0.01) respectively, in comparison with (0.18 ± 0.06) , $p < 0.01$, T-test), and (0.97 ± 0.07) , $p > 0.05$) for the unoptimized and $((0.39 \pm 0.00)$, $p < 0.01$, T-test), and (0.94 ± 0.01) , $p > 0.05$) for the random. For the optimized scheme, compared

to plastic scintillator detectors, sensitivity (specificity) were 0.88 ± 0.06 $p > 0.05$ (0.98 ± 0.01 $p < 0.01$), 0.88 ± 0.07 $p > 0.05$ (0.95 ± 0.02 , $p < 0.01$), and 0.87 ± 0.08 $p > 0.05$ (0.86 ± 0.06 , $p < 0.01$) respectively for plastic scintillators, semiconductor diodes, and mosfet. **Conclusion:** We demonstrated that our algorithm improves sensitivity and specificity using plan-specific IVD optimization when compared with unoptimized and random groups. Permitting the tailoring of IVD at the end of the planning process before treatment, minimizing disruption from false positives and maintaining an acceptable true positive detection rate. Our simulations show that high sensitivity and specificity can be achieved with a range of detector types, although practical and logistical considerations were not considered in this analysis.

PO-GePV-T-06

Performance Evaluation of a Novel Quality Assurance Device for High Dose-Rate Brachytherapy

L Sensoy^{1*}, N Bassiri², P De Jean³, S Benedict⁴, (1) UC Davis Medical Center, Sacramento, CA, (2) UC Davis, Sacramento, CA, (3) Luca Medical Systems Inc., Palo Alto, CA, (4) UC Davis Cancer Center, Sacramento, CA

Purpose: A novel system composed of a monocrystalline scintillator and optical camera has been developed for Quality Assurance (QA) on high dose-rate (HDR) brachytherapy afterloaders. HDR QA requires adherence to US-NRC regulations, and includes high definition archival image documentation of the source positioning. HDR QA is required for (1) daily use of the system, (2) periodic source exchanges, (3) validation of applicators, and new developments call for (4) patient specific QA. The new proto-type commercial system uses radioluminescence imaging to determine position and dwell-time accuracy of the source and can provide patient specific QA for complex deliveries. **Methods:** The scintillator and optical camera system (OriQA, Luca Medical Systems, Palo Alto, CA) with high spatial and temporal resolution was tested on a Varian GammaMediX HDR afterloader (Palo Alto, CA). The evaluations included position and timer accuracy as well as cumulative activity measurement over a range of doses typically prescribed for gyn brachytherapy. The accuracy and standard deviation were then evaluated for dwell time and position, and cumulative activity for various configurations. **Results:** The system readily acquires and analyzes images of the source position in accordance with standard practice for HDR daily QA. Several dwell positions over a 10 cm range with varying dwell times between 0.3 - 20 seconds were employed. The position error of the QA device was identified as $-0.01 (\pm 0.04)$ centimeters, the time error was $-0.08 (\pm 0.11)$ seconds, and the error in cumulative activity was $< 1\%$. **Conclusion:** A new, novel, and practical HDR QA system has been devised that includes a monocrystalline scintillator and optical camera system. The radioluminescence technology of the device is highly accurate and precise, and with its low-cost camera based optical imaging system provides QA documentation in accordance with NRC regulations. The potential for applying this technology to patient specific QA is also investigated.

UC Davis has a research agreement with OriQA, Luca Medical Systems

PO-GePV-T-07

Commissioning of Lumen Markers for Needle Visualization on MRI Scans in HDR-Gyn Brachytherapy

V Chaswal^{*}, R Tolakanahalli, J Contreras, Miami Cancer Institute, Miami, FL

Purpose: Use of interstitial needles with pose a challenge during MRI-imaging due to patient/organ movement, lack of signal and due to diameter of sheathe being comparable to imaging slice thickness. Due to challenging catheter reconstructions on MRI, despite inferior soft-tissue contrast, CT scans are still used in addition to MRI for manual reconstruction of needles in image-guided brachytherapy. This workflow does not account for change in plastic needle position due to missing stylet during MRI and treatment. Flexi-needles are often in a different position due to changing tissue, organ forces and proximity to ovoids. To address these challenges, MRI Lumen markers were commissioned for clinical use to improve delineation of needles on MRI-scan for treatment planning in HDR gynecological-intracavitary implants with needles. **Methods:** MRI lumen markers™ (Theragenics Inc.) were inserted in the plastic needle sheaths in different media (water, soft-bolus material, in-house poured silicone and on solid-water slabs with soft bolus on top) to assess accuracy of visualization of tip of the needle and delineation of interstitial needles, alongside an empty flexi-needle. Images acquired using clinical protocols on 3T MRI scanner and 0.35T MR-Linac TRUFI (Viewray Inc) scans were compared to CT images of the needles with metal stylets for verification of the tip. **Results:** Use of soft-bolus (102 HU) and in-house poured silicone phantom (194 HU) were verified as suitable media for needle visualization study using CT and 0.35T MR linac. Needle marker tips on the TRUFI Images were localized to within ± 1 mm of the CT-scans. Needle without the marker was visualized within ± 1.3 mm. Results on the 3T MR scanner were inconclusive due to age/resue of markers warranting additional investigation. **Conclusion:** Needle markers are visible on 0.35MRI across multiple sequences, and image orientations facilitating treatment planning dosimetry directly on MR-Linac through accurate source path localization and reconstruction.

PO-GePV-T-08

Determination of Changes in Dosimetric Parameters with Co-60 and Ir-192 Source in High Dose Rate Brachytherapy of Cervical Carcinoma

S Srivastava^{1*}, N Moirangthem², N Singh³, (1) King George's Medical University, Lucknow, India (2) Dr. Borooah Cancer Institute, Guwahati, India (3) King George's Medical University, Lucknow, India

Purpose: To determine the differences in dosimetric parameters of cervical cancer patients treated with interstitial and intracavitary high dose rate brachytherapy using Co-60 and Ir-192 sources. **Methods:** CT-based treatment plans of 20 patients with cervical carcinoma treated with brachytherapy were retrospectively studied. Patients with interstitial implants were planned for 24 Gy in 4 fractions with inverse planning simulated annealing using Co-60 and Ir-192 source keeping same dose objectives. Patients of intracavitary brachytherapy (ICBT) were planned for 21 Gy in 3 fractions with both sources keeping the same dwell positions. The dosimetric parameters Co-60 and Ir-192-based plans were compared in terms of HR-CTV coverage, OAR doses, homogeneity index (HI), and conformity index (CI). **Results:** In interstitial brachytherapy, mean V100 values for Co-60 and Ir-192-based plans were $97.03 \pm 1.99\%$ and $96.42 \pm 2.25\%$ respectively. Average values of D2cc in the bladder for Co-60 and Ir-192-based plans were 4.30 ± 0.57 Gy and 4.27 ± 0.54 Gy respectively while in the rectum were 3.96 ± 0.43 Gy and 4.08 ± 0.49 Gy respectively. There were no significant differences between V100 and D2cc values from both sources. Ir-192 based plans were more homogeneous (HI= 0.68 ± 0.09) than the Co-60 plans (HI= 0.59 ± 0.10), however, the conformity was similar with both the sources. In ICBT plans, mean D90 values for Co-60 and Ir-192 were 4.86 ± 1.29 Gy and 4.94 ± 1.43 Gy respectively. Mean D2cc values in the bladder for Co-60 and Ir-192-based plans were 6.19 ± 2.72 Gy and 5.93 ± 2.44 Gy respectively while in the rectum were 4.17 ± 1.73 Gy and 4.29 ± 1.94 Gy respectively. We did not find any significant difference in the dosimetric parameters of Co-60 and Ir-192-based ICBT plans. **Conclusion:** There are no significant differences in dosimetric parameters and no clinical advantage of using Co-60 over Ir-192-based brachytherapy. However, when it comes to cost-management, Co-60 has a longer half-life, which reduces the cost of frequent source replacement and disposal.

PO-GePV-T-09

MRI-Based Organ Segmentation of Pelvis Using Deep Learning for Brachytherapy Treatments

N Demez^{1*}, A Hoover², D Soultan³, R Badkul⁴, (1) University of Kansas Hospital, Overland Park, KS, (2) Kumc- Department of Radiation Oncology, (3) Kansas University Medical Center, Westwood, KS, (4) University of Kansas Medical Center, Kansas City, KS

Purpose: In this study, we investigate the accuracy of deep learning-based contouring algorithm compared to manual contouring practice and how this

algorithm can help in our clinic to standardize consistent contouring. **Methods:** Over 500 T2- weighted MRI slices from 9 different cancer patients were selected for this study. The MRI slices and contour structures were exported for pre-processing to create masks. The mask is acquired from the MRI slice by detecting edges of OAR contour and by assigning pixel value of 1 inside the contour's boundary and 0 outside. For training, U-net based deep learning approach was implemented by using Pytorch open source machine learning framework. In training phase, the algorithm should make one complete pass through dataset to extract millions of trainable parameters. 30 epochs were used in our study and dice similarity coefficient was employed to quantify accuracy of prediction with respect to expected result which is also called ground truth **Results:** We have carried out this pilot study by only using 9 patients MRI data and only single GPU (graphics processing unit) computing power. The dice similarity coefficient for the bladder and rectum segmentation were around 69 %. Although accuracy of predicted location of said OARs are excellent, the algorithm is coming short on predicting whole contour in respective slice. We are expecting the similarity between predicted contours and ground truth contours to be over 95 % with adequate computing power and patient data which are essential in deep learning algorithms **Conclusion:** Deep learning approach has benefits for radiation oncology doctors by improving their time efficiency in labor-intensive contouring process. This, in turn, will lead to increased patient comfort and quality patient care. However more patient datasets are needed for training step to increase contouring accuracy to accepted level.

PO-GePV-T-10

Dose Optimization of Vaginal Cylinder: A New Planning Method for Patients with Endometrial Adenocarcinoma

X Wu*, A McDonald, S Shen, S Marcrom, R Kim, University of Alabama Birmingham, Birmingham, AL

Purpose: To explore the relationship between applicator surface dose and 5 mm depth dose and to optimize both locations simultaneously for three most used cylinder sizes (2.5, 3.0 and 3.5 cm in diameter) in treating patients with endometrial adenocarcinoma. **Methods:** Total 216 plans were created (9 dose levels x 4 plans/level x 3 Cylinder size x 2 patients/size): if the prescription is on the surface, dose will be optimized on the surface alone or both. In the later plan, surface points will be given a higher priority (100 ~ 150%) than points at 5 mm lines (60% ~ 70%). The same strategy is applied to dose prescribed at 5 mm depth. We use VEGO TG-43 Volume Optimization (Varian Eclipse) for planning and single channel to treat patients. **Results:** A dose table between surface and 5 mm depth and its fifth order polynomial mapping function were established for each applicator size, so any prescribed dose at one site can find the prescription dose on the other for optimization at both locations. For dose prescribed at 5 mm, the maximum surface dose can be as high as 30% and 40% on the surface, and 5% and 12% high at 5 mm w/o surface dose optimization. For dose prescribed on the surface, the maximum doses are similar (10% ~ 15%) w/o 5 mm dose optimization, but the addition of 5 mm dose optimization can slightly improve the minimum dose (~5%) on both locations. **Conclusion:** 1. Proposed three dose tables and their mapping functions between surface dose and their corresponding 5mm depth doses for three different applicator sizes; 2. Proposed a new method to optimize doses at both locations simultaneously; 3. Reduce the maximum surface dose from 30 - 40% to 10% or so if changing prescribed dose from 5 mm to applicator surface.

PO-GePV-T-11

Uncertainties in MR-To-MR Image Registration for HDR Cervical Brachytherapy

B Shen*, Z Chang, C Wang, S Meltsner, J Chino, O Craciunescu, Duke University Medical Center, Durham, NC

Purpose: To evaluate the dosimetric effects of uncertainties in shared DICOM coordinates registration between MR sequences used clinically in planning the HDR brachytherapy component for cervical cancer patients. **Methods:** Thirteen locally advanced cervical cancer patients treated with HDR intracavitary/interstitial boost were included in this study. The HDR treatment was performed using Varian titanium tandem and ovoid applicators with optional free-hand interstitial needles. The implants were stabilized with Alatus balloons. The imaging protocol consisted of a planning CT for applicator digitization, a T1 weighted isotropic spoiled GRE sequence for registration with planning CT, and T2 weighted sequences for target and organ at risk contouring. A custom workflow was created in MIM Maestro to break the inherent registration between the MR sequences and re-register the T1- and T2-weighted series using intensity-based rigid registration. The physician contours were transferred from T2 images to CT using the new registration. Clinically relevant equi-effective dose metrics for the clinical CTV_{HR}, CTV_{IR} (D₉₀, D₉₈) and bladder, rectum, sigmoid, bowel and vagina (D_{2.0} [cm]³) were then compared with metrics calculated on the new contours. **Results:** A total of 60 fractions were used in this study. The mean percent difference (±standard deviation) between clinical and reregistered contours were -0.60% ±1.49, 0.56% ±1.06, -0.49% ±1.71, -0.53% ±1.13 for CTV_{HR} D₉₀, CTV_{IR} D₉₀, CTV_{HR} D₉₈, CTV_{IR} D₉₈, respectively and -0.05% ±2.13, 0.61% ±2.85, 1.67% ±1.93, 1.76% ±2.04, and 1.75% ±2.10 for bladder, bowel, rectum, sigmoid, and vagina D_{2.0} [cm]³, respectively. **Conclusion:** As expected for the target, due to the stabilizing presence of the vaginal balloons there is minimal difference between the two registrations. However, organs at risk have more variability due to potential movement between scans. Further analysis will allow us to identify these specific cases and adjust the clinical flow to account for potential anatomical differences between MR scans.

PO-GePV-T-12

Dosimetric Evaluation of Rectal Hydrogel Spacer in Prostate HDR Treatments

I Veltchev*, T Lin, X Chen, C Lee, T Dougherty, J Wong, M Hallman, E Horwitz, R Price, C Ma, Fox Chase Cancer Center, Philadelphia, PA

Purpose: An injectable rectal hydrogel spacer (RHS) is used in both external beam and HDR treatments of the prostate to create spatial separation between the target and the rectum. In a re-planning study, we evaluated the dosimetric impact of the presence of RHS on prostate HDR plan quality. **Methods:** Eighteen patients with RHS who recently underwent prostate HDR treatment, were re-planned with modified objectives in order to simulate the absence of the spacer. Patients with three types of treatments were included in this study: monotherapy (9 patients; 27Gy in 2 fractions), salvage therapy (7 patients; 24Gy in 2 fractions), and boost (2 patients; 15Gy in one fraction, following external beam treatment of 46Gy in 23 fractions). The clinical plans were dosimetrically compared to the post-treatment re-plans, which were optimized with modified goals aiming at sparing the urethra, bladder, and RHS (as a surrogate for rectum). The trends in target coverage as well as organ-at-risk sparing were statistically analyzed. **Results:** The analysis of 33 plan pairs showed that the presence of RHS significantly reduced the rectal volume receiving >75% of the prescription dose: from mean V75%=0.63cc without RHS to 0.02cc with RHS. Without RHS, the mean prostate coverage was reduced by 1.5% and the urethral volume receiving >125% of the prescription dose on average increased by 0.1cc (from 0.02cc to 0.12cc). No change in the bladder dose was observed. The plan heterogeneity index (V150%/V100%) was slightly worsened for the plans without RHS: from 0.35(5) to 0.36(4). **Conclusion:** This dosimetric study clearly demonstrated the benefits of injectable RHS in prostate HDR treatments. Excellent rectal sparing was achieved as well as improved target coverage and marginally better urethral sparing. Injectable RHS was shown to be indispensable in both salvage and boost HDR treatments, where organ-at-risk sparing is of critical importance.

PO-GePV-T-13

Commissioning of High Dose Rate Brachytherapy Surface Applicator System

B Wichman¹*, D Francom², T Howard³, A Wilkinson¹, R Posey⁴, (1) Texas Oncology, Austin, TX, (2) Texas Oncology, Ft. Worth, TX, (3) Texas Oncology, Dallas, TX, (4) Texas Oncology, Waco, TX

Purpose: A high-dose-rate brachytherapy surface applicator set has been commercially available for several years with sparse description in the literature. A thorough verification of the available dose distributions and dose output from all applicators as well as determining the optimal clinical settings for patient use

was necessary for clinical implementation. **Methods:** Measurements of dose distribution and absolute dose at depth under the applicators were made. Absolute dose was measured using a commercial diamond detector and radiochromic film. The diamond detector was calibrated for Ir-192 using a known dose in water. This calibration was used to measure the dose given in water at 1-5 mm depths for each surface applicator. Radiochromic film was used in plastic water at 3 mm depth to measure dose distributions and absolute dose of different dwell positions. **Results:** All applicator/insert combinations have a pronounced dip in the center of the dose distribution due to the metal channel entering the applicator perpendicular to the patient surface. There are two logical dwell position options, and for all applicator/insert combinations the 129 cm dwell position led to a smaller dip in the center of the distribution (generally 20-25% vs. 20-44% for 128.5 cm dwell position). Using the 129 cm dwell position, dose in water was measured for each applicator/insert combination and tabulated for use in patient calculation. Absolute dose measurements from the radiochromic film agreed with the diamond detector measurements with a mean difference of 4.5%. **Conclusion:** The skin applicator set is clinically useful though must be used with a specific dwell position to reduce the asymmetry of the dose distribution. Further recommendations for the use of the applicator set should be followed closely to assure optimal patient treatment, as there are multiple possibilities for asymmetric dose distribution in the center and periphery of the applicator.

PO-GePV-T-14

A Retrospective Dose Analysis of High-Dose Rate (HDR) Tandem and Ovoid and Interstitial Needle Cervical Brachytherapy Cases with a Model-Based Dose Calculation Algorithm (MBDCA)

B Radcliffe*, S Meltsner, Z Chang, J Chino, M Huang, O Craciunescu, Duke University Medical Center, Durham, NC

Purpose: To investigate and compare calculated dose in cervical cancer patients using Varian's model-based dose calculation algorithm Acuros 13.5, and standard Task Group 43 (TG-43) formalism. **Methods:** A set of locally advanced cervical cancer patients treated with MR based HDR brachytherapy using tandem and ovoid applicators and free-hand interstitial needles were selected. These implants were stabilized using Alatus vaginal balloons with a 5% IsoVue to 95% saline fill ratio. The current clinical flow utilizes manual digitization of all applicators followed by planning and dose calculation using the TG-43 formalism. For this study, every patient fraction was replanned using the Fleture-Suit Delclos-style solid applicator (SA) library in Brachy Vision that matched the set used clinically. The Ti needles were copied from the clinical plan. The dose-to-medium-in-medium ($D_{m,m}$) was calculated using Acuros and several key equi-effective dose (EQD2) dosimetric parameters were compared between the two formalisms. We report D_{90} , D_{98} for CTV(HR) and CTV(IR), and D_{2cm^3} for organs at risk (OAR) including bladder, rectum, sigmoid, bowel, and vagina. Mean and absolute differences from the two plans were investigated with linear regression, and Bland Altman analysis. **Results:** In this subset of 15 patients each with 5 fractions, where prescription dose is 550 cGy, the Acuros plans resulted in an average dose reduction to CTV(HR) by $4.5\% \pm 0.37$ (D_{98}) and $4.4\% \pm 0.22\%$ (D_{90}), and to CTV(IR) by $4.1\% \pm 0.19$ (D_{98}) and $4.0\% \pm 0.17$ (D_{90}). Normal structures also showed a dose reduction to D_{2cm^3} regions of bladder as $5.0\% \pm 0.31$, rectum $8.1\% \pm 0.39$, sigmoid $5.1\% \pm 0.43$, bowel $6.2\% \pm 0.30$, and vagina $4.8\% \pm 0.28$. **Conclusion:** Acuros estimates lower doses to target and normal structures. However, considering that the cervical brachytherapy consensus guidelines are based on TG43 data, it is unclear if using MBDCA calculations will be a clinical improvement.

PO-GePV-T-15

HDR Brachytherapy as An Alternative to SBRT for Treating Selective Lung Cancer Patients

University Hospitals-Seidman Cancer Center

Purpose: High-dose-rate (HDR) brachytherapy is attractive modality for several reasons, including steep dose-fall off, less susceptibility to target/organ motion, better sparing of normal tissue and organs at risk (OARs), and reduced chance of geometric miss. Aim of this study is to investigate the potential of HDR brachytherapy as an alternative to stereotactic body radiation therapy (SBRT) for lung cancer treatment. **Methods:** Randomly selected 27 patients who had prior SBRT near the chest wall were evaluated by simulating interstitial HDR plans. The HDR plans were created in Oncentra TPS (version 4.5, Ir-192 source), utilizing 5-10 needles inside of the target volume and placed in-between ribs. Clinically used SBRT prescriptions ranged 50-55Gy in 4-5 fractions, while the HDR plans had 30Gy in one fraction. **Results:** The HDR plans showed comparable dosimetric coverage of the target volume and marked reduction in the OARs' doses, especially for the chest wall and ribs. Average values of D_{1cc} , D_{5cc} , and D_{10cc} to the chest wall for SBRT were 50.0Gy, 44.0Gy, and 39.7Gy. Respective HDR doses were 16.5Gy, 11.5Gy, and 9.3Gy. Average maximum dose to the ribs from SBRT was 53.9Gy vs 24.6Gy for HDR. The mean lung dose from SBRT was 6.4Gy, while 1.5Gy was for HDR. For target coverage, average D_{90} for SBRT was 104.2% of Rx and for HDR was 107.0% of Rx. Average gradient and conformity indices for SBRT were 5.0 and 1.1, and those for HDR were 3.1 and 0.8, respectively. **Conclusion:** This study indicates that single fraction HDR brachytherapy can be a plausible and attractive modality for treating selective lung cancer patients who have tumors near the chest wall. The HDR brachytherapy can have similar target coverage, while having considerable reduction in dose to the OARs.

PO-GePV-T-16

Comparison of Dose Distribution in Different Types of Cylindrical Applicators Using High Dose Rate Cobalt-60 Source Brachytherapy in Gynecological Cancer

M Abtahi¹*, S Gholami², A Maddah-safaei³, (1) Tehran, IR, (2) Cancer Institute-Imam Khomeini hospital-TUMS, Tehran, IR, (3)

Purpose: The aim of this study is to conduct an assessment of dosimetric properties of single channel, multichannel and shielded cylinder applicators through dose-volume-histograms. **Methods:** This study utilizes a uterus phantom with nine different volumes of bladder and rectum to perform dose measurement around the cylindrical applicators. GAFCHROMIC EBT3 model film was used to measure dose distributions in water phantom around the bladder, rectum, applicator and CTV. In order to properly compare the performance of the shielded applicator with multichannel and single channel applicators, we consider the both cases of a one sided CTV and two CTVs placed on both sides of the vagina. **Results:** Dose-volume histograms analysis shows no statistically significant difference in tumoral region for the two types of CTV between cylindrical applicators. The received dose in a volume of at least 2 cm³ (D_{2cc}) for two-sided CTVs for single channel and multichannel is 2Gy, 0.7Gy in bladder and 2.52Gy, 0.39Gy in rectum. As for the one-sided CTVs, the results are the same for single channel, but it is 0.39Gy, 0.7Gy in bladder and 0.69Gy, 2.2Gy rectum for multichannel applicators. When CTV assumed one side of vagina, the multichannel applicator demonstrates a significant dose reduction in both bladder and rectum compared with single channel, and shielded applicator exhibits a better dose reduction in rectum compared with multichannel applicator. However, in the case of two-sided CTV coverage, the multichannel applicator demonstrates a noticeable dose reduction in bladder and rectum. **Conclusion:** The results indicate that employing multichannel applicator in vaginal high dose rate cobalt-60 source brachytherapy can reduce the received dose to organs at risk without any significant loss of received dose in CTV, which is contributed to its asymmetric or symmetric dose distribution that depend on which channels are activated.

PO-GePV-T-17

Evaluation of Post-Implant Dosimetry in LDR Permanent Interstitial Brachytherapy for Prostate Cancer

Y Khouj^{*}, T Harris, D O'Farrell, E Neubauer Sugar, P Nguyen, P Orio, M King, I Buzurovic, Dana-Farber/Brigham and Women's Cancer Center, Harvard Medical School, Boston, MA

Purpose: To present the dosimetry analysis of low dose rate (LDR) prostate brachytherapy patients treated over a three-year period. To compare dosimetry on the implant day (D_0) and post-implant dosimetry at the nominal optimal dosimetry time (D_{30}) for patients implanted with 125I. **Methods:** A total of 118

patients diagnosed with prostate cancer were treated with LDR brachytherapy using I-125 seeds (activity 0.371mCi at implant) between 2018-2020. 67% patients received 145 Gy while 33% received 108/110 Gy boost prescription. Transrectal Ultrasound (TRUS)-based intraoperative planning was used to obtain real time images for dosimetry on D0. Prostate (target) and organs-at-risk (OAR) volumes were contoured based on MR-TRUS registration or TRUS-only. The planning was performed while the patient was under anesthesia in real-time using Oncentra Prostate treatment planning system based on inverse-planning to optimize and analyze target and OAR dose metrics. After plan approval, patient specific needles were built using QUICKLINK® seed loader (BARD). Day 30 post-implant dosimetry was performed using MR-CT or CT-only for contouring, and CT-based planning. Target and OAR dosimetric parameters were reported. **Results:** D0 target dosimetry was as followed: D90 111.7±3.7%, V100 96.1±2.8%, V150 48.6±5.7%. The corresponding D30 target dosimetry was D90 108.9±7.3%, V100 94.0±3.3%, V150 49.7±9.4%. The urethra D0 V125 0.03±0.08cm3 and V150 0.00±0.01cm3 shifted to D30 V125 0.14±0.18cm3 and V150 0.02±0.04cm3. Rectum D0 metrics were V100 0.05±0.11cm3 and V69 1.43±0.62cm3. Rectum D30 values settled at V100 0.23±0.43 cm3 and V69 1.25±1.30 cm3. **Conclusion:** D30 dosimetric parameters revealed high consistency in dosimetry compared to D0. Post-implant dosimetry complied with the American Brachytherapy Society recommendations. The intraoperative technique takes advantage of the real-time images to allow for accurate needle placement, seed localization, and dose distribution optimization, all of which may contribute to dosimetric stability from D0 to D30.

PO-GePV-T-18

Dosimetric Differences of Line-Source Versus Point-Source Approximation for Prostate Seed Implant

K Lyons^{1*}, E Fredman², G Guo³, R Ove⁴, T Podder⁵, (1) University Hospitals-Seidman Cancer Center, Beachwood, OH, (2) University Hospitals Cleveland Medical Center, (3) University Hospital Cleveland, (4) (5) University Hospitals Cleveland Medical Center, Cleveland, OH

Purpose: Line-source consideration is appropriate for dose calculations in low-dose-rate prostate seed implant (LDR-PSI) cases when stranded sources are used, as the orientation of the seed is known. Some RTOG protocols, however, recommend use of a point-source approximation. The purpose of this study is to evaluate the differences in target and organs-at-risk (OAR) dosimetry of point-source as compared to line-source approximations on intra-operative planning of ultrasound-guided LDR-PSI. **Methods:** Out of 30 randomly selected PSI patients, 15 utilized I-125 (Theragenics AgX100), 15 had Pd-103 (Theragenics TheraSeed-200), and 15 patients who were treated with I-125 were replanned using Cs-131 (IsoRay CS-1 model). Dosimetric computation was performed on TRUS images using MIM Symphony TPS for both point-source and line-source approximations to evaluate dosimetric differences in OARs and target. **Results:** In most cases, point-source underestimated dose to OARs. For rectum, mean dose difference between line-source and point-source for D0.1cc D1cc, and D2cc were -1.9% (+/-1.6), -3.1% (+/-1.3), and -3.3% (+/-1.9), respectively. Similarly, D10 of urethra was underestimated by point-source, with mean difference of -3.4% (+/-1.9). For prostate, mean difference for D90 was -0.3% (+/-1.7), but for V150 and V200, point-source dosimetry overestimated in comparison to line-source by 2.3% and 9.0%, respectively. I-125, Pd-103, and Cs-131 isotopes exhibited mixed results on OARs. Rectum D1cc and D2cc for Pd-103 and Cs-131 were approximately 1% lower for point-source compared to I-125, while point-source overestimated for Cs-131 target parameters. The largest noted difference was found in V100 for urethra, with a mean difference for I-125 of -23.1% (+/-79.9%), and for Pd-103 -4.5 (+/-5.6). **Conclusion:** Overall, point-source approximation, compared to line-source, underestimated dose. Dose difference between I-125, Pd-103, and Cs-131 showed variation, depending on OAR parameters considered. When orientation of the implanted source is known, it is reasonable to use line-source approximation to achieve accurate dosimetry for LDR-PSI.

PO-GePV-T-19

MRI-Based Virtual Volume Study for Permanent Prostate Brachytherapy (PPB)

Y Le^{1*}, S Ng², Y Yue³, G Guo⁴, J Holmes⁵, (1) Indiana University- School of Medicine, Indianapolis, IN, (2) Indiana University Methodist Hospital, Indianapolis, IN, (3) Indiana University, Carmel, IN, (4) University Hospital Cleveland, (5) Indiana University- School of Medicine

Purpose: Traditionally, an ultrasound-based volume study is performed during an in-person visit for patients who choose to receive PPB. This study is to investigate the feasibility of using diagnostic staging MR images for pre-planning of PPB in replacement of ultrasound-based volume study to minimize patients' in-person visits. **Methods:** Diagnostic staging MR images of fifteen previous PPB patients were retrospectively retrieved. High resolution T2 images (0.5mmx0.5 mm in plane, 3mm thickness) were imported into brachytherapy treatment planning system. Prostate volumes were delineated and compared with volumes from both ultrasound-based pre-treatment volume study and intra-operative planning study. Treatment plans using I-125 seeds were generated by the same physician/physics team. The prescription dose, seeds activity and dosimetric criteria of MRI-based plans were kept the same as their corresponding ultrasound-based plans. The number of seeds required in MRI-based plans were compared with ultrasound-based plans. The patterns of needles and seeds were visually compared too. **Results:** The prostate volumes of 15 patients from MRI-based volume study range from 21.5cc to 76.2cc with average of 36.1cc ± 15.1cc (1SD). The volume difference between MRI-based pre-plan and ultrasound-based pre-plan is 2.0cc ± 1.5cc (1SD) and not statistical significant (p value=0.77). The similar small difference 2.9cc ± 2.2cc (1SD), (p value=0.88) was observed between MRI-based pre-plan and ultrasound-based intra-operative plan. The number of seeds used in MRI pre-plan is very close to the number used in ultrasound-based plans with average difference 3±2 (1SD), (p value=0.81). The implant pattern, particularly the seeds pattern in each needle can be very different due to probe caused gland deformation and imaging slicing orientation between MRI imaging and ultrasound study. **Conclusion:** MRI-based virtual volume study can generate similar plan as ultrasound-based volume study and be used for ordering loaded seeds. However, using MRI-based plan to order pre-loaded needles need to be further studied.

PO-GePV-T-20

Evaluation of Dosimetric Parameters of Two Brachytherapy Ophthalmic Sources Using Monte Carlo Simulation

P Ramon^{1*}, A Quevedo², T Pianosi³, (1) Federal University of Health Sciences of Porto Alegre, Porto Alegre, RS, BR, (2) University of Sao Paulo, Ribeirao Preto, SP, BR, (3) Federal University of Health Sciences of Porto Alegre, Porto Alegre, RS, BR

Purpose: Dosimetry in brachytherapy is of paramount importance to ensure equality between the prescribed and delivered dose to the patient. Due to the high dose gradient in regions close to the source, experimental dosimetry is highly complex. Therefore, the American Association of Physicists in Medicine (AAPM) recommends using Monte Carlo simulation as an alternative. In this work, the relative depth dose, the radial dose function and the anisotropy function (at the reference distance for dosimetry in brachytherapy, 1 cm) were analyzed, for two sources commonly used in ophthalmic brachytherapy, using Monte Carlo simulation with PENELOPE code. **Methods:** The models used were IR06-103Pd and OncoSeed 6711 for ¹⁰³Pd and ¹²⁵I, respectively. Both were modeled and positioned in the center of a 30 cm cubic phantom, filled with water and divided into 101 pixels in the three directions of the Cartesian axis. The 8 and 5 main emission lines were inserted for the ¹⁰³Pd and ¹²⁵I sources, respectively. **Results:** Comparing the relative depth dose from the two sources, the source of ¹²⁵I has 5.4 p.p less than ¹⁰³Pd source, due to the distribution of the radioactive material being different in both sources. Analyzing the radial dose function, the major difference was 0.03 at 1.2 cm, being greater for ¹²⁵I. In the anisotropy function, both showed the same behavior, but with higher values for the ¹⁰³Pd source, with the major difference 0.13 at 135°. **Conclusion:** For the dosimetric parameters analyzed, the sources of low dose rate showed similar behavior in dosimetric parameters and difference in relative depth dose, due to the distribution of radioactive material by the source geometry. Thus, the PENELOPE package presents as a promising tool for dosimetric calculations for brachytherapy sources.

Thanks to FAPERGS for the financial support for this research.

PO-GePV-T-21

A Comparison of Surgical Bed Biologically Effective Dose from Permanently Implanted Collagen Tile Embedded Cs-131 Brachytherapy Vs Stereotactic Radiosurgery in Patients with Resected Brain Tumors

A Turner*, M Choi, D Brachman, GT Medical Technologies, Tempe, AZ

Purpose: To compare, in patients with brain tumors, surgical bed biologically effective dose (BED) from GammaTile (GT), a permanently implanted collagen tile embedded with Cs-131 seeds (GT Medical Technologies, Tempe, AZ) versus BED with commonly used stereotactic radiosurgery (SRS) protocols. **Methods:** In four patients who underwent GT implants (60Gy prescribed at 5mm depth from the operative bed surface), absolute dose was calculated on post-operative thin-slice CT using a commercial treatment planning software (MIM Symphony, MIM Software Inc, Beachwood, OH) and AAPM TG-43U1 formalism. Voxel dose was converted to BEDGT using a validated linear/quadratic model ($\alpha/\beta=10$) that accounted for half-life (9.7days), cellular repair half-life (1.5hours), and tumor doubling time (5.4days). Absolute dose and BED covering 90% (DGT90% and BEDGT90%) and 95% (DGT95% and BEDGT95%) of the target volumes (tumor bed [TB]+0-5mm) were calculated. Prescription doses to target volumes (TB+2-3mm) commonly used for single- and fractionated-SRS -- 12, 14, 15, 17, 18, or 20Gy/1 fraction; 27Gy/3 fractions; and 30Gy/5 fractions -- were converted to BED1fx, BED3fx, and BED5fx, respectively, using the external beam linear/quadratic model ($\alpha/\beta=10$). BEDGT90% and BEDGT95% were compared to BED1fx, BED3fx, and BED5fx. **Results:** BED for SRS was 26.4–60Gy (12-20/1fx), 51.3Gy (27 Gy/3fx), and 48Gy (30 Gy/5fx). For TB+margins of 0, 1, 2, 3, 4, and 5 mm, mean BEDGT90% was 145.5±56.9Gy, 116.3±40.2Gy, 92.9±29.9Gy, 78.5±25.1Gy, 65.6±19.9Gy, and 55.2±17.1Gy, respectively. Mean BEDGT95% for TB+0, 1, 2, 3, 4, and 5mm was 126.5±51.8Gy, 100.6±35.2Gy, 80.6±26.0Gy, 67.9±21.7Gy, 56.7±17.1Gy, and 47.8±15.0Gy, respectively. **Conclusion:** This preliminary work indicates that GT delivers equivalent or higher BED than commonly used SRS protocols. Investigations with a larger sample size are underway, and may be informative for interpreting efficacy and safety results using this novel brachytherapy device, which is FDA-cleared to deliver radiation therapy in patients with newly-diagnosed malignant intracranial neoplasms and recurrent intracranial neoplasms.

PO-GePV-T-22

A Comprehensive Dosimetric Evaluation of Circular Collaborative Ocular Melanoma Study (COMS) Plaques and Eye Physics Plaques On a Standard Eye Model

E Quan*, B Teh², A Scheffler³, R Pino⁴, (1) UT MD Anderson Cancer Center, Houston, TX, (2) Houston Methodist Hospital, Houston, TX, (3) Houston Methodist Hospital, Houston, TX, (4) Houston Methodist Hospital, Houston, TX

Purpose: To evaluate dosimetric differences between circular COMS and Eye Physics (EP) plaques for uveal melanomas to provide clinical guidance in the selection of eye plaque for various tumor sizes and heights. **Methods:** Tumors with basal diameters (D_{base}) ranging from 6mm to 18mm, and heights ranging from short (3mm) to tall (10mm), were simulated on the equator of a standard eye model in the Plaque Simulator planning system. Treatment plans with a COMS plaque selected based on the COMS convention and one or two EP plaques with similar diameter were calculated for each tumor. 85Gy was prescribed to tumor apex for tall tumors and prescribed to cover to at least tumor apex and 95% of the tumor base plus 2mm margin for short tumors. **Results:** For short tumors, most EP plaques produce lower tumor base D_{max} (D_{max_TB}) and V85Gy of entire eye, and achieve similar coverage at shorter prescription height, than their corresponding COMS plaque, with an average reduction of 66Gy, 1.1%, and 0.7mm, respectively; this difference is more pronounced for D_{base} ≥ 12mm. For tall tumors with D_{base} > 14mm, EP and COMS plaques show similar D_{max_TB}, but, with D_{base} ≤ 14mm, EP plaques reduce D_{max_TB} by an average of 161Gy. However, for both short and tall tumors, EP plaques increase outside-of-margin D_{max} (D_{max_OOM}) by an average of 29Gy and 103Gy, respectively, although D_{max_OOM} is on average 40% lower than D_{max_TB}. **Conclusion:** EP plaques generate lower max dose at tumor base, indicating potentially reduced ocular toxicity, compared to similar-sized COMS plaques, especially for tall tumors with small to medium base size and short tumors with medium to large base size. EP plaques do produce increased dose-spill outside of tumor, which should be carefully evaluated when tumor is located close to critical structures such as optic nerve and macula.

PO-GePV-T-23

Dosimetric Impact of Atlas Generated Contours for Post-Prostate Seed Implant Evaluation

A Antolak*, J Ciezki, M Kolar, Cleveland Clinic Foundation, Cleveland, OH

Purpose: The purpose of this work is to generate an atlas for the automatic segmentation of contours for post-prostate seed implant evaluation and to investigate the dosimetric impact of using these contours for post-plan analysis. **Methods:** A prostate atlas was generated in the MIM software package using expert (radiation oncologist) defined contours for the bladder, rectum, and prostate for 40 patients. A workflow was developed that implemented several pre-processing steps to improve the contouring accuracy. Processing steps included the automated detection of metal (seeds) and air and masking these image values in order to allow the atlas registration framework to focus on the patient anatomy and not on the metal/air that could bias the result. Post-plans from 10 additional patients were exported from the clinically implemented VariSeed TPS to MIM for dosimetric analysis. The RTplan from VariSeed was used to calculate a new dose distribution in MIM using the same seed locations and source strengths. Relevant dosimetric parameters were calculated using both the expert and atlas defined contours. **Results:** An atlas and workflow was successfully generated in MIM for the automatic segmentation of the prostate, rectum, and bladder. Minimal dosimetric differences were observed between VariSeed and MIM when using expert defined contours, consistent with previously published results. When atlas generated contours were used, there were larger differences in dosimetric parameters for the prostate and rectum. The average difference in prostate volume, V₁₀₀, and D₉₀ was -0.3+/-4.3 cm³, -0.7+/-1.4%, and -1.3+/-6.6%, respectively. The average difference in V₅₀ for the rectum was 0.6+/-2.6 cm³. **Conclusion:** Despite large differences in dosimetric parameters observed when using atlas defined contours for post-plan analysis, the magnitude of these differences are generally small with respect to clinical tolerances. In addition, the improved efficiency of using automatically generated contours has the potential to significantly improve clinical workflow.

PO-GePV-T-24

Dosimetric Analysis of Real-Time Intra-Operative Planning and Post Implant Planning for the Prostate Permanent Brachytherapy Implants

R Badkul*, H Jiang, S Awan, X Shen, N Demez, RC Chen, University of Kansas Medical Center, Kansas City, KS

Purpose: To compare and analyze various dose-volume-parameters of real-time intra-operative plans using ultrasound-images with those of CT-based postimplant plans for prostate-brachytherapy. **Methods:** 15 patients were selected for this study who received permanent brachytherapy implants using Iodine-125. Five patients received monotherapy of 145Gy and 10 received 110Gy as a boost combined with external-beam. 5mm ultrasound axial images were captured into the VariSeed treatment-planning-system. Prostate, urethra, and rectum were contoured, a treatment-plan was generated to cover 90-97 % of prostate with prescription-dose at the same time not to exceed tolerance doses to urethra and rectum. Seeds were implanted using real-time ultrasound images utilizing Mick applicator. Post implant CT based planning was performed after 4-6 weeks to evaluate the dose coverage to the prostate and organs at risk

volumes(OARs) doses. Prostate volumes and dose volume parameters such as V100, V150, V200, D90 for prostate and V100, D0.1cc, D1cc and D2cc for the rectum were compared and analyzed. **Results:** The mean intra-op prostate volume was 40.3cc(SD14.5), mean post implant prostate volume was 37.8cc(SD14.8)($p<0.06$). The intra-op means for prostate V100, V150, V200, D90 were 93.8(SD2.6), 57.0(SD5.1), 30.8(SD6), and 108.5(SD5.8), while the post implant means were 92.3(SD5.2), 64.6(SD13.6), 38.1 (SD10.1), and 110.1(SD18.3), with their P-values being 0.103, 0.026, 0.011, and 0.343, respectively. Rectum mean V100, D0.1cc, D1cc, D2cc for Intra-op plans were 0.4(SD0.3), 110.4(SD14.6), 88.1(SD9.0), 78.4(SD8.5) and post-implant plans were 0.3(SD0.4), 104.5(SD29.6), 75.8(16.1), 63.8(SD12.2) with p-values of 0.173, 0.251, 0.008, 0.000 respectively. **Conclusion:** Small differences exists between intra-op and post implant dosimetric results, however this study suggests that intra-operative real-time dosimetry system provides a close match to the actual delivered doses and a good predictor of quality of the implant. These data support the use of real-time intra-op system to modify and adapt the implantation of seeds during the surgery to achieve more favorable dosimetric results.

PO-GePV-T-25

Evaluation of Dose Distribution from An Ophthalmic Brachytherapy Through the TOPAS Code

I Knoll¹*, L de Souza², A Quevedo³, M Alva⁴, (1) , Porto Alegre, RS, BR, (2) , Porto Alegre, RS, BR, (3) University of Sao Paulo, Ribeirao Preto, SP, BR, (4) Universidade Federal de Ciencias da Saude de Porto Alegre, Porto Alegre, RS, BR

Purpose: Ophthalmic applicators used in brachytherapy are placed in contact or close to the region to be treated, administering a high dose gradient in a few millimeters, making the determination of dosimetric parameters become a challenge. Thus, the TG-43 protocol proposed by the American Association of Physicists in Medicine (AAPM) recommends the use of Monte Carlo simulation to determine the dosimetric parameters of this type of source. Therefore, the objective of this work was to analyze the relative dose distributions through the TOPAS simulation code from a source $^{90}\text{Sr}/^{90}\text{Y}$ used in brachytherapy. The obtained results were compared with the PENELOPE code. **Methods:** The applicator simulated in this work was the model SIA.20, which contains a source of $^{90}\text{Sr}/^{90}\text{Y}$, with 9 mm in diameter used in the treatment of ophthalmic brachytherapy. A spherical phantom with 30 mm in diameter, representing the patient's eye, was placed below the applicator. For the evaluation of the TOPAS code, a beam profile was obtained through a dose distribution at 1 mm depth of the phantom, as recommended by dosimetry protocol. The shape of the beam profile is similar to a Gaussian curve, so, the values of average width at half maximum (FWHM) were compared with the PENELOPE code, as the same condition of simulations. **Results:** The FWHM values were 0.219 and 0.362 for PENELOPE and TOPAS, respectively. Comparing the values of dose relative at 2.5 mm from the center of the source, a region with a high dose gradient, a difference of 5.5% was found, due to the contribution of the electron edge effects. **Conclusion:** The results obtained in this work show that the TOPAS code presents as a promising tool for dosimetry in brachytherapy.

PO-GePV-T-26

Evaluation of MIM Symphony Treatment Planning System for Post Prostate Seed Implant (PPSI) Planning

H Zhao*, F Su, X Li, J Kunz, G Nelson, P Rassiah-Szegedi, K Hopfensperger, G Stinnett, Y Huang, University of Utah, Salt Lake City, UT

Purpose: To evaluate MIM Symphony treatment planning system for PPSI planning. **Methods:** PPSI planning procedure was evaluated and compared between MIM Symphony and Varian VariSeed on five patients, including image import, contour, seed placement/identification, dose calculation, plan evaluation, and plan printout documentation. **Results:** MIM Symphony is an add-on function of MIM software, and it is compatible with all other MIM functions. We believe this module could potentially improve workflow for PPSI planning, especially for patients boosted with external beam radiation. It is also possible to generate cumulative EBRT and brachytherapy equivalent dose and contour sharing. In MIM, the imported PPSI CT images can be fused to MRI, PSI ultrasound, and other external beam planning CTs. Contouring can be efficiently performed based on various contrasts provided by different image modalities and within one module. MIM Symphony seed auto-identification function is comparable with the widely used VariSeed planning system. The seed auto-identification parameters can be constructed in MIM Symphony and adjusted for individual PPSI plans, including seed intensity threshold, PTV/CTV margins for seed search, and seed size upper and lower limits. The dose calculation algorithms for MIM Symphony and other commercially available LDR treatment planning systems are identical, which is based on AAPM TG-43. Dose constraints for target and organs-at-risk can be incorporated to standardize plan evaluation. The plan printout document of MIM Symphony can be customized to fit each clinics' individual requirements, and templates can be generated. **Conclusion:** Our initial tests have shown that MIM Symphony for PPSI is comparable to other LDR treatment planning systems, and has the extra advantages of ease of contouring, contour sharing and equivalent dose accumulation. We believe it has the potential for more streamline workflow and therefore improving PPSI process efficiency.

PO-GePV-T-27

Automating Brachytherapy Treatment Plan Document Generation by Using Eclipse Scripting API (v15.6)

R Sheu*, N Vassell, C Teng, Y Lo, Mount Sinai Health System, New York, NY

Purpose: To simplify generating brachytherapy treatment plan documents in Eclipse (Varian) and to streamline the process of independent dose check, an Eclipse Script API (ESAPI) "uPRINT Brachy" has been developed to automate the preparation of treatment plan documents. **Methods:** ESAPI (v15.6) has been used to retrieve brachytherapy treatment plan parameters from Eclipse. An independent dose check was built in based on simple inverse-square law algorithm. Eclipse viewing plane parameters are not accessible in current ESAPI version; therefore, an ARIA SQL query was implemented for retrieving these parameters in order to replicate the display in the Eclipse application. Additionally, an XML parser and "VarianSolidApplicator" class were implemented in order to import the solid applicator definition from Varian applicator files (.acrx) and render its 3D geometry in isodose display. The planning document is generated in HTML format and can be printed or saved as PDF via web browsers. **Results:** Scripting plan printing simplifies the brachytherapy treatment plan document preparation, and the built-in independent dose check further streamlines our workflow. The dose check automatically applies all reference points with physical locations, and users can select/unselect them for reporting. Since brachytherapy plans are often displayed in arbitrary rotated views, aligning applicators using pre-set viewing plane parameters from Eclipse (retrieving from ARIA database) is highly recommended for automation and minimizing user intervention. The solid applicator rendering feature retains the same visual quality compared to an Eclipse screenshot when there is no CT/anatomy present. **Conclusion:** ESAPI version 15.6 enables users to access brachytherapy plan treatment parameters. Our work demonstrates an implementation of automating the brachytherapy plan document preparation process by using ESAPI. This work not only can improve efficiency and reduce errors, but can also provide matching graphic quality of documents currently prepared using Eclipse printing/screenshot functions.

PO-GePV-T-28

Evaluation of Eclipse Smart Segmentation for Liver Yttrium-90 Selective Internal Radiation Therapy

J Li*, R Anne, Thomas Jefferson University, Philadelphia, PA

Purpose: In resin Yttrium-90 (Y-90) selective internal radiation therapy (SIRT) of metastatic liver cancer, liver volume sizes are needed for determining Y-90 activity with the body-surface-area method, which are obtained from liver contours delineated by physicians. The aim is to evaluate Eclipse Smart Segmentation, a knowledge-based auto-segmentation module, for potential application in liver delineation for resin Y-90 SIRT. **Methods:** CT images of 10 patients treated with resin Y-90 were studied. Auto-segmentation of liver was performed with the Smart Segmentation in an Eclipse treatment planning system

(Version 15.6). For each case, an expert case in the built-in library, which had the highest similarity to the studied case as indicated by the system, was selected for auto-segmentation. Liver contours generated with the Smart Segmentation were compared with physician manually-delineated contours. The latter were taken as the standard. To evaluate the auto-segmentation accuracy, Dice similarity coefficient (DSC) was calculated and liver volume sizes were compared. **Results:** The average DSC was 0.77 (standard deviation: 0.10; range: 0.56-0.9). The average relative volume difference was 12% (standard deviation: 9%; range: 0.4%-22.6%). **Conclusion:** The Smart Segmentation can be used to generate initial liver contours, which need to be reviewed and edited by physicians. Application of the Smart Segmentation will save contouring time and improve the efficiency of the workflow in resin Y-90 SIRT.

PO-GePV-T-29

Validation of ACE: Advanced Collapsed Cone Engine Heterogeneity-Corrected Brachytherapy Dose Calculation with Gafchromic EBT3 Film

D McIlrath*, E Schnell, University of Oklahoma HSC, Edmond, OK

Purpose: To validate Elekta's Oncentra ACE TG-186 heterogeneity-corrected calculation of dose with heterogeneous materials using Gafchromic EBT3 film dosimetry. **Methods:** A phantom was created to deliver a uniform dose to a 5 cm by 10 cm area of EBT3 Gafchromic film using a Nucletron MicroSelectron HDR afterloader with an Ir-192 source. The phantom composed of bolus, five plastic catheters attached to a solid water support, a variable density layer (e.g. bolus, cork, bone), and EBT3 film attached to a solid water base. The phantom was imaged using a GE Lightspeed CT simulator with a slice thickness of 1.25 mm. Layers were contoured within Varian's Eclipse and assigned program-defined material with uniform density values. Materials of water and air were assigned to bolus/solid water and cork respectively. Plans were created using Oncentra Brachy TPS. Doses of 200 cGy were delivered to a normalization point located at the center of film. EBT3 film was calibrated for absolute dosimetry using a 6MV linear accelerator beam. **Results:** Film irradiated through a layer of cork produced an average dose of 194 cGy at the normalization point. Doses for each trial were less than the ACE-calculated 200 cGy in Oncentra. **Conclusion:** Model-based dose calculation algorithms (MBDCAs) are of great importance in cases where heterogeneities are present, and its accuracy is paramount for research. There is a need for experimental validation of these engines to assure meaningful results, as well as guidance for best practice when assigning material definitions. Gafchromic EBT3 film is a great practical option since it offers minimal additional heterogeneities into the dose validation calculation. This work indicates the possibility of using film as a means for dosimetric validation of ACE calculated plans.

PO-GePV-T-30

Investigation of Impact of Systematic Errors in Applicator Reconstruction On Doses of Organs at Risk and Target Volumes in Intracavitary Brachytherapy

G Singh^{1*}, A Mourya², B SINGH³, D Thaper⁴, R Kamal⁴, A Oinam¹, V Kumar³, B Rai¹, (1) Post Graduate Institute of Medical Education and Research, Chandigarh, IN, (2) Banaras Hindu university, Varanasi, UP, IN, (3) Centre for Medical Physics, Punjab University, Chandigarh, IN, (4) ILBS, Delhi, IN

Purpose: To investigate the impact of systematic errors in applicator reconstruction on DVH parameters of different organs at risk (OARs) and target volumes (TV) in intracavitary brachytherapy (ICBT) using GEC ESTRO EMBRACE protocol. **Methods:** Retrospectively, 10 patient plans of ICBT were taken in this study in which Nucletron CT and MR imaging compatible ring applicator of 3cm ring diameter and 6 cm tandem length (Nucletron, Veenendaal, The Netherlands) were used. Planning and contouring of OARs (Bladder, Rectum, Sigmoid) and TVs (HRCTV) were done on Oncentra TPS (Nucletron) with MRI images and applicator geometry was reconstructed manually and considered as zero position. Further, systematic errors were introduced in the spatial coordinates of applicator geometry by translating the applicator in -5 mm to +5 mm in a step size of 1 mm from the zero position in x-, y- and z-axis respectively by using an in-house program. The impact of systematic errors was quantified using DVH parameters of different OARs and TVs respectively. **Results:** The mean value of relative percentage variation of dosimetric parameters for 0.1cc, 1cc, 2cc, and 5cc volumes of the bladder, rectum, sigmoid colon and D90%, D98% and V90% for HRCTV in x-, y- and z- directions were calculated and shown in Table 1. **Conclusion:** The reconstruction of applicator geometry is very sensitive to the systematic errors that significantly affect the doses of OARs and TVs. This study reveals the quantitative impact of systematic errors on the OARs and TVs doses.

PO-GePV-T-31

Focal-Boost Dose Escalation in High-Dose-Rate Brachytherapy

C Guthrie*, T Harris, M King, I Buzurovic, R Cormack, Dana-Farber/Brigham and Women's Cancer Center, Harvard Medical School, Boston, MA

Purpose: High-Dose-Rate Brachytherapy (HDR-BT) is one treatment options for localized prostate cancer. Magnetic resonance imaging (MRI) allows for delineation of the dominant lesion (DL) and thus offers the potential of a focal boost. The question remains of how much dose can safely be prescribed to the dominant lesion without increasing toxicity during whole gland treatments. **Methods:** The retrospective planning study includes 50 patients who previously underwent HDR-BT to the whole gland. All patients had the DL contoured. Plans were re-optimized with our in-house planning-system allowing for constrained optimization. Plans were constrained to our current clinical metrics with the objective to maximize the dose to the DL. The dose escalation for the focal boost was analyzed with respect to lesion size and location. **Results:** Volumes for the gland and DL ranged from 6.0cc-47.2cc and 0.2cc-16.8cc, respectively. D90 of the whole gland was 107.8%±1.9%. Based on a Wilcoxon rank-sum test, key metrics for urethra and rectum did not differ significantly (p>0.05) when compared to clinical approved plans. D90 for the DL was (141.6±23.5)%. The maximum dose escalation was 220% for the smallest and 110% for the largest lesion. As per study design dose metrics for organs at risk were always met. Dose escalation for the DL is anti-proportional to its size and plateauing to D90=135% of the prescribed dose for lesions greater than 4cc. Boosting the DL in the posterior portion of the gland is limited by urethra and rectum with a median D90=129.3%. This contrasts with the anterior portion with a D90=145.4%. Those findings are independent of the laterality. **Conclusion:** Focal boosts are limited by the size of the dominant lesion and location within the gland. The results are used as a baseline for achievable dose escalation and can be incorporated in the treatment planning for MRI guided HDR-BT.

PO-GePV-T-32

Recommendations for Previous Treatment Assessment of Non-CT Based IVRT Brachytherapy

D Aramburu Nunez, V Brennan, M Kollmeier, K Alektiar, A Damato*, G Cohen, Memorial Sloan-Kettering Cancer Center, New York City, NY

Purpose: To review dosimetry and associated toxicity in patients treated with CT-guided IVRT in an effort of predicting prior radiation dose volume constraints in patients who have received non-CT guided IVRT, and present with recurrence requiring re-irradiation. **Methods:** 29 patients with endometrial cancer treated at our institution with upfront surgery +/- RT +/- chemo subsequently presented with an isolated vaginal recurrence and were salvaged with brachytherapy +/- EBRT. All patients received CT-guided IVRT (prescriptions ranging from 4 x 5 - 5 x 5 (Gy x fx)) and 18/29 received EBRT (prescription 1.8 Gy x 25fx). Bowel, rectum, bladder, and rectosigmoid) were contoured at the time of the IVRT. D2cc was retrospectively analyzed for each OAR as physical dose (Gy) from the IVRT course only, using DVHs. Toxicity was collected for each patient prospectively at routine clinical follow-up and graded according to Common Terminology Criteria for Adverse Events v5.0. **Results:** The median (range) D2cc for bowel was 1.86 (4.2 - 0.94 Gy), for rectosigmoid was 2.1 (4.75 - 0.4 Gy), for bladder was 3.4 (5.3 - 2.0 Gy), and for rectum was 3.4 (5.0 - 1.7 Gy). One patient treated with EBRT and IVRT experienced a grade 3 sacral insufficiency fracture (3.4%). Grade 1 and 2 toxicity was recorded in 14 (48.3 %) and 13 (44.8%) patients respectively. D2cc for bladder, rectum, bowel and rectosigmoid was less than prescription dose in 90%, 86%, 100%, and 100% of the patients respectively. **Conclusion:** Overall salvage IVRT was well tolerated.

14% of patients received OAR D2cc greater than prescription with only 2 with grade 2 toxicities. These preliminary results suggest that using D2cc equal to the prescription dose is clinically acceptable for all OAR as a prior radiation dose volume constraint in patients who have received non-CT IVRT, and requiring re-irradiation.

PO-GePV-T-33

Role of Planning Ring Structure in Volume Optimization for High-Dose-Rate Prostate Brachytherapy

Z Shen*, O Ragab, W Yang, S Balik, A Zhuang, J Cui, A Shiu, E Chang, University of Southern California, Los Angeles, CA

Purpose: Manual HDR prostate planning can be time-consuming and user-dependent. Anatomy-based inverse optimization is an effective way to achieve a HDR prostate plan with desirable dose distribution. This study evaluated the optimum planning ring structure for HDR prostate using BrachyVision. **Methods:** Five patients treated with single fraction HDR prostate brachytherapy were selected. Five HDR plans were created for each patient by varying the planning ring structure during volume optimization. The planning ring structures were 4 cm wide with 0, 1, 2, 3, and 4 mm gap from the high-risk CTV, respectively. Other planning parameters were kept constant, including the step size, max dwell time, source dwell positions, and dose constraints. Each plan was evaluated for target coverage (V100, V125, V150), urethra, rectum, bladder sparing (D0.1cc), and conformity index (CI=ratio of prescription isodose volume to target volume receiving prescription dose). One-way ANOVA tests were performed. **Results:** All plans achieved over 97% target coverage. V100 significantly increased with the planning ring structures with increasing gap from the CTV ($p < 0.001$). The mean V100 values were 97.2%, 98.0%, 98.3%, 98.5% and 98.6% for ring structures with 0, 1, 2, 3, and 4 mm gap. No significant differences were found in V125, V150, D0.1cc rectum, D0.1cc bladder, and D0.1cc urethra. The CI significantly increased with planning ring structures with increasing gap from the CTV ($p = 0.024$), indicating less conformal plans. The mean CI were 1.32, 1.41, 1.46, 1.52, and 1.54 for ring structures with 0, 1, 2, 3, and 4 mm gap. **Conclusion:** When using planning ring structures with increasing gap from the CTV, the target coverage significantly increased at the cost of losing conformity. Since the ring structure with 0 mm gap achieved the most conformal plans with target coverage over 97%, we recommend using it as a starting point for volume optimization.

PO-GePV-T-34

Interfractional Dosimetric Variations of the Target and OARs for HDR GYN Brachytherapy

B Washington*, M Randall, D Fabian, W Luo, University of Kentucky, Lexington, KY

Purpose: To investigate the interfractional dose variations of the target and organs at risk (OAR) with respect to the prescription and its potential effect. **Methods:** We retrospectively analyzed 29 cervical cancer patients treated with intracavitary high dose rate (HDR) brachytherapy using tandem and ovoids from January 2020 to November 2020. Prescriptions ranged from 5 Gy to 7 Gy per fraction for 2 to 5 fractions. Treatment planning were conducted in the Varian Eclipse brachytherapy treatment planning system (TPS). The HRCTV dosimetric parameter of interest was the dose that covers 90 % of the HRCTV (D90). The dosimetric parameter for OAR evaluation was the absorbed dose by 2 cc of the volume of interest (D2cc). Each fraction's dosimetric parameter was normalized to the prescription and first fraction value to determine the proportional, and thus, percentage difference. For prescription normalization, OARs were normalized to the recommended OAR tolerance values from the International Commission on Radiation Units report 89 (ICRU 89) of 80% of the prescription. Statistical analysis was performed in Python 3.7 with the utilization of the Statistics package. **Results:** The mean variations for the HRCTV were 23.9 ± 17.3 % for prescription, respectively. Mean dose variations from the dose constraints were 19.1 ± 19.9 , 16.6 ± 17.3 , and 26.4 ± 17.5 % for rectal, bladder, and sigmoid, respectively. The dose deviation from the first fraction followed a similar pattern. A shift to high dose regions indicated the dose delivered to the target and critical structures was higher than the prescription. **Conclusion:** A pattern of dose variation including a shift to higher dose in both the HRCTV and OARs was observed. Such deviations may have potential effect on dose prescription and plan evaluation, which will be further investigated.

PO-GePV-T-35

Calculation of Stopping-Power Ratios for Electron Beams Used in Total Skin Electron Therapy

G Ding*, Vanderbilt University, Nashville, TN

Purpose: The electron beams for total skin electron therapy (TSET) are always used at extended distances and degraded by a scatter plate. Dose measurements according to AAPM TG-51 dosimetry protocol require the beam quality conversion factor, k_Q , which is derived from a standard beam ($SSD=100$ cm with 10×10 cm²). Since k_Q is directly related to the water/air stopping-power ratios (SPRs) at electron reference depth, d_{ref} , it is important to know if the SPRs of a clinical degraded beam differ from that of a standard beam. This study calculates SPRs for these beams in order to determine if k_Q is still applicable. **Methods:** The calculation of SPRs in this study is carried out in two steps, viz. the generation of the clinical incident beams followed by their use as incident beams to compute the SPRs. The Monte Carlo code BEAMnrc is used to simulate clinical 6 MeV HDTEe beams from Varian accelerators. **Results:** R_{50} in water decreases approximately 1 mm for each additional 100 cm extended distance ranging from 2.24 cm at $SSD=100$ to 1.72 cm at $SSD=700$ cm. For beams passing through a scatter plate, R_{50} is 1.76 cm (1.14) at $SSD=300$ and 1.48 cm (0.85 cm) at $SSD=600$ cm with an Acrylic plate thickness of 3 mm (9 mm) respectively. Although significant differences in calculated SPRs as a function of depth occur at depth beyond d_{max} between a clinical beam and a standard beam, less than 1% variation is found at d_{ref} for all beams. **Conclusion:** The SPRs as a function of depth for a standard electron beam provided by AAPM TG-51 protocol may not be accurate to convert a measured depth-ionization curve into a depth-dose curve accurately. However, k_Q in the protocol, is still applicable in the dose determination at d_{ref} for a beam used in TSET.

PO-GePV-T-36

Variability of Bremsstrahlung Among Modern Detectors in Total Skin Electron Treatment

S Kucuker Dogan*, M Gopalakrishnan, I Das, Northwestern Memorial Hospital, Northwestern University Feinberg School of Medicine, Chicago, IL

Purpose: Bremsstrahlung component in electron beam can be a limiting factor for the treatment especially for total skin electron treatment (TSET). Measurements are challenging due to the magnitude of bremsstrahlung at 3-5 meter distances. Additionally, suitability of electrometers in pico-Coulomb readings and detectors that are sensitive enough in electron and photon beams are investigated in this study. **Methods:** Multiple detectors (0.6 cm³ Farmer chamber, Markus parallel plate ion chamber, Electron diode, Edge detector, microSilicon, microDiamond and EBT3 film) were used to measure bremsstrahlung component from a Varian TrueBeam® 6MeV high-dose-rate (2500MU/min) beam. Measurements were made in solid water and in small water tank. PTW Unidos reference class electrometer was used for data collection. Analysis is made in terms of signal-to-noise ratio. For EBT film proper scaling for exposure in electron and bremsstrahlung and other film precautions were used. **Results:** Previously published data on Saturn machine using Markus chamber showed that component of bremsstrahlung increases with increasing distance up to 5% (Med Phys 21:1733-1738, 1994). However, this could be due to signal-to-noise ratio of some detectors and electrometer combination. It is confirmed that Markus parallel plate and microDiamond could give erroneous results due to saturation of the signal. Our data with various detectors which provide large signal indicated that bremsstrahlung increase is relatively modest (0.6-2%) with increasing distance. EBT3 film and other detectors provided nearly identical bremsstrahlung magnitude in TSET. A fitted exponential function ($Br = 0.67e^{0.0017x}$) from mean values of measurement data is provided. **Conclusion:** Care should be warranted for bremsstrahlung measurement as it is overwhelmed with poor signal with clinical electrometers. Farmer chamber, Edge, EFD, microSilicon and EBT films are best suited for TSET. The bremsstrahlung increase with distance is modest and a functional form is used to estimate the magnitude.

PO-GePV-T-37

Verification of Electron Beam Energy Stability

J Foy*, S Kucuker Dogan, M Gopalakrishnan, I Das, Northwestern Memorial Hospital, Northwestern University Feinberg School of Medicine, Chicago, IL

Purpose: Monthly energy verification quality assurance (QA) evaluates the stability of the energy spectrum delivered by a Linac. Modeling the QA setup may allow physicists to determine whether failures during QA are due to changes in Linac operation or measurement setup. **Methods:** Electron energy verification records measured with an IBA Matrixx detector array on an Elekta Versa Linac were collected from the years 2018-2020. Electron energies included 6MeV, 9MeV, 12MeV, and 15MeV. Matrixx assesses the electron energy using eight ion chambers shielded by different thicknesses of high-Z inserts to simulate different effective depths. The signal measured in each detector is normalized by an unshielded chamber on the central axis to obtain an effective percent depth dose (PDD_e) curve. Measurements were compared to the reference measurements acquired during commissioning with a $\pm 2\%$ tolerance applied to each chamber. The detector array and high-Z inserts were simulated in Pinnacle Treatment Planning System (TPS). The dose to each chamber was calculated with the reference conditions used during energy verification QA: 100 monitor units and a 20x20cm² field. For each electron energy, the PDD_e was compared between the Pinnacle simulation and those obtained during each energy verification measurement. **Results:** From 2018-2020, 42 measurements were acquired with one failure for both 6MeV and 15MeV beams; 9MeV and 12MeV beams resulted in no failures. Differences between measurements and reference ranged from 0.0%-2.9% (mean: 0.37%), 0.0%-1.8% (mean: 0.19%), 0.0%-1.2% (mean: 0.29%), and 0.0%-2.1% (mean: 0.62%) across chambers for 6MeV, 9MeV, 12MeV, and 15MeV beams, respectively. Simulated doses differed from reference measurements on average by 3.16%, 2.65%, 1.53%, and 1.04% for 6MeV, 9MeV, 12MeV, and 15MeV beams, respectively. **Conclusion:** Simulating the energy verification measurement setup and adjusting the energy in the TPS may allow for an assessment of beam stability relative to commissioning and changes in the energy spectrum.

PO-GePV-T-38

An Investigation of Dosimetric Effects From Handlebars During Total Skin Electron Therapy

N Brovold*, E Dziemianowicz, K Verdecchia, Henry Ford Health System, Detroit, MI

Purpose: Total skin electron therapy (TSET) is a radiotherapy technique to treat Mycosis Fungoides; a condition where tumors form on the skin. Spoiled, low-energy electron beams (3-7 MeV) can be utilized to treat very superficial lesions on the skin. The Stanford method consists of six patient-oriented dual-fields that uniformly deposit a prescribed dose of 36 Gy to the skin. Commonly, skin areas that do not react to the radiation require a radiation boost. To aid in patient comfort and treatment position reproducibility, handlebars may be used; however, poorly characterized handlebars may attenuate low-energy electrons. The purpose of this study is to assess the dosimetric effects from holding handlebars during TSET. **Methods:** All measurements were performed with a newly commissioned high-dose rate (2500 MU/min) 6 MeV energy (Varian TrueBeam) that is spoiled by 10 mm Lucite. At our center, the Stanford six dual-field technique (gantry angles of 288° and 252°) is employed at an SSD of 424.5 cm on a total body irradiation stand by Radiation Products Design, Inc. Both, parallel-plate chamber (P11) and OSLD measurements were acquired at an off-axis (OAX) position typical for hand placement. Three configurations were investigated: no attenuation, handlebar, and handlebar with bolus (1cm, Superflab) to simulate additional self-shielding from fingers; all measurements were performed with an SAD of 424.5 cm to assess relative attenuation effects. **Results:** The average dose from both measurement modalities (P11 and OSLD) decreased by 79.8 $\pm$ 6.3% and 82.2 $\pm$ 5.9% when comparing the handlebar and handlebar/bolus to the standard (i.e. no buildup), respectively, indicating a large attenuation by the handlebars. **Conclusion:** We recommend investigating low-energy attenuation by handlebars when commissioning TSET to guide personalized clinical decisions, such as handlebar usage, radiation boosting of the palms, and, if possible, educating the patient to place opened-hands before the handlebars.

PO-GePV-T-39

Real-Time in Vivo Dosimetry for Electron Beam Therapy Using Amorphous Silicon Based Flexible Thin Film Combined with Scintillating Powder

S Jeong*, Y Kwon, S Park, D Shin, Y Lim, J Jeong, H Kim, W Cheon, S Lee, National Cancer Center, Goyang-si, 41KR

Purpose: The present study evaluated the clinical feasibility of the amorphous silicon (a-Si) based flexible thin film solar cell coated with scintillating powder for in vivo dosimetry for electron beam therapy. **Methods:** Scintillating powder was coated on a thin film solar cell using an optical adhesive to enhance the sensitivity of in vivo dosimetry system. Calibration factors of this system was acquired by dividing the dose measured at a reference depth for 6-20 MeV electron beam energy using the Markus chamber which was used as reference chamber and the signal measured using solar cell under the same condition. Energy dependence, source-to-surface distance (SSD) dependence, angular dependence and dose linearity of this system were evaluated. Also, surface doses measured using solar cell in vivo dosimetry system, Markus chamber, and thermoluminescent dosimeter (TLD) were compared to evaluate the feasibility of thin film solar cell for in vivo dosimetry for electron beam therapy. **Results:** The signals generated through interaction between solar cell and electron beam increased linearly with absorbed dose and were independent to electron energy, SSD and beam angle. Calibration factors for each electron beam energy were verified through comparison between the dose calculated using solar cell and that measured using Markus chamber at R90. The dose difference between the solar cell and the Markus chamber was less than 5%, while the dose measured using TLD showed a difference of about 7%. **Conclusion:** Clinical feasibility of the a-Si flexible thin film solar cell based real-time in vivo dosimetry system for electron beam therapy was evaluated by comparing the surface dose measured using this system with those measured using Markus chamber and TLD. The results in this study suggest that this system has the potential for in vivo dosimetry of electron beam therapy.

PO-GePV-T-40

Evaluating a Commercial Electron Monte Carlo Algorithm Using Oblique Incidence and Irregular Surfaces Present On Custom Wax Phantoms

E Cichewicz*, E Salari, E Parsai, University of Toledo Medical Center, Toledo, OH

Purpose: To evaluate obliquity and irregular surfaces as addressed by a commercial electron Monte Carlo dose calculation algorithm using custom made phantoms. **Methods:** GAFChromic EBT-3 film was exposed using a Varian Linac and an edge-on orientation between acrylic slabs in order to validate obliquity factors as calculated by RayStation's eMC algorithm along the central axis of the beam for 6, 9, 12, 16, and 20 MeV electron beams. Calculated and measured obliquity factors are tabulated in increments of 10 percent of each beam's practical range. Calculated and measured shifts in dmax, d80, and d50 were also recorded. Next, phantoms approximating the challenging patient geometries of a nose and forearm were created out of beeswax (~100 HU). Additionally, an acrylic phantom approximating the curvature of a chest wall was used. Again, GAFChromic EBT-3 film was exposed using the edge-on orientation – this time to compare dose distributions in an axial slice along the beam's central axis. Gamma analysis was performed using RIT's Complete Patient QA tool. **Results:** The majority of obliquity factors matched calculated values within 5 percent, and oblique incidence of 45 degrees was sufficient to result in dmax shifting upstream by over 5 mm in 6 MeV and 9 MeV beams, while shifting downstream approximately 20 MeV beams. An average of 88.72 percent of pixels passed gamma analysis (criteria between 3%/3mm and 5%/5mm). **Conclusion:** This work demonstrates that custom-made phantoms can be constructed out of inexpensive materials in order to determine the performance of a TPS in challenging clinically relevant situations. Access to complex phantoms allows the user to go beyond the minimum requirements for a commercial system outlined in MPPG 5a. RayStation's eMC algorithm handled the complexity introduced by oblique patient geometries effectively. Future work could benefit from added complexity by introducing heterogeneities within the same wax phantoms.

PO-GePV-T-41

Development of a Software Tool for FLASH Dose and Dose Rate Optimization for IntraOp Mobetron

A Ayan*, D Blakaj, A Chakravarti, N Gupta, J Woollard, Ohio State Univ, Dublin, OH

Purpose: To develop a method to select optimal combinations of PRF, PW and N based on current pre-measured machine characteristics in order to achieve the requested dose and the dose rate with IntraOp Mobetron for FLASH dose delivery. **Methods:** We have developed a mixed integer optimization based computer program in MATLAB to evaluate the various irradiation geometries and find the optimum combination of operating parameters in order to best provide a prescribed dose and dose rate (DR). At FLASH DRs, this machine can only be programmed to deliver an integer number of pulses (N) with a set pulse repetition frequency (PRF) and pulse width (PW). Many different irradiation geometries are possible utilizing 3 different cones and various cone sizes. The cone and cone size used to shape the beam and SSD determines the dose per pulse (Dpp). The optimization code minimizes a function of dose and DRs for a given beam energy, cone size and irradiation geometry. When the exact dose and DR cannot be achieved, optimization proposes PRF, PW, N, and SSD resulting in the closest dose and the DRs. **Results:** The developed optimization allows for optimal combinations of PRF, PW and N based on current pre-measured machine characteristics in order to achieve the requested dose and DR; hence eliminating the creation, use and updates of big spreadsheets to cover all PRF, PW, N, cone size, and geometry combinations and increases efficiency when planning for irradiation of large number of samples. **Conclusion:** We have developed a code that selects the optimum combination of PRF, PW, and N parameters in order to achieve the requested dose and the dose rate, thus increasing efficiency when planning for the irradiation of a large number of samples.

PO-GePV-T-42

eFLASH Dosimetry On a Conventional Linac Using Pulse-Gated Delivery

C Duzenli*, C Mendez, M Petric, J Sweeney, D Ta, T Karan, BCCA Vancouver Centre, Vancouver, BCCA

Purpose: To build on previous experiments and improve reproducibility of electron FLASH delivery on a conventional linear accelerator, a pulse-gating circuit was constructed and tested with several dosimeters. **Methods:** FLASH mode was achieved by operating a Varian iX linear accelerator with 15MV photon operating parameters, with the target and flattening filter retracted and a 12MeV electron foil in the beam's path. Pulse gating was achieved by an Arduino-based circuit interfaced with the linac gating module and a scintillator-photodiode sensor that was in the beam's path to count pulses. Dosimeters were placed at a source-to-surface distance of 47-47.5cm, with 0-5mm of build up and 2-3cm backscatter. Measurements were performed in open fields and on cut-outs ranging from 1x2cm² to 3x3cm². Doses were measured using a 0.01cc volume ion chamber, optically stimulated luminescence dosimeters (OSLDs), Gafchromic MD film and a novel plastic scintillation detector and Hyperscint spectral analysis. Film profiles and PDD were used to confirm dosimetry measurements were performed in a region receiving >90% of maximum dose. **Results:** A dose rate of 225 ± 11 Gy/s was achieved in FLASH mode. The pulse-gating method delivered the specified pulse count in 89% of irradiations and was within 2 extra pulses for 11% of the beams, as confirmed by scintillator. Corrected ion chamber, OSLD and scintillator doses showed excellent agreement for a range of 0-60Gy, while film showed saturation effects past 30Gy. The dose per pulse varied from 1.1Gy/pulse (7 pulses delivered) to 1.3Gy/pulse (40 pulses delivered). Oscilloscope and scintillator readings indicated consistently lower amplitude of the first pulse compared with subsequent pulses. **Conclusion:** A prototype pulse-gating method for eFLASH deliveries on a conventional linear accelerator was implemented. Further efforts will aim to reduce circuitry delays resulting in extra pulse delivery and compensation for pulse height for more consistent dose delivery.

PO-GePV-T-43

Analog FLASH Pulse Integration Using An External Diode Circuit

J Vadas^{1*}, R Halford², G Wilson¹, D Yan¹, M Snyder¹, (1) Beaumont Health, Royal Oak, MI, (2) Beaumont Hospital, Dearborn, MI

Purpose: Dosimetric control of electron FLASH radiotherapy systems demand pulse level control, as each pulse delivers a non-trivial fraction of the overall dose. In our delivery system, an initial beam current ramp results in a variable dose per pulse, limiting the accuracy of dose determination through digital pulse counting. Here we describe our initial attempts at describing this effect through analog dose integration using an external diode. **Methods:** We created a 10MeV FLASH beam that delivers roughly 200Gy/s at the mylar window of the machine. We placed an external diode into the beam and connected a custom low-noise amplifier circuit which delivers a time-dependent analog signal to an oscilloscope and a digital pulse counting signal to an Arduino Uno. We used the Arduino to interrupt the pulse forming network of the linac after a preset number of pulses and attempted to relate pulse height as measured on the oscilloscope to delivered dose. We used radiochromic film to measure absolute dose. **Results:** Our diode circuit saturated at the 6th pulse in all trials. We, therefore, delivered pulse trains of 2, 3, 4, and 5 pulses and plotted integrated pulse height (V) vs dose (Gy). The goodness of fit of the linear curve was $R^2=0.9965$. Removal of the 5 pulse data point improved the fit to $R^2=1$. This is likely due to the 5th pulse nearing diode saturation. **Conclusion:** Preliminary tests indicate a simple proportional relationship between pulse height when not near diode saturation. Tuning the diode amplifier circuit and performing analog integrating of pulse heights should provide better dosimetric beam control than our current digital pulse counting system.

PO-GePV-T-44

Bremsstrahlung Dose of the Electron Beam at Extended Distances Used in Total Skin Electron Therapy

G Ding^{1*}, S Kucuker Dogan², I Das³, (1) Vanderbilt University, Nashville, TN, (2) Northwestern Memorial Hospital, Chicago, IL, (3) Northwestern Memorial Hospital, Northwestern University Feinberg School of Medicine, Chicago, IL

Purpose: Electron beam from a Linear accelerator is commonly used in total skin electron Therapy (TSET) for advance cutaneous T-cell lymphoma. The high percentage bremsstrahlung dose up to 5% was reported for a 6 MeV electron beam at extended distance of 500 cm from source by Das et al. (Med Phys 21, p.1733, 1994). The significant increase in bremsstrahlung dose is a clinical concern as the electron beam for TSET is always used at extended distances. This study re-evaluates the reported high bremsstrahlung dose by both measurements and Monte Carlo simulations. **Methods:** We measured bremsstrahlung doses of 6 MeV HDTSe beams from Varian accelerators by using different detectors at extended distances. The Monte Carlo simulations were done by using the EGSnrc Monte Carlo codes, BEAMnrc/DOSXYZnrc, to simulate incident beams and to calculate dose distribution in the measurement phantoms. The simulated beams with jaws opening to 40 x 40 cm² were benchmarked with experiments in water phantom. **Results:** The result of previous reported high bremsstrahlung dose up to 5% at extended distances can only be reproduced by measurement using a parallel plate ion chamber. The results from Monte Carlo simulations show an insignificant (1%) of percentage bremsstrahlung even at SSD=500 cm. The measurements by using cylindrical chambers and other detectors confirmed the results from Monte Carlo simulations. **Conclusion:** Previously reported significant high percentage bremsstrahlung doses for 6 MeV electron beam at extended distances were inaccurate because a parallel plate ion chamber was used in the measurements. The reason that an incorrect high bremsstrahlung dose is measured by a parallel plate chamber needs further investigation. Although the bremsstrahlung tail increases with the increasing of extended distances, the percentage bremsstrahlung doses of a 6 MeV electron beam are 0.5% to 1% for SSD from 100 to 500 cm respectively.

PO-GePV-T-45

Creation and Validation of An Interactive Electron Cutout Library in a Clinical Environment

M Keohane^{1*}, K Croteau², A Riegel³, (1) Hofstra University, New York, NY, (2) Hofstra University/Northwell Health, Hempstead, NY, (3) Northwell Health, Lake Success, NY

Purpose: Electron treatments often require custom blocks for each field. Blocks may be purchased from a fabricator, often used once, and returned to the vendor or discarded. Previously, we designed a software tool to catalog and match existing electron cutouts to desired cutouts to encourage cost and time saving through reutilization. The current objective is to test the feasibility and functionality of the tool in a clinical environment by surveying three dosimetrists. **Methods:** A library of 140 electron plans were created from all-electron treatments between 10/01/2019-10/01/2020. A sample of 10 electron plans not included in the library was chosen. Electron blocks from the sample were exported and compared using the software. The software's closest 3 matches were imported back into the treatment plan for each patient. Each dosimetrist had the flexibility to adjust the SSD, collimator angle, and isocenter to get the best coverage and conformity. The dosimetrists were asked to rank the coverage, conformity, and most suitable plan (if any). **Results:** In both the conformity and coverage tests, the dosimetrists agreed that a library-selected block conformed and gave adequate coverage for 7 out of 10 of the chosen patients. The average rank of the chosen block assigned by the dosimetrists agreed with the algorithm. The D90 for each cutout was compared against the clinical cutout, with the accepted cutouts per plan varying by less than 3.7%. The D90 varied more than 3.7% from clinical for the 3 rejected cutouts. **Conclusion:** All dosimetrists agreed that the tool was easy to use. On average the dosimetrists agreed that the system works well in a clinical environment and that it would significantly increase the speed of treating patients. Future work includes translation into an API script and growth of the electron cutout library.

PO-GePV-T-46

A Thorough Validation of Electron Monte-Carlo Dose Calculation Algorithm and Generation of Correction Factors for Independent Monitor Units Hand Calculations in Clinic

A Skinner^{1*}, S Sour², J Baker³, E Sudentas⁴, G Gill⁵, (1) , Hempstead, NY, (2) NewYork-Presbyterian, Great Neck, NY, (3) Northwell Health and Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Lake Success, New York, (4) Mount Sinai West, New York, NY, (5) New York Presbyterian-Queens, Flushing, NY

Purpose: The purpose of this study is to thoroughly validate electron Monte-Carlo (eMC) calculation algorithm from simple to complex custom-made phantoms that simulates real clinical cases and generate correction factors for independent hand calculations. **Methods:** For five TrueBeam accelerators, beam modeling was performed for seven electron energies (6, 9, 12, 15, 18, 20, and 22 MeV) utilizing Eclipse treatment planning system. First part of the study validated the eMC dose calculation algorithm in the planning system by following AAPM Medical Physics Practice Guidelines (MPPG) 5.a. tests 8.1, 8.2, and 8.3. The data collection includes point measurements with ion chamber and profile checks with ion chamber array. To test eMC calculation accuracy for challenging geometries, such as obliquity, irregular surface and heterogeneity corrections, various tests were set up to simulate real clinical scenarios utilizing homemade phantoms. The collected data for each scenario for these cases was compared with water tank measurements. Three correction factors were calculated, gantry obliquity factor (GOF), irregular surface factor (ISF), and heterogeneity correction factor (HCF) respectively. These factors were plugged in our MU hand calculation and compared with TPS MUs. **Results:** : The results showed a good agreement between ion chamber measurements and Eclipse eMC calculations. The point measurements of all MPPG 5.a. tests were under 5%, and profiles and PDDs were 97±2% (3% dose difference and 3mm DTA tolerance) for all electron energies. Three correction factors calculated as gantry obliquity (GOF, range 0.89-0.99), irregular surface (ISF, range 0.89-.95), and heterogeneity correction factor (HCF, range 0.88-0.97 respectively. After plugging these correction factors, an adequate agreement was found (<5%) for all clinical cases. **Conclusion:** Our methodology provides a unique method to compare the hand calculation MUs with planning system. Treatment planning system with eMC model accuracy calculates the dose for complex cases with obliquity, irregularity and heterogeneity involved.

PO-GePV-T-47

A Monte Carlo Study of Patient Dose Distributions Between Stanford Six-Field and Rotational Techniques in Total Skin Electron Therapy

G Ding^{1*}, Z Chen², W Zhong³, T Zhu³, (1) Vanderbilt University, Nashville, TN, (2) Yale University School of Medicine, New Haven, CT, (3) University of Pennsylvania, Philadelphia, PA

Purpose: Total skin electron therapy (TSET) has proven to be one of the most effective treatments for advanced-stage cutaneous T-cell lymphoma. Many techniques have been developed to deliver a uniform dose to skin. Two most used techniques are the Stanford six-field and rotational techniques. This study compares patient skin dose distributions as function of depth between these two techniques. **Methods:** The Monte Carlo code BEAM/DOSXYZnrc was used to simulate a 6 MeV HDTSe beam from a Varian Linac. The simulated beams were benchmarked and validated against experiments. The simulated dual-field beams passed a 3 mm thick of Acrylic scattering plate of 50 cm x 200 cm before incident on the patient at extended distance. The dual-field beams were then used to calculate the patient dose distributions on a CT-based patient images. The calculations assumed the same patient standing on a platform and the patient's different postures were ignored for the Stanford six-field technique in the dose calculation for direct comparison of the two techniques. The resultant patient doses were analyzed as a function of skin depth-dose coverage and evaluated using dose-volume-histograms (DVH). **Results:** Although small dose differences were observed in some local areas, no clinically significant differences were found in the patient 3D dose distributions between the Stanford six-field and rotational techniques. When dose coverage DVH curves were compared, they are visually the same between these two irradiation techniques for mean dose to skin depth of 0-5 mm, 5-10 mm and 10-15 mm from the skin surface, respectively. **Conclusion:** Both the Stanford six-field and rotational techniques provide similar dose distributions to patient skin with only small differences in some local areas. The comparison did not consider different patient postures in the Stanford technique, which could affect the comparison of the doses to the limbs.

PO-GePV-T-48

A Clinical Workflow for Creating 3D Printed Bolus with Isocenter and Orientation Labels for Placement

L KUO^{*}, S Hellman, M Trager, C Huang, M Aristophanous, C Barker, G Li, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: To facilitate the clinical use of 3D printed bolus (3DPB) with accurate placement during setup based on projected isocenter and bolus orientation and with a new clinical workflow to allow a coherent link between radiotherapy planners, machine-shop engineers, and therapists. **Methods:** An Eclipse plugin program to export 3DP_Bolus.stl file with 3DPB structure and ISO-points.txt file containing 3 key-point coordinates, including the projected isocenter and two points that are 1cm away from the isocenter in the X1 and Y2 directions (Varian jaw definition) to the external surface of the 3DPB. A special ARIA carepath with patient treatment information and bolus labeling instruction was created to pass the 3DPB task from planners, to machine-shop, and to therapists. Based on the ISO-points.txt file, three 2mm-diameter hemispheres were created and merged with the 3DPB-bolus.stl file before printing. Machine-shop staff labeled it with a crosshair at the isocenter, writing 4 orientation labels and patient ID, and shipping it to a specified treatment room. 3DPB was placed after the initial patient setup by aligning the room lasers with the crosshair. Seven patients were used in this clinical 3DPB test, including 4 breast electronic-boost, 2 nasal, and 1 extremity cases. **Results:** The 3DPB labeling is accurate for 7 patients' cases by visually checking the isocenter locations and bolus orientation against the plans. Bolus placement with laser alignment is taken seconds and taped down to secure its position. It provides a conformal shape to the skin without distorting the local anatomy. The new clinical workflow ensures necessary handshakes between clinical staff. **Conclusion:** This study has demonstrated that

the new tool for printing and labeling 3DPB is accurate, facilitating bolus placement and that the new clinical workflow helps to ensure a reliable custom bolus production for treatment. This procedure is ready to be implemented in our hospitals.

PO-GePV-T-49

Quality Assurance and Acceptance of Eyeshields for Use in Electron Radiotherapy

H Kadji^{1*}, B Lewis^{1, 2}, R Teboh Forbang^{1, 2}, (1) Hackensack Meridian Health at Mountainside Medical Center, Montclair, NJ, (2) Hackensack Meridian Health at Hackensack University Medical Center, Hackensack, NJ

Purpose: Eyeshields offer protection to the organs underneath by virtue of the beam energy attenuation through the materials. This is especially important for radiotherapy of the eyelid with a need to protect the cornea and lens. An important specification from the manufacturer is the transmission. As a quality assurance (QA) measure and part of acceptance, this needs to be confirmed onsite. We describe our clinical filmless approach for a quick evaluation of the eyeshield prior to use on patients. **Methods:** Our work was based on the Tungsten eyeshield (RPD Inc., Albertville, TN) which comes in 2 thicknesses, 2mm/3mm and 5 sizes. We used the 3mm, S-size with a 0.5 and 1mm Al caps. In the first method, we used an IC profiler to determine the transmission with and without the Al caps. The RPD transmission is specified at a depth of 3mm. The IC profiler has an inherent depth of 9mm; therefore, we used several additional water slabs to measure transmission at several depths and by linear extrapolation determined the transmission at 3mm. In the second method, we used Exradin1DH 97241 diode, inherent effective depth of 0.8mm, with additional slab on the diode to measure transmission at 3mm depth. **Results:** The RPD specified transmission at 3mm, 9MeV beam was 3.3%, 2.9%, and 2.8% for the eyeshield with no cap, 0.5mm Al cap and 1mm Al cap respectively. The corresponding IC profiler values (inherent depth of 9mm) were 10.9%, 11.3%, and 11.9%. However, after applying the linear extrapolation to 3mm depth, the corresponding transmission were 1.0%, 1.3%, and 2.1%. The corresponding measured transmission using Exradin1DH were 3.2%, 3.1%, and 3.3%. **Conclusion:** We have described a simple technique of acceptance and QA of an eyeshield prior to patient use. This was done for a 9MeV energy but can be repeated for 6MeV.

PO-GePV-T-50

A Practical Approach for Commissioning a Total Skin Electron Treatment Program

I Alecu^{1*}, T Martin², D Saenz¹, P Myers¹, K Rasmussen¹, S Stathakis¹, N Papanikolaou¹, N Kirby¹, (1) UT Health San Antonio MD Anderson Cancer Center, San Antonio, TX, (2) Comprehensive Cancer Center of Nevada, Henderson, NV

Purpose: To efficiently commission and clinically implement a program for total skin electron (TSE) treatments using an affordable surrogate phantom and dual-field angle optimization jig designed from readily available materials and optically stimulated luminescent dosimeters (OSLDs). **Methods:** The TSE treatment modality for the modified Stanford technique was commissioned for a Varian Novalis Tx linear accelerator. This dual-field technique relies on the delivery of two equal exposures, one from each of the two angled components of the dual field, to improve dose uniformity over areas large enough to be representative of typical patient size. The optimal value for the angle between the two angled fields was experimentally determined from OSLD measurements made at 30 cm intervals along the vertical profile of a simple jig constructed using solid water slabs affixed to a supporting foam board. A TG-51 calibration was completed and then extended SSD and B-factor values were characterized and validated via an end-to-end test. Measurements made with a parallel plate ion chamber were used to determine the TSE beam quality and the inverse square factor at extended SSD. The setup for the determination of the B-factor involved the placement of 18 OSLDs on two 6-gallon buckets filled with water and stacked on top of each other, meant to approximate a patient's head and torso, respectively. The OSLDs were placed at different heights – meant to represent the abdomen, chest, and head positions. **Results:** Optimal gantry angles of 70.5° and 109.5° were established for the Stanford dual-field technique using the angle optimization jig. A value of 3.06 was established for the B-factor using the practical surrogate phantom, which is within the recommended range of 2.5 – 3.1 specified in TG-30. **Conclusion:** The TSE modality was efficiently commissioned using the surrogate phantom and angle optimization jig constructed from inexpensive, readily available materials.

PO-GePV-T-51

Development and Validation of ESAPI Script Based Electron Cutout Digitizer

T Chen^{*}, H Wang, J Teruel, D Barbee, New York University, New York, NY

Purpose: To develop an Eclipse script based digitizer for electron cutout using photos of plastic plate templates with cutout outlines, and evaluate the accuracy of the method using simulated images. **Methods:** Executable script was developed and tested with Eclipse Scripting API (ESAPI). Multiple testing cases were generated on transparent plastic plate templates of all available sizes. Experimental outlines of cutouts were contoured on the plates, and photos were taken with the camera central axis pointing to the plate at a relatively vertical angle and at least 50cm away from the surface of the plate. The images were stored electronically in .jpg format with standard pixel size and default compression settings. The testing photos were read by the script and displayed in a Graphical User Interface (GUI). The four corners of the template were manually picked to establish a projective transformation mapping the pixels in the photo to the corresponding positions in the Beam Eye View (BEV) of electron beams. The cutout contours were then semi-manually (automatically if the photo was taken with white background) digitized in the 2D domain of BEVs for the generation of electron cutouts. **Results:** 10 testing photos have been generated and digitized to generate electron cutouts importable to treatment plans in Eclipse. The projective transformations have been successfully established for all testing photos. Cutout outlines were digitized with acceptable accuracy (max difference <2mm) for testing cases. **Conclusion:** The script-based digitization provided a free and reliable alternative solution for the generation of electron cutout from plastic templates. The accuracy of the method has been verified on limited set of testing cases. For following work, the script will be revised to make the digitization process more automated, and clinically used electron cutouts with more complicated shapes will be re-digitized to further validate the accuracy of the method.

PO-GePV-T-52

Comparison of Electron Beam Characteristics According to Applicator Type in Small Field

S Han^{*}, M Park, J Kim, M Han, D Kim, C Hong, H Kim, J Kim, K Park, Yonsei Cancer Center, Seoul, 41KR

Purpose: This study focused on comparison of electron beam characteristics according to applicator type in small field. **Methods:** Measurement were carried out in small field (2,3,4,5 cm) of 6 MeV electron beam of Elekta Infinity Linear accelerators. The two type of applicator were general applicator with circular Cerrobend block and stainless steel of tubular applicator by applied vendor(Elekta).The beam characteristics of electron were as follows that beam quality (R_{50}) from PDD curve depending on SSD (95,100,105 cm), output factor(SSD 100, ref. field :10 cm x 10 cm) and beam profile. All data were measured by micro diamond detector Type 60019 (PTW Freiburg, Germany) in 3D water phantom (BeamScan, PTW Freiburg, Germany).The gamma evaluation(2% DD/ 2 mm DTA) was used to compare beam profile in two type applicators. **Results:** The beam quality($R_{50,mm}$) of circular Cerrobend block were 23.58 ± 0.27 (2 cm), 25.03 ± 0.10 (3 cm), 25.39 ± 0.24 (4 cm), 25.35 ± 0.07 (5 cm). Those of stainless steel of tubular applicator were 23.13 ± 0.10 (2 cm), 25.03 ± 0.16 (3 cm), 25.36 ± 0.10 (4 cm), 25.44 ± 0.18 (5 cm). Output factor of circular Cerrobend block were 0.685 (2 cm), 0.789 (3 cm), 0.843 (4 cm) and 0.867 (5 cm). Those of stainless steel of tubular applicator were 0.452 (2 cm), 0.650 (3 cm), 0.763 (4 cm) and 0.791 (5 cm). The results of comparison on beam profile using gamma analysis were passed (100%) in all field size. **Conclusion:** The beam characteristics of two applicator types were compared in 6 MeV small field. Beam quality was overall similar, and the beam profile was consistent within 2% /2 mm. On the other hand, Output factor could confirm that the circular Cerrobend block

applicator was larger than the stainless steel of tubular applicator

PO-GePV-T-53

A Comparative Study of Different Collimation Methods for Quantification of Required Skin Margin During Electron Treatment

N Shrestha^{1*}, M Brenner², G Narayanasamy¹, S Morrill¹, Z Su¹, G Lewis¹, F Kalantari¹, (1) Department of Radiation Oncology, University of Arkansas for Medical Sciences, Little Rock, AR, (2) Department of Radiation Oncology, Mercy Health System, Rockford, IL

Purpose: To quantify and compare the effectiveness of electron treatment with cutout and skin blocks for high and low energy electrons in terms of required physical margin and dose uniformity. **Methods:** Monte Carlo simulations were performed in a cube water tank phantom (30 cm sides). RayStation 8A, modeling electrons in Elekta Versa HD and Eclipse v 15.5, modelling electrons in Varian Truebeam STx were used for dose calculation. Each TPS performed 12 different simulations including three different circular cutouts of 3 cm, 5 cm and 7 cm in diameter and their equivalent skin blocks for two different electron energies of 6 MeV and 15 MeV. For all setups, an SSD of 100 cm and a 10 cm x 10 cm cone was used. Doses were calculated by delivering predefined 100 MUs for each setup and uncertainty of 0.5%. Dose was prescribed to 2 cm for 6 MeV and to 4 cm for 15 MeV electrons. The calculated isodose distributions were compared based on the physical margin required for each method, and dose uniformity within the prescribed isodoseline. **Results:** Both TPS systems produced comparable dose distributions for all 12 setups. Our results showed that a margin of 5 mm on the skin surface provide enough coverage at 50% of prescribed dose for both 6 MeV and 15 MeV electrons. Larger margins should be used for treatment of deeper targets. **Conclusion:** Although skin collimators can reduce the required margin on the skin level, no significant difference was observed for treating deep lesions. Electron cutouts still provides sufficient dose coverage laterally to the targets. Smaller cutouts and lower energy electrons may use an additional 1 mm margin as compared to higher energies and larger cutouts. Skin collimator creates hot spots that are more pronounced for high energy electrons and smaller diameters.

PO-GePV-T-54

Dosimetric Effects of a Commercial Breast Board Patient Support System

D Pearson¹, E Schodowski^{2*}, A Wilkinson³, (1) University of Toledo, Toledo, OH, (2) University of Toledo, University of Toledo, Toledo, OH

Purpose: In prone breast treatments a carbon fiber support device resides under the contralateral breast. Tangent beams are designed to encompass the treated breast and these often pass through the board at a shallow angle, resulting in significant attenuation. Our planners account for this attenuation by added field-in-field dose to the deep part of the breast, through the board. Concern was raised about how accurate the treatment delivery is when the inherent uncertainties of patient position are accounted for. Further, transmission measurements are usually carried out perpendicular to the board; a non-clinical situation. The goal of this study is to evaluate the dosimetric effect of board and the robustness of the plan to positional uncertainty. **Methods:** Twenty two breast patients treated on a commercial prone breast board between 2017 and 2020 were selected for this retrospective study. To evaluate the board's attenuation we compared the plans with the board removed from the dose calculation. To quantify the robustness of this technique we moved the beam isocenter wrt the patient and board. **Results:** When the breast board is removed from a plan which was designed to account for the board attenuation, the average point dose increases by 7.48%, with a maximum of 22%. Comparing results with a mixed ANOVA and least square means analysis, our robustness evaluation indicates that anterior shifts at every magnitude (1mm through 5mm) make a significant difference in all dose statistics (D95, max, 95% prescription coverage and homogeneity index) investigated. Right/left shifts resulted in an insignificant change in dose statistics. **Conclusion:** Prone breast boards can add significant dosimetric uncertainties into the treatment delivery process. Accounting for plan robustness in the design of the plan is highly recommended. Prone breast board design, with supports moved away from the beam-path, is warranted.

PO-GePV-T-55

Initial Characterization and Validation of a Commercial Head and Neck Immobilization System for MR-Guided Radiotherapy

J McCulloch^{1,2*}, A Gutierrez^{1,2}, T Romaguera^{1,2}, D Alvarez^{1,2}, K Mittauer^{1,2}, (1) Miami Cancer Institute, Baptist Health South Florida, Miami, FL, (2) Florida International University, Herbert Wertheim College of Medicine, Miami, FL

Purpose: Head-and-neck (H&N) cancers are challenging to treat with non-coil bridge MR-guided radiotherapy (MRgRT) linacs due to non-integration/compatibility of the receiver coils into common radiotherapy H&N immobilization systems. We developed, characterized, and clinically implemented the first commercial H&N immobilization system for a non-coil bridge MRgRT linac. **Methods:** The H&N immobilization system includes an indexable custom baseplate that affixes to a head cradle, an open-face thermoplastic mask, and head-mold cushion. The baseplate is composed of clear acrylic and white Delrin and is constructed as the negative imprint of the H&N receiver coil. We quantified the baseplate's radiographic integrity, dosimetric attenuation, dosimetric impact of daily IGRT localization positioning shifts relative to the baseplate, and image quality effects due to its presence in a 0.35T magnetic field. **Results:** Mean baseplate CT # was -54.7±212.5 HU. For a single posterior beam, attenuation measured was 4.1% versus TPS calculated of 2.8%--difference of 1.3%. For a 13-field IMRT plan delivered to a 3D-IMRT QA array positioned anterior to the baseplate, the 3D gamma 3%/2mm passing rate was 98.8%. The dosimetric impact of IGRT localization was negligible (<0.1%) for couch shifts of 1, 2, 5, 10, and 50mm in AP/LR/CC directions as measured by shifting the baseplate ROI and comparing 3D gamma 3%/2mm passing rate between shifted and non-shifted calculated dose distributions. Image quality metrics in presence of baseplate and without baseplate (n=6 months) was 0.95 versus 0.89 (max geometric fidelity diameter 350mm, p=0.05), 37.5 versus 35.9 (SNR, p=0.35), 224 versus 435 (uniformity diameter 300mm, p<0.01), 2.12 versus 1.91 (high-contrast spatial resolution FWHM PSF, p=0.01), respectively. **Conclusion:** The H&N immobilization system presented here provides a clinically viable immobilization solution for H&N patients on an MRgRT linac. The immobilization system does not appear to induce significant dosimetric perturbations and does not significantly impact the MR image quality.

Dr. Mittauer reports personal fees from ViewRay Inc, other from MR Guidance LLC, grants from ViewRay Inc.

PO-GePV-T-56

Accuracy and Precision of Surface Tracking on Bra-Fitted Breast Radiation Treatment

T Lin*, C Ma, Fox Chase Cancer Center, Philadelphia, PA

Purpose: Radiotherapy for patients with large and pendulous breasts is often associated with higher lung and heart doses. One way to localize the pendulous breast away from the chest wall is to lift it into a tightly fitted bra. Surface detection-based localization is often utilized for real-time tracking for breast radiotherapy to ensure accurate treatment delivery. However, the breast and adjacent surface topography is manipulated by way of fitting the bra for large breast patients. This study is to investigate the accuracy and precision of Chabner XRT (CiVCO, Orange city, IA, USA) bra with AlignRT® (Vision RT, London, UK) surface tracking. **Methods:** From 12/2020-2/2021, 58 breast patients received radiation treatment with surface tracking. Nineteen patients were treated with Chabner XRT bra and localized with AlignRT®. MV verification films were taken daily to compare with VisionRT surface tracking deltas in the patient SI, AP and LR directions. **Results:** About 30% of breast patients utilized Chabner XRT bra during their radiation treatment in our institution. 85% (16 out of 19) of these bra-fitted patients showed good surface tracking (within 1mm in all 3 directions) with AlignRT®. However, for smaller breast depths (differences between upper chest and bust circumferences, e.g., C cup) together with a relatively larger lower chest band (e.g. 40 inches), the breast tissue of

these patients (3 out of 19) tends to be equally distributed to their entire breast in the treatment position, resulting in a lower bra precision to reflect the breast surface. The bra surface could mislead the surface tracking. Because of this, these three patients required daily film verification. **Conclusion:** Bra with surface tracking is accurate and precise for normal breast sizes. When the patient has a small breast depth and larger lower chest band circumference, surface tracking could be compromised.

PO-GePV-T-57

Clinical Implementation of An Abdominal Compression Belt on a Double Scattering Proton Machine

X Wang^{1*}, Y Zhang¹, J Zhu¹, K Qing², K Nie¹, T Cui¹, N Yue¹, B Liu¹, (1) Rutgers-Cancer Institute of New Jersey, Rutgers-Robert Wood Johnson Medical School, New Brunswick, NJ, (2) City of Hope National Medical Center, Duarte, CA

Purpose: To evaluate the dosimetric effects of the Qfix SBRT Abdominal Compression Belt in proton radiotherapy and to validate its water equivalent thickness (WET) modelled by the Varian Eclipse treatment planning system (TPS). **Methods:** Physical measurements of WET were performed using EBT3 film sandwiched between solid water slabs wrapped around by the compression belt in a way as it would be used clinically. A CT scan was acquired with the same setup for TPS WET calculation. The percent depth dose (PDD) was measured by delivering proton beam with range of 12cm on a Mevion S250 proton machine through a slit, so that the film was parallel to the beam direction and perpendicular to the long side of slit. Different parts of the belt were put in the beam path for each measurement. The relative range shift due to the presence of device was evaluated and compared to the WET modeled in the TPS. **Results:** The relative range shift measured by film showed that the belt and velcro had almost 0mm WET, which is consistent with the reading of 0.1mm for belt only and 0.6mm for belt with velcro in TPS. The WETs of the paddle center and 5cm superior/inferior to the paddle center were estimated to be 4mm and 7.5mm on the film measurement, respectively, comparable to 5.3mm and 8mm, respectively, from TPS. The differences between TPS and measurements were within 1.5mm. The buckle of the belt showed high WET in TPS, with 10.5mm WET. **Conclusion:** The TPS model of the compression system agrees well with measurement results, proving feasibility to use abdominal compression belt in proton therapy, provided that the system is included in dose calculation in TPS. The buckle should be avoided in the beam path due to its high WET and poor reproducibility in patient daily setup.

PO-GePV-T-58

Comparison of Three Cushion Types for Gamma Knife Icon Mask Treatment

D Luo*, T Briere, E Han, M McAleer, UT MD Anderson Cancer Center, Houston, TX

Purpose: For mask treatment on Gamma Knife Icon, our clinic uses Moldcare cushion (QFix, Avondale, PA, USA) to mold underneath the patient's head and upper neck for comfort and reproducibility inside the mask adaptor before a thermoplastic mask is molded around their face for immobilization. In order to treat an anterior lesion, the mold is made very thin to avoid collision. Occasionally the lesion is so anterior that, instead of the moldable cushion, a 3-mm bolus, as readily available in all radiation oncology department, or a grip shelf liner, a common consumer product, may be used to further reduce the distance between the skull and the mask adaptor. This study investigates the relative dosimetric effect from the two non-conventional material compared to the Moldcare cushion. **Methods:** Two plans were delivered to an anthropomorphic head phantom with an ionization chamber inside. Plan-A had one shot of all 8 sectors of 16-mm collimation centered at the ion chamber. Plan-B has 3 posterior sectors at 16-mm and the rest at Block position. The phantom was placed inside Moldcare, or on top of the 3-mm bolus, or the grip shelf liner. **Results:** Compared to Moldcare, both plans delivers > 1% less dose when the phantom is on top of the 3-mm bolus. One layer of liner received the same dose as the Moldcare from Plan-A, but 0.8% more dose from Plan-B. The 3-layer liner configuration received the same dose as the Moldcare from Plan-B. **Conclusion:** The 3-mm bolus, while more accessible and easy to use, has more than 1% dose difference from the standard of care. The grip shelf liner is very easy to use and has less attenuation than the Moldcare. While all measured dose are lower than the planned dose, the dose from the liner is the closest to planned.

PO-GePV-T-59

Risk Mitigation Strategies for Custom Software in the Clinic

R Cardan*, E Covington, R Popple, UAB University of Alabama, Birmingham, Birmingham, AL

Purpose: One of the evolving roles of MedPhys 3.0 practice encompasses in-house software development and software development oversight. While in-house clinical software development is not new in medical physics, its widespread adoption and available vendor-provided tools are growing rapidly. Many physicists who are untrained in the best practices of software development have begun creating scripts for clinical use. There is an increasing need on guidance for both developers and medical physicists to code wisely in the clinic. **Methods:** We surveyed both medical physics and non-medical physics literature and regulatory documents for guidance which could be applicable for custom clinical software. We then began practicing these techniques internally for clinical software development. The review was integrated with our institutional experience to form a practical guide to educate medical physicists in software best practices and to begin implementing these techniques in the clinic. **Results:** We found little literature for custom software development guidelines targeted at medical physicists. However, we found several risk mitigation techniques including unit testing, code review, source control, end user testing, and commissioning from non-medical physics literature and created institutional guidelines for evaluating software for risk and implementing these strategies. The mitigation technique requirements were stratified by risk level of the software: low risk, moderate risk and high risk. **Conclusion:** Our findings indicate there is a lack of guidance for developing in-house software for medical physicists. We integrated a literature review and institutional experience to form guidelines to help facilitate a safe software development practice for the next generation of medical physicists.

PO-GePV-T-60

Creation of a Database to Utilize Patient Outcomes for Radiation Plan Improvement

B Morris*, B Walker, A Beggs, B Rumenapp, V Coffman, S Petro, K Lai, S Hedrick, Provision Cares Proton Therapy Center, Knoxville, TN

Purpose: To deliver truly personalized cancer care, we need to bridge the gap between patients and clinical decision-makers. During the treatment of a patient, there are countless decisions made by physicians, physicists, and dosimetrists that impact the plan and delivery of therapy. Clinicians record treatment outcome information obtained during interactions with patients, but often there is no integrated way to systematically monitor and fully utilize this data. Our initiative strives to create an environment in which patient outcome information is automatically pulled into a global database in real-time, for immediate evaluation of the treatment plan delivery and its impact. By analyzing and trending this data, it will be possible to directly correlate a multitude of planning techniques and parameters with outcomes and recognize areas that have potential for improvement. **Methods:** Patient on-treatment and follow-up information, including side effects and quality of life assessment, is exported from the EMR, then automatically imported into a patient database via in-house scripting. This outcome data is coupled with treatment planning data, such as beam dose, spot distribution, etc. that has been exported directly from the TPS. The data can then be analyzed for trends and correlations between planning parameters and patient outcome information. **Results:** Patient outcome information is readily available to physicians, physicists, and dosimetrists in a format that can be used to evaluate and improve therapy delivery for individual patients, as well as planning techniques for the entire patient population. **Conclusion:** This initiative has provided a useful tool for optimizing planning techniques, based on real-time analysis of patient outcome information. Future directions for the work involve inclusion of a more comprehensive set of patient complication, recurrence, and survival information, as well as the integration of analysis techniques and tools including machine learning to further illuminate correlations between plan

parameters and their therapeutic impact.

PO-GePV-T-61

Recommendations for a Medical Physics Pre-Simulation Breath Hold Consultation: Medical Physics 3.0 in Practice

E Cichewicz*, C Windsor, J Seekamp, D Pearson, University of Toledo, Toledo, OH

Purpose: To take initiative within the clinic by preparing and delivering patient education materials regarding breath hold treatments prior to simulation. **Methods:** Several PowerPoint presentations were prepared to educate breath hold patients prior to simulation. These presentations were designed to be relevant to L Breast, general DIBH, and general EEBH patients. These presentations take less than 10 minutes to deliver. Several key pieces of information are communicated to the patient. First, we explain that this process is important for reproducible positioning during treatment. We next explain that they will be asked to hold their breath during some of the images taken at simulation and during each treatment. To alleviate patient concern, it is important to communicate that a breath hold of roughly 15 seconds will be beneficial, and that patients will have time to catch their breath. Shifting focus to the start of treatment, we emphasize that the treatment machine will automatically turn off when the patient stops holding their breath, and patients will have time to catch their breath. Usually, around 2.5 minutes of total breath hold time is sufficient to complete an entire treatment. **Results:** In general, patients are receptive to this education. By educating the patients in a consultation room, there are no other distractions or demands of the patient; they can focus on the instructions. Physicians have noted that simulations take less time when the MP has consulted the patient. Patients are generally more comfortable and confident when educated about breath hold treatments. As a cautionary note, patients almost always ask about potential side effects. **Conclusion:** Patient education prior to breath hold simulations/treatments is an excellent opportunity for medical physicists to ensure that patient care is effective and efficient.

PO-GePV-T-62

Comparison Between Two Treatment Planning Systems On IMRT Planning: UIH Versus Monaco

Y Yang*, Y Fang, J Wang, J Zhao, W Hu, Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, China Department of Oncology, Shanghai Medical College

Purpose: To investigate the performances of IMRT plans on various cancers between two commercial treatment planning systems (TPS): UIH and Monaco, and evaluate the feasibility of develop photon beams calculation model of Elekta infinity linear accelerators (LINACs) with UIH TPS. **Methods:** Twenty patients, include nasopharynx, breast, lung and rectal cancer were enrolled in this study. Two IMRT plans were generated using both UIH and Monaco TPS for each patient. The direction, number and energy of beams were the same in the plans from both systems for each treatment site. Same clinical objectives were provided for each plan. The TPS were compared in terms of homogeneity and conformity, mean and maximum doses about PTV or relevant organs-at-risk (OARs). **Results:** For the nasopharynx cancer, homogeneity and conformity were comparable for both TPSs. UIH provided a significantly lower maximum and mean dose for OARs, particularly the Optic nerve (-19.2%), chiasm (-12.02%) and parotid (-4.8%), but the spinal cord (5.98%) and larynx (6.01%) were higher. For the breast cancer, UIH had a better conformity and lower maximum dose (-3.21%) in PTV, while the mean dose in lung (6.87%) and heart (8.5 cGy) were higher. For the lung cancer, UIH plans had a lower mean dose of lung (-3.29%), however the maximum dose of spinal cord (1.72%) was larger. There was no significant difference between two TPSs for rectal cancer. Meanwhile, Monaco require longer optimization time and more monitor units. **Conclusion:** For various cancers, a comparable quality IMRT plans was found for both TPSs. Further, comparisons between measurements and calculations for two TPS should be done in absolute dose terms.

PO-GePV-T-63

Skin Toxicity Assessment Using Optical-Wavelength Video Processing

R Culcasi^{1,2*}, M Snyder¹, (1) Beaumont Hospital, Royal Oak, MI, (2) Wayne State University, Detroit, MI

Purpose: To evaluate skin toxicity through daily changes in blood flow to the skin from optical-wavelength video processing. **Methods:** A conventional digital camera was used to record daily videos for two weeks of skin damage caused by an incidental sunburn in an investigator self-monitoring feasibility study. The camera and investigator's leg were positioned reproducibly to maintain imaging conditions. A fingertip pulse oximeter was utilized to provide a ground-truth heart rate. Videos were post-processed to identify cardiac signals using a binned pixel technique. For each frame, the original videos were down-blurred and progressively resampled to obtain a final 1D signal with improved signal-to-noise ratio (SNR). Heart rate was then identified by Fourier transforming this signal. The original 1920x1080 pixels video was downsampled to a coarse grid of 4x4 pixels for increased SNR. Each bin was Fourier transformed, and the frequency component amplitude corresponding to heartrate was presented in a false color image power map. Variations in the amplitudes of these power maps were evaluated. **Results:** Subtle oscillations of skin tone during the cardiac cycle were able to be extracted from 10-second videos. The technique evaluated changes in the magnitude observed in binned regions of the power map for both undamaged and damaged skin, theoretically representing differences in blood moving into and out of areas of the skin. Regions of higher magnitude in the power map were correlated with skin damage. The first day, the average measure of amplitude was 37.6% higher in the damaged skin, whereas at the end of the two weeks it was only 8.6% higher. **Conclusion:** This feasibility study evaluated this novel signal processing method's capability to track changes in power map magnitude over time. These power map changes should be correlated with blood flow and may be usable as prognostic indicators for skin toxicity during radiotherapy.

PO-GePV-T-64

Impact on Patient Reported Quality of Life From Reducing Prostate Margins in Patients Who Underwent Radiotherapy: A Prospective Clinical Trial

A Kumarasiri*, S Brown, M Elshaikh, I Chetty, B Movsas, Henry Ford Health System, Detroit, MI

Purpose: To investigate the impact of reducing planning target volume (PTV) margins on patient reported quality-of-life (QOL) for patients with localized prostate cancer after radiation therapy (RT). **Methods:** A cohort of 20 patients were included in a single institution IRB-approved prospective study, out of which 9 were planned with reduced margins (5 mm uniformly except 4 mm at prostate/rectum boundary), while 11 were control patients with standard margins (10/6 mm). At time points pre-treatment, post-treatment, and at 2, 6, 12, 18, 24, 36, 48, and 60 months follow-ups, EPIC-26 based patient reported QOL data was collected. Validated EPIC-26 methodology was used to baseline correct and standardize all post-RT QOL scores to five separate EPIC QOL domains on a [0-100] scale. Correlations between QOL scores and dosimetric parameters were investigated, and the overall QOL differences between the two groups (QOL(M-R)-QOL(control)) were calculated for each time point. **Results:** Age, Gleason score, and PSA level differences between the two groups were statistically insignificant ($p>0.2$). Median QOL follow-up length for the 20 patients was 48 months at the time of reporting. At 48 months post-RT, standardized and baseline-corrected mean QOL(M-R)-QOL(control) were improved for "Urinary Incontinence", "Urinary Irritative/Obstructive", "Bowel", and "Sexual" EPIC domains by 3.5, 14.8, 10.2, and 16.1, respectively. QOL differences between groups were clinically significant for the last 3 domains, while statistically significant for only "Urinary Irritative/Obstructive" domain ($p=0.03$). PTV/rectum ($p=0.03$) and PTV/bladder ($p=0.14$) intersection volumes were larger for the control group (7.2 ± 5.8 , 18.2 ± 8.1 cc) compared with the margin-reduced group (2.6 ± 1.8 , 12.5 ± 8.3 cc), while the dose to these intersection volumes did not reach statistical significance ($p>0.1$) between the groups. PTV/rectum intersection volume showed a moderate correlation ($R=-0.6$, $p=0.01$) to "Bowel" EPIC domain. **Conclusion:** Margin-reduced group exhibits clinically meaningful improvement in Urinary, Bowel, and Sexual QOL domains. More patients are needed to draw unequivocal conclusions.

PO-GePV-T-65

NTCP Modeling of Patient Reported Dysphagia Using the EAT10 Scoring System 12 Months After Radiotherapy for Oropharyngeal Cancer

B Chera¹, A Tzikas^{2*}, E Lavdas², R Amdur³, W Mendenhall³, N Sheets¹, R Green¹, L Marks¹, S Das¹, P Mavroidis¹, (1) UNC at Chapel Hill, Morrisville, NC, (2) University of West Attica, Department Of Biomedical Sciences, Athens, Greece, (3) University of Florida Hospitals, Gainesville, FL

Purpose: To determine the values of two normal tissue complication probability (NTCP) models for pharyngeal constrictors regarding the endpoint of patient reported severity of dysphagia based on the EAT10 scoring system 12 months after radiotherapy for oropharynx cancer. Additionally, to identify risk thresholds. **Methods:** 151 patients with HPV-associated oropharyngeal squamous cell carcinoma were treated with 60Gy IMRT. Dysphagia was assessed based on the EAT10 score as the top 5% percentile of net difference from baseline at 12 months post-RT. The DVHs of the superior (SPC) and combined pharyngeal constrictors were exported for each patient. The clinical data was fitted by the Lyman-Kutcher-Burman (LKB) and Relative Seriality (RS) NTCP models. **Results:** Dysphagia was observed in 5.3% of the patients. The values of the D50, m and n parameters of the LKB model were 69.1Gy, 0.11 and 1.0 for SPC and 65.4Gy, 0.10 and 0.22 for the combined constrictors. Similarly, the values of the D50, γ and s parameters of the RS model were 74.6Gy, 2.1 and 0.0001 for SPC and 65.6Gy, 6.7 and 1.0 for the combined constrictors. The AUC values of the correlations ranged between 0.75-0.77. Statistically significant Odds Ratios (ORs) of 5.5 (95%CI: 1.3-23.6) and 6.5 (1.5-28.3) were found for the SPC for the two NTCP models for a gEUD threshold of 58Gy. The respective ORs for the combined constrictors were 9.2 (1.5-57.5) and 11.6 (1.8-76.2) for the LKB and RS models for a gEUD threshold of 58Gy and 63Gy, respectively. **Conclusion:** The LKB and RS NTCP models could fit the clinical data and determine the dose-response curve of SPC and combined constrictors regarding dysphagia based on the EAT10 score at 12 months post-RT. gEUD < 58Gy to SPC or combined constrictors was found to significantly reduce by 5-12 times the risk for patient reported dysphagia.

PO-GePV-T-66

Investigating the Time and Organ Dependency of NTCP Modeling of Patient Reported Sticky Saliva After HPV Associated Oropharyngeal Cancer

B Chera¹, A Tzikas^{2*}, E Lavdas², R Amdur³, W Mendenhall³, N Sheets¹, R Green¹, L Marks¹, S Das¹, P Mavroidis¹, (1) University of North Carolina, Chapel Hill, NC, (2) University of West Attica, Department Of Biomedical Sciences, Athens, Greece, (3) University of Florida Hospitals, Gainesville, FL

Purpose: This study aims at analyzing the dependency of normal tissue complication probability (NTCP) modeling on follow-up time and organ dose regarding the endpoint of patient reported (PRO) sticky saliva after radiotherapy. **Methods:** A dose of 60Gy treated with IMRT was prescribed to 151 patients with HPV-associated oropharyngeal squamous cell carcinoma. Sticky saliva was assessed based on the PRO-CTCAE score and it was defined as a ≥ 2 point increase from baseline at 6, 12 and 24 months post-RT. The dose volume histograms (DVH) of the contralateral glands (parotid and submandibular glands combined), contralateral parotid and salivary glands (ipsilateral and contralateral parotid and submandibular glands combined) of each patient were exported. The dose and response data were fitted by the Lyman-Kutcher-Burman (LKB) and Relative Seriality (RS) NTCP models. **Results:** Sticky saliva was observed in 31%, 20% and 15% of the patients at 6, 12 and 24 months, respectively. The AUC values were highest (0.7) for the contralateral glands at 12mo post-RT. For the contralateral glands, the values of the D50, m and n parameters of the LKB model were 44.1Gy, 0.43 and 0.65, whereas the values of the D50, γ and s parameters of the RS model were 48.7Gy, 0.74 and 0.92 at 12mo post-RT. Statistically significant Odds Ratios (ORs) of 6.0 (1.3-28.6) and 7.8 (1.7-35.1) were found for the contralateral glands for biological doses (gEUD) < 43Gy and 45Gy for the LKB and RS models, respectively. **Conclusion:** The dose-response curves of PRO sticky saliva at 6, 12 and 24 months post-RT could be determined by the LKB and RS NTCP models for different combinations of salivary glands. Keeping the gEUD to the contralateral glands < 43Gy was found to significantly reduce by 6-8 times the risk for patient reported sticky saliva.

PO-GePV-T-67

NTCP Modeling and Dose-Volume Correlations of Significant Blood Count Drops 3 Months After Prostate Radiation Therapy

P Papanikolaou^{1*}, G Swanson², S Stathakis³, P Mavroidis⁴, (1) Long School of Medicine, UT Health San Antonio, San Antonio, TX, (2) Baylor Scott & White Health, Temple, TX, (3) UT Health San Antonio MD Anderson Cancer Center, San Antonio, Texas, (4) University of North Carolina, Chapel Hill, NC

Purpose: The aim of this study was to model the correlation of the dose to different parts of the pelvis with a significant drop in hematocrit 3 months after prostate cancer radiotherapy. **Methods:** 221 patients with complete treatment and follow-up data were included in this analysis. Patients received either 78Gy to primary prostate or 70Gy post-prostatectomy and 54Gy to the pelvic lymph nodes. All patients had complete blood counts (CBCs) collected at baseline (pre-RT) and 3 months post-RT. The net difference of each CBC metric post-RT vs. baseline was calculated and the level of the 15 percentiles defined the thresholds of response in each case. The doses to 8 different pelvic structures were derived and fitted 20 CBC metrics using the Relative Seriality (RS) NTCP model and the biologically equivalent uniform dose (BEUD). **Results:** The structure os coxae upper (above acetabulum) bilateral (OCUB) showed the highest correlation for a significant level of hematocrit drop. The values for the D50, γ and s parameters of the RS model were 26.9 Gy (25.9-27.9), 1.3 (1.2-2.2) and 0.12 (0.10-0.83), respectively. The AUC of BEUD was 0.73 and patients with BEUD to UCUB ≥ 27 Gy had 8.2 times higher rate of significant hematocrit drop vs. < 27Gy. The bone volume of the whole pelvis (BVWP) and the os coxae total bilateral (OCTB) also showed significant correlations for the same endpoint (AUC values of 0.72 and 0.69, respectively). In those cases, similar BEUD thresholds were found (27Gy and 28Gy, respectively) but with lower odds ratios (2.8 and 2.9, respectively). **Conclusion:** The dose-response curve of os coxae upper bilateral for a significant hematocrit drop could be determined by fitting the clinical data with the RS NTCP model. A threshold of BEUD < 27Gy was found to significantly reduce the risk for this endpoint.

PO-GePV-T-68

A Framework for Exploring the Correlation Between Radiation-Induced Toxicities and Dosimetric Quantities

A Abdel-Rehim^{*}, H Wan Chan Tseung, Mayo Clinic, Rochester, MN

Purpose: To develop a framework to automate the analysis of large cohorts of patients regarding the correlation of toxicities and patterns of failure with various dosimetric and geometric parameters. **Methods:** A software package has been built to process data from patients with radiation-induced toxicities or recurrence after proton and photon radiation therapy at our institution. The package is written in C++ and allows for flexibility in processing large cohorts of patients and exploring a large parameter space. It takes as input CT, RTPLAN, RTDOSE, REG and RTSTRUCT dicom files from the TPS, as well as Monte Carlo-generated LET and dose distributions. Correlation metrics include: DVH metrics, Dice Coefficient, Jaccard Index, Hausdorff and centroid distances and volume of overlap between the toxicity structure and iso-dose and iso-LET levels. Toxicity structures and recurrence volumes were contoured by physicians. **Results:** The software is used to analyze a cohort of brain patients. The metrics were computed within the TPS and compared with our calculated values to check for correctness. The code is found to be robust and can be used to analyze a large cohort of patients efficiently. For proton patients, it also facilitates the evaluation of biological dose models, allowing us to explore the relationship between their predictions with physician-contoured radiation-induced injury regions. **Conclusion:** Understanding the correlation between radiation-induced toxicities and dosimetric quantities within the framework of various biologic dose models is of great interest. As a first step, we built and tested an in-house framework for automating the calculation of relevant metrics for a large cohort of patients.

PO-GePV-T-69

4D Treatment Planning for Lung Proton Therapy: Treatment Design and Evaluation

V T Taasti*, D Hattu, F Vaassen, R Canters, M Velders, J Mannens, J van Loon, I Rinaldi, M Unipan, W van Elmpt, Department of Radiation Oncology (MAASTRO), GROW - School for Oncology, Maastricht University Medical Centre+, Maastricht, The Netherlands

Purpose: Intensity-modulated proton therapy for lung tumors with large tumor movement is challenging. Often a 5mm tumor movement cut-off is used for proton patient selection. We propose a robust and easily implementable treatment planning strategy for lung tumors with motion larger than 5mm, and a 4DCT robust evaluation strategy. **Methods:** We created an internal target volume (ITV) based treatment planning strategy. The plans were robustly optimized on the 4DCT-based average-CT. Clinical plan acceptability was judged on robust evaluation, computing voxel-wise minimum/maximum (VWmin/max) doses over 28 error-scenarios on the average-CT. Plans were calculated for sixteen lung patients with 4-26mm tumor motion in RayStation (RaySearch) with Monte Carlo dose-engine for a Mevion S250i Hyperscan system (Mevion Medical Systems). We developed a 4D robust evaluation (4DRobAvg). The 28 scenario-doses were computed on all eight 4DCT-phases. For each scenario, the doses on the individual phases were deformed to the reference phase (50%expiration) and combined to an average scenario-dose. From these 28 phase-averaged scenario-doses, VWmin/max were computed. The 4DRobAvg was compared to two other 4D evaluation strategies: re-computing nominal dose on each 4DCT-phase (4DNom), and computing robust VWmin/max doses on each phase (4DRobInd). **Results:** A clinically acceptable plan was feasible for all patients with adequate tumor coverage and no organs-at-risk over-dosage. The 4DNom and 4DRobInd evaluations under- or overestimated the dosimetric effect of tumor movement, respectively; 4DNom on average showed 1Gy higher target dose, and 4DRobInd showed target under-dosage for five patients, not observed in 4DRobAvg. The accuracy of dose deformation in 4DRobAvg was acceptable and dose differences were generally less than 1Gy. **Conclusion:** The proposed ITV-based planning strategy on the average-CT was found clinically feasible even for large tumor movement. The proposed 4D robust evaluation, 4DRobAvg, was shown to give an easily interpretable understanding of the effect of respiratory motion on the dose distribution.

This work was partly supported by Mevion Medical Systems.

Dose Enhancement Effects of High-Z Nanoparticles in Proton Therapy

K Duke, S Ahmad, A Lau, University of Oklahoma Health Sciences Center, Oklahoma City, OK

Purpose: To study using Monte Carlo simulation techniques the dose enhancement due to gold foils in energetic proton beam irradiation. The presence of high-Z nanoparticles has been recently studied for their ability to increase the number of secondary electrons thus enhancing dose to the target and shifting the Bragg peak location towards proximal depth. This Monte Carlo study compares the dose of a custom water phantom with gold foils to that of a control water phantom. **Methods:** Two water phantoms of 30cmx30cmx40cm were created using the Topas 3.6.1 toolkit. The control phantom consisted of pure water and the custom phantom consisted of a 0.4 mm wide gold foil in water. The location of the foil was in the proximal to distal 80% Bragg Peak width of a 226 MeV proton beam with spot size of 2.7 mm diameter. Dose was scored in 0.1 mm resolution. The dose enhancement factor (DEF) as well as the shift in the Bragg Peak were quantized. Modular physics list which include g4em-standard_opt3, g4h-phy_QGSP_BIC_HP, g4decay, g4ion-binarycascade, g4h-elastic_HP and g4stopping were used. 5 million histories for DEF, and 0.2 million for the Bragg Peak shift were used. **Results:** The introduction of gold foils in water phantom shifted the Bragg peak upstream by about 6 mm, and narrowed the peak from 8.1 to 3.1 mm. Our DEF findings showed an increase in enhancement as high as 1.46 situated around the Bragg Peak. **Conclusion:** In this study, we simulated gold nano-particles placed in a foil with a proton beam. Our results showed a dose enhancement effect as well as a Bragg Peak shift. This preliminary study validates our simulation environment for future investigations. Future work will include simulation with many beam energies using different densities of gold nano-foils and other foils of different materials.

PO-GePV-T-71

Radiobiological Evaluation of Physical Metrics in IMPT and VMAT Planning for Prostate Cancer Patient with Metal Hip Prostheses

W Hsi¹*, T Lee², (1) University Florida Health Proton Therapy Institute, Jacksonville, Florida, (2) Indiana University Health Arnett, Lafayette, IN

Purpose: The aims of this study are to 1) evaluate dosimetric deviations between treatment plans of optimized on the original CT and re-calculated on the metal-artifact-reduced CT for prostate cancer patient with metal-hip-prostheses, and 2) investigate radiobiological deviation of physical metrics. **Methods:** Optimized and re-calculated plans of 16 cases were for intensity-modulated-proton-therapy (IMPT) using two-field pencil-beam-scanning proton beams and for volumetric-modulated-arc-therapy (VMAT) using two-photon-arcs. The prescribed dose to clinical-target-volume (CTV) over 44 fractions in optimized plan of each patient was 72 Gy for IMPT and 79.2 Gy for VMAT. Two IMPT plans sets were evaluated, LAT plan with two lateral-fields and HipAvd plan with one-lateral and the other posterior-oblique avoiding hip-prostheses. Obtained IMPT/VMAT plans were evaluated with previously developed Radio-Therapy-Plan-Evaluation-Tool (RTPET). The 1.1 constant radiobiological effectiveness for IMPT target was applied in RTPET. The radiobiological evaluation was conducted with tumor-control-probability (TCP), and normal-tissue-complication-probability (NTCP) with physical metrics e.g. Cumulative DVHs, Conformity-Index (CI), Dose-Homogeneity-Index (DHI). **Results:** The presence of metal artifacts barely affected VMAT plans with all metrics within +/- 2.0% differences, while it significantly affected IMPT plans in TCP/NTCP values that could result in tumor control deficiency. Dividing plans with single and bilateral hip-prosthesis, the TCP_CTV for LAT plans varied <10% for single, but > 80% for bilateral. The larger TCP_CTV deviation of bilateral corresponds to > 40 Gy deviation of minimum dose in CTV. The values of NTCP for bladder and rectum for LAT varied < 0.5% for single, but more > 2% for bilateral. The variation of the mean and maximum dose to bladder or rectum were < 2 Gy. **Conclusion:** The presence of metal artifacts without any correction in planning could compromise radiobiological outcomes as well as surrounding normal tissue sparing power of IMPT.

PO-GePV-T-72

Developing a Workflow Using Supercomputer Accelerated Monte Carlo Simulation Based On Machine Log-Files for Patient Specific Quality Assurance of the Mevion S250i Proton Therapy System

B Chiang*, Y Chen, S Ahmad, University of Oklahoma Health Sciences Center, Oklahoma City, OK

Purpose: The measurement based proton specific quality assurance (PSQA), a time-consuming process, plays an important role for proton therapy. The purpose of this work has been to develop a unique workflow of running machine log-files based Monte Carlo simulation on supercomputer for PSQA of the Mevion S250i proton therapy system. The proposed method not only takes the delivery errors into account but also saves personnel and machine beam-on time. **Methods:** The Mevion beamline was modeled in detail using TOPAS Monte Carlo code. The machine log file was acquired during delivery and converted by our in-house batch file converter to create the input file for running machine log-files based Monte Carlo simulation on supercomputer. The 3D dose was then reconstructed in a solid water phantom. Similar to measurement based PSQA, the 2D Gamma analysis was conducted in three different depths that include isocenter, proximal and distal fall-off and compared with the corresponding doses calculated from the treatment planning system. **Results:** Simulation time for 10⁸ protons on 5x5x5 cm³ uniform cubic plan was reduced from almost 2 days using 10 cores on the local server to 1.9 hours using 20 compute nodes on supercomputer. The 2D dose profile comparison at three different depths showed good agreement between simulation and treatment planning system. The Gamma index passing rates for both one beam 5x5x5 cm³ uniform cubic plan and two beam IROC pelvis plan were passed more than 95% satisfying 4%/4mm

criteria. **Conclusion:** A unique workflow of how to utilize supercomputer for log-file based Monte Carlo simulation has been developed, which can improve both efficiency and authenticity of utilizing Monte Carlo simulation for PSQA of proton therapy within the clinically acceptable level.

PO-GePV-T-73

Analysis of the Difference in Calculation of Physical Dose for Each Patient Site of SECT and DECT Using TOPAS

E Yoon*, S Jung, J Son, B Kim, C Choi, J Kim, J Park, Seoul National University Hospital, Seoul, 11KR

Purpose: To calculate the carbon ion dose based on single-energy CT (SECT) and dual-energy CT (DECT) through Monte Carlo (MC) simulation, and analyze the dose calculation results by patient site. **Methods:** We used TOPAS code (version 3.4) for MC simulation and modeling. For carbon ion beam scanning, a 3-D active beam scanning system was modeled. Both SECT images and DECT images were acquired with Philips IQon spectral CT which is a dual-layer detector type. 120 kVp CT images for SECT and effective atomic number (EAN) and electron density (ED) images for DECT were obtained. Then, material information for each pixel was imported into TOPAS for simulation. SECT images were imported through the stoichiometric method embedded in the code, and DECT images were imported through the in-house material converter. After dose calculation, in order to compare the dose calculation results using the two images, integral depth dose (IDD) profiles were obtained for the monoenergetic carbon ion beam irradiated from the lateral direction (case 1) and the perpendicular direction (case 2), respectively. In addition, the dose difference was analyzed after beam scanning, using the modeled beam scanning system (case 3). **Results:** Before evaluating the dose calculation results for various patient sites, one site (abdomen) of the patient CT with an IRB-approved was evaluated as a preliminary result. In Cases 1 and 2, the Bragg peak position of monoenergetic ion in DECT was $-1.6 / +1.7$ mm from the SECT, and the dose difference at the peak was $-3.8 / +3.7\%$ respectively. In Case 3, the dose difference for each pixel was up to 47% from the SECT at Bragg peak. **Conclusion:** The difference in dose calculation for SECT and DECT image was confirmed through preliminary calculation. Dose calculations and analyzes will be performed for various patient sites.

PO-GePV-T-74

A Fast Deterministic Method for Calculating Doses and Fluence Spectra for Proton Beam Therapy

O Vassiliev*, S Kry, C Peterson, D Grosshans, R Mohan, MD Anderson Cancer Ctr., Houston, TX

Purpose: Treatment plan optimization in proton beam therapy involves multiple calculations of spatial distributions of physical dose and relative biological effectiveness (RBE). We develop a novel fast and accurate method for calculation of doses and fluence spectra. Fluence spectra provide physical data that is sufficient for RBE calculations using almost any of the current models. **Methods:** Our method is deterministic, it does not involve any random sampling. It is based on exactly the same physics as the most rigorous Monte Carlo algorithms, which ensures high accuracy of our method. Monte Carlo algorithms rely on multiple scattering models to generate random particle trajectories. Our algorithm uses the same models, but differently, to find the solution using an iterative procedure. By eliminating random sampling, we achieve high computing speed. Our algorithm accounts for energy loss straggling using Vavilov distribution, inelastic nuclear reactions and particle trajectory curvature. **Results:** We have tested our algorithm for 40 to 220 MeV protons propagating in water. The CPU time was 1.6-3.8 sec in Matlab on a quad-core 4.2 GHz processor. In each run our code calculates doses and fluence spectra at ~40 depths. Our method agreed with MCNPX 2.7.0 Monte Carlo code. In the plateau region the root mean square difference in doses (Gy/particle) between our code and Monte Carlo was 0.3%. We did not find the difference exceeding 2% in any of the tests. The maximum distance to agreement near the Bragg peak was 0.8 mm. The maximum difference in the energies of fluence spectra maximum was 0.6 MeV and the maximum discrepancy in full widths at half maximum was 0.9 MeV. These spectra comparisons included depths on both sides of the Bragg peak. **Conclusion:** Our new method achieves high calculation speed with uncompromised accuracy. There is a potential for substantial further improvement of its performance.

PO-GePV-T-75

Development of a Machine Learning Model to Predict Dosimetric Impact of Proton Spot Delivery Errors

M Newpower*, S Ahmad, Y Chen, University of Oklahoma Health Sciences Center, Oklahoma City, OK

Purpose: A machine learning model was trained on historic data of spot position errors and MU delivery errors, taken from log files from our Mevion S250i Hyperscan proton therapy system. The output of the model will serve as input into a workflow to predict the spot position errors before treatment and the objective of this work is to assess the dosimetric impact of those errors as part of pre-treatment quality assurance. **Methods:** In previous works, a MATLAB script was developed to extract spot position errors and MU delivery errors from a large collection of log files. This script generated data for approximately 4×10^6 spots from 108 patients. Planned spot positions and Monitor Units (MUs), delivered spot positions and MUs, gantry angle and snout extension were used as input for a supervised machine learning algorithm. The MATLAB Statistics and Machine Learning toolbox was used to train a shallow feedforward neural network with 5 neurons. Seventy percent of the data was used for training, 15% for validation and 15% for testing. **Results:** The mean squared error of the model fit on the testing data was 0.301 and $R=0.99985$. **Conclusion:** The model was trained well, as evidenced by the R value close to unity. Output from this model will serve as input for the next step in a workflow to input the predicted spot position errors and MU errors back into the RaySearch RayStation Treatment Planning System and recalculate the dose on the patient CT. This recalculated dose, based on the predicted beam delivery, will then be compared to the dose calculated with the optimal spot positions and MUs. These comparisons will be reviewed as part of a pre-treatment quality assurance program.

PO-GePV-T-76

Open Source TPS for Bragg Peak Proton FLASH Treatment Plans

L Hotoiu^{1*}, A Pin², S Deffet³, E Sterpin^{3,4}, R Labarbe⁵, (1) Ion Beam Applications SA, Louvain-la-neuve, WBR, BE, (2) Ion Beam Applications Sa, Louvain-la-neuve, WBR, BE, (3) Universite catholique de Louvain, Molecular Imaging Radiotherapy and Oncology MIRO, Louvain-la-Neuve, BE, (4) KULeuven, Laboratory of Experimental Radiotherapy Department of Oncology Faculty of Medicine, Leuven, BE, (5) Ion Beam Applications (IBA), Louvain-la-neuve, WBR, BE

Purpose: FLASH irradiation implies delivering the treatment dose at high dose-rates (typically > 40 Gy/s) to elicit sparing in irradiated healthy tissue. To fulfill the FLASH time constraints and achieve high dose-rates in proton PBS irradiation, a working approach is scanning the pencil-beam in a monoenergetic delivery, whilst ensuring the target coverage within the generated Spread-Out-Bragg-Peak (SOBP). **Methods:** We present a way to generate a proton FLASH treatment plan unraveling the full potential of proton Bragg-peak for high dose-rate FLASH irradiations, alleviating the limitations in the current shoot-through, transmission-FLASH approach that negates the advantage of the Bragg-peak. **Results:** The solution consists in passing the proton pencil-beam at the highest cyclotron energy through a range shifter setting the beam maximum range and through a spatially non-uniform ridge filter (the "hedgehog"). The ridge filter base height controls the distal modulation while the height of its spikes defines the proximal modulation depth at each position, giving a conformal dose distribution over the non-uniform CTV surfaces. The spike shapes determine the SOBP plateau flatness. The ridge filter and range shifter are patient and field specific, responsible in generating the SOBP covering the target volume. Its design is based on the weight of each beamlet in the field, by optimizing a standard IMPT plan using an analytical algorithm in MIROpt (<http://openmiropt.org/>), alongside the MCsquare dose engine (<http://www.openmcsquare.org/>). A

modified MIROpt version optimizes the spot scanning trajectory and computes the percentile dose-rate at each CT voxel. The shape of the ridge filter generated by MIROPT and MCsquare is validated by comparing with the dose distribution computed using MCNPX Monte Carlo. **Conclusion:** An open-source TPS considering the time constraints of FLASH irradiation was designed, based on a Conformal Energy Ridge Filter approach that converts a monoenergetic 230MeV proton beam delivery into an SOBP.

This work was supported by the Walloon Region, grant No. 8341.

PO-GePV-T-77

Virtual Particle Monte Carlo (VPMC), a New Concept to Avoid Simulating Secondary Particles in Proton Therapy Dose Calculation

J Shan*, M Fatyga, W Liu, Mayo Clinic Arizona, Phoenix, AZ

Purpose: In proton therapy dose calculation, conventional Monte Carlo (MC) simulation may not take full advantage of GPUs because the random secondary-particle-generating processes result in unbalanced workload for different threads of GPUs. Therefore, we propose a novel concept of virtual particle (VP) in MC (VPMC) to avoid simulating secondary particles with clinically acceptable accuracy in proton therapy dose calculation. **Methods:** We interpreted the track histories from a conventional MC code, MCsquare, in a new way (Figure 1). The dose of one primary proton and its secondaries, named realistic particles, can be regarded as if it is deposited by multiple VPs, which results in the same dose distribution as realistic particles. Each VP corresponds to one realistic particle. However, VPs start at the same starting position of the primary proton. After converting the histories of realistic particles into histories of VPs, we can induce a probability model to describe the behaviors of VPs. The model includes a continuing-slowing-down-approximation (CSDA) model and a large angle event model corresponding to nuclear interactions for VPs. In this study, to simplify the calculation, we ignored neutrons and gamma rays, locally deposited the dose of electrons, heavy ions, and nuclear fragments, and converted the tracks of deuterons into tracks of protons. Finally the dose distribution from realistic particles was calculated by simulating only VPs in VPMC, which was then carefully benchmarked with the one calculated by MCsquare. **Results:** The curves of integrated-depth dose, percentage-depth dose, iso-dose contours, and lateral-dose profiles all matched very well (Figure2). The 3D Gamma passing rate with a threshold of 1%/1mm/2%/2mm between VPMC and MCsquare is 97.8%/99.4% in water phantoms and 96.5%/99.4% in inhomogeneous phantoms, respectively. The calculation is highly efficient (1.3×10^7 particles per second with 6 Nvidia T4 GPUs). **Conclusion:** VPMC achieved high accuracy and efficiency in proton therapy dose calculation.

PO-GePV-T-78

Experimental Validation of Clinical Proton Dose Calculation Algorithms for Breast Prostheses and Tissue Expanders

C Chen*, P Tsai, S Huang, JI Choi, H Lin, New York Proton Center, New York, NY

Purpose: The clinical proton dose calculation algorithms using pencil-beam convolution superposition (PCS) and Monte Carlo (MC) methods in Eclipse™ TPS were validated in a phantom with the metallic port of a Natrelle-133 tissue expander (Allergan, PLC) placed between a silicone-filled prosthesis (Mentor, LLC) and solid water. **Methods:** A proton spot-scanning field was generated to deliver a homogeneous dose to a target volume in the phantom. The metallic port was contoured based on geometrical dimensions provided by the manufacturer. The Hounsfield units (HUs) were assigned based on the corresponding stopping powers from lectures (silicone: 0.94, Titanium: 3.17, magnet: 5.50, solid water: 1.02) for PCS (PCS 15.6) algorithm. The materials used for MC (AcurosPT 13.7) calculation were selected (silicone: wax, Titanium: Aluminum, magnet: Brass) to have the closest stopping powers. The 2D planar doses at multiple depths close to the distal-dose fall off were measured using a MatriXX-PT detector (IBA-dosimetry, Germany) and compared with the calculations. **Results:** The measured 2D planar doses at distal target edge (36.5 mm below the prosthesis) matched both PCS (35.4 mm) and MC (37.4 mm) calculations within 1 mm discrepancy in depth. The depth-doses collected from 2D planar doses behind the breast prosthesis were found to over-range in measurements by 1.0 mm and 0.0 mm versus PCS and MC calculations, respectively. However, a 5-8 mm over-range outside the target volume was observed when protons passed through the metallic port. **Conclusion:** The assigned HU (-124) for silicone-filled breast prostheses with the institutional CT curve was experimentally validated for both PCS and MC algorithms. Limited by the lateral scattering in PCS algorithm and material selections for MC method, the disturbed doses caused by the high-Z metallic port cannot be predicted precisely. A two-field beam arrangement is suggested to average out and confine the uncertain doses inside the tissue expander.

PO-GePV-T-79

Development of a Fast and Memory-Efficient Monte Carlo Code for Proton Dose Calculation

H Lee*, J Shin, J Verburg, H Paganetti, Massachusetts General Hospital, Boston, MA

Purpose: Monte Carlo (MC) code's running times are significantly reduced with the development of general-purpose graphic processing unit (GPGPU) based algorithms. However, some calculations, like dose influence matrix (D_{ij}) calculation or temporal dose calculation, cannot take full advantage of the GPGPU due to the limited memory size and the expensive computational cost of memory transfer. We developed a memory-efficient framework to fully utilize GPGPU within our novel GPU-based MC code for proton therapy, "moqui". **Materials and Methods:** To increase the efficiency of the code, we have adopted the hash table, one of the key-value pair data structures, to the scoring system of our MC code. We put the voxel index in the key and accumulated the voxel's dose deposition in the value. There are two advantages of using the hash table. (1) Only voxels that interact with particles occupy the memory (2) A hash function of a key determines the address of a pair, thus reducing the time for searching over the data structure to check a pair's existence and the existing pair's address. To demonstrate the efficiency of the developed code, we calculated the D_{ij} matrix and compared with an array scoring system, which is a conventional data structure used for scoring. **Results:** For simulating 40 million particles, the hash table scoring system took about 115.9 seconds, while the array scoring system took 151.4 seconds. With the hash table scoring system, we can score every voxel that interacts with particles. In contrast, the array scoring system was only able to score selected voxels using twice of the memory used for the hash table scoring system. **Conclusion:** The MC code with the hash table scoring system runs faster and has better memory-efficiency than the conventional scoring system. It is incorporated in the "MOnte carlo for QUICK proton dose calculation" (moqui).

Three-Dimensional Dose and LETd Prediction in Proton Therapy Using Artificial Neural Networks

F Pirlepsov*, V Moskvina, L Wilson, A Breuer, T Merchant, A Faught, St. Jude Children's Research Hospital, Memphis, TN

Purpose: The dose weighted linear energy transfer (LETd) is one of the parameters defining the response of the tissue in proton therapy. Estimating LETd requires treatment planning information and time-consuming Monte Carlo (MC) simulations. We expand our reported artificial neural networks (ANN) three-dimensional dose prediction model to include MC dose and LETd. **Methods:** 27 patient subset from an institutional craniopharyngioma treatment protocol comprised the study. All patients received a prescribed dose of 54 CGE. MC dose and LETd for model training were calculated using the Tool for Particle Therapy Simulation. Predicted beam path masks were created by expanding existing clinical target volume contours and raytracing along the beam directions.

Using MATLAB's neural network toolbox, voxel features within the predicted beam path were used to train feed forward ANN models that predicted dose and LETd. ANNs were trained with several network training and activation functions with varying number of deep layers and neurons. The final model is the one with lowest root mean square error (RMSE). **Results:** The final trained model used 3 layers and 25 neurons with RMSE of predicted dose and LETd 5.8 CGE and 0.5 MeV/mm/(g/cm³), respectively. The percentage of voxels within $\pm 5\%$ of the MC calculated values were 70.8% and 50.2% within the CTV, 44.9% and 38.1% 0-5mm from the CTV and 13.5% and 28.9% 5-15mm from the CTV in dose and LETd, respectively. Model agreement trended worse near sharp dose gradients, suggesting spatial uncertainty in the predicted values. **Conclusion:** We implemented an ANN algorithm to predict dose and LETd. The benefits of upfront dose prediction are well documented in the knowledge-based planning community. Supplementing the treatment planning process with an LETd prediction allows for careful consideration of treatment geometries to limit the potential biologic impact of high LETd regions in normal tissues.

Systematic Analysis of the Neutron Equivalent Dose in a Mevion S250 Proton Therapy Machine Using Geant4 Monte Carlo Simulation

N Tatari^{1,2*}, M Baradaran-Ghahfarokhi^{1,3}, B Roeder⁴, T Zhao¹, R Khan¹, L Sobotka^{2,5}, A Darafsheh¹, (1) Department of Radiation Oncology, Washington University School of Medicine, St. Louis, MO (2) Department of Physics, Washington University, St. Louis, MO (3) Department of Radiation Oncology, Vanderbilt University Medical Center, Nashville, TN (4) Cyclotron Institute, Texas A&M University, College Station, TX (5) Department of Chemistry, Washington University, St. Louis, MO

Purpose: To study the contribution of different components in a Mevion S250 proton therapy system's vault, including the room, proton therapy machine, and the patient itself, in the neutron equivalent dose. **Methods:** Geant4 Monte-Carlo was used to simulate the room geometry and the proton therapy machine. A $40 \times 40 \times 40$ cm³ water phantom was placed at the isocenter. The measured proton depth dose and lateral profiles were used to benchmark the simulation. Also, the experimental results obtained from a previous study of the neutron spectrum was used for benchmarking. Three different proton energies corresponding to the 1st, 9th, and 18th steps of the range modulation wheel were considered. We utilized the Root data analysis framework to collect the information on individual neutron interactions at any point within the simulation geometry. Such information was used to find the contribution of each object to the total neutron equivalent dose absorbed in the water phantom. The impact of the brass aperture opening on the neutron dose to the patient was also studied. **Results:** Most of the neutron dose (>65%) absorbed to the water phantom representing a patient comes from the internal neutrons generated inside the water phantom. Among the sources of the external neutron dose, the major contributor is the brass aperture followed by the synchrocyclotron body. A small fraction of dose comes from the floor and the ceiling, however, the impact of the walls to the dose was small. A quasi-exponential behavior in the reduction of the neutron dose as a function of the longitudinal distance from the treatment nozzle was noted. A quasi-Gaussian distribution of neutron dose in lateral direction with respect to the nozzle was noted. **Conclusion:** Our results shed light on the origin and energy spectrum of the secondary neutrons in a Mevion S250 proton therapy vault.

PO-GePV-T-82

Determination of Plan Deliverability and Treatment Time Estimation for Proton Pencil Beam Therapy Using a Machine Emulator Script

S Mossahebi^{1*}, E Makdsay Hana¹, J Williams¹, B Algawwam¹, A Meijers², B Yi¹, (1) University of Maryland Medical School, Baltimore, MD, (2) Varian Medical Systems, Palo Alto, CA

Purpose: Availability of field delivery time estimate during the treatment planning allows to better assess if a given plan is tolerable for a patient delivery time-wise and can provide an input for patient scheduling in the treatment rooms. It is also desirable to determine the deliverability of plan prior to patient specific QA or the actual treatment. The aim of this study is to evaluate a tool which can determine the plan deliverability and the treatment time of proton pencil beam therapy. **Methods:** Treatment Time Calculator (TTC, Varian) algorithm has been developed and tested to estimate treatment delivery time and deliverability by considering several room-specific parameters such as minimum spot duration, layer switching time, beam currents, and beam line transmission. Fifteen deliverable (46 total fields) and 10 undeliverable treatment plans (47 total fields) of various anatomic sites were selected and tested by TTC tool. The actual delivery time of each deliverable plan were obtained for multiple fractions (average=7) from oncology information system and compared to TTC estimated time. **Results:** The TTC average estimated treatment time predicted to be lower ($-22.7 \pm 5.6\%$) than the actual delivery time as TTC reports the ideal treatment delivery and doesn't consider daily fluctuations of the system. By applying a form factor of 23%, average difference can be reduced to 6%. Based on our daily QA records, daily treatment time can vary up to 15%. For the same plan, both calculated and measured delivery time can vary up to 30% in different treatment rooms. Additionally, prediction of treatment plan deliverability by TTC shows high sensitivity (85.0%) and specificity (99.7%). **Conclusion:** Using TTC, undeliverable plans can be filtered out at the time of treatment planning and prior to delivery, which can eliminate last-minute replanning. Treatment time determination enables proper selection of treatment rooms depending on the plan configuration.

Characterizing the Entrance Dose Induced by a Dynamic Collimation System for Pencil Beam Scanning Proton Therapy Using a Commercial Multilayer Ionization Chamber

N Nelson^{1*}, W Culberson¹, B Smith², R Flynn², D Hyer², P Hill³, (1) University of Wisconsin-Madison, School of Medicine and Public Health, Department of Medical Physics, Madison, WI, (2) University of Iowa, Department of Radiation Oncology, Iowa City, IA, (3) University of Wisconsin-Madison, School of Medicine and Public Health, Department of Human Oncology, Madison, WI

Purpose: To characterize changes in entrance dose resulting from low-energy scatter induced from the Dynamic Collimation System (DCS), an energy layer-specific collimator designed for low-energy pencil beam scanning proton therapy using a commercially available multilayer ionization chamber (MLIC). **Methods:** Uncollimated integral depth dose (IDD) curves were acquired with an IBA Stingray parallel plate ionization chamber scanned in a water tank and the IBA Giraffe multilayer ionization chamber (MLIC). IDD for beamlets collimated by various collimator orientations were then measured with the Giraffe MLIC. Results were compared to identical simulations performed using a benchmarked Monte Carlo model of the DCS. Simulated IDDs consisted of tallying the dose to water in a 0.1mm mesh with a diameter identical to the 12-cm diameters of Giraffe MLIC and Stingray chambers. Simulated and measured collimated IDDs were compared using 1D overall 0.5%/0.5mm gamma tests. **Results:** For the uncollimated scenarios, the MLIC measurements exhibited a significant decrease in dose at the Bragg peak when compared to the uncollimated Stingray measurements that is most likely due to rise a rapid change in the mass stopping power ratios of water to Giraffe-equivalent material near the end of range. To account for this, uncollimated Stingray and MLIC measurements were then used to derive energy- and depth-dependent correction functions that were then applied to the collimated MLIC measurements. For the pristine collimated beams, 0.5%/0.5mm gamma pass rates increased from 17.5% to 89.6% with the use of the correction. For the range shifted collimated beams, pass rates increased from 39.0% to 95.4%. **Conclusion:** We have demonstrated a need and implemented a method to correct IDDs acquired with an MLIC for the purpose of characterizing changes in entrance dose resulting from collimation.

Research reported in this abstract was supported by the National Cancer Institute of the National Institutes of Health under award number R37CA226518. Hyer, Flynn, and Hill are co-inventors on a patent that has been licensed to IBA.

Log File-Based Patient Specific Quality Assurance: 5 Years of Experience in Pencil Beam Scanning Pediatric Proton Therapy

O Ates*, F Pirlepsov, C Hua, T E Merchant, L Zhao, St. Jude Children's Research Hospital, Memphis, TN

Purpose: To report the trend analysis of an in-house log file-based patient specific quality assurance (QA) method in pencil beam scanning pediatric proton therapy over 5 years from 2016 to 2020. **Methods:** In-house log file-based software was implemented as a part of clinical patient specific QA process to complement 2D array absolute dose measurements. The software extracts beam specific information from treatment delivery log and automatically compares spot MU, lateral position of each spot against the intended values from treatment plan to determine any discrepancies in beam delivery. This software monitors spot width for various energies and gantry angles recorded by spot position monitor against the established baseline at the time of acceptance. Since 2016, the software has analyzed 286 pediatric patients, 476 plans, 1182 fields, and more than 22M proton spots. **Results:** The trend analysis showed that proton system has been very stable in delivering patient QA fields within the proton energies of 69.4-221.3 MeV and MU range between 0.003 and 1.473 MU per spot. The planned mean and standard deviation (STD) of energy and spot MU were found to be 114.5 ± 26.4 MeV, and 0.0108 ± 0.0096 MU, respectively. The mean and STD of spot MU and position differences between delivered and planned spots were $1.49 \times 10^{-7} \pm 2.35 \times 10^{-4}$ MU, and $0.0289/-0.0073 \pm 0.0497/0.0447$ mm in X/Y axes for random, $0.0126/0.1343 \pm 0.1874/0.1758$ mm in X/Y axes for systematic positional differences. The mean and STD of spot width comparison were determined as $0.0927/0.0981 \pm 0.1368/0.1734$ mm in X/Y axes between the acceptance and delivered values. **Conclusion:** We developed an in-house tool to extract crucial information about the stability of the proton pencil beam scanning delivery and monitor the system performance since 2016. Each patient's plan has been verified pretreatment to ensure the delivery accuracy per machine delivery tolerance.

PO-GePV-T-85

Feasibility of Delivering Exchanged PBS Treatment Plans in Two Gantries of Multiroom Proton Therapy System

C Fang¹, Y Huang^{2*}, T Yang³, L Cao¹, G Zhang⁴, B Qu³, Z Wang¹, Y Zhang⁴, S Xu³, (1) Hebei Yizhou Cancer Hospital, Zhuozhou, Hebei, CN, (2) The Hong Kong Polytechnic University, Kowloon, Kowloon, HK, (3) Chinese PLA General Hospital, Beijing, Beijing, CN, (4) Beihang University, Beijing, Beijing, CN

Purpose: Inspired by the beam-matching concept in medical linear accelerators, the feasibility of delivering exchanged pencil beam scanning treatment plans without replanning and recalculations in gantries of IBA ProteusPLUS proton system through analyzing the commissioning data and quality assurance (QA) results, is studied in this work. **Methods:** Proton beam characteristics including integral depth dose (IDD) and spot profiles for 33 energy levels (70-226.09MeV) of two gantries (GTR2/GTR4 in our hospital) were measured and established beam models. 36 cases of nasopharyngeal-carcinoma, lung cancer and prostate cancer were retrospectively selected to generate patient-specific QA plans based on the beam model of gantries. Each QA plan was respectively delivered in both gantries, meanwhile, planar dose measurements were done, and were compared and statistically analyzed. **Results:** Through comparison between two gantries' models, their IDD were analyzed. It is found that the spot profiles at each energy level had slight differences. Independent of delivering the same QA plans in GTR2 or GTR4, the average passing rates of measured doses had not changed much, reaching a high level of 95% when using a 3mm/3% criterion. While the paired sample t-test shows that these differences were not statistically significant, the Pearson correlation analysis proved a certain correlation between the passing rates of two gantries. Few abnormal cases could be seen only when the stringent criterion of 2mm/3% was used, but when using the less rigorous 3mm/3% criterion which was widely used in clinical practice, there was no exception. **Conclusion:** The beam dosimetric characteristics in different rooms showed high consistency and the tolerance was kept within a reasonable range while the difference of the same treatment plan delivered on two gantries met the requirement of clinical treatment. It was recognized that the same treatment plan could be delivered directly in different treatment rooms without affecting the treatment efficacy.

This work was supported in part by the grant from the National Key R&D Program of China (No.2017YFC0112105). The authors have no competing interest to report.

Quantitative & Statistical Analyses of Monthly OBI QA on Varian ProBeams

Z Diamond*, A Stanforth, R Slopsema, K Langen, Emory Proton Therapy Center, Atlanta, GA

Purpose: Routine quality assurance of onboard imaging systems (OBI) for proton therapy is a standard practice performed monthly according to the recommendations given in the American Association of Medical Physics Task Group Report No. 224 (AAPM TG #224). Methods utilized to carry out such tests are nearly identical to those in standard photon radiotherapy (AAPM TG #142) for both planar-kV imaging and CBCT imaging, where all measurements taken in subsequent months are with respect to a pre-determined baseline measurement. This study examines the variability of obtained image quality parameters across four proBeam treatment rooms and varying imaging techniques. Furthermore, this study examines the effects of possible artifacts and routine imager recalibration specific to ProBeam systems. **Methods:** ProBeam OBI monthly quality assurance statistics were extracted from myQA and placed into another spreadsheet for statistical analysis. Descriptive statistics were obtained for each imaging parameter, from which a distribution of imaging parameters were obtained. A two way ANOVA test was also performed to compare the distribution of imaging parameters across all four rooms to determine if room dependence existed with respect to image quality. **Results:** Of the tests undertaken, image quality statistics across the four treatment rooms were shown to be fairly uniform per specific room, but varied slightly when compared to each other. This was expected due to variability across rooms as well as initial commissioning data. **Conclusion:** OBI systems for proton therapy are fundamental to ensure proper patient setup and alignment for treatment, and routine quality assurance tests are fundamental for proper safety. Furthermore, the utilization of a succinct SOP ensures that imaging parameters obtained will be as uniform as possible, despite that parameters will most likely be different across rooms.

PO-GePV-T-87

Radiation Therapy Interference with Cardiovascular Implantable Electronic Devices; Comparison of Proton Beam Therapy Versus Intensity-Modulated Radiation Therapy

A Anvari*, T Alfonzetti, A Butala, M Carpenter, A Kassae, I Paydar, J Jones, D Mihailidis, University of Pennsylvania, Philadelphia, PA

Purpose: To determine whether Proton Beam Therapy (PBT) is associated with less radiation dose than Intensity-Modulated Radiation Therapy (IMRT) to cardiac implantable electronic devices (CIEDs). **Methods:** We investigated retrospectively the radiation dose to the CIEDs for 33 patients underwent PBT at our institution between 2010-2020, with targets located close to the CIED, including thoracic, H&N, and esophagus. For each patient, quantitative comparison of dose to the CIEDs between PBT and IMRT was performed. **Results:** The CIED distance from edge of field (50% isodose line) ranged 1.5 cm to 22 cm for PBTs. However, due to spread out of dose in IMRTs, edge of fields was closer to the CIEDs, where the distances ranged 1.4 cm to 18 cm. Our results indicate that CIED dose for both PBT and IMRT of all 33 patients were <2Gy, except one patient that IMRT exceed 2 Gy. For this case, IMRT was delivered as initial plan in first 5 fractions, then switched to PBT. We found that the CIED dose in PBT is negligible compare to IMRT. For PBTs of 33 patients, max and mean doses to the CIED were 52.6 and 4.2 cGy, respectively. However, IMRT delivered overall greater dose to the CIED, in which max and mean doses were 216.9 and 73.4 cGy, respectively. **Conclusion:** Our study revealed that the clinical treatments with PBT delivered lower dose to the CIEDs (with potentially less induced malfunctions) than those with IMRT. Regardless of treatment modality, the CIED dose depends directly on the distance of the device to the radiation

field. However, in PBT, field arrangement is crucial for avoiding irradiation of the device with the distal edge of the Bragg-Peak.

PO-GePV-T-88

Output Estimation by Analytical and Machine Learning Models in a Double Scattering Proton System

J Zhu*, T Cui, Y Zhang, Y Zhang, C Ma, B Liu, K Nie, N Yue, X Wang, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ

Purpose: This study aims to design an empirical method using the analytical and machine learning (ML) models to estimate proton output in a double scattering proton system. **Methods:** Three analytical models using polynomial, linear fitting, and logarithm-polynomial equations were generated on a training datasets consisting 1544 clinical measurements to estimate proton output for each option. Meanwhile, three ML models using Gaussian process regression GPR with exponential kernel, squared exponential kernel, and rational quadratic kernel were also created for all options combined. The accuracy of each model was validated against additional 241 clinical measurements as testing datasets. Two most robust models were selected, and the minimum number of samples needed for either model to achieve sufficient accuracy ($\pm 3\%$) was determined by evaluating the mean average percentage error (MAPE) with increasing sample number. The differences between the estimated outputs using the two models were also compared for 1000 proton beams with randomly generated range, and modulation for each option. **Results:** The polynomial model and the ML GPR model with exponential kernel yielded the most accurate estimations with less than 3% deviation from the measured outputs. At least 20 samples of each option were needed to build the polynomial model with less than 1% MAPE, whereas at least a total of 400 samples were needed for all beam options to build the ML GPR model with exponential kernel to achieve comparable accuracy. The two independent models agreed with less than 2% deviation using the testing datasets. **Conclusion:** The polynomial model and the ML GPR model with exponential kernel were built for proton output estimation with less than 3% deviations from the measurements. They can be used as an independent output prediction tool for a double scattering proton beam, and a secondary output check tool for cross check between themselves.

PO-GePV-T-89

Clinical Evaluation of Optically Stimulated Luminescence Dosimeters Dose Accuracy in Intensity Modulated Proton Therapy

J Yu*, A Wroe, A Gutierrez, Miami Cancer Institute, Baptist Health South Florida, Miami, FL

Purpose: To evaluate the accuracy of measured dose using optically-stimulated-luminescence-dosimeters (OSLD) for intensity-modulated-proton-therapy (IMPT) plans with and without range shifter, with pencil-beam (PBA) or Monte-Carlo (MC) algorithms, and at various beam angles. **Methods:** OSLDs were calibrated in solid water under two conditions: 1) without range shifter at 1.2 cm depth using a uniform planar dose, and 2) with a range shifter in the middle of a uniform cubic dose at superficial depth (5cm range and 5cm modulation). In both cases, OSLD dose was compared to PBA and MC calculated dose over a dose range of 0.5-10 Gy, RBE. Once calibrated, OSLDs were used to compare PBA and MC calculated doses for uniform fields and clinical breast plans. Angular dependence of OSLD was investigated in a spherical phantom from 0 to 330°. **Results:** A polynomial function yielded the best fit ($R^2=0.9997$) using both calibration conditions. A 2.7% difference between the calibrations with and without range shifter was noted—however, this difference was within OSLD response uncertainties of 2.9%. For uniform fields, the differences of OSLD and calculated doses were 2.5% for MC and 3.5% for PBA. For clinical breast plans, the differences were 5% for MC and 8% for PBA. OSLD response exhibit variations to beam angles within 2%, with the largest discrepancies at 90 and 270 degree where it is parallel to beams. Therefore, the total uncertainties of OSLD dose are 7% for PBA plans, and 10% for MC plans. **Conclusion:** The OSLD calibration conditions with or without range shifter do not significantly differ. A single calibration curve may be used for plans with or without range shifter and for MC or PBA algorithms. OSLDs should be placed en-face to the beam and avoid tangential beams. The overall uncertainties of OSLD are 7% for PBA plans, and 10% for MC plans.

PO-GePV-T-90

Influence of Beam Quality Correction Factors on Measurement Depth in Scanning Proton Beams Using Monte Carlo Calculation

M Ichihara^{1*}, K Yasui², C Omachi³, T Toshito³, J Nagata¹, R Oshika¹, S Kurata¹, N Hayashi², (1) Graduate school of Health Sciences, Fujita Health University, Toyoake, Aichi, JP, (2) School of Medical Science, Fujita Health University, Toyoake, Aichi, JP, (3) Nagoya Proton Therapy Center, Nagoya, Aichi, JP

Purpose: In radiotherapy, determination and management of delivery dose by measuring the absolute dose are important. The reference dose for clinical proton beams is based on ionization chamber dosimetry. However, there are few data on the beam quality correction factors ($k(Q)$) required for calculating the absolute dose for the proton beam. Furthermore, the perturbation correction factor ($P(Q)$) of ionization chambers is assumed to be unity for proton beams in the IAEA TRS-398 CoP. Hence, the aim of this study is to calculate $k(Q)$ and $P(Q)$ for ionization chambers in scanning proton beams using the Monte Carlo simulation (MC). **Methods:** We used PTSIM a particle therapy simulation framework based on MC code Geant4 version 10.05.p01. We reproduced a spot scanning nozzle (PROBEAT-III: Hitachi,Ltd) and calculated the $f(Q)$ and $P(Q)$ for the cylindrical ionization chamber (30013: PTW). f is determined by the ratio of the absorbed dose of water $D(w)$ to dose of cavity $D(air)$ in the chamber. We investigated four different monoenergetic beams and one modulated beam (SOBP) with a range of 12 cm. The former was measured at 2 cm, the latter was measured at various depths with different dose gradient. **Results:** For the maximum difference in monoenergy, the $f(Q)$ between this work and Baumann et al (2020) was 0.4%. The $f(Q)$ of the modulated proton beam at the SOBP center was 1.1249. At proximal region the $f(Q)$ increased up to about 2.0%. Perturbation correction factor $P(cel)$ was about 0.4% different than unity and was independent in the energy and measurement depth. **Conclusion:** We calculated $f(Q)$ and $P(cel)$ for cylindrical ionization chamber in monoenergetic and modulated proton beams. We will investigate other individual components of $P(Q)$ using cylindrical ionization chamber.

PO-GePV-T-91

Adaptation of A commercial Daily QA Device for Daily Spot Positioning QA

J Kraus*, R Cardan, K McConnell, UAB University of Alabama, Birmingham, Birmingham, AL

Purpose: For Pencil Beam Scanning systems, AAPM TG-224 recommends measuring the absolute and relative spot positioning accuracy within 2mm and 1 mm respectively. We have adapted a the IBA MyQA Daily commercial daily QA device to measure spot position with the required accuracy. **Methods:** We created a pattern of 5 spots directed at ion chambers on the MyQA Daily Device. The measurement database is queried after spot delivery, and a Gaussian fit is performed to the measured dose distributions to determine the spot locations. The measured spot positions are then compared to the expected and a pass/fail message is presented to the operator. The software used in the analysis was created with C# using open source packages available on GitHub. To test sensitivity, intentional offsets from the expected distributions were delivered to see if the system would reject out of tolerance spots. **Results:** The analysis code run over the data collected by the MyQA daily device was shown pass spot distributions when expected to and to flag mismatches appropriately. **Conclusion:** Compared to dedicated spot measurement systems such as scintillator or aSi panels, use of the MyQA Daily has the advantage of being relatively inexpensive and simpler for operators to use. The myQA Daily device is also used for the daily machine output check with the same setup, speeding up the daily QA measurement compared to using different detectors for output and spot positioning.

Author receives honorarium and consulting fees from Varian Medical Systems.

PO-GePV-T-92

Evaluation of the PRESAGE Dosimeters for Spot- Scanning Proton Therapy

A Xu^{1*}, H Lin², C Chen², Y Wang¹, J Adamovics³, C Wu¹, (1) New York Presbyterian/Columbia University Irving Medical Center, New York, NY, (2) New York Proton Center, New York, NY, (3) HEURIS, INC., Skillman, NJ

Purpose: To evaluate the energy and dose rate dependence of the PRESAGE response for the application of the 3D dosimeters to Proton therapy dosimetry. **Methods:** Measurements were made using 4 PRESAGE dosimeters of 10 cm diameter and 10 cm length. Each phantom was setup at a 226-cm SSD and irradiated using 4 single-spot proton pencil beams with intended maximum doses around 1 Gy, 3 Gy, 5 Gy and 10 Gy using Varian ProBeam system. Proton pencil beams with 2 energies (100 MeV and 70 MeV) and 2 dose rates (700 nA and 350 nA Cyclotron currents) were used. The irradiated phantoms were scanned using a newly designed broad-beam optical CT scanner that utilizes fiber optic taper for collimation of transmitted lights. The scanning time for each phantom is about 10 minutes with 1 mm resolution. Dose response curves were generated from each phantom along the central axes of the pencil beams at 3 different depths and analyzed for the energy dependence and the dose rate dependence. Three-dimensional comparisons were also made between the dose distributions from the measurements and the treatment planning system. **Results:** The measured Bragg peak depths for the 100 MeV and 70 MeV beams are 70 mm and 38.0 mm, compared with 75.3 mm and 40.3 mm in water, respectively. The measured water-equivalent thickness is 1.07 which is comparable with the physical density of PRESAGE (1.07 gm/cm³). No energy and dose rate dependence was observed for this PRESAGE formula within the accuracy of the experimental approach. The measured central depth dose curve for each energy agrees well with the planning system for small depths but is in general 10-35% lower than the plan in the Bragg peak region. **Conclusion:** Preliminary results indicate that the Presage dosimeters can be used for proton therapy dosimetry with adequate corrections for the physical density of the dosimeters and the dose quenching effect.

PO-GePV-T-93

Can An Ionization-Chamber Array Be Used for QA of Proton SBRT Beams?

A Stanforth^{1*}, Z Diamond¹, P Sabouri², M Zhu¹, J Zhou¹, R Slopesma¹, (1) Emory University, Atlanta, GA, (2) Miami Cancer Institute, Miami, FL

Purpose: SRS and SBRT are beginning to be used in proton therapy. Currently, there are no criteria for patient specific quality assurance for proton SBRT. This presents certain challenges due to the small size of the fields and high dose fall off. Film provides high spatial resolution and measures absolute dose but can be cumbersome to use. In this study, we look at clinically available detectors and their ability to address issues. **Methods:** Two patients were selected: one with a spinal lesion and one with a brain lesion. The evaluation PTVs were both under 60 cc. Each field was measured with a MatriXX PT (32x32 array, 7.6mm spacing). Additionally, the MatriXX was shifted by half the detector distance in the x and y directions. These two measurements were combined with Matlab code and interpolated to create a measurement with higher spatial resolution. A high resolution relative dose measurement was taken with a scintillation detector (Lynx, IBA). The dose was scaled to the maximum dose of the plane. For volume averaging effects, the planned dose was calculated at a 0.5mm resolution. The dose to each detector was calculated with this fine resolution plane and compared to the MatriXX measurements. **Results:** The three measurement methods showed similar passing rates across all criteria. The MatriXX alone had a 2%/2mm passing rate of 99.74%±0.62% across all fields, the MatriXX with interpolation had a passing rate of 98.16%±0.62%, and the Lynx a passing rate of 97.8%±1.34%. The volume averaging showed an average of -40.22±34.02 mGy across all fields. This corresponds to a 1.67%±1.25% dose difference. **Conclusion:** The MatriXX with interpolation will provide a satisfactory method for measuring small fields with more heterogeneities. This has the advantage over the Lynx by measuring absolute dose. Volume averaging also provides a promising solution to account for heterogeneities.

PO-GePV-T-94

Novel Collimator for High-Throughput Proton FLASH-RT Murine Hemithorax Irradiations

S Mossahebi, Y Poirier*, A Gerry, C Repetto, Z Vujaskovic, I Jackson, A Sawant, University of Maryland School of Medicine, Baltimore, MD

Purpose: To develop and validate a novel collimator with for high-throughput hemithoracic irradiations of mice using 250 MeV protons delivered at FLASH-RT dose rates. **Methods:** Varian ProBeam 250 MeV FLASH-RT protons have a range in water of ~38 cm. We designed a brass collimator of 7.62 cm width, corresponding to ~44 cm in water equivalent thickness. Six 13 mm apertures (approximate length of the mouse lung) were precision-machined to allow concurrent ipsilateral lung irradiation of six mice while sparing contralateral lung, head and neck, and abdominal organs. Radiochromic EBT-XD Gafchromic film was used to measure radiation dose profiles at various depths of solid water below the apertures to assess radiation penumbra and field size. A radiation survey of the neutron activation of the block was also performed to ensure that the dose exposure to technical staff would not exceed federal dose limits. **Results:** A “halo effect” caused by scatter within the collimator was observed, as the dose at the surface nearest to the collimator edge exceeded the central axis (CAX) by ~50%. The homogeneity of the radiation profile improved with depth in solid water, but at the cost of a wider penumbra. At 20 mm depth, the radiation field edges delivered only 80% of the central axis dose (CAX), but showed a sharp profile edge, with a 80-20% penumbra measuring at ~0.4 mm. The four outer apertures had full width half-maxima (FWHM) of 13.5 mm while the two nearest to the isocenter had FWHM of 13.3 mm despite best attempts to match beam divergence. According to the radiation survey, radiation dose to technical staff would stay below federal limits if the workload stays below 240 Gy/hr. **Conclusion:** We designed and constructed a brass collimator able to perform 6 concurrent hemi-thoracic proton irradiations while sparing other organs.

PO-GePV-T-95

Design, Fabrication, and Characterization of Range Modulators for SOBP Proton FLASH Beams

A Darafsheh^{1*}, X Zhao¹, Y Hao¹, T Mazur¹, T Zwart², M Wagner², T Evans², F Reynoso¹, T Zhao¹, (1) Washington University School of Medicine, St. Louis, MO, (2) Mevion Medical Systems, Littleton, MA

Purpose: FLASH radiotherapy, beam delivery at ultra-high dose rates (>40 Gy/s), is an emerging technique to better spare healthy tissues compared to radiotherapy at conventional dose rates (~0.5 Gy/s). The purpose of this work is to design, fabricate, and characterize range modulators to create proton SOBP FLASH radiation fields using a proton therapy synchrocyclotron. **Methods:** The design of the range modulator was composed of arrays of holes with diameter a and spacing between them b on a block of PMMA plastic with thickness t. The parameter t gives the desired modulation depth. The a and b parameters were optimized at each modulation depth to provide the most flat depth dose profile. 3D printing or mechanical machining was used to fabricate the range modulators. A clinical Mevion HYPERSCAN synchrocyclotron was fine tuned to generate ultra-high dose rate proton pencil beams. The range modulator was placed before a boron carbide absorber in the beam path and irradiated with proton pencil beams with nominal energy of 230 MeV. The integral depth dose (IDD) was measured with a PTW Bragg Peak® ionization chamber. The lateral beam profile was measured with radiochromic film. The average dose rate was measured using a PPC05 plane-parallel ionization chamber. **Results:** By selecting proper combination of hole sizes and modulator thickness, SOBP proton fields with >98% depth dose flatness can be generated from a single pencil beam. The optimal hole size depends on the desired modulation depth. By scanning four spots with optimal distancing, lateral flatness >98% over a 1×1 cm² area can be obtained. **Conclusion:** SOBP proton beams can be generated from pencil beams using range modulators composed of arrays of holes on a flat plastic slab. A flat SOBP profile with at least 1 cm³ volume can be generated using such range modulators.

Dosimetry and Dose Rate Evaluation of Transmission Proton Pencil Beam Scanning FLASH Treatment Planning for Hypofractionated Lung Cases: A Comparison Study with Intensity Modulated Proton Therapy

S Wei¹*, (1) New York Proton Center, East Setauket, NY

Purpose: To date, the plan quality of the transmission FLASH plans is not well defined. This study aims to evaluate transmission proton pencil beam scanning (PBS) FLASH radiotherapy (RT) planning for lung cancer patients. The dosimetry characteristics of the FLASH plans were quantified in comparison to conventional intensity-modulated proton therapy (IMPT)-stereotactic body radiation therapy (SBRT) plans. **Methods:** Proton transmission plans of 34Gy in 1 fraction for a cohort of 7 consecutive lung cancer patients were optimized with 5 fields using multiple-field-optimization (MFO) and an in-house developed tool. 400 minimal MU/spot with a spot peak dose rate (SPDR) of 670Gy/s was used for planning. The 3D average dose rate (ADR) and dose-averaged dose rate (DADR) distributions were calculated. RTOG0915 dose metrics were used to compare the FLASH and clinical lung IMPT plans. **Results:** The FLASH plans resulted in worse CTV Dmax compared to the IMPT plans, as 114.7±4.6% vs 107.7±2.1% (p<0.01). The lung V7.0Gy and V7.4Gy were 717.5±378.0cc and 667.8±359.2cc compared to 488.2±245.5cc and 464.5±231.2cc between FLASH and IMPT plans (p<0.01). The FLASH plans yielded significantly higher (both p<0.05) D5cc (13.9±7.2Gy vs. 6.7±11.5Gy) and Dmax (20.9±13.6Gy vs. 17.1±13.1Gy) for esophagus. Similar trends were observed in the other OARs but did not achieve statistical significance due to the variation of target location and small cohort size. The average ADR V40Gy/s of the OARs is 79.0±3.5%, lower than that using the DADR which is 97.0±0.9%. **Conclusion:** Transmission plans result in inferior plan quality to conventional IMPT due to the nature of transmission beam and less optimization flexibility. A 400 minimal MU/spot can ensure 80-100% OAR FLASH dose rate coverage for both ADR and DADR. The potential biological benefit of transmission FLASH despite its inferior dosimetry requires investigation. New planning strategies and delivery techniques are needed to improve delivery quality of FLASH RT.

PO-GePV-T-97

Optimizing Design And commissioning of a Synchrotron Proton Beamline for FLASH Preclinical experiments

U Titt¹*, M Yang¹, X Wang¹, S Lin¹, X Zhu¹, K Iga², N Sahoo¹, A Koong¹, X Zhang¹, R Mohan¹, (1) MD Anderson Cancer Center, Houston, TX, (2) Hitachi America, Ltd.

Purpose: The purpose of this work was to optimize beam shaping devices to produce small volumes (up to ~8 cm³) of uniform dose in a spread-out Bragg peak to achieve ultrahigh dose rates appropriate for FLASH experiments. We modified the characteristics of our ocular beamline to spill the accelerated protons in times as short as 2 milliseconds. **Methods:** Monte Carlo simulations were employed to design custom beam modifiers. These included a scattering foil and a conical flattening filter to maximize the flux of protons into the region of interest, ridge filters, range compensators, and apertures. Shapes, sizes and positions of the last three components were optimized to provide various field sizes and SOBPs in preparation of experiments to be performed. The stability and reliability of the beamline was ascertained, and dose distributions computed with Monte Carlo simulations for each configuration have been validated experimentally. **Results:** With the modified devices we produced circular field sizes of 10, 15 and 20 mm diameter and SOBP modulation widths of 10, 15 and 20 mm. System tests revealed excellent stability and flatness of lateral dose profiles at the center of the SOBP was within ± 3%. Assessment of systematic uncertainties, such as impact of misalignments and positioning uncertainties was performed using simulations and the results used to make appropriate adjustments. **Conclusion:** As a result of this project, the modified beamline is now capable of delivering proton flash beams for in vitro and in vivo experiments.

PO-GePV-T-98

Achievable Flash Dose-Rate by Cyclotron Based Proton Therapy Systems

S Mossahebi, A Sawant, J Polf, E Bentefour*, University of Maryland School of Medicine, Baltimore, MD

Purpose: The current beam configuration use the transition mode of proton Flash beam to irradiate treatment targets. This practice is dictated by the limited capability to the current proton therapy systems to deliver Flash dose-rate over clinically sufficient beam range span. In this study, we investigate the dependency of achievable dose-rate to the main beam parameters for the cyclotron based proton therapy systems. **Methods:** The achievable dose-rate versus the beam energy, the beamline transmission efficiency and the cyclotron's beam current were computed. The beam energy is varied between 70 MeV to 250 MeV (1 MeV step-size), the beamline efficiency is varied from one-tenth to ten folds of the typical beamline transmission at any given proton beam energy. The calculations are repeated for a set of cyclotron beam currents ranging from 100 nA to 1000 nA (100 nA step-size). The maximum achievable dose-rate by the various designs of the commonly used clinical proton therapy systems is indicated thereafter. **Results:** Based on our simulation, the maximum achievable dose-rate is 1080 Gy/sec at the beam of 250 MeV where the machine's beamline transmission efficiency is about 100% and with cyclotron current of 1 µA. For other beam energies, the dose-rate value strongly depends on the beamline transmission efficiency, which varies in average between 10% (high energy) to 0.05% (low energy). In this case, the maximum achievable integral dose-rate is about 110 Gy/sec for 249 MeV and the lowest achievable Flash dose-rate (40 Gy/sec) occurs at the beam energies between 102 MeV and 226 MeV depending on every machine specific beamline transmission efficiency. **Conclusion:** We developed an open source calculator for achievable proton Flash dose-rate with input parameters that can be made specific to any cyclotron based proton therapy facility.

PO-GePV-T-99

The Software Controller of Isocentric Rotation Chair Positioner for Treating Patients with Head/Neck Cancers in Fixed Carbon-Ion Beamline

W Hsi¹*, X Zhang², F Yang², R Zhou², (1) University Florida Health Proton Therapy Institute, Jacksonville, Florida, US (2) College of Physical Science and Technology, Sichuan University, Chengdu, Sichuan Province, China

Purpose: To utilize an isocentric rotating chair as a positioner for a clinical application, a software controller was built by implementing the mathematical manipulations of specific coordinate transformation to the IEC fixed (If) reference coordinate for each movement mechanism of chair. **Methods:** A software controller to execute any required displacement under a treatment workflow was evaluated. The three major motion mechanisms in the chair positioner are a 360° rotating platform, a Hexapod, and a 3D translation module. To execute a 6 DoF displacement by the controller over the chair, the mathematical manipulations was developed in a matrix formula in the If coordinate through a proper transformation on each mechanism. The trend of deviations on the displacements between ideal and misaligned mechanism for each parameter was investigated and measured by using an optical tracking system. The tolerance of each parameter was investigated to achieve the accuracy of +/- 1.0 mm in translation and +/- 1.0° in rotation on any required displacement executed by the chair positioner. **Results:** Developed mathematical manipulations in the matrix formula with measured deviations of parameters were integrated into a visual user interface. When a large deviation of 6 DoF displacement occurred due to misalignment of any mechanism that were reproducible in the Validation-and-Verification (VnV) procedure, the reproducible deviations were internally corrected in the Hexapod. A commissioning was conducted to meet clinical requirements after the VnV procedure. 17 patients was successfully treated by using this chair positioner. **Conclusion:** The chair positioner using the software control with implemented mathematical manipulations was embedded to conduct a clinical trial under the workflow with an existing image-guided treatment system. The deformation of tilted posture on the Hexapod and/or the 3D platform will be further investigated as one of concern for using over 5° tilt fields.

PO-GePV-T-100

3D Thoracic Motion Phantom Study for Interplay Effect of Pencil Beam Proton Scanning

H Grewal^{1,2*}, S Ahmad², M Chacko^{1,2}, B Tesfamichael¹, H Jin², (1) The Oklahoma Proton Center, Oklahoma City, OK, (2) University of Oklahoma Health Sciences Center, Oklahoma City, OK

Purpose: Interplay effect which causes dose degradation from intended delivery depends on a number of factors including proton beam spot size in a pencil beam scanning (PBS) proton therapy. This study accesses interplay effect for different range of motion amplitude with a three-dimensional thoracic phantom using EBT3 films. **Methods:** The study involved Mevion S250i with Hyperscan PBS beam delivery system with spot size relevant to this research from 17.4mm ($\approx 33\text{MeV}$) to 10.4mm ($\approx 120\text{MeV}$). Four-dimensional computed tomographic scan of QUASAR respiratory motion phantom was obtained for 6-, 10-, and 14-mm motion amplitude. Three respiratory gated and nine free-breathing (FB) plans with volumetric repainting (VR) number of one, three and five for three motion amplitudes were created using appropriate scans. The phantom used 15 breaths per minute to mimic adult breathing pattern and gated treatment plan used 20%-40% gating window for planning and delivery. Monte-carlo optimization and dose calculation algorithm were used. Dose distribution of the irradiated EBT3 film was compared with planning using three gamma analysis criteria: 3%/2mm (Task Group 218), 3%/3mm (clinical), and 7%/5mm (IROC lung) with passing criteria of 90%, 95%, and 85%, respectively. **Results:** Gated treatment for three motion amplitudes results in more than 95% of gamma passing rate for all gamma criteria studied. The 6-mm and 10-mm FB motion amplitude meets gamma passing criteria but 14-mm did not with 82.2% and 90.5% for 3%/2mm and 3%/3mm, respectively. As the number of VR increases, gamma index passing percentage improves as a general trend for all FB motion amplitudes. **Conclusion:** With large proton beam spot size, PBS technique can be implemented for moving thoracic tumors with an acceptable accuracy up to 10 mm motion amplitude. Respiratory gated and VR appeared to decrease interplay effect and can thus increase tumor motion treatable amplitude range beyond 10 mm.

PO-GePV-T-101

Experimental Assessment of Conformal 4D-Optimization in Lung Cancer Particle Therapy

M Lis^{1,2*}, W Newhauser^{1,3}, M Donetti⁴, T Steinsberger^{2,5}, M Wolf², C Graeff², (1) Louisiana State University, Baton Rouge, LA, (2) GSI Helmholtz Center for Heavy Ion Research, Darmstadt, DE, (3) Mary Bird Perkins Cancer Center, Baton Rouge, LA, (4) Fondazione CNAO, Pavia, Italy, Pavia, IT, (5) Technical University Darmstadt, Darmstadt, DE

Purpose: For this study, we compared treatment quality and projected treatment outcomes for two approaches to treating moving tumors with ion beams: synchronization of delivery to the motion of a moving target, and delivery to a motion-encompassing internal tumor volume (ITV) with rescanning. **Methods:** We created 4D optimized treatment plans for proton and carbon ion beams. Two 4DCTs of NSCLC patients were used to generate several treatment plan types: motion-synchronized deliveries, ITV treatments with rescanning, static deliveries and uncompensated deliveries. Each plan was delivered with the same dose delivery system. Dose delivery data was measured with a 2D ionization chamber array detector that was mounted to a linear stage, moving with periodic respiratory-like motion. Likewise, beam monitoring data from log files was used to reconstruct the delivered dose distributions in water and in patient 4DCTs, to compare to measurements and assess delivery quality. Conformity, uniformity, tumor coverage, and extent of hotspots within the target volume were assessed, and projected clinical outcomes (normal tissue complication probability (NTCP) and tumor control probability (TCP)). **Results:** The motion compensated and static treatments showed acceptable dosimetric performance, and dose coverage was above 95% for all these treatments. The greatest conformity (62 %) was achieved with the motion-synchronized approach, while the lowest was observed for ITV rescanned treatments (49 %). However, higher overdose and lower homogeneity were observed for the motion-synchronized delivery approach due to radiation leakage during beam gating. Despite this, projected therapeutic outcomes favored the motion-synchronized treatment approach, with the highest equivalent uniform dose and the lowest NTCP. **Conclusion:** Our findings strongly suggest the feasibility to implement a motion-synchronized treatment strategy, using an M-DDS that provides superior organ sparing compared to ITV based rescanning.

This project received funding from the EU Horizon 2020 research and innovation programme under Marie Skłodowska-Curie grant agreement No 675265, OMA Optimization of Medical Accelerators. The research presented here is a result of an R&D project experiment SBIO at the SIS-18 in the frame of FAIR Phase-0, supported by GSI.

PO-GePV-T-102

Practical Implementation and Dosimetric Implications of a Novel Dose Painting Delivery Strategy: Minimal Energy Modification (MEM) During Proton Therapy of Thoracic and Abdominal Tumors

S Vedam^{*}, B Zhang, S Mossahebi, W Yao, M Zakhary, B Yi, University of Maryland Medical School, Baltimore, MD

Purpose: Dose painting in proton treatment is often implemented by splitting a field into two or three, which increases number of beams, resulting in prolonged treatment duration. This study examines feasibility and dosimetric implications of a novel dose painting delivery strategy with reference to non-dose painting (NDP) based planning for proton therapy treatment plans of mobile tumors. **Methods:** A practical method to implement dose painting is to split layers of proton beam in a field rather than split the field. To make this field deliverable, the energies of the split layers are minimally altered from the NDP plan (a difference of ~ 0.1 MeV per energy layer and delivery of a fraction $\sim 50\%$ of the MU's per painting iteration). Above alterations were made after an optimized NDP plan was approved clinically for treatment. Dose was then recalculated to yield a minimal energy modification dose painting (MEM-DP) based plan. Dosimetric comparison of the NDP and MEM-DP based plans was performed retrospectively on 10 patient cases to ensure there were no significant differences clinically. **Results:** Target (CTV) D95 for the NDP and MEM-DP plans differed from each other by $0.1 \pm 0.1\%$, indicating good agreement. No significant differences in normal tissue sparing were observed. Total average savings in beam delivery time with MEM DP approach was ~ 4 minutes, with a min and max of 55 seconds and 14 minutes per treatment session respectively. **Conclusion:** It is feasible to deliver MEM-DP based treatments and achieve savings in beam delivery time within our existing clinical environment without any significant changes to NDP based plan quality.

PO-GePV-T-103

Dosimetric Comparison of Intensity Modulated Radiation Therapy (IMRT), 3D Conformal Proton Therapy and Intensity Modulated Proton Therapy (IMPT) for Metastatic Brain Cancer

M Sullivan^{*}, S Ahmad, H Jin, University of Oklahoma Health Sciences Center, Oklahoma City, OK

Purpose: To compare IMRT against proton treatment (conformal or IMPT) plans for metastatic brain cancer. **Methods:** Ten IMRT patients with brain cancer were retrospectively chosen, all of which received doses in the range of 20 to 40 Gy and in 3 to 5 fractions by Varian TrueBeam STx. Three proton plans (conformal: double scattering, static-IMPT: single collimation, and dynamic-IMPT: layer-by-layer collimation) were generated for the same patient using Mevion S250 (conformal) and S250i (IMPT) to compare. Each plan had respective treatment planning systems: Brainlab iPlan for IMRT, Varian Eclipse for proton conformal, and RaySearch Raystation for IMPT. Dosimetric comparisons were carried out through dose-volume histogram analysis of the target and the organs at risk. **Results:** Average target dose conformity indices are 2.42, 2.79, 2.25 and 2.30 and homogeneity indices are 1.61, 5.08, 8.05, and 9.07 for IMRT, proton conformal, static-IMPT and dynamic-IMPT, respectively. Average maximum target doses differ with respect to prescription dose by 1.19%,

5.2%, 8.19%, and 9.26% for IMRT, proton conformal, static-IMPT and dynamic-IMPT, respectively. Normal tissues are in general spared more on average with proton compared to photon treatments. The following percentages represent average maximum dose relative to prescription dose to the brainstem and optic chiasm, respectively. IMRT: 37.61% and 14.86%, Proton Conformal: 22.18% and 10.89%, IMPT Static: 28.12% and 12.93%, IMPT Dynamic: 27.27% and 14.08%. **Conclusion:** Target dose homogeneity was better with IMRT compared to proton, whereas overall dose conformity was found somewhat better with IMPT than IMRT. Normal tissue doses were better for both conformal proton and IMPT compared to IMRT when the tissues are not in close proximity to the target.

PO-GePV-T-104

Dosimetric Comparison of Volumetric Modulated Arc Therapy (VMAT), 3D Conformal Proton Therapy and Intensity Modulated Proton Therapy (IMPT) for Lung Cancer

M Sullivan*, S Ahmad, H Jin, University of Oklahoma Health Sciences Center, Oklahoma City, OK

Purpose: To compare VMAT against proton treatment (conformal and IMPT) plans for lung cancer. **Methods:** Ten patients with lung cancer were retrospectively chosen, each of which received doses of 55 Gy in 5 fractions using 6X photon beam from Varian TrueBeam STx machine with VMAT technique. The treatment plans were done using Varian Eclipse treatment planning system (TPS). Two proton treatment plans (conformal: double scattering, and static-IMPT) were subsequently generated for each patient using Mevion S250 and Mevion S250i for conformal and IMPT, respectively. Varian Eclipse TPS was used for proton conformal, and RaySearch Raystation was used for IMPT. Dosimetric comparisons were carried out through dose-volume histogram analysis of the target volume and the organs at risk. **Results:** Average target dose conformity indices are 2.90, 2.70, and 2.0 and homogeneity indices are 3.2, 6.1, and 11.4 for VMAT, proton conformal and static-IMPT, respectively. Average maximum target doses differ with respect to prescription dose by 6.8%, 9.1%, and 13.3% for VMAT, proton conformal, and static-IMPT, respectively. Normal tissues are in general spared more on average with proton treatments when compared to photon treatments. The following percentages represent average maximum dose relative to prescription dose to the spinal cord, uninvolved lung, and heart, respectively. VMAT: 15.8%, 20.6%, and 15.5%; Proton Conformal: 3.3%, 5.2%, and 15.1%; and IMPT: 6.1%, 5.3%, and 12.3%. **Conclusion:** Target dose homogeneity was better with VMAT compared to proton treatments, whereas overall dose conformity was found to be somewhat better with IMPT than proton conformal and VMAT. Normal tissue doses were better for both conformal proton and IMPT compared to VMAT, with IMPT being the best.

PO-GePV-T-105

Dose-Averaged LET Evaluation in Head and Neck Adenoid Cystic Carcinoma Patients for Carbon-Ion Radiotherapy

R Kohno^{1*}, S Lee², A Yamamoto¹, K Yamaoka¹, M Suga³, M Koto¹, (1) National Institute of Radio. Sciences, Chiba, JP, (2) Yamagata University, Yamagata, JP, (3) Kanagawa Cancer Center, Kanagawa, JP

Purpose: In carbon ion radiation therapy (CIRT), the dose-averaged LET (LET_d) is one of the important factors in determining clinical outcomes. In order to investigate the local control of adenoid cystic carcinoma (ACC) and the optic neuropathy of optic nerve (ON)s in CIRT, the effects of the LET_d were evaluated clinically. We propose novel tumor control probability (TCP) and normal tissue complication probability (NTCP) models with D90-value of RBE-weighted dose and LET_d as clinical parameters. **Methods:** Total 99 patients with head and neck ACC who received CIRT at the National Institute of Radiological Sciences were investigated. The physical dose and LET_d distributions for each patient were recalculated using in-house treatment planning system. For ACC tumor, minimum-value of dose-averaged LET and D90-value of RBE-weighted dose as an indicator of evaluation were estimated. For ONs, maximum-value of LET_d and maximum-value of RBE-weighted dose were evaluated. **Results:** For each prescribed RBE-weighted dose of 57.6 and 64 Gy (RBE), no statistical significance for local control by RBE-weighted dose was found, but for 64 Gy (RBE), we observed the LET_d may be a marginally significant. For ONs, it was obvious that the optic neuropathy had a greater effect from RBE-weighted dose rather than dose-averaged LET. The proposed models could be applied to both TCP and NTCP prediction, and was found that the clinical outcomes from low to high LET_d region were predictable. **Conclusion:** We analysed clinically the physical dose and LET_d distributions for 99 patients with head and neck ACC. Our results indicated that LET_d may be a determining factor for local control for ACC tumors. For ON, the RBE-weighted dose was related to optic neuropathy rather than LET_d. The proposed approach may be helpful to predict whether LET_d will affect clinical outcomes and be useful when constraining not only RBE-weighted dose but also LET_d.

Dose to Cardiac Implantable Electronic Devices in Patients Receiving Proton Beam Therapy

T Alfonzetti*, A Anvari, A Butala, M Carpenter, A Kassae, I Paydar, J Jones, D Mihailidis, University of Pennsylvania, Philadelphia, PA

Purpose: To investigate the dose to Cardiac Implantable Electronic Devices (CIEDs) for patients receiving proton beam therapy (PBT). We also characterized major factors contributing to delivered dose to the CIED in PBT. **Methods:** 118 adult patients with the CIED who received PBT- either pencil beam scanning or double-scattering- for brain, Head&Neck, thorax, abdomen, pelvis had their treatment plans and delivery information retrospectively analyzed. Eclipse treatment planning system (TPS) was utilized for proton planning in this study. Patients without the CIED included in their simulation computed tomography scan were excluded from studies investigating the distance of the CIED from 50% and 5% isodose lines. **Results:** Patient information including age, gender, anatomical site treated, OSLD dose, TPS estimated dose to the CIED, proton beam delivery technique, and fractionation scheme information is tabulated. Outdata show that the CIEDs receive negligible to no dose when the device is at medium/significant distance from the treatment area, with its relative location to the treatment volume being the most influential factor for evaluating the dose (both estimated and measured). **Conclusion:** For PBT, OSLD and TPS assessed dose to the CIEDs does not have a level of accuracy to draw any significant conclusions. It is generally seen that planning an appropriate treatment with effort taken to avoid the CIEDs will result in doses that do not exceed or approach the 2 Gy limit. Thus, it is our proposal that patients with a CIED receiving proton therapy be managed in proportion to their dependence on their cardiac device and in line with recommendations from TG-203.

PO-GePV-T-107

Dosimetric Comparison for Unfavorable Early Stage Lung Cancer: Intensity Modulated Proton Therapy Versus Volumetric Arc Photon Therapy

S O'Reilly*, P Singh, B Hartl, E Diffenderfer, K Cengel, W Levin, A Berman, S Feigenberg, University of Pennsylvania, Philadelphia, PA

Purpose: Stereotactic body radiotherapy is now the standard of care for management of early stage lung cancer; however, for exceptionally large or ultra-central tumors a less aggressive hypo-fractionated approach (60Gy, 15 fractions) is available. We sought to identify patients previously treated with hypo-fractionated volumetric arc photon radiotherapy (VMAT) that may benefit from proton therapy and identify what organ-at-risk (OAR) dose reductions could be statistically significant. **Methods:** Ten non-small cell lung cancer patients with either large (PTV largest diameter > 5cm) and/or ultra-central (7 patients) treatment volumes treated with hypo-fractionated (60Gy, 15 fractions) VMAT were re-planned using 3 to 5 field pencil beam scanning (PBS) proton therapy using the same fractionation. The iGTV was robustly optimized (multi-field) using 3.5% range uncertainty and 5mm isocenter shifts. The PTV was nominally optimized and field-specific targets were generated for spot placement. Planning was performed on the average CT and forward calculated on the exhale and inhale phase CTs to check coverage stability. Statistical analysis was completed using a 2-sided paired t-test for each OAR. **Results:** The spinal cord (D5cc),

esophagus (D0.03cc, D5cc), trachea (D10cc), bronchus (D10cc), and Lungs-iGTV (mean) dose differences were all found to be statistically significant ($p < 0.05$) showing improvement with protons. All patients also had reduced mean doses to heart, great vessels and ipsilateral lung. Five patients had not met the chest wall constraint for the clinical plan due to PTV overlap and the proton plan was able to significantly ($p = 0.03$) reduce the dose (D50.00cc) to the chest wall for these patients (average reduction 3.3Gy). The proton plans were able to meet conformity index and gradient measure metrics and coverage remained stable on phase CTs. **Conclusion:** PBS proton therapy could improve dose metrics for patients whose anatomy is unfavorable to meet hypo-fractionated planning constraints using VMAT, particularly those near the chest wall.

PO-GePV-T-108

Effective Treatment Plan Integrity Verification for Passive Scattering and Pencil Beam Scanning Proton Therapy

Y Zhang^{1*}, M Ho², C Liu^{1,3}, X Liang¹, P Johnson¹, J Park¹, M Artz¹, (1) University of Florida Proton Therapy Institute, Jacksonville, FL, (2) Johns Hopkins Medicine, Washington, DC, (3) University of Science and Technology of China, Hefei, Anhui, CN

Purpose: The majority of the automatic error detection studies are focused on photon radiation therapy. Few have been reported in the proton community. The purpose of this study was to develop and implement a framework for automating aspects of the initial physics plan check for passive scattering and pencil beam scanning (PBS) proton radiotherapy, with the overall goal of improving workflow efficiency and increasing error detection. **Methods:** A RayStation script, Auto-IniCheck, was developed based on a set of comprehensive checklists designed to standardize the initial physics plan check and incorporate recommendations from AAPM's TG-275 report. The checklists are categorized by treatment site and proton modality. Specific items are characterized into beam set independent and dependent groups. The former includes items related to patient assessment and data management; the latter contains items related to patient modeling, plan design, optimization, and evaluation. Each item that could be automated was included in Auto-IniCheck. Items that could not be automated are highlighted for manual review. The results are summarized in a PDF report displayed to the user. **Results:** 75%-80% of checklist items could be automated. The script takes less than 15 seconds to run and drastically decreases the amount of time needed to check each item. Additionally, Auto-IniCheck enables the detection of specific errors that would not have been readily apparent through manual reviews, such as validating the isocenter coordinates truncated to one decimal place or that PTV margins match institutional protocols. **Conclusion:** A new script, Auto-IniCheck, was developed to automate several aspects of the initial physics check for passive scattering and PBS proton plans. By improving the efficiency of the review and the visibility of specific errors, the system enhances the plan check. It allows the reviewer more time to focus on critical areas such as plan quality and clinical decision making.

PO-GePV-T-109

Dosimetric Comparison of Pencil Beam Scanning Proton Plans with Different Aperture Modes

Y Yuan^{1*}, D DeBlois¹, Y Chen¹, C Frame¹, D Pang¹, (1) Department of Radiation Medicine, MedStar Georgetown University Hospital, Washington DC

Purpose: The Mevion S250i HyperScan proton system employs a mini-MLC (Adaptive Aperture (AA)) to trim lateral spots for sharpened penumbra, which can be achieved through a static single layer trimming (SA) or dynamic layer-by-layer trimming (MLA). This study investigates potential dosimetric benefits that maybe offered by MLA in pancreatic cancer treatment. **Methods:** Six clinical hypofractionated pancreatic treatment plans were retrospectively re-planned using these two different spot trimming techniques. Raystation TPS (V.10a) was used for planning, which models the AA either as a single static collimator in SA or multiple collimators of varying sizes in MLA. Treatment plans, which consists of 2 to 3 beams, were optimized to meet the clinical goals at the minimum and further optimized for additional improvements possible. Robust optimization incorporating a 3.5% range uncertainty and 5 mm position uncertainty in all directions were performed. Isodose distributions and DVHs for targets and OARs were compared. Conformity index (CI) of the 50% isodose line and a dose gradient index (V20%-V80%) were calculated and compared. **Results:** While both SA and MLA plans meet the clinical goals for similar CTV coverage, on average, plans with MLA achieved better sparing of GI OARs (e.g., 20% reduction of V15Gy for small bowel). No statistically significant difference was observed for the CI. The SA plans yielded slightly better (4%) gradient index. **Conclusion:** For pancreatic cancer treatments using the Mevion HyperScan proton system, the benefits of MLA were demonstrated in reduced bowel dose. Benefits in other anatomical sites will need further evaluation and are likely site dependent.

PO-GePV-T-110

Systematic Study of Penumbra Reduction with Adaptive Aperture for Hyperscan Spot Scanning Proton Beams

Y Chen, C Frame*, Y Yuan, T Ma, D Pang, MedStar Georgetown University Hospital, Washington, DC

Purpose: To quantify lateral penumbra reduction of field with adaptive aperture (AA) compared to the same field without AA for the Mevion HyperScan proton system under different energies, air gaps, field sizes, and depths. **Methods:** RayStation Monte Carlo proton TPS was used to optimize various single energy layer plans without AA to thin target of size of 3x3, 10x10, and 18x18 cm at ISO. The same plans were re-calculated with AA that conforms to the known field size. EBT3 film and a PTW Octavius 1500XDR detector were used to measure lateral penumbra at the depth of Bragg peak for energies of 28, 120, 180, and 227 MeV. For 10x10 field of 120 MeV, plans with varied air gaps of 1.4, 5, 10, 15, 20 cm were created and measured. For 10x10 fields of 120 and 227 MeV, we also measured penumbra at surface and other 3 intermediate depths. **Results:** Penumbra reduction decreases greatly from 78% to -4% as energy increases from 28 to 227 MeV. A change of 55% to 47% is observed for air gap of 1.4 to 20 cm for 120 MeV. There is no clear field size dependence except for 227 MeV where the change of 3.5% to -11% for field of 3 to 18 cm indicates no benefit with AA for the field larger than 6 cm. The smallest penumbra of 1.2mm is observed at surface of 227 MeV field with AA where the spot size is the smallest too. Consistent with energy change, penumbra reduction decreases linearly as depth (or range) increases. There exists a turning point of 29.5cm (216MeV) after which the penumbra with AA becomes worse than without AA. **Conclusion:** The significant penumbra reduction is observed for low energy or shallow depth. A mild advantage with AA is demonstrated by reducing air gap.

PO-GePV-T-111

Reducing Beam Delivery Time for Proton PBS Treatment with Breath-Hold Motion Management Technique

M Zhu*, A Stanforth, Z Diamond, Y Lin, K Langen, Emory University School of Medicine, Atlanta, GA

Purpose: Breath-hold is an effective motion mitigation strategy to reduce tumor motion interplay effect with active scanning pencil beam proton therapy. This work explores the possibility of reducing beam delivery time by decreasing the number of energy layers or proton spots. **Methods:** Ten plans were re-created in a commercial TPS for 5 esophageal and liver cancer patients, with the same parameters as the clinical plans (Plan_C), except for the energy layer spacing (ELS) or the spot spacing (SS). In Plan_C, ELS and SS were usually set to values smaller than the system default. For each Plan_C, a Plan_ELS was optimized with the energy layer spacing changed to the default, i.e., fewer number of energy layers, while keeping all other parameters unchanged. Similarly, a Plan_SS with setting the spot spacing to default. All 15 plans were delivered on a clinical PBS proton machine and the beam delivery time was recorded for each field. **Results:** Compared with the Plan_C, both Plan_ELS and Plan_SS achieved the same target dose. The Plan_ELS also had near identical OAR doses, while Plan_SS had slightly higher doses to selected OARs. Recorded beam delivery times were 55.5±11.9 s, 43.6±9.0 s, and 53.7±10.7 s for Plan_C, Plan_ELS, and Plan_SS, respectively. Number of energy layers were reduced by 34.9±4.4% in Plan_ELS; as a result, the beam delivery times were 21.4±4.0%, or 12.0±3.7 s, less than Plan_C. The Plan_SS had 26.5±4.8% fewer number of spots, while the delivery times were reduced by 2.9±2.6% (1.8±1.7 s) compared to Plan_C.

Conclusion: Although the spot spacing setting only had a marginal improvement on beam delivery time; using less energy layers can significantly reduce the beam delivery time without compromising plan quality. Future investigation will focus on achieving the optimal trade-off between plan quality and beam delivery time.

PO-GePV-T-112

A Novel Worst-Case Robust Optimization Method That Combines Geometric and Target Volume Definition Uncertainties

G Buti^{1*}, K Souris¹, A Barragan Montero¹, J Lee¹, E Sterpin^{1,2}, (1) Institut de Recherche Experimentale et Clinique (IREC), Center of Molecular Imaging, Radiotherapy and Oncology (MIRO), Universite Catholique de Louvain, 1000 Brussels, Belgium (2) Department of Oncology, Laboratory of Experimental Radiotherapy, Katholieke Universiteit Leuven, 3000 Leuven, Belgium

Purpose: A fixed margin expansion (GTV-to-CTV) holds some limitations when the uncertainty of target volume definition is considered explicitly in the treatment planning process. For instance, worst-case scenarios can become unnecessarily improbable when a fixed GTV-to-CTV expansion is combined with extreme geometric uncertainty scenarios. This work proposes a statistically sound worst-case approach that combines target volume uncertainties with geometric uncertainties. **Methods:** The method consists of two steps: (1) scenario definition and (2) robust optimization. (1) The entire space of uncertainties (so-called scenario space) is considered by sampling n error scenarios according to their uncertainty distributions. This includes a dimension with tumor infiltration errors to account for the uncertainty in target volume definition. Infiltration errors are modeled by isotropically dilating the GTV, followed by correcting for anatomical barriers. The scenario space is subsequently partitioned in k -equiprobable clusters with a k -means clustering algorithm. Finally, the optimization scenarios are defined as the k cluster centers. (2) During optimization, the 10% worst scenarios are discarded in order to guarantee a 90% confidence interval in dosimetric space. Minimax is performed with the 90% best scenarios, re-evaluated at each iteration. The proposed method ($n = 1000$, $k = 60$) is tested for a lung tumor patient (60 Gy prescription), treated with IMPT. The results are benchmarked against regular CTV-based worst-case optimization. The evaluation procedure consists of recomputing the dose for 250 scenarios after sampling tumor infiltration errors, setup errors, range errors and breathing motion. **Results:** The proposed method achieves a reduced esophagus dose (-7.9 Gy of D2) whilst maintaining similar levels of robustness: target worst-case D95 of 57.4 Gy and 57.6 Gy for regular method and proposed method, respectively. **Conclusion:** A novel worst-case approach is proposed that allows for improved control over the confidence interval with improved OAR sparing.

Monte Carlo Modeling of a Proton Portal Imaging System Using in Vivo Generated Neutrons

S Thompson*, S Samant, J Nimmagadda, L Maloney, University of Florida, Gainesville, FL, Erik Kryck, University of Florida Health Proton Therapy Institute, St. Charles Health System

Purpose: To present a proton portal imaging (PPI) system which uses in situ generated spallation neutrons to produce images of patient anatomy; and to provide an accurate Monte Carlo model which enables the optimization of the detector placement and geometry, as well as to provide spectral data on the spallation neutrons and photons in order to ensure optimal detection efficiency. **Methods:** The proposed PPI system will make use of scintillation cameras (modeled as LiF-ZnS) to capture the in vivo generated neutrons. An MCNP 6.1 model was constructed to optimize the detector placement, geometry, and to ensure adequate sensitivity to neutrons while also displaying low sensitivity to gamma radiation. This model also serves to generate modulation curves, which can be compared to measurements to determine the limiting spatial resolution for the system. A line pair phantom was constructed with calcium bars of thicknesses and spacings from 2-8 mm to determine the limiting spatial resolution. The Monte Carlo model was compared to measurements obtained in a clinical double-scattering proton system with a typical treatment field. **Results:** Modulation plots are presented for the limiting bar thicknesses and spacings. The bar pattern is indiscernible at about 4-5 mm, which is the limiting spatial resolution of the system. Photon spatial intensity maps are also presented to verify that neutron interactions in the scintillator dominate photon interactions, as these are the interactions of interest in this study. Neutron and photon spectra plots were also produced in the phantom to study the sensitivity of detector placement on neutron capture efficiency. **Conclusion:** The limiting spatial resolution for the proposed PPI system is between 4-5 mm. The interaction of neutrons in the scintillator outweighs the contribution of photons to the acquired signal, which is essential for PPI using in vivo generated exit neutrons.

PO-GePV-T-114

Initial Experience with a Head and Neck RapidPlan Model for Pencil Beam Scanning Proton Therapy

K McConnell*, J Snider, J Nemecek, R Cardan, UAB University of Alabama, Birmingham, Birmingham, AL

Purpose: Varian Eclipse 16.1 includes the capability to create a proton RapidPlan (RP) model. We tested the feasibility of using RP for generating clinically appropriate pencil beam scanning head and neck treatment plans. **Methods:** Twenty-six left, right, and bilateral head and neck cases treated at our center were used to create the RP proton model. Five of the cases that were used for training and two cases not included in the training set were re-planned with RP for model validation. The RP model was trained without optimization and ring structures. Additionally, the RP cases were run only once using the same beam arrangement as the clinical plan. The re-planned and dosimetrist-planned cases were blinded and evaluated by an academic radiation oncologist specializing in head and neck cancer and proton therapy. **Results:** While the 7 RP model plans passed our institutional plan and dose criteria, the radiation oncologist preferred the dosimetrist planned case over the RP in all 7 cases. Five of the 7 RP plans were determined to be clinically appropriate and not meaningfully different than the clinical plan. Two RP plans were deemed to require minor edits; no RP plans were judged inappropriate or to require major edits. Dose homogeneity and conformity were identified as the primary distinctions between the planning methods. **Conclusion:** While the RP cases were not chosen as the preferred final plan, the model has demonstrated significant potential as a consistent starting point for the dosimetry team. The RP model also offers substantial time savings as it does not require generation of optimization structures. The relatively minor issues noted by the radiation oncologist were parameters that can be added to the model or addressed by a dosimetrist on editing the RP. Additional investigation is warranted into the clinical role of this tool.

Author receives honorarium and consulting fees from Varian Medical Systems.

PO-GePV-T-115

Should We Be Considering Biological Robustness in Proton Therapy?

A Faught*, L Wilson, M Gargone, F Pirlepsov, V Moskvina, C Hua, St. Jude Children's Research Hospital, Memphis, TN

Purpose: Treatment planning strategies that minimize end-of-range uncertainties associated with high linear energy transfer (LET) in proton therapy are needed. We replanned clinical cases to assess changes in LET and compromises to dose. **Methods:** Four patients were chosen to represent various brain tumor shapes, locations, and proximity to the brainstem. Treatment plans were developed for each patient by changing one of the following factors from the clinical plan and re-optimizing: optimization method (i.e., single field versus multi field), spot restrictions at end range, beam orientation, number of beams, and

scenario-based robust optimization parameters. Including the original clinical plans, a total of 28 unique treatment plans were used to calculate dose and dose-weighted LET (LETd) using TOPAS Monte Carlo code. Dose distributions with a constant RBE of 1.1 were assessed to judge clinical feasibility of the plan. Volume of LETd exceeding 6 keV/micron in regions receiving greater than 80% of the prescription dose, defined as a high-risk volume, mean LETd, and dose-times-LETd were used to assess changes in potential biological implications. **Results:** Clinically acceptable plans were achieved for all strategies in 3 of 4 patients. Planning strategies inconsistently affected the high-risk volume (range = 0.3 to 8.1cc) and dose-times-LETd distribution in normal brain. Mean LETd in brainstem was higher in the modified plans by an average of 1.1 and 1.9 keV/micron when adding a third beam or decreasing the intersection angle between beams, respectively. The maximum change in the brainstem among all other techniques was 0.3 keV/micron. **Conclusion:** Forward-based strategies to mitigate LETd hotspots are patient dependent, but generally possible in a way that does not compromise dose distribution quality. Beam geometry is a greater predictor for undesirable LETd placement than optimization parameters or restricted spot placement. We recommend the use of two parallel-opposed fields in the treatment of cranial targets.

Assessment of A Knowledge-Based Planning for Robustly-Optimized Intensity Modulated Proton Therapy for Head and Neck Cancer

Y Xu*, M De Ornelas, J Cyriac, E Bossart, K Padgett, M Butkus, T Diwanji, M Samuels, N Dogan, University of Miami, Miami, FL

Purpose: Knowledge-based planning (KBP) tools, which incorporates prior treatment planning experience, has the potential to improve the quality and consistency of treatment plans. In this work, we evaluated the performance of a proton-specific KBP model in the generation of robustly optimized IMPT (RO-IMPT) plans for treatment of head and neck (HN) patients. **Methods:** Sixty head and neck cancer patients previously treated with volumetric modulated arc therapy (VMAT) were selected and replanned with RO-IMPT. Plans were robustly optimized using ± 3 mm setup uncertainty (in cardinal directions) along with $\pm 3\%$ proton range uncertainty. Fifty IMPT plans were selected to build the HN proton KBP model library. The remaining ten patients were used for model validation. The model quality was assessed using model generated plots such as DVH plots, regression and residual plots. The comparison of the dosimetric indexes for target and OARs between KBP generated and expert plans were performed by two-sided paired t-test, $p < 0.05$ indicating significance. **Results:** Compared with expert plans, the nominal KBP plans delivered significantly lower doses to almost all OARs ($-4.9\text{Gy} \pm 2.74\text{Gy}$ for larynx Dmean, $-6.16\text{Gy} \pm 3.87\text{Gy}$ for constrictor Dmean, $-6.84\text{Gy} \pm 4.65\text{Gy}$ for spinal cord Dmax, $-7.06\text{Gy} \pm 4.66\text{Gy}$ for left cochlea Dmean) except the mandible and the oral cavity which showed no statistically different significance. When including all uncertainty scenarios, the target coverage was better in the KBP plans ($4.59\% \pm 7.58\%$ for CTV70 V100, $4.07\% \pm 5.84\%$ for CTV56 V100). **Conclusion:** This work demonstrated that the proton-specific KBP model was able generate plans with similar target coverage and much better OAR sparing as compared to the ones generated by the expert for HN patients. The HN KBP plans were also more robust and homogenous. Use of proton KBP model for generation of IMPT plans has a potential to improve treatment planning efficiency.

Knowledge-Based Planning for Robustly-Optimized Intensity Modulated Proton Therapy of Prostate Cancer

Y Xu*, N Brovold², E Bossart¹, K Padgett¹, M Butkus¹, T Diwanji¹, A King¹, A Dal Pra¹, M Abramowitz¹, A Pollack¹, N Dogan¹, (1) University of Miami, Miami, FL (2) Henry Ford Health System, Southfield, MI

Purpose: To assess the performance of a Proton-specific Knowledge Based Planning (KBP) model in creation of robustly optimized IMPT plans for treatment of prostate cancer patients. **Methods:** Forty localized prostate cancer patients previously treated with volumetric modulated arc therapy (VMAT) were included. All the patients were replanned with robustly optimized Intensity Modulated Proton Therapy (IMPT). Thirty prostate patients were included in creation of proton KBP model. The remaining ten patients were used for model validation. KBP model quality and accuracy was evaluated based on the model-provided organ at risk (OAR) regression plots and metrics. To compare the robustness of the IMPT plans, we simulated the $\pm 3\%$ proton range uncertainty with 5mm translational error in six directions, resulting in twelve uncertainty scenarios for each plan. The expert and KBP generated IMPT plans were compared using the clinical dose volume constraints for clinical target volume (CTV), bladder, and rectum. **Results:** The resulting R^2 (0.87 ± 0.07) between dosimetric and geometric features, as well as χ^2 (1.17 ± 0.07) between the original and estimated data, showed good quality of the model. All the KBP plans were clinically acceptable. Looking only at the nominal plans, KBP plans delivered marginally higher dose to the rectum ($0.42 \pm 0.56\%$ for rectum V65Gy) than the expert plan, but otherwise there was no statistically significant difference in dose-volume indices for CTV and bladder. When all uncertainty scenarios are included, the KBP plans showed much greater CTV V100 ($11.64 \pm 20.09\%$) and lower HI (-1.81 ± 1.91) than the expert plan did. **Conclusion:** This study demonstrated that the robustly optimized IMPT plans created by a proton KBP model are of high quality and are at least comparable to the expert plans. Furthermore, the KBP model are able to generate more robust and homogenous plans compared to the expert plans.

PO-GePV-T-118

Assess the Interplay Effect Based On the Cyclotron Accelerator Proton Therapy System Machine-Specific Delivery Sequence Model

L Zhao^{1*}, G Liu¹, J Shen², A Lee³, D Yan¹, R Deraniyagala¹, C Stevens¹, W Zheng¹, X Li¹, S Tang³, X Ding¹, (1) Beaumont Health System, Royal Oak, MI, (2) Mayo Clinic, Phoenix, AZ, (3) US Oncology, Coppell, TX

Purpose: Proton Pencil Beam scanning delivery sequence is critical to the evaluation of the motion interplay effect. We proposed an experimental approach to build a precise machine-specific model for standard, volumetric, and layer repainting delivery based on a cyclotron accelerator system. Then we assessed the interplay effect using a 4D mobile lung target phantom compared to a generic delivery sequence model (WPE) using the same type of cyclotron accelerator proton system published previously. **Methods:** Test fields and clinical treatment plans were used to drive each beam delivery parameters that impacted BDT: energy layer switching time, spot switching time, and spot drill time. To quantitatively evaluate the interplay effect, a series of digital thoracic 4DCT image sets were used. The interplay effect was assessed based on the 4D dynamic dose accumulation method. Target motion was simulated based on the periodic respiratory motion with an amplitude 5 mm and breathing cycle 4s. Two-field Single Field Uniform Dose plans were generated using PA and lateral field. Standard delivery, volumetric and layer repainting delivery were simulated based on the machine-specific delivery sequence model and WPE model. The total BDT is also calculated. D99 (Dose received by 99% of target volume) of the target is used to estimate the delivery accuracy. **Results:** The results show that the interplay effect is very different between the two models even though the BDT is similar. More specifically, the WPE model leads to a very different result from the machine-specific model from this study in layer repainting technique. The delivery sequence comparison with the actual log files shows that the WPE model has a difference delivery sequence, resulting in the difference in the interplay effect evaluation. **Conclusion:** A precise machine-specific delivery sequence is highly recommended to ensure an accurate estimation of mobile target treatment's interplay effect.

The senior author Xuanfeng Ding received personal fee from IBA speaker Bureau.

PO-GePV-T-119

Determination of Virtual Source Points for Mevion S250i Pencil Beam Scanning Proton System

Y Chen*, C Frame, T Ma, Y Yuan, D Pang, MedStar Georgetown University Hospital, Washington, DC

Purpose: The Mevion S250i proton system utilizes for energy selection a technique of binary insertion of Lexan plates of various thicknesses, resulting in an energy dependence of virtual source distance (VSD). We present our study on the VSD determination. **Methods:** Two methods were used to determine the VSDs: 1) EBT3 film and XRV3000 scintillation camera were used to measure spot size in air of different energy beams at points of -20, -10, 0, 10, 16.5 cm distance from ISO along the beam axis; 2) A Markus chamber was used to measure dose of single spot at the same points. Corrections to the measured doses were made to factors introduced by chamber size and beam shape. A linear fit to spot sigma vs position yields both VSD and beam divergence, and an inverse square law fit to dose also yields the VSD. **Results:** For the 11 energies selected from 227 to 28.7 MeV, the spot sigma at ISO and beam divergence increase linearly from 4.0 to 25.6 mm and 0.15 to 3.17 degree, respectively. The VSD measured with the two methods agree within 5%, demonstrating a rapid decrease from 154 to 52 cm when the energy changes from 227 to 184 MeV, followed by only a slight further decrease from 52 to 47 cm when the energy is reduced to below 184 MeV. Incidentally, this seemingly transitioning point of 184 MeV coincides with insertion in the beam path of the two most downstream and thickest plates of 3.324 and 6.641 cm WET. **Conclusion:** The unique design of the energy selection system of the Mevion S250i has resulted in an unique energy dependence of the VSD, exhibited by a rapid decrease in the higher energy range of 227-184 MeV, and remains virtually unchanged in the lower energies of 184 to 28.7 MeV.

PO-GePV-T-120

Effects of the Activated Dental Metal Induced by Proton Beam Irradiation for Head and Neck Cancer: A Phantom Study

R Kato^{1*}, T Kato^{1,2}, T Sagara¹, Y Narita¹, K Takayama¹, M Murakami¹, (1) Southern Tohoku Proton Therapy Center, (2) Fukushima Medical University

Purpose: In proton therapy (PT) for patients with head and neck cancer, dental metals are known to largely perturb the dose distribution compared to that in photon therapy. The dental metals are basically removed before PT but removing them are often difficult. If the dental metals are irradiated by the proton beam, these can be activated by protons or secondary neutrons. However, there are no reports on effects of the activated dental metals. We aimed to fundamentally investigate the effects of the activated dental metals using Monte Carlo simulation and measurement. **Methods:** The beam data on 150 MeV proton beam with 60 mm spread-Out Bragg peak (SOBP) size was used. Ti alloy and 12% Au-Ag-Pd alloy that are used as standard dental material in Japan were placed in the SOBP center in water phantom. Radionuclides induced by the proton beam irradiation were identified using Particle and Heavy Ion Transport code System (PHITS) and DCHAIN. Also, gamma-rays emitted from the activated dental metals were counted by high purity germanium (HP-Ge) detector. In addition, dose enhancement caused by the activated dental metals was calculated by PHITS. **Results:** The spectra of the activated dental metals obtained in HP-Ge detector had the same energy peaks as the radionuclides estimated by PHITS. In addition, the dose around Ti alloy and Au-Ag-Pd alloy increased slightly as compared with the prescription dose. **Conclusion:** The radionuclides induced from the dental metals were mostly dominated by nuclides with short half-lives. The dose enhancement caused by the activated dental metals was significantly lower compared with the prescription dose.

PO-GePV-T-121

Tuning, Calibration and Testing of a Dynamic Collimation System Controller for Pencil Beam Scanning Proton Therapy

K Patwardhan*, T Geoghegan, B Smith, R Flynn, D Hyer, University of Iowa Hospitals and Clinics, Iowa City, IA

Purpose: The purpose of this work was to tune and calibrate the Dynamic Collimation System (DCS) controller and measure the delivery time of an example treatment plan for a number of different jerk values where jerk is defined as the rate of change of acceleration. The control system needs to be tuned for the given electro-mechanical setup and the desired motion parameters in order to reduce oscillations in the motion. **Methods:** A DCS prototype was built consisting of two pairs of orthogonal nickel trimmers independently translated by Parker T1S linear motors. Test motions were used to identify the motor response and tune the control system. Trimmer motion was observed for different jerk values before and after tuning the controller. The trimmer sequence from a sample test plan consisting of 244 trimmer positions and 3 ms dwell times was simulated with variable jerk values to determine the impact of this parameter on treatment time. Trimmer position accuracy was also tested for different DCS orientations of 90 and 180 degrees. **Results:** Controller tuning and calibration provided stable and accurate trimmer motion. A maximum overshoot of 0.7 mm was observed prior to tuning as compared to 0.04 mm after tuning. Treatment time for the sample test plan with a jerk of 4×10^5 mm/s³ was 21.6% (98 s) faster than with a jerk of 5×10^4 mm/s³ (125 s). Trimmer position profiles were nearly identical for different orientations of the DCS with the positional accuracy found to be within ± 0.1 mm. **Conclusion:** The DCS controller can be integrated within a commercial Ion Beam Applications (IBA) Pencil Beam Scanning (PBS) system and used to accurately and automatically position the trimmers for treatment delivery, improving dose conformity with minimal impact to treatment time.

Research reported in this abstract was supported by the National Cancer Institute of the National Institutes of Health under award number R37CA226518. Hyer and Flynn are co-inventors on a patent that has been licensed to IBA.

PO-GePV-T-122

Dosimetric Investigation of Inverse-Optimized Proton GRID and Lattice Treatment Plans with a Clinical Pencil Beam Scanning System

M Zhu^{1*}, H Chen², J Snyder³, W Regine⁴, J Bradley¹, M McDonald¹, P Patel¹, P Sabouri², K Langen¹, (1) Emory University School of Medicine, Atlanta, GA, (2) Emory Healthcare, Atlanta, GA, (3) University of Alabama At Birmingham, (4) University of Maryland, Baltimore, MD, (5) Miami Cancer Institute, Miami, FL

Purpose: We report inverse-optimized GRID and Lattice pencil beam scanning (PBS) proton treatment techniques and their dosimetric characteristics. **Methods:** GRID and Lattice plans were created in a water phantom in a commercial treatment planning system with a clinical PBS proton system. An in-house script generated evenly spaced cylinders and spheres within a 10 cm cube centered at 10 cm from surface; the cylinder axes and the sphere lattice were positioned along the vertical direction. The diameter of the cylinders and spheres was 3 mm; patterns with 4 different center-to-center spacings were tested: 1.5 cm, 2.0 cm, 2.5 cm, and 3.0 cm. Two plans were created for each center-to-center spacing, a GRID plan and a Lattice plan, using the cylinders and the spheres as targets, respectively, with a single beam from gantry angle 0. All plans were optimized to deliver a uniform dose (15 Gy in 1 fraction) to the target while minimizing dose outside of the targets. **Results:** At the depth of 10 cm (center of cube), the peak-to-valley ratios (PVRs) are 1.54, 3.47, 9.52, 26.79 for the GRID plans and 1.52, 3.26, 9.15, 22.39 for the Lattice plans for the center-to-center distances of 1.5 cm, 2.0 cm, 2.5 cm, and 3.0 cm, respectively. The ranges of PVR at different depths for the GRID plans are: 1.27-1.71, 2.48-4.32, 5.39-13.54, and 17.65-34.88, respectively. For the Lattice plans, the ranges are: 1.23-1.67, 2.33-3.90, 5.13-9.15, and 15.00-29.41, respectively. **Conclusion:** Proton GRID and Lattice plans were feasible with multiple center-to-center distances. The achievable PVRs are mainly determined by the center-to-center distances for both GRID and Lattice plans. For the same center-to-center distance, GRID plans have slightly higher PVRs than the Lattice plans. The PVRs decrease with depth for both GRID and Lattice plans.

PO-GePV-T-123

Evaluation of Distorted Lateral Beam Profiles in MRI-Guided Proton Therapy

H Ueda^{1*}, Y Fujii^{1,2*}, K Umegaki^{1*}, T Matsuura^{1*}(1) Hokkaido university, Sapporo, JP(2) Hitachi Ltd., Ibaraki, JP

Purpose: In order to realize MRI-guided proton beam therapy system, it is important to evaluate the characteristics of distorted dose and relative biological effectiveness (RBE) distributions in the MRI scanner. The deflected proton beams in the perpendicular magnetic field result in asymmetrically distorted lateral

beam profiles. The purpose of this study is to clarify these profiles by analyzing dose, mean energy and dose-averaged linear energy transfer (LETd) distributions under the various magnetic fields. **Methods:** Monte Carlo simulations using Geant4.10.2.p02 were performed for proton beam analysis in magnetic fields ranging from 0 to 3 T. Initial proton energies are set from 70 to 220 MeV and the proton source is assumed to have no energy spread and angular divergence. A water phantom was installed in the MRI scanner where the magnetic field was applied perpendicular to the beam incident angle. The three-dimensional dose distributions in the phantom were calculated. The lateral dose profiles were fitted using the primary Gaussian, secondary Left, and Right tail functions. Then the ratio of the coefficient of Left to Right function (γ_R to γ_L) was evaluated to quantify the magnitude of asymmetric distortion. **Results:** The distortions of the lateral beam profile were observed near Bragg peak region, leading to non-negligible asymmetrical changes in the dose distributions. The asymmetric ratio of γ_R to γ_L , which indicates the magnitude of distortion, increased as the strength of the magnetic field increased. The ratio became 2.4 under the 3T magnetic field. In addition, it was shown that the mean energy and LETd distributions also have non-negligible distortions which will affect RBE distributions. **Conclusion:** We quantitatively evaluated the distortion of the dose distribution in the magnetic field using the fitting functions. Non-negligible dose deformations at the Bragg peak area were identified and distortion of LETd also affected RBE.

PO-GePV-T-124

Feasibility of Treating Large Mobile Targets Using a Breath-Hold Technique with a New Adaptive Collimation Leaf Sequencing Algorithm for Intensity Modulated Proton Therapy

M Prusator^{1*}, J Cooley², J Wang², M Watts¹, C Tohtz¹, B Sun¹, T Zhang¹, T Mazur¹, T Zhao¹, (1) Washington University School of Medicine, St. Louis, MO, (2) Mevion Medical Systems Inc, Littleton, MA

Purpose: Fast delivery of an intensity modulated proton therapy (IMPT) plan utilizing an adaptive aperture (AA) enables treatment of patients under breath-hold (BH). Field delivery time has several influencers, including dose-per-pulse, and number of energy-layers and spots. In the past the AA has prohibitively increased time such that only small targets could be treated with BH. The goal of this study is to determine the feasibility of treating larger targets on BH with a new commercially available AA positioning algorithm for a single-room proton therapy system. **Methods:** Eight patients, ranging in target volume from 2.3 cc to 153 cc were planned with an AA to meet clinical standards. Based upon the dose per spot, number of energy layers and spots, and leaf sequence of the AA, delivery times were calculated for each field both with and without the new leaf positioning algorithm. Delivery time was also calculated without the AA for comparison. Assuming a maximum unassisted patient BH capability of 15 seconds, the delivery times were compared with target volume to predict the threshold target size such that fields could be delivered in a single BH. **Results:** Delivery time is related to the target volume being treated, largely due to the strong influence on treatment time from AA motion, accounting for about 50% of the total time of delivery per field. Without using the AA, fields for target volumes over 100 cc could be treated in a single BH. However, the new leaf positioning algorithm significantly reduces delivery time with the AA, such that target sizes up to 60 cc could likely be treated in a single BH per field. **Conclusion:** The once prohibitive time requirement of AA motion has greatly been reduced with a new leaf positioning algorithm, making a BH IMPT delivery technique feasible for larger targets.

Monte Carlo Evaluation of Neutron Dose Equivalent Topatients Treated with Vertex Beams in IMPT and PSPT

U Titt^{*}, D Grosshans, N Sahoo, X Zhu, R Mohan, UT MD Anderson Cancer Center, Houston, TX

Purpose: Patients treated with protons are subjected to secondary neutrons originating from the beam delivery system and inside the patient. Treatment plans featuring vertex beams, i.e., proton beams oriented in the superior-inferior direction, raised concerns of increased neutron exposure to the patients. A study was performed to assess the neutron dose equivalent to patients treated with such beam configurations. **Methods:** A Monte Carlo model of the complete treatment room, including all relevant beam line equipment, was produced for IMPT and PSPT treatments, each equipped with a simplified representation of an adult and a 10 year old pediatric patient. Proton beams of about 15 cm range in water were simulated to the heads of the phantoms in the vertex beam orientation and from a lateral direction. The neutron fluences in the phantom's arms, legs, torso, as well as head and neck were scored as a function of neutron energy and converted to neutron dose equivalent. **Results:** The IMPT treatments yielded moderately reduced neutron dose equivalent values for Vertex Beams, mostly to the neck of the phantoms. Using PSPT, there was a noticeable systematic reduction in neutron dose equivalent in the Vertex Beam configuration. **Conclusion:** We found that the neutron dose equivalent to the phantoms was more dependent on the distance to the beam line/nozzle than on beam direction, and that the application of Vertex Beams does not pose additional hazards to a proton therapy patient due to neutron exposure.

Novel Dynamic Apertures for Reducing Spot Sizes in Proton Therapy

J Holmes^{1*}, S Patel¹, W Wong¹, R Foote², W Liu¹, (1) Mayo Clinic, Phoenix, AZ, (2) Mayo Clinic, Rochester, MN

Purpose: To improve nearby normal tissue protection in proton therapy, spot sizes must be controlled and reduced if possible, which can be achieved by a novel concept of dynamic pinhole aperture (DPA). In this work, we investigate the clinical viability of the DPA based on its ability to reduce spot sizes while retaining a reasonable dose rate. **Methods:** The DPA is a small device mounted to a motor assembly, capable of moving along the beam axis and two lateral directions. The DPA has a cylindrical opening with a range shifter attached that follows and trims each spot. The DPA alters the dose distribution by changing its positions instead of changing its shapes. MCsquare, an open-source Monte Carlo code, has been enhanced to support DPAs and used to calculate the dose distributions with varying parameters of DPAs to find the optimal parameters for clinical use in shallow tumors. The resulting spot sizes are compared among the DPA, an optimal thickness range shifter, and the extended range shifter (ERS). The beam transmission ratio is characterized for the DPA, on- and off-axis, to indicate the reduction of the dose rate. **Results:** Compared to ERS, spot sizes are reduced 50% when the DPA is placed 5 cm from the patient at depths less than 50 mm. For a DPA of 3 mm radius positioned 5 cm from the patient, the spot size is reduced by 30% compared to an optimal range shifter placed at the same position. The beam transmission ratio is between 10-50% for a 3 mm radius DPA. **Conclusion:** The device is simple, compact, and effective, especially for shallow tumors. Since the DPA adds treatment time for each spot, its use should be limited to a subset of spots of the treatment plan where the reduction in spot sizes is most beneficial.

Considerations in Lung SABR IMPT Using Two Different PBS Systems

Z Su^{1*}, W Hsi¹, E Brooks¹, (1) University Florida Health Proton Therapy Institute, Jacksonville, FL

Purpose: Stereotactic Ablative Body Therapy (SABR) is an effective treatment for early-stage lung cancer. To effectively implement Lung SABR IMPT, effective spot size, plan dosimetric quality, and delivery time needed for practical and effective clinical treatment were evaluated for two different proton

systems. **Methods:** A compact proton therapy delivery system (Proteus-one, P1) was configured to deliver large spot IMPT similar to Proteus-plus with universal nozzle (P+). Total of 9 patients with 10 tumors were selected for this study. Seven targets were prescribed 60Gy in 10 fractions; three targets were 48Gy in 4 fractions. Raystation 8A were used to generate treatment plans for each nozzle type with exact same optimization objectives. P1 plans used 4cm range-shifter placed at 45cm from isocenter to create large in-air beam spots, which were compared to the P+ in-air spots without range-shifter. P+ plans used 7cm range-shifter placed 4cm away from patients, to minimize spot size degradation. Target coverage was optimized to prescription dose covers 100-percent GTV with 90-percent covers PTV. Dose to the OARs were compared to QUANTEC metrics. Three volumetric dose-repainting was performed. Plan beam-on times were obtained to evaluate treatment delivery efficiency. **Results:** The in-air beam spots were comparable between P+ without and P1 with range shifter. All target coverage are acceptable. OAR doses were comparable and within the QUANTEC limits. The beam-on time of P+ plans were 3 to 6 time of those of P1 plans. When combined with patient setup and image guidance time, patient discomfort could lead to higher uncertainty in P+ treatment. **Conclusion:** P1 system range-shifter configuration can effectively simulate a large spot P+ system. For the two proton systems, plan qualities were dosimetrically comparable; volumetric dose-repainting were applicable to reduce interplay effect. However, P1 delivery was significantly shorter than that of P+.

Dynamically Collimated Spatially Fractionated (GRID) Pencil Beam Scanning Proton Therapy

B Smith*, B Allen, D Hyer, University of Iowa, Iowa City, IA

Purpose: The dosimetric advantages of protons, which include a pronounced Bragg peak and low entrance dose, are desirable traits when considering GRID therapies. The objective of this work was to investigate the applicability of using a dynamic collimation system (DCS), an energy layer specific collimator, to improve PBS GRID treatments by allowing variable grid ratios and to demonstrate the viability of this technique between different cancer cell lines. **Methods:** GRID dose distributions were simulated using Geant4 with an experimentally benchmarked IBA UN beam line model and physics list. Individual 4 cm spread-out-Bragg peak beamlets were calculated that were collimated with equivalent square fields ranging from 0.25 cm to 1.0 cm. Treatment planning dose distributions were generated in MATLAB by optimizing the spot spacing and collimation width for various cancer cell types. A linear quadratic model was used to assess the cell survival between malignant and nonmalignant tissues when irradiated under full-field and GRID irradiation conditions. **Results:** As expected, the effectiveness of GRID treatments were largely impacted by changes in spot spacing or collimation, as these variables directly influence the resulting dose distribution. However, it is not necessarily the case that maximizing the difference between adjacent low- and high-dose regions resulted in a superior dose-volume effect. In fact, no combination of spot spacing and collimation width was universally optimal but rather depended on the cell radiosensitivity and the desired cell kill fraction. **Conclusion:** An optimal GRID dose distribution reflects the malignant and non-malignant cell radiosensitivities at the desired dose level. Given the capacity of the DCS to perform energy-layer specific collimation, it appears that this technology may help tailor treatments towards the specific radiobiology of a patient's tumor in order to maximize the therapeutic benefits from GRID treatments.

Impact of Noise Level on the Analysis of Proton Exposed Targets

F Saheli^{1*}, N Vosoughi², Z Riazzi³, H Shahabinejad⁴, F Rasouli⁵, (1) Sharif, Tehran, IR, (2) (3) (4) (5)

Purpose: Accurate online determining of the elemental composition of irradiated tissue in proton therapy plays an important role in treatment verification, since it leads to accurate estimation of the depth of Bragg peak, the proton range and the stopping power map of irradiated tissue. A hopeful approach for elemental analysis in proton therapy is employing the proton induce characteristic prompt gamma-rays. In this work, the effect of gamma spectrum noise level on estimating elemental analysis of irradiated target and proton range are investigated. **Methods:** In the present study, the Geant4 toolkit has been used to simulate the prompt gamma-ray spectra of phantom in different noise levels. Analysis done using correlation between the mass concentration of elements and net counts of selected peaks in proton induced prompt gamma spectra of irradiated phantoms. To investigate the effect of noise levels on the accuracy and precision of the results, different noise levels are simulated, and the errors of elemental mass are calculated. Also the error propagation applied to estimate error of analytical calculated proton range. **Results:** The results show that both the accuracy and the precision of estimated elemental weight percent decrease by increasing noise levels. The quantification results show that the elemental weight percent errors in high noise level lead to deviations less than 1% in mass rang (in g/cm²) of protons. **Conclusion:** In conclusion, the applied analysis method can be used to estimate weight percent of irradiated tissue from its recorded prompt gamma spectra even in the presence of high noise levels. However, the increment in the standard deviation of the results is unavoidable.

A Preliminary Study of DECT- and Kernel-Based Dose Calculation Algorithm for Carbon Beam Therapy

W-G Shin^{1,2,3}, E Yoon³, B Kim³, S Jung^{1,2,3}, J M Son^{1,2,3}, J M Park^{1,2,3}, J-I Kim^{1,2,3}, C H Choi^{1,2,3}, (1) Department of Radiation Oncology, Seoul National University Hospital, 03080 Seoul, KR, (2) Biomedical Research Institute, Seoul National University Hospital, 03080 Seoul, KR, (3) Institution of Radiation Medicine, Seoul National University Medical Research Center, 03080 Seoul, KR

Purpose: This study aims to develop a kernel-based dose calculation algorithm for carbon beam therapy using DECT image and to verify the plausibility of the dose calculation algorithm. **Methods:** At first, the carbon beam kernels of 100-430 MeV/u are assessed using Geant4 Monte Carlo toolkit. The pencil beam dose calculation algorithm of matRAD software is revised for using the calculated beam kernel and dual energy computed tomographic (DECT) image. The DECT and single energy CT (SECT) images of abdomen case are obtained by Philips IQon Spectral double-layer CT and given algorithm. And then, the images are converted to relative stopping power ratio (RSP) maps for the dose calculation. In order to evaluate the influence of DECT based dose calculation method, the doses on DECT and SECT images are compared with each other. **Results:** The RSP maps obtained by DECT and SECT images basically show similar tendency, however, the SECT image overestimates RSP up to 5% compared to that of DECT even in homogeneous media. Moreover, the physical dose calculation results show slight range disagreements due to the RSP differences. The carbon range in the target on SECT image is shorter than the range of DECT up to 2 mm in the same treatment plan. **Conclusion:** The plausibility of the beam kernel-based dose calculation algorithm has been verified in this study. We figured out that DECT can be used to correct the range uncertainty due to the CT conversion of conventional SECT about 2 mm. This work does not consider the biological effectiveness of the carbon beam, in further, the influence of DECT on biologically effective dose will be quantitatively evaluated with more patient cases in the other therapeutic regions.

This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korean government (No. NRF-2019 M2A2B4095126 & NRF-2019M2A2B4096540).

PO-GePV-T-131

Assessment of Metal Artifact Reduction in Dual-Layer Dual-Energy Computed Tomography for Carbon Ion Radiotherapy

S Jung*, B Kim, E Yoon, J Park, J Kim, J Son, C Choi, Seoul National University Hospital, Seoul, 11KR

Purpose: This study aims to assess a dosimetric impact metal artifact reduction in carbon ion radiotherapy with dual-layer dual-energy computed tomography (DL-DECT) in terms of relative stopping power ratio (RSP). **Methods:** DL-DECT images of 2 patients implemented metallic structure were analyzed. The scan were performed with a commercial DL-DECT system (IQon Spectral CT, Philips Healthcare). One patient had metal hip implants and the other had a dental implant. Each patient was scanned once and the images were reconstructed with metal artifact reduction (O-MAR) and without metal artifact reduction. When the images were reconstructed, the spectral based images (SBLs) were also acquired to extract effective atomic number (Zeff) and relative electron density (RED) map. By using the Zeff and RED, RSP for each image (i.e., with O-MAR and without O-MAR) were calculated. **Results:** Metal artifacts in 120 kVp conventional images were significantly reduced when O-MAR was applied to each image set. In addition, artifacts in Zeff and RED map were also reduced. In both cases of metal hip replacement and dental implant, the difference in RSP ranged from -1.5 to 1.5. **Conclusion:** The metal artifacts significantly affected the accuracy of Zeff, RED, RSP, and dose calculation for carbon ion radiotherapy. Adequate metal artifact reduction algorithm is required to be applied in case the patient had metallic implant.

This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korean government (No. NRF-2019M2A2B4095126 and NRF-2020R1F1A1073430)

PO-GePV-T-132

Preliminary Investigation of the Dosimetric Impact of Common Dental Restorative Materials On Proton Beams

A Gomez^{1*}, M Leyva², L Coutinho¹, E B Rosen¹, N Kalman¹, M Hobson¹, (1) Miami Cancer Institute, Baptist Health South Florida, Miami, FL, (2) Provision Cares Proton Therapy Center, Knoxville, TN

Purpose: To quantify the dosimetric impact of 70 MeV proton beams in the vicinity of materials commonly used in current dental practice. **Methods:** Two-millimeter-thick metallic, Titanium (Acnis), Cobalt-Chromium (MESA), and Zirconium (Nacera), and non-metallic, PEEK (Juvora), Pekkton (Cendres+Metaus), and PMMA, samples were studied. A uniform monoenergetic 70 MeV scanned proton field was delivered by an IBA ProteusPLUS PBS proton therapy system (Ion Beam Applications, Louvain-la-Neuve, Belgium). Samples were placed 60 mm apart edge-to-edge in a 3D printed tray on top of a 10x25x25 cm³ block of solid water with an additional 1, 2, or 3 cm of solid water added to the top surface. Relative profiles were measured using Gafchromic EBT3 film placed immediately proximal or distal to the sample tray and normal to the beam direction. Pixel values in regions of interest (ROIs) (1x1 cm²) centered at and in the absence of the materials were averaged and compared. **Results:** Backscatter measured directly at the entrance surface was negligible compared to measurements made in absence of the samples, with relative pixel value differences (RPVDs) of -1.2%±1.4% to 0.9%±1.5%. The dose effects at the distal surface were greater for metals than for nonmetals, with RPVDs for non-metals ranging from -1.7%±1.5% to 0.9%±1.3% and -25.7%±1.5% to 61.9%±2.2% for metals. **Conclusion:** Metallic dental restorations can cause downstream dose perturbations with the extent dependent on the material and position of the material relative to the Bragg peak. Future work will include validating these results with ion chamber measurements and with additional energies with and without the presence of a range shifter and comparing measurements to the WET of samples to examine dose perturbations from secondary interactions.

Credit Panthera Dental Lab as they prepared all the samples to Evan Rosen at no cost.

PO-GePV-T-133

Wireless Device for Adaptive Planning Based Upon Thermoacoustic Range Estimates - Design and Benchtop Validation

S Patch^{1*}, M Narayanaswamy², (1) UW-Milwaukee, Milwaukee, WI, (2) Swamy Enterprises

Purpose: Transitioning thermoacoustic range verification from benchtop experiments with cumbersome research equipment to clinical practice is the purpose of our work. A wireless device for thermoacoustic range verification with correlation to online ultrasound images has been developed for initial application to adaptive planning (Fig. 1). **Methods:** A 7 x 5.5 x 3.5 cm detector (NucSafe) requiring 5V power supply replaces the 0.5 m long prompt gamma detector that required -2 kV (Fig. 2a). The new detector provides both analog and digital signals to quantify proton pulse shape and serve as a trigger. Oscilloscopes are replaced by a wireless data acquisition board (DAQ) with 1 MSPS ADC and vertical resolution of 38 uV. 6 acoustic channels are amplified. 2 channels for compact gamma detector inputs (analog and digital) are not amplified. Data is acquired continuously for up to 30 minutes and stored on a secure data card for retrieval via a serial port after the exam. Two different types of transducers provide broadband response in a compact form factor (Fig. 2c). **Results:** A custom receive chain provides improved 10-18 dB greater sensitivity over the relevant frequency band (10-100 kHz, Fig 2b). Transducers positioned to either side of the ultrasound imaging array are up to 8 dB more sensitive to low frequencies (Fig 2c). The new DAQ provides 10 dB greater amplification. A wireless ultrasound imaging array (Clarius P4-1) provides greater imaging depth, 30 cm vs 7 cm, and smaller footprint (Fig. 2d). **Conclusion:** This improved device provides greater ease of use, positioning flexibility and receive sensitivity which could enable range verification during pulsed delivery of a 2 Gy fraction. Although validation on phantoms in proton therapy vaults is required, nonintervention patient studies could quickly follow because "listening" for thermoacoustic signals generated during the normal course of therapy is entirely passive.

NIH-NCI SBIR #R43CA243764. Dr. Patch founded Acoustic Range Estimates and holds US patent #10,758,127. Mr. Narayanaswamy is founder of Swamy Enterprises.

PO-GePV-T-134

Sensitivity of Target Coverage and Patient Specific IMPT QA to Spot Positioning Errors

S Mossahebi^{1*}, P Sabouri², B Zhang¹, E Makdsay Hana¹, J Williams¹, S Chen¹, (1) University of Maryland Medical School, Baltimore, MD, (2) Miami Cancer Institute, Miami, FL

Purpose: The clinical efficacy of intensity modulated proton therapy (IMPT) requires accurate delivery of the spot pattern. As a result, patient specific quality assurance (QA) is required for each new plan. However, sensitivity of commonly used patient QA systems to spot positional errors, and the conditions where position delivery errors can be detected in patient QA have not previously been examined. This work evaluates the sensitivity of current patient-specific IMPT QA procedures to minor spot positioning errors. **Methods:** Dosimetric effects of delivery uncertainties in proton spot position was evaluated for ten head-and-neck patients. Each spot position was perturbed randomly assuming a uniform distribution with interval-width of 0.75, 1, 1.5, 2.0, 2.5, and 3.0 mm at isocenter. Dose distributions and dose-volume histograms of original and perturbed plans were recalculated and compared using CTV coverage metrics. Additionally, absolute dose and 2D-planar dose measurements using 2D array ion chamber (MatriXX-PT) were performed. The impact of spot position uncertainties on the patient QA results was examined using a gamma criteria of ±3%/3mm and the gamma passing rate greater than 90% considered as criteria for validation of a clinical plan. **Results:** Comparison of TPS calculated dose between original and perturbed plans suggest the effect of random spot position uncertainties on target dose parameters such as D2%, D95%, D98% was not significant (less than 2%) until 1.5mm internal-width. Additionally, the patient-specific IMPT QA all perturbed plans up to 1.5mm tolerance was acceptable within clinical criteria (±3%/3mm). **Conclusion:** Our results show that the target coverage was not sensitive to random spot position uncertainty up to 1.5 mm. Additionally, this uncertainty did not affect patient IMPT QA results.

PO-GePV-T-135

Impact of Spot Position Uncertainties on Intensity Modulated Proton Therapy Plans for Head and Neck Cancers

P Sabouri^{1*}, S Mossahebi², B Zhang², S Chen², (1) Miami Cancer Institute, Miami, FL, (2) University of Maryland Medical School, Baltimore, MD

Purpose: Intensity modulated proton therapy (IMPT) utilizes complex patterns of spot placement to generate highly conformal dose distributions and rapid fall-offs. Therefore, a high confidence level in the positional accuracy of each spot is demanded. However, the dosimetric impact of uncertainties associated with delivered spot positions, particularly in regions that involve several complex anatomical structures such as head-and-neck has not been investigated. **Methods:** Fifteen patients with head and neck cancers were randomly selected for this study. Patients were treated with $\geq 95\%$ of the largest CTV receiving the prescription dose (Rx: 59.4 Gy) according to a single integrated boost regimen. For each patient plan, random uncertainties in spot position were simulated by perturbing the spot position according to uniform (or Gaussian) distribution with interval width equal to the vendor-set tolerances (1.2 mm/1.45 mm in X/Y direction at monitoring chamber for Varian ProBeam). Impact of spot position uncertainties on target coverage was studied using the minimum, maximum (dose to 0.01cm³), and dose to 95% of CTV volume (D95%). **Results:** Distributions for target coverage metrics were normal with standard deviations ranging between 0.5% to 5% of Rx dose (180cGy/fx). D95% exhibited the lowest sensitivity, and was within 2% of the clinical plan for all patients. Larger deviations in Dmin (<10%) and Dmax (<6%) were observed suggesting potential for target under-dosage, or unwanted hot spots. No significant correlation between coverage variation and target volume was found. **Conclusion:** While in comparison to MLC based intensity modulated radiation therapy (IMRT), IMPT is more sensitive to positional uncertainties, spot positional uncertainties within the vendor supplied 1.2 mm tolerance do not pose significant clinical impact.

PO-GePV-T-136

Impact of Esophageal and Biliary Stents on Proton Dose Calculation

S Mossahebi^{1*}, P Sabouri², G Kim¹, J Polf¹, J Molitoris¹, B Greenwald¹, P Darwin¹, S Chen¹, (1) University of Maryland Medical School, Baltimore, MD, (2) Miami Cancer Institute, Miami, FL

Purpose: Hepatobiliary and esophageal malignancy patients who are commonly implanted with stents are often treated with radiotherapy. To date, the impact of the newer stents on proton calculated dose is unknown. This study aims to analyze and compare the radiation dosimetric impact of newer esophageal and biliary stents to determine if dose adjustments in areas with stent presence are needed. **Methods:** Five esophageal and seven biliary stents were secured inside a water phantom and CT scans were acquired. The water equivalent thickness (WET) values of each sample were obtained using a multilayer ionization chamber and 2D-planar dose measurements of a proton field were performed using an ion chamber array. Dosimetric impact and WET of stents on treatment planning system (TPS) calculated dose was compared with measurements. **Results:** WET values for all esophageal stents were less than 1mm (0.35 - 0.85 mm) and values for all biliary stents were less than 0.5mm (0.15 - 0.45 mm). For planar dose measurements in water, no difference (<1%) was observed for both esophageal and biliary stents, thereby implying that the perturbation effect of the stents was within the measurement uncertainty and not detectable. For biliary stents TPS indicated changes in WET values as large as 2 mm. This inconsistency between measured and TPS calculated WET values are due to CT artifacts and inaccuracy of SPR estimation. **Conclusion:** Our study's results show that the presence of biliary and esophageal stents has minimal impact on proton dose. However, inaccuracies associated with SPR estimation suggest that these devices can perturb calculated dose.

PO-GePV-T-137

Non-Radioactive Elements for Prompt-Gamma Production Enhancement in Proton Therapy

P Galanakou^{*}, T Leventouri, W Muhammad, Florida Atlantic University, Boca Raton, FL

Purpose: To develop a new Prompt Gamma Spectroscopic (PGS) technique that enhances the production of PG rays emitted from ¹²C* and ¹⁶O* de-excitations, by injecting a non-radioactive element in the tumor area. Positive results will lead in accurate monitoring of proton range and target-tissue characteristics during the treatment. **Methods:** The Tool for Particle Simulations (TOPAS) Monte Carlo (MC) package was used to simulate 10⁷ proton histories of 75 MeV and 100 MeV incident in a co-centric cylindrical geometry. The outer cylinder was filled with water, and the inner cylinder was filled with water plus 0.01%-25% fractions in weight of the elements ¹⁹F, ¹⁷O, ¹²C, ¹H, and ¹²⁷I, respectively. We identified the characteristic peaks in the PG spectra, and then we assessed the PG enhancement of the 4.44 MeV peak (P1) resulting from ¹²C* de-excitations, and the 6.13 MeV peak (P2) resulting from ¹⁶O* de-excitations. **Results:** For the 75 MeV incident proton beam the maximum P1 and P2 enhancement was 20.1% and 3.71% when 0.01% of ¹²⁷I and 1% ¹⁹F enriched the inner cylinder placed at surface, with respect the outer cylinder. For 100 MeV incident proton beam the maximum P1 enhancement was 8.88% when 0.01% ¹⁹F was added to the inner cylinder. When the inner cylinder was placed at depth of 2 cm for the 75 MeV incident proton beam, and at 5 cm for the 100 MeV incident proton beam, with respect to the outer cylinder, the PG enhancement dropped to half. The Bragg peak was not affected by the enrichment of the inner cylinder with the studied elements. **Conclusion:** It was found that the enhancement of PG production yield is possible by enriching the inner cylinder with the used non-radioactive elements. This is an ongoing study and simulations with more tissue-like materials such as brain-tissue are in progress.

PO-GePV-T-138

The Benefit of Novel Beam Arrangements Made Feasible by Range Uncertainty Reductions in Proton Therapy for Brain and Skull Base Tumors

S Tattenberg^{1,2*}, T Madden², B Gorissen³, T Bortfeld², K Parodi¹, J Verburg², (1) Department of Medical Physics, Faculty of Physics, Ludwig-Maximilians-Universitaet Muenchen, Garching, Germany (2) Division of Radiation Biophysics, Department of Radiation Oncology, Massachusetts General Hospital and Harvard Medical School, Boston, MA, (3) Stanley Center for Psychiatric Research, Broad Institute of Harvard and MIT, Cambridge, MA

Purpose: In proton therapy, conforming the dose distribution to an organ at risk (OAR) using the sharp dose fall-off at the distal beam edge may improve OAR sparing. Currently, the lateral beam edge is often used instead to reduce the effects of uncertainties in the in vivo proton range. However, range uncertainty reductions may allow for greater use of the distal beam edge. We quantified the benefits of such novel beam arrangements in a set of nine cases with targets abutting the brainstem. **Methods:** For each case, six treatment plans robust to 2 mm set-up as well as 0-5% range uncertainty were created for the traditional clinical beam arrangement and a novel beam arrangement making greater use of the distal beam edge to conform the dose distribution to the brainstem. Metrics including the brainstem normal tissue complication probability (NTCP) with the endpoint of necrosis were determined for all plans and set-up and range uncertainty scenarios. **Results:** For the traditional beam arrangement, reducing the range uncertainty from the current level of approximately 4% to a potentially achievable level of 1% reduced the brainstem NTCP by up to 0.6 percentage points when averaging over all scenarios and by up to 0.9 percentage points in the worst-case scenario. A switch to the novel beam arrangement at 1% range uncertainty increased these values by a factor of about 2, to 2.0 percentage points and 2.9 percentage points. The novel beam arrangement achieved a lower brainstem NTCP in all cases at a range uncertainty of 2% when averaging over scenarios and at a level of 1% in the worst-case scenario. **Conclusion:** The benefits of novel beam arrangements may be of the same magnitude or even exceed the direct benefits of range uncertainty reductions. The benefits of range uncertainty reductions may therefore previously have been underestimated.

PO-GePV-T-139

Incident Learning During the Early COVID-19 Pandemic

B Chera^{1*}, K Kujundzic², A Raldow³, J Olsen⁴, H Demoss⁵, S Weintraub⁶, B Salter⁷, S Evans⁸, (1) UNC at Chapel Hill, Morrisville, NC, (2) ASTRO, Arlington, VA, (3) UCLA, Los Angeles, CA, (4) Department of Radiation Oncology, University of Colorado School of Medicine, Aurora, CO, (5) Clarity PSO, Chicago, IL, (6) Southcoast Hospitals Group, Fall River, MA, (7) University of Utah, Salt Lake City, UT, (8) Yale University, New Haven, CT

Purpose: To assess the impact of the early COVID-19 pandemic on incident learning through evaluation of RO-ILS: Radiation Oncology Incident Learning System. The Radiation Oncology Healthcare Advisory Council hypothesized that the pandemic would impact participant engagement in reporting to the patient safety organization and the characteristics of reported events. **Methods:** The RO-ILS database was queried for events reported pre-COVID (March 1, 2019 to July 31, 2019) and during early COVID (March 1, 2020 to July 31, 2020). Events were segregated based on practices in early COVID hotspot states as identified by the CDC (WA, CA, AZ, TX, FL, NY, NJ, CT, MA, PA, MD) and their reporting status (Top 5). Descriptive statistics were used to describe trends in reporting and differences in data elements pre-COVID and during-COVID. **Results:** There was a 16% absolute reduction in event reporting during-COVID (n=1255) as compared to pre-COVID (n=1759). Practices located in COVID-hotspots had a 33% absolute reduction in reporting, while those not in hotspots had a 23% reduction. However, initial analysis did not identify drastic change in event classification. Amongst the Top 5 reporting practices, there was a 48% absolute reduction in incident reporting; of note, three of these practices did not report any events during-COVID. During-COVID, errors more often occurred and were discovered during treatment planning, regardless of hotspot status. Practices rated more events as moderate-severe during-COVID (25%) than pre COVID (18%). No appreciable difference was observed in the types of treatment techniques nor magnitude of dosimetric deviations pre-COVID and during-COVID. **Conclusion:** Reporting to RO-ILS declined during the early COVID-19 pandemic, especially in hotspot areas. Three of the five top reporting practices that ceased reporting have since reported events after the analysis timeframe, suggesting the decline may be temporary. Stability in event classification suggests that practices continued to report a variety of events.

The Radiation Oncology Healthcare Advisory Council (RO-HAC), managed by Clarity PSO, provides subject-matter expertise, analyzes, interprets and reports on RO-ILS data. RO-HAC members receive an honorarium from program sponsors ASTRO or AAPM.

PO-GePV-T-140

Radiotherapy Prescription Quality

R Larouche*, N Lahaie, A Veillette, T Vu, S Michalowski, Centre hospitalier de l'Universite de Montreal(CHUM), Montreal, QC, CA

Purpose: In 2020, 16% of the incident reports submitted to our Incident Learning program were related to Radiotherapy prescriptions. As these are a critical part of Radiotherapy treatments, a large amount of resources and time are invested within our department to check for and correct these issues before treatment starts. We decided to investigate in further detail the error rates, and their causes to better understand the quality of Radiotherapy prescriptions and how to improve it. **Methods:** We used three different methods to measure and investigate Radiotherapy prescription errors: first, we reviewed past incident reports to find all reports related to Radiotherapy prescriptions; second, we organised a two-week survey to identify and quantify the type and number of issues with Radiotherapy prescriptions; third, a chart audit of 100 targeted patients was done to identify any unreported errors. Patient selection was done purposefully to ensure that all Radiation Oncologists, treatment sites, techniques and modalities were represented within the audit. **Results:** Whereas the incident reports represented 2.3% of Radiotherapy prescriptions treated in our department in 2020, the survey identified 13 radiotherapy prescriptions having errors out of 135 investigated (9.6%), and the audit identified 20 radiotherapy prescriptions having errors out of 100 investigated (20%). We categorized the errors for the survey and audit investigations, noticing that most of the errors that could have led to treatment errors where associated with treatment sequencing and treatment site identification. **Conclusion:** The important number of reports submitted to our Incident Learning program alerted the team to investigate prescription errors, but it was clearly underreporting the importance of these issues despite being a highly functional program. We hope to review and improve our processes with a Failure Modes and Effect Analysis, making sure to repeat our survey and audit experiments to measure the outcomes of any process changes.

PO-GePV-T-141

Retrospective Review and Analysis of Treatment Planning Errors

M Joo*, M Lin, A Godley, D Sher, E Chambers, C Wallace, A Pompos, UT Southwestern Medical Center, Dallas, TX

Purpose: Our department performs regular process review as part of the quality improvement efforts. The goal of this study was (1) to retrospectively analyze treatment planning- and chart setup-related errors in a controlled sub-sample of patients and (2) to identify potential sources of these errors to reduce and avoid future occurrences. **Methods:** To ensure consistency and accuracy of data statistics, a complete set of treatment plans, which were checked by a single physicist over a 7-month period, was included in the study. The plans, in which no errors were found, consist the control sample, while the rest of the plans, where errors were found by the physicist or other staff involved in the patient care, define the variance sample. Errors related to treatment planning and chart setup were analyzed. Analysis metrics included hypothesized correlations of various timelines along the treatment planning process with error rate. Significant difference between the control and variance groups was investigated. **Results:** 207 plans in the control group and 115 reported errors in the variance group were analyzed. No significant difference was observed between the control and variance groups in errors occurring at various time points. The variance group had a slightly larger fraction of plans that violated our planning timeline (0.42 vs. 0.39) and a larger fraction of plans that had a shorter timeline between patient simulation and the start of treatment. Planning efficiency and planner variable were found not to be factors in clinical errors. **Conclusion:** The results did not find any correlation between the control sample and the variance sample with respect to the treatment planning timelines. As continuous review of adverse events helps improve clinical processes and prevents future similar errors, further examination is needed to investigate other root causes of the errors.

PO-GePV-T-142

Automated Plan Checking Software Demonstrates Continuous and Sustained Improvements in Safety and Quality: A 3-Year Longitudinal Analysis

D Stuhr, Y Zhou, H Pham, J Xiong, S Liu, J Mechalakos, S Berry*, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: Perform a longitudinal analysis of the performance of our automated plan check tool (PCT) by retrospectively evaluating the number of errors identified in plans delivered to patients in three, month-long, data collection periods taken between 2017 and 2020. **Methods:** 11 automated checkers were retrospectively run on 1169 external beam radiotherapy treatment plans identified as meeting the following criteria: planning target volume (PTV) based multi-field photon plans receiving a status of treatment approved in either March 2017, March 2018, or March 2020. The number of “passes” and “flags” were recorded. “Flags” were sub-categorized into “false flags”, “false flags due to naming conventions”, or “real flags”. 2x2 contingency tables using a two-tailed Fischer’s exact test were utilized to determine whether there were nonrandom associations between the output of PCT and whether the check was manual or automated at the original time of treatment approval. **Results:** A statistically significant decrease in flags between the pre- and post-automation datasets was observed for four contour-based checkers, namely adjacent structures overlap, empty structures and missing slices, overlap between body and couch, and laterality, as well as a checker that determined whether the plan’s global maximum dose was within the planning target volume. Analysis of the origin of false flags resulted in recommendations for algorithmic or configuration modifications to circumvent such flags in the future. **Conclusion:** Periodic and longitudinal review of the performance of automated software is essential for monitoring and understanding its impact on error rates as well as for optimization of the tool

to adapt to regular changes of clinical practice. PCT has demonstrated continuous contributions to the safe and effective delivery of external beam radiotherapy to our patient population, an impact that extends beyond its initial implementation and deployment.

The plan check tool project is part of a co-development agreement between MSKCC, University of Michigan, and Varian Medical Systems. At the time of data collection Sean Berry held a grant from Varian Medical Systems unrelated to this work.

PO-GePV-T-143

The Impact of Using Daily CT for 2D EPID-Based In-Vivo Dosimetry

B Feng^{1,2*}, J Wang^{1,2}, L Yu^{1,2}, E Mo^{1,2}, L Chen^{1,2}, J Zhao^{1,2}, W Hu^{1,2}, (1) Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, CN, (2) Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, CN

Purpose: The difference of anatomical structure and positioning between planning and treatment may lead to bias in EPID based in-vivo dosimetry calculation. The purpose of this study is to use daily CT instead of planning CT as reference for EPID-based in-vivo dosimetry calculation and to analyses the necessity of using daily CT for EPID-based in-vivo dosimetry calculation in terms of patient quality assurance. **Methods:** Twenty patients were enrolled in this study. These plans include 8 sites (Cervical, Nasopharyngeal, oral cavity, rectum, prostate, bladder, lung, Esophagus). All treatments were delivered with (CT-linac 506c, UIH, Shanghai) using 6MV photon beams, this machine was equipped in-orbit diagnosis level fan-beam CT and amorphous silicon EPID (XRD1642, Varex Imaging Corporation, Utah). A Monte Carlo algorithm was developed to calculate the in-vivo transit dose distribution. A pre-treatment measurement was performed to access system accuracy by delivery on homogeneous phantom (RW3 slab, PTW, Freiburg). During treatment, each patient was received a CT scanning before delivery by in-orbit CT every one week. Meanwhile, transmit EPID image was acquired for each field when delivery. The reference of transmit EPID image was calculated based on both planning and daily CTs. The gamma passing rate were calculated. **Results:** The average (standard deviation) of gamma pass rate in RW3 slab phantom was $99.6\% \pm 1.0\%$ (3mm3%), $98.9\% \pm 2.1\%$ (2mm3%), and $97.2\% \pm 3.9\%$ (2mm2%). For patient measurement, the average (standard deviation) of gamma pass rate was $87.8\% \pm 14.0\%$ (3mm3%), $82.2\% \pm 16.9\%$ (2mm3%) and $74.2\% \pm 18.9\%$ (2mm2%) by using planning CT as reference, while $93.6\% \pm 8.2\%$ (3mm3%) $89.7\% \pm 11.0\%$ (2mm3%) and $82.8\% \pm 14.7\%$ (2mm2%) by using daily CT as reference. There were significant differences between planning CT and daily CT results. All p-values (paired t-test) were less than 0.01. **Conclusion:** Due to changes in internal anatomical structure, planning CT may introduce bias in reference image calculation for EPID-based in-vivo dosimetry verification. Using daily CT is recommend for EPID-based in-vivo dosimetry.

PO-GePV-T-144

Radiotherapy Dose Accumulation Routine (RADAR) - a Fast Dose Accumulation Tool for Planning with Previous Treatments

Y Hu*, L Kuo, J Mechalakos, L Zhang, N Shah, A Ballangrud, A Li, J Deasy, L Cervino, P Zhang, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: To pre-clinically evaluate a new treatment planning tool for re-irradiation risk evaluation which accumulates equivalent dose in 2-Gy fractions (EQD2) or physical dose from previous treatments with either rigid or deformable registration using a novel method to account for uncertainty in registration. **Methods:** Radiotherapy Dose Accumulation Routine (RADAR), developed as an Eclipse plug-in, matches previous and current plans using the existing rigid or deformable registrations in Eclipse and accumulates either physical dose or EQD2 with structure-specific α/β . Physical dose can be converted into EQD2 either with structures in previous plans, or with structures in the current plan after physical dose is transferred. To account for registration uncertainty, dose given to a voxel inside organs-at-risk is conservatively estimated as the local maximum within an ellipsoid centered on the voxel. The ellipsoid's 3 principal radii are user-configurable depending on the mobility of the structure and accuracy of registration. To further remove ambiguity, RADAR provides a structure matching option for the uncertainty ellipsoid to only include voxels with paired structure label between the previous and current plans. Overlay ratios of matched structures are calculated to inform possible issues of contouring and registration. **Results:** In a sanity check, physical dose accumulation via RADAR generates the same dose distribution as the Eclipse plan sum with rigid registration. RADAR finished within 7 and 40 seconds, for a 2.5mm and 1.25mm grid resolution, respectively, for a typical brain metastases case. Structure matching prevents non-relevant dose from being unreasonably assigned to organs-at-risk. Site-specific quality assurance checks have been performed to ensure its applicability. **Conclusion:** We are developing an EQD2 dose accumulation tool capable of handling both rigid and deformable registrations, additionally with local search options to account for registration uncertainty, providing an efficient and integrated workflow clinically needed to assess the risk for patients with previous treatments.

PO-GePV-T-145

Validation of Radiochromic.com Gamma Analysis Software

I Mendez^{1*}, J Rovira Escutia², B Casar¹, (1) Institute of Oncology Ljubljana, Ljubljana, 061, SI, (2) Centro Nacional De Dosimetria. Ingresa, Valencia, ES

Purpose: Agnew and McGarry presented a suite of images to evaluate software for gamma analysis, and verified with it a comprehensive set of commercial programs [Agnew CE, McGarry CK. A tool to include gamma analysis software into a quality assurance program. Radiotherapy and Oncology. 2016 Mar 1;118(3):568-73]. The purpose of our study was to validate the implementation of gamma analysis in Radiochromic.com (Radiochromic SL, Benifaió, Spain) by using these tests. Two different versions of Radiochromic.com were evaluated: currently available version 3.3 and a pre-release version. **Methods:** The Agnew and McGarry's (AG) tests consist of four synthetic geometric images and two clinical images (IMRT and VMAT plans). The synthetic images have known gamma results assuming that the evaluated image is not interpolated. However, real dose distributions are continuous, and more accurate gamma values are obtained by interpolating the evaluated images. The results of the clinical AG tests depend on the interpolation used. Both Radiochromic.com versions apply bicubic interpolation, although the resolution of the interpolated images may differ. Also, the pre-release version has the option of not interpolating, employs parallel computation, and can calculate 1D to 3D gammas. **Results:** In the clinical tests, Radiochromic.com v3.3 had a mean passing rate and standard deviation of $99.0 \pm 1.4\%$, while in the pre-release version it was $98.9 \pm 1.5\%$. For comparison, from the AG paper, mean passing rates for FilmQAPro, PTW Verisoft v6.1, and Sun Nuclear SNC v6.5 programs were $96.2 \pm 6.0\%$, $98.8 \pm 1.9\%$, and $98.5 \pm 2.1\%$, respectively. In the synthetic tests, the pre-release version obtained exact results and v3.3 had errors of $-0.1 \pm 0.5\%$ as a consequence of interpolation. **Conclusion:** The accuracy of the implementation of the gamma analysis was validated in both versions of Radiochromic.com.

B Casar acknowledges partial financial support from the Slovenian Research Agency through the research Grant P1-0389. I Mendez and J Rovira Escutia are co-founders of Radiochromic.com.

PO-GePV-T-146

Radiation Oncology Community Site Integration Experience - Tools and Checklist

S Rahman^{1*}, S Chen², B Yi³, B Zhang⁴, (1) University of Maryland Medical Center, Baltimore, MD, (2) University of Maryland School of Medicine, Baltimore, MD, (3) University of Maryland School of Medicine, Baltimore, MD, (4) University of Maryland School of Medicine, Baltimore, MD

Purpose: To share our experience, findings, tools, and checklists from a successful integration of radiation oncology information system (ROIS) of community site into a centralized ROIS and to illustrate the role of medical physicists and IT support. **Methods:** An integration steering committee led by a qualified

medical physicist (QMP) oversees the whole integration for safe patient care. This integration procedure can be categorized into six major sub-processes: staff readiness, treatment delivery machine readiness, patient data integration, machine reconfiguration, clinical process integration, and post-integration verifications. Based on their natures, these processes can progress before or after the integration, in parallel or in sequence. Staff readiness and machine readiness are a pre-integration process without system disruptions. During patient data integration and machine reconfiguration, no patient treatments can be performed due to system disruption/configurations. Clinical process integration and post-integration verification will happen right after patient data integration and machine reconfiguration. **Results:** These integration processes produced successful integration of a new member practice site into our academic radiation oncology system (already integrated with five clinics) including a Proton site with a centralized radiation oncology information system. The successful planning and detailed technical preparedness resulted in no patient treatment delays at the existing sites. However, due to the availability of the vendor's assistance for machine reconfiguration to our centralized database, the patient treatments at the newly integrated community practice were postponed for one day. Although we integrated a community practice with its specific infrastructure, the whole integration procedure suggested in this report is infrastructure- and vendor-neutral and can be easily adopted by other institutions. **Conclusion:** Our experience shows that careful planning, effective communication, various combination of expertise, and coordination of functional groups (including vendors) would lead to efficient and seamless integration of a community radiation oncology practice to an existing ROIS.

PO-GePV-T-147

Automated Verification of Treatment Parameter Transfer Between TPS and OIS Databases Via Direct Value Comparison

W Donahue*, E Draeger, D Han, Z Chen, Yale University School of Medicine, New Haven, CT

Purpose: Transferring treatment plans from a treatment planning system (TPS) to an oncology information system (OIS) for treatment delivery can introduce data errors, especially when manual manipulation is required. The accuracy of data transfer must be validated before commencing a treatment. The current practice of manual checks does not review all field parameters (e.g., MLC leaf positions). The purpose of this work was to automate this critical component of chart checks between Varian's Eclipse TPS and Elekta's Mosaic OIS. **Methods:** Eclipse-Mosaic Transfer Validation (EMTV) was developed using the Eclipse Scripting API to read field parameters directly from Eclipse. It queries values from the Mosaic database for comparison. EMTV checks the prescription dose, fractionation, and field parameters including individual control points. To test and validate the EMTV, two physicists performed chart checks with and without using EMTV. Errors detected by both processes were recorded to determine the validity of EMTV. Times used in chart check with and without EMTV were recorded to determine time savings. **Results:** A total of 53 patient plans were evaluated. Manual checks revealed one error, while the EMTV flagged two plans with errors. A prescription mismatch for a patient transferred from a satellite was discovered by both; the fraction number was adjusted in Mosaic but not in Eclipse. Another error, only detected by EMTV, occurred in individual control points; caused by rounding during the data transfer. The manual check averaged 2.5 ± 1.8 minutes while EMTV averaged 6.2 ± 5.3 seconds. **Conclusion:** An automated tool for treatment parameter transfer verification has been developed and validated. EMTV was shown capable of catching mismatches in the plan parameters. It was 16 times faster than the current methods while being more comprehensive. The EMTV has a potential to streamlining the clinical workflow while improving patient safety.

PO-GePV-T-148

Application of FMEA to Review and Analyze Software Error Messages

B Miller*, S Gardner, C Smith, Z Sun, N Wen, I Chetty, Henry Ford Health System, Detroit, MI

Purpose: Error messages from vendors can often be confusing and lacking in clarity. Our department has implemented an internal "Problem Ticket" website where staff can enter problems with clinical equipment, including error messages encountered on clinical systems. We propose a systematic review of these errors so they can be fully understood in a multidisciplinary manner through including working with radiation oncology staff, vendors, and departmental/hospital IT. The overall goal of this process is to provide staff with appropriate and timely feedback to help mitigate any negative consequences caused by error messages. The purpose of this study is to report on high impact error messages observed within our department. **Methods:** TG-100 describes a method to prospectively find/rank failure modes (and associated failure pathways) using process mapping, FMEA, and fault tree analysis. In this study, we perform a systematic review of error messages using FMEA to retrospectively analyze and rank error messages reported at our institution. Reports are categorized and prioritized using FMEA/RPN formalism. **Results:** In total, 307 error messages were reviewed from the departmental "Problem Ticket" website and assigned values for Occurrence(O), Severity(S), and Detectability(D) to calculate RPN. Of the 307 messages, 24 were identified with RPN>200 and further analyzed/categorized. Two high-frequency categories were Network/Services and Data Import to the TPS. Both issues caused increases in response time to resolve the error. For both categories, the corrective action/troubleshooting step was not clear from the error message content, so reviewing and communicating the recommended steps to staff has the potential to improve the effectiveness and efficiency in real-time response to both categories. **Conclusion:** Development of a systematic and department-wide method to analyze error messages using FMEA can help to fully understand error messages and ensure that appropriate staff are notified, thereby improving both effectiveness and efficiency in troubleshooting error messages in the clinical setting.

PO-GePV-T-149

A Custom-Made Cassette for In-Water Film Dose Measurements and Quality Assurance of Cs-137 Blood Irradiators

H Moktan*, S Jayarathna, R Tailor, S H Cho, UT MD Anderson Cancer Center, Houston, TX

Purpose: To develop a cassette capable of holding custom-sized radiochromic film in a reproducible manner for in-water dose measurements and quality assurance (QA) of Cs-137 blood irradiators. **Methods:** The currently developed film cassette was made of two thin (0.8mm) Lexan sheets cut to 19.4cm x 12.3cm. It contained a rectangular hole at the center (9.7cm above the bottom of the canister) and circular holes at six off-center locations (2.5cm and 5cm lateral to the center, and 8 cm above and below the center). The holes facilitated uniform exposure within the designated regions of measurement without any interference from the cassette material. To measure and verify the dose output and dose distribution of Cs-137 blood irradiators, a GAFChromic EBT-3 film was sandwiched in the cassette and placed diametrically vertical inside the water-filled canister. The film was then irradiated for the specified set time to deliver the desired dose (~8 Gy) based on the manufacturer-quoted dose rate. The film was scanned using Epson Expression 1000XL scanner one day after the irradiation. The measured optical density of the film was converted to the dose using the film calibration curve derived from prior measurements with an ionization chamber-calibrated (reference) Cs-137 irradiator. The film calibration curve was verified on the date of measurement by exposing two 2cm x 2cm pieces of the same film to a known dose (~8 Gy) using the reference Cs-137 irradiator. Another 2cm x 2cm piece of unexposed film provided the background reading. **Results:** The measured doses at the center and off-center locations using the film cassette agreed with the manufacturer-stated doses within $\pm 5\%$ over three periodic QA sessions. **Conclusion:** The currently developed film cassette was found efficient and reliable for in-water dose measurements and periodic QA of Cs-137 blood irradiators.

PO-GePV-T-150

Development of An In-House Off Axis Mechanical Isocentricity Test

J Seekamp*, D Pearson, University of Toledo, Toledo, OH

Purpose: To develop and analyze an off-axis isocentricity test for the evaluation of a LINAC's multiple metastasis single isocenter treatments and determine

the machine's off-axis limitations. **Methods:** A QA plan was developed for use with an existing phantom in our department. The existing QA phantom has a series of 0.75 cm diameter BBs positioned throughout itself. The two BBs used for evaluation in this test were located at the beam's isocenter and at a combined 3 cm lateral, 2 cm longitudinal, and 2 cm vertical displacement. The radial displacement of this BB from the isocenter is 4.12 cm. Images were acquired with various couch, gantry, and collimator rotations using the EPID. An in-house script was developed to analyze these images and calculate the absolute 3D error of the machine's isocenter off axis. **Results:** The error in the test machine's mechanical isocenter was observed to be 0.74 mm. At the off axis BB the absolute 3D error was observed to be 1.49 mm. A visual inspection was used to verify the accuracy of the script's BB identification routine. The location of the BB as denoted by the script agreed with our visual inspection. **Conclusion:** This proof of concept tool can successfully identify and localize two BBs in three dimensional space using a series of MV images. These tests confirmed that small mechanical errors are magnified away from the machine's isocenter. This work paves the way for future simultaneous evaluation of several points off the beam axis. This future work will allow one to determine an acceptable cutoff for single isocenter multi-metastasis treatments.

PO-GePV-T-151

Validation of Automated Segmentation Algorithms for Clinical Radiation Therapy Treatment Planning

W Watkins*, D Du, K Qing, J Liu, C Ladbury, A Liu, City of Hope National Medical Center, Duarte, CA

Purpose: To introduce a systematic method of clinical validation of automated-segmentation algorithms including patient- and organ-specific variations. **Methods:** Patient- and organ- specific variations were quantified for two algorithms (A1-2). Eighty computed-tomography scans including a range of treatment sites and scanning protocols from head to pelvis with 34 different organs-at-risk were included. For each patient, Algorithm-generated contours were compared to humans using nine volume, surface, and statistical measures. Validation of A1 and A2 were performed based on accuracy, consistency, and potential problems in specific-patients and specific-OARs prior to clinical introduction. **Results:** Sample means were compared to the population means to identify outliers flagging OARs including femurs, esophagus, larynx, and pharynx. The range of volume and surface metrics in femurs was 0.27-0.52 and 17.8-66.4mm in A1 implying the algorithm was failing. However, these differences represented the difference between A1 contouring only the femoral head, and clinical contours including lateral and inferior aspects of the femur; this is an example of institutional vs. algorithmic definition, not contouring error. This was one of several examples of variations in the "ground truth" dataset and the auto-contour models. Per-patient variations revealed issues in image artifacts, large slice spacing (>5mm) combined with small structures, and issues predicting bladder in scans extending significantly beyond pelvis. Per-organ analysis revealed volume- and boundary- metrics combined to correlate well to high-quality auto-segmentations. However, statistical metrics such as variation of information identified different issues like large boundary error in few slices. **Conclusion:** Automated-segmentation will reduce human workload and standardize clinical practice but has the potential to introduce clinical errors; manual review/editing of erroneous auto-contours can negate efficiency benefits. Per-patient and per-organ validation of automated segmentation will detect problematic contours and enable seamless clinical integration.

PO-GePV-T-152

Application of Automatic Plan Checking and Report Printing to Improve Clinical Workflow Accuracy and Efficiency

P Yan*, D Mynampati, S Hsu, A Basavatia, P Brodin, C Velten, W Tome, Montefiore Medical Center, Bronx, NY

Purpose: The pre-treatment plan check by a physicist is a key component to ensuring patient safety and treatment plan quality. The report is also a critical part for the radiation therapy. The purpose of a computer assisted plan check and report is to ensure plan quality, accurate patient setup instruction, and correct documentation of patient and plan information. **Methods:** To implement an assisted plan check a script was written using the ESAPI and C#. The plan check list and report follow TG275 and TG315 guidelines. The plan check includes prescription, structure, collision, constraints and parameters checks. The "print" button generates the report and saves it in patient's folder. The report includes the coversheet with the ACR recommended checklist and patient setup instruction, the prescription table, plan summary, 2D-view, constraints table, parameters table and DVH. The setup instruction includes the import information about the plan such as DIBH, Bolus etc, shifts, SSD and table vertical position. This information is helpful to therapists to setup and treat the patient correctly. **Results:** The script has been tested by physicists for 6-month, and was then implemented in clinic for 5-month. The script saved at least 30-minute for each plan check and printing. The script created report includes all the recommended items in the TG315 report. The most errors recorded by the script are the "reference-point-dose-limit" and "tolerance-table". Since the implementation of this assisted plan check script, our near miss rate has dropped from the value prior to its implementation. **Conclusion:** Automating some processes of the plan check and report reduces the errors, voids manual input mistakes, and improve plan check efficiency. This standardized treatment plan report can be used as a consistency check for planners, a pretreatment check by therapists, a quick review for the physicist's initial, weekly and final checks, and billing verification.

PO-GePV-T-153

Towards Implementation of a Knowledge-Based Decision Support System for Treatment Plan Auditing Through Automation

S Liu^{1*}, K Ohri², J Bertini³, S Berry⁴, D Yang⁵, C Della-Biancia⁶, (1) Memorial Sloan Kettering Cancer Center, New York, NY, (2) Memorial Sloan-Kettering Cancer Center, New York, NY, (3) University of Chicago, Chicago, IL, (4) Memorial Sloan Kettering Cancer Center, New York, NY, (5) Washington University in St Louis, St Louis, MO, (6) Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: To identify the needs and opportunities in standardizing and improving our external beam radiotherapy (EBRT) treatment planning procedure across all 7 campuses of our institution, a knowledge-based anomaly detection algorithm to provide decision support for our manual retrospective plan auditing process was developed and implemented. **Methods:** 710 lung SBRT (Stereotactic Body Radiation Therapy) plans that were delivered from 2015 to 2020 have been acquired automatically from our clinical treatment planning systems. A total of 44 plan parameters were extracted from each plan and pre-processed. A knowledge-based anomaly detection algorithm, namely "isolation forest" (iForest), was then applied. Each plan was recursively isolated by randomly selecting a plan parameter and a split value, represented by an isolation tree (iTree). Subsequently, an iForest is assembled from a collection of developed iTrees and an anomaly score is determined from the path length between the root node and a terminating node on the iTree. Anomalous plans are more susceptible to such isolation mechanism, thereby having higher anomaly scores. To evaluate the feasibility of the proposed method, top 20 plans ranked with the highest anomaly scores together with the extracted plan parameters were validated manually by two plan auditors. **Results:** The two auditors certified that 12 out of 20 plans with the highest iForest anomaly scores have similar "alarming" qualities to further investigate and improve our planning procedures and staff training. A manual audit of one chart is estimated to take 45 minutes, while with the guidance of iForest it is estimated to save approximately 7.5 minutes per chart, a time savings of 16.7%. As our internal audit process typically consists of review of 250 charts annually, the total time savings are substantial. **Conclusion:** The iForest method effectively detects anomalous plans with high sensitivity and provides decision support to our cross-campus manual plan auditing procedure.

PO-GePV-T-154

A Methodology and Open Source Tool for Radiotherapy Dose Transformation QA

H Clark*, British Columbia Cancer Agency, Surrey, BCCA

Purpose: Owing to improved palliative treatment options and increased survivorship, a growing number of patients require multiple distinct radiotherapy treatments. This presents unique planning challenges, and it is now commonplace to use image registration and biologically-effective dose (BED) methods for

lifetime organ-at-risk dose estimation. However, quality assurance (QA) options are limited, and often involve spot-checks. In this work, we present a simple and universal method and software implementation for QA of dose transformation methods like BED. **Methods:** The equivalent dose in 2 Gy fractions (EQD2) paradigm is based on the linear-quadratic cell survival model. How dose is transformed in clinical scenarios depends on the fractionation and α/β , which is tissue- and outcome-specific. Inverting the EQD2 model provides a way to estimate α/β across the entire body, voxel-by-voxel, given the fractionation, EQD2 dose, and original dose. Histograms of α/β -volume can be extracted for individual regions-of-interest and analyzed automatically via percentile extraction, or maps can be visually inspected to survey the entire body quantitatively. Model inversion is sensitive to human transcription and selection errors involving the original fractionation, ensuring appropriate courses were used, α/β settings, selection of appropriate regions-of-interest, and also that the anticipated EQD2 model was selected. A free and open source implementation of EQD2 model inversion is provided. Simulated errors were tested to confirm detectability. Results of being used clinically in a supplementary role to spot-check QA for 21 plans are provided. **Results:** Errors resulting from incorrect region-of-interest selection or overlap handling, use of incorrect EQD2 models, incorrect fractionation and course selection can all be detected. Clinically, instances of incorrect α/β were detected for two plans with EQD2 model inversion that were not detected using spot-checks (invalid region-of-interest selection and invalid α/β). **Conclusion:** Model inversion is an effective approach for independent QA of BED-based dose transformations.

PO-GePV-T-155

Challenges On Implementing An Hybrid AI-And-Rules Based Plan Check Tool in Clinical Practice - a Pilot Study

S Luk*, E Ford, M Kim, M Phillips, K Hendrickson, A Kalet, University of Washington, Seattle, WA

Purpose: Artificial Intelligence (AI) has become a focus of research in radiation oncology in recent years, demonstrating potential for improvements in clinical safety in multiple studies. However, there are hurdles to the implementation of AI applications in ways that can realize those improvements clinically. In this work, we report a pilot study on implementing an in-house developed hybrid rules-and-AI based tool designed to assist medical physicists in initial plan checks. The goals of the study are to identify the key challenges and evaluate these aspects of system implementation into clinical workflow. **Methods:** The web-based plan check tool takes a hybrid method approach, consisting of a rules-based component and a Bayesian network (BN)-based AI model. In the pilot study, three volunteering clinical medical physicists use the tool to assist their routine plan check process. Potential errors that are flagged by the tool are verified by the physicists and report as true positive or false positive results. Feedback is collected from the volunteers on their concerns using the tool. **Results:** The simple logic system has shown excellent performance in the pilot study, while the BN-based AI tool successfully flags different potential logical errors in clinical plans. However, the AI tool also reported multiple false positive flags, and volunteers have reported that these repeated false positive errors combined with the lack of understanding on the AI model reduced their confidence in relying on the tool. **Conclusion:** The BN-based AI tool was found to be useful to physicists in identifying errors in treatment plans during routine checks. We also found that interpretability of results presented a challenge to users, and understanding how to manage trade-offs between reliability, efficiency, and efficacy of the model needs to be explored.

PO-GePV-T-156

Development of An Automated Pre-Treatment Plan Evaluation

J Rembish*, P Myers, C Kabat, N Bice, K Rasmussen, D Saenz, N Kirby, N Papanikolaou, S Stathakis, UT Health San Antonio MD Anderson Cancer Center, San Antonio, TX

Purpose: To ensure high-quality care, radiation oncology teams conduct pre-treatment plan evaluations which review the machine treatment parameters, patient set-up instructions, prescriptions, and radiation dose distributions. The current process is performed manually, which consumes a great deal of time and introduces the risk of human errors. Automating pre-treatment plan evaluations can improve clinical efficiency and reduce errors. **Methods:** Using Python, a web-based user-interface was created to automatically compare the data from the DICOM export and the Mosaic SQL database. Various machine parameters, prescription details, and patient information are taken into consideration when cross-comparing between the two systems. The results are displayed side-by-side for each field being evaluated, and any discrepancies are highlighted for easy recognition. Additionally, the DVH is calculated and structures are assessed to determine if, and by how much, all constraints are being met. These scripts are publicly available through PyMedPhys. **Results:** A data-transfer check has been developed to ensure a plan's DICOM files and Mosaic's database information are consistent between general patient information and beam specific information. The comparison can be performed in a matter of seconds, making it significantly less time consuming than a manual comparison. Additionally, plan quality can be determined through DVH analysis and compared to an archive of patients. **Conclusion:** The data transfer portion of a pre-treatment check can be automated and used to drastically reduce the amount of time required to complete the task while minimizing opportunity for human error. Implementing this into clinical workflow has the potential to increase efficiency while also increasing error detection sensitivity and improving plan quality.

An End-To-End Test to Evaluate Off-Axis Targeting Accuracy for Single-Isocenter Multitarget Stereotactic Radiosurgery

C Guthier*, S Friesen, Brigham and Women's Hospital, Dana-Farber/Brigham and Women's Cancer Center, Harvard Medical School

Purpose: Single-isocenter multitarget radiosurgery (SIMS-RS) is a treatment option for multiple brain metastases. Precise alignment of rotational axes of the linear accelerator is crucial and must be checked frequently. The drawback of current quality assurance (QA) procedures is that targeting accuracy is only evaluated at isocenter. This study introduces a hidden target end-to-end (E2E) test allowing to check targeting accuracy for off-axis targets. **Methods:** The E2E follows our current clinical workflow. Targets are three BBs placed inside the Rando head phantom. The procedure is similar to the Winston and Lutz isocentricity test (WL-test). A 10cmx10cm field size allows that the implanted BBs were visible in the recorded portal images. For evaluation, an in-house tool for image analysis and 3D reconstruction of target positions was developed. The algorithm allows reconstruction of multiple BB positions in a non-homogeneous phantom. In addition, a multi-view 3D reconstruction is used to automatically identify the BBs and to calculate its 3D positions. The automated analysis consists of a classic WL-test for the central BB as well as a comprehensive 3D analysis of all BBs. **Results:** The median distance for the center BB to the CAX was 0.46mm. The reconstructed size of the isocenter was 0.36mm for collimator/gantry combinations and 1.0mm for couch rotations. This is in agreement with an independent WL-test. For the off-axis BBs with an displacement of 5.6cm and 7.0cm the reconstructed center size was 0.49mm and 0.72mm, respectively. Couch rotation led to an uncertainty 1.05mm for the proximal and 1.26mm for the distal BB. A 3D point registration showed that the total target accuracy was 0.43mm. **Conclusion:** The proposed E2E test in combination with the developed processing algorithm allows a streamlined assessment of SIMS-RT targeting accuracy and can be used as an additional QA step for those complex treatments.

PO-GePV-T-158

How AI Can Support Personalized Risk Mitigation During Automated Treatment Planning

M Bach*, G Spira², (1), Overath, NW, DE, (2), Cologne, DE

Purpose: To automatically determine individual risk priority numbers for patients during the radiation therapy process due to potential human and technical errors and to demonstrate how to mitigate some of these risks through artificial intelligence (AI). **Methods:** APIs (Application Programming Interfaces) for

treatment planning systems are used to expand their scope of functionality and be used to interface AI algorithms. In this work, a C# environment was used to implement an Expert System (own activity), supervised Machine Learning (ML.NET, Microsoft), and Eclipse Scripting (ESAPI, Varian Medical Systems). Ratings for the risk factors severity S, occurrence O, and detectability D were created for several error scenarios and grouped into three phases of an automated planning workflow (load patient with associated demographic information; checking prescription and consistency of PTV/OAR structures; calculating plan setup, dose, and quality metrics). The program calculates risk priority numbers ($RPN = S \times O \times D$) during each planning step and compares these with values mitigated by the AI algorithms. **Results:** Several AI mitigations were successfully integrated, among them binary classification, anomaly detection, and recommendations. In more than 80% of automated planning workflows with initially critical (RPN between 30 and 125) or unacceptable risk levels (RPN above 125), the AI-supported treatment planning found mitigations to reduce values to an acceptable level (RPN below 30). Where algorithms could perform no mitigations, root cause analysis identified either missing branches in the Expert System or missing data. **Conclusion:** This work demonstrates the potential for significant risk reduction by embedded AI support during treatment planning. With prior trained machine learning models and expert systems, the gain in safety comes basically without additional costs; and the modular structure of ESAPI also allows the implementation of other mitigations programmed by third-party institutions.

PO-GePV-T-159

Failure Modes and Effects Analysis of Low Dose Bilateral Whole Lung Irradiation Treatment for COVID-19 Positive Patients Requiring Respiratory Ventilation

A Swanson*, D DiCostanzo, N Gupta, K Hintenlang, A Cetnar, The Ohio State University, Columbus, OH

Purpose: To identify high priority risks in a new radiation treatment workflow for alleviating severe COVID-19 pneumonia using a multi-phase failure modes and effects analysis (FMEA). **Methods:** A comprehensive FMEA survey of 133 possible causes of failure was developed for a clinical trial workflow treating mechanically ventilated COVID-19+ patients with low-dose whole lung radiation therapy (Phase I). The occurrence, severity, and detection risk of each possible cause of failure was scored by 3 physicists using an adapted scoring guide based on TG-100 recommendations. High-risk potential failure modes were identified using the average risk priority number (RPN) and severity scores. The responses were used to create a second targeted survey containing high-priority risks throughout the treatment workflow (Phase II). The second survey was completed by 13 participants in Radiation Oncology including therapists, physicians, and physicists. Scores from the Phase II survey were evaluated to identify steps requiring possible intervention and examine risk perception patterns. **Results:** Based on the results of the initial survey, 30 high-priority failure modes were selected for the Phase II survey. Strong internal consistency was shown in both surveys using Cronbach's alpha ($\alpha > 0.82$). The 10 failures with the largest RPN values concerned COVID-19 transmission ($N = 6$), wrong treatment ($N = 3$), and patient injury ($N = 1$). The average RPN was larger for COVID-related failures ($RPN = 108$) than other failure types ($RPN = 67$) due to the perceived difficulty of failure detection. **Conclusion:** The high ranking of failures concerning nosocomial transmission of COVID-19 suggest that these steps may require the most quality management intervention for the treatment of critically ill COVID-19+ patients. The results also suggest that a multi-phase FMEA survey may provide useful information for assessing risks in radiation therapy procedures, supporting efforts to adapt FMEAs to clinical procedures in the literature.

PO-GePV-T-160

Failure Modes and Effects Analysis (FMEA) for Multi-Site, Multi-Institutional Deep Inspiration Breath Hold (DIBH) Treatments

M diMayorca*, S Wadi-Ramahi, R Lalonde, T Wilhite, S Ellsworth, A Hays, M Huq, UPMC Hillman Cancer Center and University of Pittsburgh School of Medicine, Pittsburgh, PA

Purpose: Deep inspiration breath hold (DIBH) is a motion management technique used for various treatments, notably left breast irradiation. We performed a multi-institutional TG100 recommended risk analysis of DIBH for lung, abdomen and breast irradiations to identify where quality management can be improved. **Methods:** A detailed process map was outlined for DIBH treatments of both institutions and fault tree analysis (FTA) of all potential failure modes (FM) was performed. A team comprised of two radiation oncologists, four physicists and one radiation therapist ranked occurrence (O), severity (S) and detectability (D) on a 1 to 10 scale. Ranking was subjective based on personal expertise treating DIBH within each center. FMs with the both the highest risk priority number (RPN) and highest severity scores were considered top priority and fault tree analysis was examined to identify ways to improve our workflow. **Results:** The process of DIBH treatment was divided into four sub-processes: motion study, DIBH image acquisition, treatment planning, and treatment delivery, each with multiple steps. We identified 22 FM's for the motion study sub-process, 52 for DIBH image acquisition, 8 for treatment planning and 20 for treatment delivery, for a total of 102. The RPN scores ranged from 12-245, 36-120, 18-150 and 24-144 for each sub-process respectively. The severity scores ranged 3-5 for each sub-process. Many quality assurance and control steps have been suggested for clinical implementation based on this analysis. **Conclusion:** FMEA analysis revealed portions of inconsistent workflow and areas needing quality management. The analysis will be discussed to improve the workflow and quality of patient care.

PO-GePV-T-161

Comparing Leakage Doses Between Three Gamma Knife Icon Machines

H Wang¹, D Luo^{2*}, R Pino³, (1) Houston Methodist Hospital, Houston, TX, (2) UT MD Anderson Cancer Center, Houston, TX, (3) Houston Methodist Hospital, Houston, TX

Purpose: With Icon's capability to treat a patient fixated with a mask and the ability of temporally suspending the treatment as soon as the patient moves out of a pre-set tolerance, it is vital to verify the leakage since the sources are parked at the Block position for a maximum of 5 times per shot, each time could be as long as 30 seconds during treatment suspension. **Methods:** Three methods were employed to measure leakage dose on three Icon machines. All methods calculate the leakage percentages using the ion chamber readings with all sectors On and the readings with some sectors Off. Method-A turns off some combinations of sectors. Method-B starts with turning Sector-1 on, and adds one consecutive sector at a time. Method-C turns on only one sector at a time. **Results:** The results from machines 1, 2, and 3 for Method-(A, B, C) are (0.08%, 0.02%, 0.10%), (0.18%, 0.13%, 0.15%) and (0.14%, 0.09%, 0.14%), respectively. **Conclusion:** Since GammaPlan requires a minimum shot time of 8.8 seconds for a shot containing 16-mm collimation (5.5 sec for 4-mm or 8-mm shots), a specification of 0.2% leakage at the Block position translates to 3.4-5.5% extra dose to the patient in the worst case. Our results show that we have met this spec.

PO-GePV-T-162

Failure Mode and Effect Analysis for Volumetric Modulated Arc Therapy for Total Body Irradiation

T Gray*, A Antolak, S Ahmed, A Magnelli, L Lu, Y Cho, P Xia, B Guo, Cleveland Clinic Foundation, Cleveland, OH

Purpose: To apply failure mode and effects analysis (FMEA) to the Volumetric-Modulated Arc Therapy (VMAT) technique for Total Body Irradiation (TBI) following TG-100 guideline. **Methods:** A process map for VMAT TBI was developed following the AAPM TG-100 guidelines. This process map gives a visual representation of the flow of steps in the treatment process from the initial simulation, treatment planning, and treatment delivery. From the process map, all potential failure modes in the process were identified. Evaluation of the occurrence (O), detectability (D), and severity of impact (S) of each failure mode according to scoring criteria (1-10) by radiation oncology staff members was carried out. Subsequent calculation of the risk priority number ($RPN = O \times D \times S$)

S) and identification of effective quality assurance methods for the highest risks proceeded evaluation. **Results:** A total of 26 failure modes were derived. Five failure modes (top 20%), identified as being high-risk were (1) CBCT patient positioning check failure (2) the treatment planning system reports incorrect MUs after re-optimization (3) incorrect patient set-up SSDs recorded in the record-and-verify system (4) patient movement during treatment and (5) organs-at-risk are contoured incorrectly, producing an inaccurate dose to critical structures. Further quality assurance and quality control measures were proposed to improve effectiveness of the procedure. **Conclusion:** Quality assurance and quality control interventions were implemented based on the FMEA results. Further checks of the treatment planning system reported dose, patient contouring, patient positioning and of the record-and-verify system were proposed to improve the effectiveness of the treatment procedure.

PO-GePV-T-163

Efficiency Analysis of the Automatic Plan Printing Application

J Park¹*, K O'grady¹, L KUO¹, W Fong¹, W Yan², R Lalonde³, L Cervino¹, (1) Memorial Sloan Kettering Cancer Center, New York, NY (2) Carnegie Mellon University, Pittsburgh, PA, (3) University of Pittsburgh Medical Center, Pittsburgh, PA

Purpose: To evaluate the efficiency and effectiveness of a script based automatic treatment plan report printing application. **Methods:** An Eclipse Scripting API (ESAPI) based C# application has been developed in two hospitals where they were printing the treatment plan document manually. The script was designed to convert the treatment planning data, such as plan parameters, image information, dose volume histogram, and dose distributions, into the department-specific plan reports. The report is saved as a single PDF file after automatic attachment of independent MU calculation form etc. Total time spent during the plan printing was measured by parsing the time stamp of an individual PDF file or manually counting the elapsed time by the planner before and after the automation. Other qualitative feedback was also collected from the planners. **Results:** In the A hospital, the mean manual plan printing time was 24.1±20.7 min (median 16.3 min) per plan, while 0.4±0.4 min (median 0.3 min) per plan was spent after the automation, which gives 19.7 min time saving per plan. Similarly, B hospital could save 3.8 min per plan after the automation, where the mean manual printing time was 5.2 min per plan. Considering the average number of treatment plans of 2,470 and 14,690 cases at each hospital, their time savings could be converted into 0.46 and 0.48 FTE, respectively. In addition to the quantitative time saving, the planners could reduce their stress with being free from mistakes and avoid reprinting. Automation improved the workflow to print out the treatment plan, resulting in more consistency, and allowing to provide more information in the report. **Conclusion:** It was found that significant time and effort are spent on the plan report printing. The plan finalization time could be reduced, and the planning workflow could be improved using the automatic plan printing tool.

PO-GePV-T-164

Sources of Systemic and Random Errors in Bleached Optically Stimulated Luminescence Dosimeter (OSLD) In-Vivo Measurements: A Retrospective Clinical Study

S Yoon^{*}, H Lin, C Kennedy, D Mihailidis, B Burgdorf, T Li, University of Pennsylvania, Philadelphia, PA

Purpose: To investigate sources of systemic and random errors in in-vivo OSLD measurements during regular clinical use, by comparing adjacently placed pairs of OSLDs in total body irradiation (TBI) and total skin electron therapy (TSET) under the assumption of equal dose delivered to both OSLDs. **Methods:** Directly adjacent pairs of NanoDot OSLDs were placed on patients with a medical tape prior to TBI and TSET, with or without 1.5cm of bolus respectively, at each anatomical site monitored. Each OSLD was read 5 times (standard error of mean $\sigma=0.2\%$). Resulting raw readings were divided by vendor-provided sensitivity (mean 0.85 ± 0.02) to obtain corrected readings (CR). Used OSLDs were bleached between each use until 1500cGy was accumulated. OSLD database was queried January 2019 to November 2020 to obtain 622 paired samples possibly used for 200cGy prescription TBI and TSET. Pairs of 101 TBI and 110 TSET measurements were verified to be present within clinical records. Relative difference in corrected counts ($\Delta CR_r = \text{pair-difference}/\text{mean}$) was fitted linearly versus sensitivity, bleaching history, cumulative dose, and age differences between paired OSLDs. **Results:** OSLDs were bleached 8 times (0~28), accumulated 942cGy (60~3015), and were used for 238days (0~819) on average before termination. ΔCR_r was normally distributed ($\sigma=\pm5.9\%$). ΔCR_r for TBI and TSET subsets deviated $\sigma=\pm4.7\%$ and $\pm6.3\%$ respectively, despite similar predictor distributions. OSLD with higher sensitivity yielded -0.68% less per +0.01 than the other ($p=4e-17$). Partial multiple linear models taking sensitivity into account found little contributions from bleaching ($p=0.89$) or cumulative dose ($p=0.047$). TBI and TSET samples yielded $\text{RMSE}=\pm4.8\%$ after sensitivity correction. **Conclusion:** Our findings suggest vendor-recommended reading correction via sensitivity division results in a small but significant systemic error. OSLD sensitivities should be considered during reading-to-dose calibration and clinical measurements. Bleaching and cumulative dose likely minimally affect measurements. Random errors were higher for TSET than TBI.

None of the authors received funding for this abstract.

PO-GePV-T-165

The Use of Statistical Process Control Methods to Evaluate Patient-Specific Delivery QA Failure as a Function of Plan Complexity

R Price^{*}, I Veltchev, T Lin, A Eldib, C Ma, Fox Chase Cancer Center, Philadelphia, PA

Purpose: To evaluate the suggestions that QA passing rates decrease as a function of plan complexity and the subsequent need for site-specific tolerance limits. **Methods:** Patient-specific ionchamber array-based delivery QA analysis for 250 previously treated, non-SBRT VMAT patients analyzed at 3%, 3mm and a threshold of 10% was repeated with gamma criteria of 3%, 2mm and a threshold of 10%. Cases were divided into H&N (n=76), Thorax (40), Abdomen (61), and Pelvis (73) with passing rates plotted as a function of an approximate modulation scaling factor (MSFapprox.). Statistical Process Control (SPC) methods were used to compare the action limit of each subset to the universal action limit (ALuniv) of 90%. **Results:** The site-specific action limits differ from the ALuniv by 0.9, -1.1, -2.3 and -4.4% for the Abdomen, H&N, Pelvis and Thorax respectively with MSFapprox. and passing rates being significant between the groups at the 1% and 5% levels, respectively. The passing rates did not reach the same level of significance due to the lower number of thorax cases available for evaluation. The correlation of passing rate as a function of MSFapprox. was "low" for all sites with pelvis having the highest r value at -0.35. The tolerance limits (TL) for the above body sites were 92.8, 91.0, 89.3 and 88.7%, respectively. **Conclusion:** Both site-specific TL and AL for our system show some variation. The site order presented above demonstrated difference from ALuniv as well as general increasing MSFapprox.. It is interesting that the Pelvis (GI, GU, GYN) site demonstrated higher plan complexity and lower AL than H&N at our institution which is contrary to what is generally thought. Additionally, correlation with plan complexity being "low" for all suggests that the need for site-specific action levels may be unwarranted.

PO-GePV-T-166

Variability of Control Limits for Mean Percent Dose Differences Across Different Anatomical Contours

H Mehrens^{*}, R Douglas, M Gronberg, K Nealon, L Zhang, L Court, University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: To investigate the use of Statistical Process Control (SPC) to monitor use of a web-based auto-contouring and planning tool. **Methods:** The Radiation Planning Assistant (RPA) is such a tool that provides plans calculated on standard linacs, which must then be recalculated by the user in their own treatment planning system for their own linac. Thirty-three 4-field box cervix plans (8 structures) and 34 VMAT head and neck plans (30 structures) were generated by the RPA. These plans were downloaded and imported into Raystation v10B where they were recalculated using fixed MUs. The final plans were uploaded

back to the RPA where the differences in mean dose for each structure was calculated. Utilizing SPC, control charts were generated with mean and control limits at the 3 standard deviation. Mean percent dose differences that fell outside of our control limits were removed from the calculation of the mean and standard deviation. **Results:** Head and neck mean percent dose difference and control limits varied per structure. For example, PTV1 (2.28%, [1.00%, 3.56%]), PTV2 (2.19%, [5.59%, -1.21%]), PTV3 (1.67%, [-0.67%, 4.01%]), and spinal cord (0.59%, [1.09, 0.09%]), and similarly, for cervix plans, L5 contour (-2.59%, [-3.43%, -1.74%]) and right femoral head (-1.79%, [-0.77%, -2.81%]). This indicates that SPC will give more individualized results per contour than can be achieved with a fixed threshold (e.g., 5%). Variability in SPC thresholds may be partially attributed to differences in dose calculations near the surface, particularly for targets near the surface for head and neck VMAT cases, and to differing body contours between Eclipse and Raystation. **Conclusion:** Specific control limits for individual contours based on percent mean dose difference can be determined and differ across anatomical sites. More study is needed to understand the underpinning of these differences and if they are effective in indicating plan errors.

PO-GePV-T-167

An Investigation of a Statistical Process Control Based Quality Assurance for Optical Stimulated Luminescence Detector (OSLD) System

K Episcopia, R Febo, D Lovelock, L Cervino, S Lim*, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: Optically stimulated luminescence detectors (OSLD) are widely used for in-vivo dosimetry. The current vendor recommended quality assurance (QA) process is susceptible to errors, such as calibration curve changes. In this study, we investigated a statistical process control (SPC) based quality assurance process to ensure improved consistency and accuracy within an institution's OSLD program. **Methods:** All the OSLD used were nanoDot™ type OSLD (Landauer, Glenwood, IL) and read out in a MicroStarr® II system (Landauer, Glenwood, IL) calibrated with a specific set of calibration OSLDs, each exposed to doses ranging from 5 cGy to 200 cGy. A control OSLD was exposed with 100 cGy. All OSLDs were exposed in a Varian 6EX. The control OSLD was read out daily after performing the vendor suggested QA. The daily variation, $V(t)$, on day t was calculated by taking the ratio between the readout dose at t and $t-1$. The upper and lower control limits, UCL and LCL, were defined as 3 standard deviations, 3σ , which were established with the initial 26 data points. **Results:** The σ of $V(t)$ was found to be 0.8% translating to a UCL and LCL of $\pm 2.5\%$. Using these limits, an additional 71 data measurements were taken. Three instances were found to breach the control limits. Two of the three failures were attributed to either calibration curve changes or chip defects that were not captured by the vendor QA. One was a false positive. The accuracy and precision of the system was estimated to be 98.5% and 66.7% respectively. **Conclusion:** A quantitative QA process was established to enhance the quality control of an OSLD program and can potentially be scaled to a large hospital network. More statistics will be acquired to establish the long-term accuracy and precision of the system.

PO-GePV-T-168

4D Monte Carlo Assessment of the Impact of Inter- and Intra-Fractional Respiratory Motion Variation On Delivered Dose

M Shiha^{1,2*}, J E Cygler^{1,2,3}, R Macrae^{1,3}, E Heath² (1) The Ottawa Hospital Cancer Centre, Ottawa, ON, CA, (2) Carleton Univ, Ottawa, ON, CA, (3) University of Ottawa, Ottawa, ON, CA

Purpose: To quantify the impact of respiratory motion variations on the delivered dose, using a previously validated 4D Monte Carlo-based dose reconstruction tool, for a cohort of non-small cell lung cancer patients undergoing curative radiation therapy treatments. **Methods:** Surface motion measurements recorded during treatment delivery using the RADPOS 4D dosimetry system were used for input in the 4D dose reconstruction tool, 4Ddefdosxyzncr, along with linac log files and the deformation vectors between the exhale and inhale phases of the 4D CT. Deformation vectors were calculated in Velocity AI (V3.2.1), and the reconstructed doses were compared to the clinical VMAT plans calculated on the average CT scan set using Monaco (V5.51.02). **Results:** We present here the results for two patients, for whom we have collected and analyzed the data over five treatment fractions. Each of the patients had the tumor located in the upper right lobe. No motion control device was used during planning CT scans and treatments. The average peak-to-peak breathing amplitude, r , was 5.23 ± 1.35 mm and 4.74 ± 0.21 mm for Patients 1 and 2, respectively. The 4D reconstructed doses show less than 0.5% inter-fraction variation for the CTV D98% for both Patient 1 and 2 and are within 3.0% of the CTV V66Gy planned in Monaco. These results are consistent with relatively small breathing motion amplitude measured for these patients. However, percent change of up to 22.3% in the mean dose to the esophagus was found for Patient 2 when comparing the planned dose to the reconstructed doses. **Conclusion:** This preliminary study demonstrated the use of a 4D reconstruction tool for a small patient sample to evaluate the effects of respiratory motion on delivered dose. Future studies will include larger number of lung patients and variety of tumor locations.

We acknowledge the support of the Natural Sciences and Engineering Research Council of Canada (NSERC).

PO-GePV-T-169

Dosimetric Impact on VMAT Plan Delivery From Tumor Motion Variations Due to Breathing Irregularities

A Schovic*, P Shukla, L Xu, X Nie, L Zhang, P Wang, A Wu, A Rimner, P Zhang, G Li, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: To simulate treatment delivery with tumor motion by moving the isocenter based on tumor motion waveforms and evaluate the dosimetric impact from the tumor motion variations that differ from the internal tumor volume (ITV) used in volumetric-modulated arc therapy (VMAT) planning. **Methods:** A motion-incorporated VMAT planning was applied to simulate plan delivery with actual and simulated tumor motion variations based on 4-dimensional computed tomography (4DCT) acquired at simulation. First, the clinical ITV-based VMAT plans of 9 lung cancer patients with single lesions were segmented into composite plans with multi-beam fields at the control points. Second, tumor motion waveforms were applied to the isocenter. Tumor motion waveforms were created by scaling down the diaphragm motion extracted from the 4DCT images to the tumor motion. The single 4DCT breathing cycle was replicated and concatenated to form a long motion waveform to cover the duration of the 2-4 arc(s) in the clinical plans. Additional tumor motions were simulated by scaling up the tumor waveforms with extra 0.5, 1.0, and 2.0cm motions. Four motion-incorporated plans were created per patient and compared to the clinical VMAT plan, which covered planning tumor volume (PTV) at D95%=100%. The native-motion-incorporated plans were first compared with the clinical VMAT plan as a control, followed by 3 simulated-motion-incorporated plans using D95%=90% as a breach for ITV and PTV. **Results:** Using the original 4DCT motion, the mean D95% from all 9 patients is found to be 0.99 ± 0.02 . The D95%=90% breach point increases with ITV and PTV, and requires consistent motion variations of 0.5-1.0cm for small tumors (ITV=5-30cc) and ~2.0cm for large tumors (ITV=80-400cc). **Conclusion:** This study has demonstrated that large tumor motion variations deviating from simulation can reduce the ITV/PTV coverage substantially. Under clinical conditions, it seems necessary to apply patient breathing monitoring for threshold-based beam gating during treatment delivery.

PO-GePV-T-170

A Practical Workflow to Streamline Treatment Planning for Reirradiation with Considering Biological Doses

A Tai*, E Quashie, E Gore, J Bovi, X Li, Medical College of Wisconsin, Milwaukee, WI

Purpose: With recent substantial increase of radiation retreatments, solutions to include biological effects of the initial irradiation (II) in the re-irradiation (RI) are demanded. In this study, we develop a practical workflow to consistently consider biological dose distributions of the II in the treatment planning of reirradiation. **Methods:** The workflow was developed using MIM software, including its extensions, to (1) host patient retreatment plan data, tumor and organ-specific radiobiological model parameters extracted from pooled clinical data using common dose volume constraints with a linear-quadratic-linear (LQ-L)

model, and (2) perform biologically effective dose (BED) calculation, deformable image registration (DIR), dose summation and plan review. To plan a RI, the workflow includes (1) converting physical dose distributions to BED distributions using the selected model parameters for both II and RI, (2) creating the composite BED distribution by DIR of both planning images with considering tissue repair between the II and RI, (3) creating planning organ at risk volume (PRV) to consider the uncertainty in DIR, (4) converting the composite BED distribution into the physical dose distribution of the prescribed RI fractionation for plan evaluation, and (5) adjusting the RI plan if target coverage and doses to organs at risk are unacceptable and repeating the workflow until the composite plan achieves the prescription goal. **Results:** The workflow has been successfully used for 6 patients. It helps to adjust dose fractionation, in addition to beam and field arrangements, to achieve the prescription for the irradiation. Up to 18% dose difference was found between calculations with the current workflow and the conventional EQD2 method. **Conclusion:** The newly developed workflow has been successfully used in the clinic and will facilitate a prospective trial that is being designed to investigate efficacy of retreatment for multiple tumor sites.

PO-GePV-T-171

Daily Portal Exit Dosimetry Images as A Way to Monitor Interfractional Dosimetric Variation: A Feasibility Study

A Haertter*, E Hubley, S Yoon, T Li, W Gu, C Kennedy, Hospital of the University of Pennsylvania; Department of Radiation Oncology, Philadelphia, PA.

Purpose: Exit dosimetry images are automatically acquired on the Halcyon™ linear accelerator for all treatment beams and could potentially be used to monitor daily treatment. We investigate the correlation between image analysis metrics calculated within the Portal Dosimetry Scripting API (PDSAPI) (version 15.1) and dosimetric changes throughout treatment. **Methods:** Daily exit dosimetry images were compared to first-fraction exit images for 8 patients undergoing 16-fraction prone breast treatments. Dose-difference images, gamma analysis (2%/2mm and 3%/3mm, with 10% threshold) images, and gamma indices were calculated within the PDSAPI. For dose-difference images, a 10-70% pixel intensity region of interest (ROI) was selected and percent variations from the first-fraction pixel values were calculated; for daily 10-70% ROI images, an average dose-difference value was calculated. A 10-70% pixel threshold helped to focus on fluences traversed through breast tissue by eliminating out-of-field and out-of-breast dose. Dose-volume differences between the planned and daily delivered PTV parameters (dV90, dV95, dV100, dV103, dV105, and dV107) and Breast Evaluation PTV size were calculated on synthetic-CTs derived from daily-CBCT images. Pearson correlation coefficients with 0.05 significance levels were calculated between image analysis metrics and clinically-relevant DVH metrics. **Results:** No gamma analysis metric produced significant correlations with any dose-volume parameters. Daily average dose-differences within ROIs and differences between -1-3% and +1-3% pixel deviations from dose-difference image metrics provided strong correlations ($r \geq 0.8$) with deviation in DVH parameters (dV90, dV95, dV103, dV105, and dV107) normalized to planning values, as well as with breast volume changes. **Conclusion:** Dose-difference tests between first and subsequent daily fraction exit portal dosimetry images could serve as a quick metric to identify overdose/underdose developments and changes in breast tissue volumes. These metrics can be easily implemented into clinical workflow using PDSAPI scripting capabilities for automated monitoring and alert for manual evaluation when large deviations are detected.

PO-GePV-T-172

Initial Experience with Varian Portal Dosimetry Patient-Specific QA

J Wong¹*, S Wisnoskie¹, W Nie^{1,2}, Y Lei¹, A Besemer¹, (1) University of Nebraska Medical Center, Omaha, NE, (2) INOVA Schar Cancer Institute, Fairfax, VA

Purpose: This work details our initial experience transitioning from ArcCheck to Varian Portal Dosimetry (PD) as our primary method for intensity-modulated radiation therapy quality assurance (IMRT QA). **Methods:** A total of 347 IMRT plans (866 beams) were measured in the initial months using Varian PD across four TrueBeams. Gamma analysis results using a 10%, 5%, and 1% threshold, with a dose difference/distance to agreement (DD/DTA) criteria of 3%/3mm and 2%/2mm were recorded for both composite and individual fields as well as mean and max calibrated unit (CU) differences. Development of departmental IMRT QA policies included a detailed troubleshooting flow chart with goal- and acceptable-level passing rates. PD plans failing to meet the action limit tolerance of $\Gamma \geq 95\%$ or $\Gamma \geq 90-95\%$ with all individual fields passing $\Gamma \geq 95\%$ at 3%/3mm (IMRT) or 2%/2mm (SBRT/SRS) would be deemed acceptable if ArcCheck passed $\Gamma \geq 90\%$ with 3%/3mm. **Results:** The number of plans with a gamma passing rate $\Gamma \geq 90\%$ and $\Gamma \geq 95\%$ was 97.1% and 91.6% using 3%/3mm and 80.1% and 66.0% using 2%/2mm (10% threshold). Min, mean(stdev), and max average CU differences were 0.5%, 2%(1.3%), and 6.9%, respectively. For PD plans with $\Gamma < 95\%$ at 2%/2mm, the mean DD/DTA needed for $\Gamma \geq 95\%$ was 2.8%/2.8mm. Out of the 17 plans that failed to meet the PD action limit and were measured on the ArcCheck, 2 failed on the ArcCheck and required re-planning. Qualitatively, some of the observed benefits of PD IMRT QA include a notably reduced physics time burden, ability to perform composite and field-by-field analysis, and ability to overlay MLC motions on gamma map. Common workflow challenges encountered include increased imaging panel calibration drift for new linacs, large fields not fitting on the EPID without a collimator rotation, and incorrect panel distances selected. **Conclusion:** Varian PD has been an effective, practical, and reliable means of IMRT QA.

Long-Term Monitoring of aSi-1200 EPID Performance

I Kutuzov*, B McCurdy, CancerCare Manitoba, Winnipeg, MBCA

Purpose: Electronic portal imaging devices have established their usefulness as two-dimensional dosimetry systems in radiotherapy. However, their performance monitoring as a routinely used clinical dosimeter has not been thoroughly examined in literature. The purpose of this research is to monitor stability and reproducibility of the dosimetric response of the EPID over an extended time frame. **Methods:** Weekly measurements of the entire two-dimensional aSi1200 EPID (Varian Medical Systems) dose response against an ion chamber positioned on central axis and an ion chamber array (MatriXX, IBA Dosimetry) were carried out. Weekly measurements of calibration fields (flood and dark) and defective pixel counts were run in parallel. The measurements were performed on two clinically used Varian TrueBeam linear accelerators. Both imaging modes (continuous and integrated), and all available beam energies (6X, 6FFF, 10X, 10FFF and 23X) were tested. Measurements took place over 18 months between September 2019 and February 2021, except when temporarily suspended from March - May 2020 due to the initial shutdown caused by the covid-19 pandemic. **Results:** The entire EPID response to the large open 'flood' field and its ratios to the ion chamber reading and the ion chamber array demonstrated good constancy with 80% of all ratios falling within 1% from their mean values over the period of observation, and 100% of measurements within 2%. Measured dark and flood fields demonstrated good constancy with the individual pixel signal variations below 2.0% over the entire 18 months period for both imaging modes and all energies tested. The defective pixel count increased by 4% and 8% depending on the acquisition mode. **Conclusion:** The long-term dosimetric behavior of the aSi1200 EPID was monitored and shown to be stable and reproducible for routine clinical dosimetry.

Source of funding: Varian Medical Systems research grant "Investigation of aSi1200 Electronic Portal Imaging Device (EPID) for absolute, water-equivalent dosimetry applications, and monitoring of system performance".

PO-GePV-T-174

Machine Learning Based Prediction for Patient-Specific Quality Assurance: Understand the Plan Complexity for VMAT

X Zhang*, Y Zhang, B Liu, N Yue, K Nie, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ

Purpose: To evaluate complexity metrics of volumetric modulated arc therapy (VMAT) plans and predict the portal dosimetry based patient-specific quality assurance (QA) results with machine learning. **Methods:** A hundred thirty consecutive VMAT plans treated for various treatment sites from Sep 2020-Feb 2021 were included in the study. Each beam was delivered on TrueBeam Linacs with portal dosimetry and the results were analyzed using 2%/2mm global dose/distance-to-agreement (DTA) gamma passing rate (GPR). Total of 313 beams, including 60 beams exceeding the GRP tolerance, were used to build the machine learning model. Forty-six features of both the plan complexity and machine performance were collected for model building. Random forest algorithm was applied in the feature selection process. With selected features, conventional logistic regression and machine-learning based method, were used to create the classification model that can predict potential failure. In addition, five-fold cross-validation was employed to evaluate the model performance. **Results:** The area under the curve (AUC) and sensitivities of the machine-learning based model and logistic regression model were 0.88 and 85%, 0.76 and 78%, respectively. MLC modulation complexity, plan irregularity and jaw tracking are the most important features to predict the potential QA failure. **Conclusion:** Portal dosimetry based QA failure might be potentially predicted by machine-learning based model for VMAT plans. This information may be integrated into the plan optimization to generate more robust plan prior to the physical QA check.

PO-GePV-T-175

Quantitative Comparison of 2D and 3D Modes of a Commercial EPID-Based Hybrid Patient-Specific QA System for Spine SBRT Treatments

S Ahmed*, J Zavala Bojorquez, P Qi, S Chao, E Murphy, J Suh, P Xia, The Cleveland Clinic Foundation, Cleveland, OH

Purpose: To evaluate different dose verification modes of an EPID-based hybrid dose verification system for SBRT treatments of cervical, thoracic and lumbar spine regions. **Methods:** An EPID-based hybrid system (PERFRACTION) was commissioned at our institution with 2D (Fraction-Zero Absolute Dose, FZAD) and two different 3D dosimetry modes using EPID or log-files. The EPID 3D mode extracts the MLC positions from the measured EPID images while the log-file mode extracts MLC positions from the log-files. Both 3D dosimetry modes reconstruct volumetric dose on the patient specific CT images while FZAD mode generate a 2D dose map in the water-equivalent phantom comparing with measured EPID images. Twenty nine spine SBRT plans with the prescription dose of 18 Gy in one fraction were delivered on EPID panel in both dosimetry and cine modes on a Varian Edge machine. The treatment plans, measured EPID images and log-files were transferred to PERFRACTION system for calculations and 2D/3D global gamma analysis at 2%/2mm, 3%/2mm and 3%/3mm levels with 10% low dose threshold. The relative point dose differences (% Δ D) were compared against the TPS calculated dose at the high dose low gradient regions. **Results:** The gamma passing rates from all modes were in a good agreement with the predicted dose. The average passing rates at 2%/2mm were 96.3% $\pm$ 2.1%, 96.9 $\pm$ 4.0% and 98.7 $\pm$ 1.1% for FZAD, EPID and log-file modes respectively. For 3%/2mm and 3%/3mm, the average passing rates were observed >98% for all modes. The average % Δ D for all modes were <0.4%. **Conclusion:** EPID-based dose verification provides a high resolution for SBRT QA. Gamma passing rates from all three modes were comparable while 2D-FZAD and 3D-EPID modes were more sensitive than the log-file based mode at a stricter gamma metric.

PO-GePV-T-176

Comparison of Pixel Sensitivity Map Methods for EPID Dosimetry Measurement

M Ahmed¹, N Dang^{2*}, V Leandro Alves², J Siebers², (1) Vanderbilt University Medical Center, Nashville, TN, (2) University of Virginia Health System, Charlottesville, VA

Purpose: To intercompare EPID imagers PSMs created with a vendor-developed shift-based calibration method with a method that does not require shifting the imager. **Methods:** The pixel sensitivity map (PSM) is used to convert the raw EPID signal output to a relative dosimetry response through correcting for pixel-specific response variations. In this study, we compared two different PSM calculation methods. The first method calculates the PSM via different image sets of large-overlapping-field irradiations acquired with the EPID. The second one is estimates the underlying fluence by fitting EPID images with 2D polynomials and then extracting PSM by division with raw images. Two EPID imaging systems aS1000 and aS1200 were utilized for this comparison. Raw signals from different field sizes of 2x2, 5x5, 10x10, and 15x15 cm² and flood field at source to detector distance (SDD) of 150 and 180 cm were taken. The inline and crossline profiles of calculated PSMs were compared and a 2D relative difference map was calculated to estimate the discrepancy between the two methods. **Results:** Both methods show good agreement in the center of the imager (relative difference up to 4%), however, discrepancies become more visible at the border with a maximum of 8%. Central crossline profiles of corrected images show good agreement, while central inline profiles show major deviations. **Conclusion:** The proposed PSM calculation method can be used in replacement for the current shifting method within some degree of agreement.

This work is supported by Varian Medical Systems. We would like to thank Varian engineers who helped finalizing the analysis of this work.

A New Generation of X-Ray Irradiator for Preclinical Research: Dosimetric Characterization

M Rezaee*, J Wong, Johns Hopkins University, School of Medicine, Department of Radiation Oncology and Molecular Radiation Sciences, Baltimore, MD

Purpose: Recent trend of preclinical research on highly conformal radiotherapy, motion management, and FLASH irradiation compels the need for a new generation of advanced preclinical irradiation system. Here, we study the feasibility of a novel x-ray irradiation cabinet system employing medical imaging x-ray sources with rotating anode technology, as an enabling technology to enhance preclinical research capabilities. **Methods:** The proposed system employs two commercially available high-capacity 150kVp fluoroscopy x-ray sources with rotating anode technology. The tubes have independent gantry rotational and radial motions. Simulation was performed for parallel-opposed and angled beam arrangements with Geant4 (v.10.04) Monte-Carlo platform. Simulated dosimetric properties were characterized for output, uniformity and field size as a function of SSD, beam current, exposure time, and filters. Additionally, dose, dose-rate, and cross-plane profiles were measured from a single kV x-ray fluoroscopy source using radiochromic films to validate the Monte-Carlo models. **Results:** The irradiator can deliver FLASH and conventional dose-rate irradiations with the fields of 25-200 mm in length. Doses over 50 Gy can be delivered to a 20-mm thick water equivalent medium at FLASH dose-rates of 40-240 Gy/s in a parallel-opposed arrangement at SSDs <50mm. A uniform depth dose-rate within $\pm$ 5% deviation is achieved over 8-12 mm in phantom central region. At extended SSD, conventional dose-rates (< 0.1Gy/s) can be achieved with the depth-dose uniformity improved to a 27-mm thickness in a 40-mm thick water phantom. Beam angling reduces high surface doses up to 39% and provides a first order capability of conformal irradiation for the parallel-opposed beam arrangement. **Conclusion:** It is feasible to irradiate small animals and cell cultures with a wide range of doses and dose-rates, including FLASH and conventional irradiation with kV x-rays from rotating anode x-ray sources in the parallel-opposed and angled beam arrangements. The system will greatly enhance basic and translational researches in the laboratory setting.

PO-GePV-T-178

An Improved Statistical Model for Gamma Index Pass Rates in Intensity Modulated Radiation Therapy Patient-Specific Quality Assurance

P. James Jensen*, William Donahue, Zhe Chen, Yale University School of Medicine, New Haven, CT

Purpose: The beta distribution was recently proposed as an appropriate statistical distribution for modelling gamma index passing rates (GIPRs) computed during patient-specific quality assurance (PSQA). As such, it has been used to infer control limits, which improve the robustness of PSQA by defining thresholds beyond which abnormal GIPRs are automatically identified. This study presents a more appropriate statistical distribution for GIPRs which produces control limits with better theoretical justification. **Methods:** Our presented distribution is a modified beta distribution, derived from the beta distribution with an

additional nonzero probability at 100% GIPR. To represent this probability, the distribution includes a separate parameter equal to the fraction of fitting data points at 100% GIPR. This parameter accounts for the cluster of plans that fall well within the gamma index's pass thresholds and achieve exactly 100% GIPR. The beta distribution assumes that these plans are infinitesimally unlikely to exist and models them incorrectly. The data points between 0% and 100% GIPR are then used to fit a separate beta distribution. The modified beta distribution was compared to the beta distribution according to the control limits produced by each distribution. These control limits were generated assuming a false positive rate of 1/370 from two years of individual plan field GIPR data from PSQA of volumetric modulated arc therapy. **Results:** The control limits derived from the patient GIPR data were 92.8% and 93.6% for the beta distribution and modified beta distribution, respectively. This difference is comparable to the differences between outliers in the data and it can impact abnormal plan detection. **Conclusion:** The modified beta distribution produces control limits which are meaningfully different from the control limits produced by the original beta distribution. Given its stronger theoretical justification, the modified beta distribution should be used over the beta distribution to improve the robustness of PSQA.

PO-GePV-T-179

EBT3 Film Calibration Using Deep Learning with Keras Functional API

L Chang*, I-Shou University, Kaohsiung, KHQTW

Purpose: Ashland Inc. EBT3 film is a widely used dosimetry quality assurance tool. The film usually is recalibrated each quarter due to the 'aging effect', and calibration uncertainties always exist between individual films even in the same lot. Instead of performing recalibration, a new method is proposed using an adaptive power function with a deep neural network (DNN) model. **Methods:** EBT3 film was calibrated several times at different dates. Following "one red-channel after three-channel method", the dose-dependent optical density (OD) of the red channel is fitted to the delivered dose using a power function with a constant fitting parameter. Instead of recalibrations, film-dose can be calculated using all the fitting parameters of the first calibration and the fresh measured background OD. A bias τ is added to the input OD to improve the fitting results and is trained using a designed DNN through the Keras functional Application Program Interface (API). The given dose is compared with the film-doses calculated using the presented DNN API method, using all new recalibrated fitting parameters, using all first fitting parameters, and using the adaptive method without τ . **Results:** The results demonstrate that the difference between the film-dose with the delivered dose using the adaptive DNN API method is within 3.5%. Without using τ , the differences may reach 7% for a delivered dose lower than 50 cGy. If using the fitting parameters of first calibration, the difference is even greater than 50% around a given 50 cGy. **Conclusion:** With the DNN model, the film-dose can be calculated using the first calibrated form and using the new measured background OD to adapt the constant fitting parameter rather than recalibrating the film. To precisely calculate the film-dose, this method can be adapted especially for each individual film.

Longitudinal Shift Limitation for Long-Field Delta4 Measurements

L Che Fru*, S Frigo, University of Wisconsin-Madison, Madison, WI

Purpose: This work aims to determine the limits to longitudinal shifts in measuring patient IMRT QA plans using the Delta4+ device. This is applicable to extended field measurements on radiotherapy plans longer than 40 cm, such as for total body irradiation plans on a Tomotherapy treatment delivery system. **Methods:** An IMRT plan was created on an anonymized CT scan of a patient, where a uniform dose distribution was optimized in a target, 60 cm long. This was to ensure that the dose distribution was longer than the length of the phantom. An IMRT QA plan was created for with a Delta4+ phantom within the RayStation treatment planning system. Three separate measurements were then performed with the phantom centered at three different locations with respect to the plan, shifted -8.0 cm, 0.0 cm and +8.0 cm. A comparison of dose accumulation in a horizontal line of the plan was performed to determine the effect of the amount of phantom material near the measurements. **Results:** Figure 1 shows the setup to measure a line profile with different shifts of the Delta4+ phantom. It was determined that the center line profile of the dose distribution measured with the phantom centered is equivalent to the measurement performed when the phantom was shifted 8 cm superiorly. However, the measurement for the same line was less when the phantom was shifted 8 cm inferiorly. This shows that the amount of phantom material preceding a line in the dose distribution affects the accumulated measured dose. **Conclusion:** Delta4+ phantom position affects dosimetry in the IMRT QA process in plans whose dose distribution is longer than the Delta4+ phantom, limiting the amount one may shift the phantom. There is an amount of needed phantom material, above which measurements remain equivalent. Additional measurements are needed to establish this amount.

PO-GePV-T-181

Initial Experience in Comparing IQM and SRS MapCHECK for Single ISO Multiple Mets Brain SRS/SRT Plan Quality Assurance

Y Liang*, D Pavord, H Lee, Z Horne, R Wegner, S Karlovits, J Sohn, Allegheny Health Network, Pittsburgh, PA

Purpose: To compare two commercial systems, Sun Nuclear SRS MapCHECK and iRT Systems Integral Quality Monitor(IQM), on quality assurance(QA) of single isocenter(ISO) multiple metastases(Mets) stereotactic radiosurgery(SRS) and stereotactic radiation therapy(SRT) plans. **Methods:** Single ISO multiple Mets SRS/SRT plans with multiple arcs were created in Brainlab Multiple Mets Elements(MME). The SRS MapCHECK is a 2D diode array of 77mmx77mm. It was designed to be inserted into StereoPHAN secured on a designated base mounted on a Linac couch. The SRS MapCHECK/StereoPHAN system was CT scanned and imported into Brainlab MME as a patient-specific QA phantom. Gamma pass rates per Met was analyzed. IQM is a single large-area 550cc ionization chamber mounted onto the Linac head. It has a sensitive area of 40cmx40cm projected at the isocenter, which only needs one plan delivery regardless of Mets number. With IQM, the measured signal per segment and cumulative signal per arc are compared to the calculated. **Results:** The patient-specific QA on three clinical plans totaling 13 Mets and 24 arcs were performed with both systems and all passed QA. With the SRS MapCHECK, the Gamma passing rates @3%/1mm criteria per Met were 90%- 100% (mean 96.9%±3.4%). With IQM, the difference between calculated and measured signal per Arc was mostly within 3%, except for the smallest segments, in which the deviations increased up to 4-7%, but well within the acceptable tolerance. The time to complete the measurements was on average 120 minutes for SRS MapCHECK and 15 minutes for IQM. The difference in time was due to the fact that with a limited measurement size, the SRS MapCHECK had to be irradiated multiple times to cover all of the Mets. **Conclusion:** There was good agreement between the QA results on both systems. The QA time was dramatically decreased with IQM by approximately a factor of 10.

PO-GePV-T-182

Clinical Implementation of Varian TrueBeam Portal Dosimetry: Comparison to Sun Nuclear MapCHECK2 for Patient-Specific Quality Assurance

S Roles*, B Broekhoven, W Godwin, A Rapchak, C Mart, D McDonald, G Owen, M Maynard, J Peng, K Fallon, Medical University of South Carolina, Charleston, SC

Purpose: Current patient-specific quality assurance (QA) methodologies adopted by the medical physics community are well established, but lack in guidance on the utilization of portal dosimetry (PD), as it continues to grow in popularity. The focus of this study was to clinically implement PD, compare the patient-specific QA analysis features to those employed by SunNuclear (SNC) MapCHECK2, and design a more robust QA program which utilizes PD to improve the efficiency of faculty resources and accuracy of complex dose distribution analyses. **Methods:** Implementation of Varian Portal Dosimetry requires 4 sets of

data: (I) diagonal profiles at dmax for largest field size; (II) Varian 5 bar fluence pattern; (III) dose normalization of the flat panel detector (FPD); (IV) measured output factors of the FPD. These data characterize the dosimetric effects of the MLC and configure the dose deposition kernel used to compute the fluence deposited on the FPD. Patient-specific QA was measured and analyzed using both PD and MapCHECK2 methods. The treatment fields assessed were comprised of clinically relevant sites associated with each beam energy (6MV, 10MV, and 16MV). SNC Patient software was used for gamma analysis of the MapCHECK2 measurements and ARIA Portal Dosimetry was used for gamma analysis of the PD measurements. **Results:** The average pass-rates across the treatment fields using a dose difference (DD) of 3% and distance-to-agreement (DTA) of 3mm was 95.2% and 97.7% for PD and MapCHECK2 respectively. For a DD of 2% and DTA of 2mm, the rates were 90.7% and 95.2%. All fields which did not pass using PD gamma analysis, passed when using SNC gamma analysis. **Conclusion:** Portal dosimetry shows promise as an improved method of patient-specific QA as it requires less faculty resources, contains increased sensitivity within its employment of gamma analysis, and has an intrinsic improvement in measurement spatial resolution.

PO-GePV-T-183

Extraction of a Large Dataset Populating the Gamma Criteria Parameter Space for EPID-Based Patient-Specific QA

P Brown*, S Tanny, D Rosenzweig, University of Rochester, Rochester, NY

Purpose: To develop a large dataset that explores the parameter space of gamma criterion using our institutional patient-specific quality assurance (PS-QA) data from the past five years of using EPID-based QA. This dataset is to be used to train and test a machine learning model that will be used to identify plans that may require additional quality review. **Methods:** A Portal Dosimetry Application Programming Interface (PDAPI, Varian Medical Systems, Palo Alto, CA, USA) application has been developed to process and extract PS-QA results applying various gamma evaluation criteria. All 27 combinations of gamma criteria involving dose differences of 1, 2, and 3%, distance-to-agreement of 1, 2, and 3 mm, and evaluation thresholds of 10, 20, and 50% of dose maximum were applied to EPID-QA images acquired at our institution since 2015. We collected average, maximum, percentage of points with gamma >1, and >1.2 gamma values for all image-criteria combinations. Average and variance value for each QA session were also calculated for comparison with values presented in the literature. **Results:** Our dataset consists of 94000 analyses with >3300 images involving >700 patients. Average percentage of points with gamma >1 for 3%/3mm/10% threshold was 3.8%, which agrees with published results of 4.1% in smaller series from other institutions. The higher the threshold for allowable points, the worse the gamma results were for all evaluations. Trending was performed demonstrating an improvement in gamma results over time from 202/735 images to 100/581 images with area of gamma >1 <90% using TG-218 criteria of 3%/2mm/20% Threshold. **Conclusion:** We have automated a gamma analysis data extraction tool and will continue to build our dataset to use in future studies evaluating contributing factors for poor gamma passing rates using EPID-based QA. Our current dataset is amongst the largest extracted datasets of patient specific QA results in literature.

PO-GePV-T-184

Development of a User-Friendly Correction Method for the Lateral Response Artifact From Flatbed Scanners in Radiochromic Film Dosimetry

G Guyer*, R Kueng, A Joosten, M K Fix, P Manser, S Mueller, Division of Medical Radiation Physics and Department of Radiation Oncology, Inselspital, Bern University Hospital and University Of Bern, Bern, CH

Purpose: In radiochromic film dosimetry, it is common practice to scan films with a flatbed scanner. A known issue affecting the accuracy is the lateral response artifact (LRA). The aim of this work is to correct the LRA with a user-friendly graphical user interface (GUI). **Methods:** This work is based on a LRA correction using a one-dimensional linear correction function. This approach was enhanced by increasing the resolution of correction function. For this purpose, two sheets of film, one blank and one irradiated uniformly with 2 Gy, were used, which enables correcting films by means of a user-friendly GUI. The films were scanned in the center of the scanner and subsequently shifted laterally in both directions. After averaging the resulting values longitudinally, the correction functions were obtained. For validation, dose measurements with films inside a solid water phantom of two VMAT plans with a prescribed dose of 1 Gy and 2 Gy were performed. The irradiated films were scanned once in the center of the scanner and shifted 5 cm and 10 cm laterally in both directions. Then, the enhanced LRA correction was applied. The corrected and uncorrected dose values were evaluated in FilmQA Pro™ (Ashland) using a gamma evaluation (3% global/ 2 mm, 20% dose threshold). **Results:** The gamma passing rate for the uncorrected films was above 99% for the red color channel in the center of the scanner but decreased to values between 70% and 91% and between 22% and 44% when scanned 5 cm and 10 cm away from the center, respectively. For the corrected films, the passing rates improved for all situations with the lowest passing rate being 97%. **Conclusion:** An enhanced correction method for LRA with a GUI was developed, validated for VMAT plans and lead to substantially reduced LRA compared to uncorrected films.

This work was funded by the Swiss National Science Foundation

PO-GePV-T-185

Stereotactic Patient QA Evaluation Between MapCheck SRS 2D Array, Electronic Portal Image Dose (EPID) and EBT3 Gafchromic Film Dosimetry

P Tsiamas*, W Cruz, W Fontenot, J Limmer, Texas Oncology, Houston, TX

Purpose: Comparing Stereotactic plans patient QA between Sun Nuclear's SRS Mapcheck (SRSMC), Varian's Electronic Portal Dosimetry (EPID) suite and Gafchromic film (EBT-3). **Methods:** For this evaluation the three different QA process mentioned above (EPID, SRSMC, EBT-3 films) were used. Two different EPID resolutions were used, an aSi-500 and an aSi-1000. Patients were selected based on their lesion size and site in order to review a spectrum of sites and sizes. Lesion sizes were specifically chosen to test the robustness of the QA processes. All plans included in the study were re-planned (Eclipse v15.6) as multiple field IMRT fields in order to have a direct comparison between the different QA methods. Plans were delivered on two different Varian-iX machines, each one having a different Eclipse model with a different CT curve. Data normalization was performed based on the Eclipse models and CT curves in order to exclude variations related with these factors. QA passing rates were set to 95% (2% - 2mm). Total number of calculation points, passing and failing points were recorded and evaluated for each one of the techniques used. **Results:** Time of setup, ease of use, accuracy, resolution, dependability, and dependencies were examined when comparing the 4 (SRSMC, EBT-3, aSi1000, aSi500) different QA devices. EPID aSi-1000 had the highest resolution while the lowest was for SRSMC. Gamma analysis showed that for 93.8% of the cases SRSMC had higher passing rates than EPID results, though the gamma passing rate standard deviation among the different measurements did not exceed 2% (average difference was 0.87%). Comparison between aSi-500 and aSi-1000 showed that passing rates for aSi-1000 was higher for 84.4% of the cases. **Conclusion:** Comparison between the different patient QA processes showed that aSi1000 will be an appropriate system for SRS QA.

PO-GePV-T-186

CNN-Based Classification of IMRT Errors from Sparsely Sampled Measurements

L J Maloney*, G Yan, N Potter, K Mund, University of Florida, Gainesville, FL

Purpose: Error detection and classification in intensity-modulated radiation therapy (IMRT) is a difficult problem exacerbated by the lack of sufficiently resolving measurement equipment. The commonly used Sun Nuclear MapCheck is a diode-based measurement device which could fulfill the purpose of measuring IMRT fields for error classification. However, its low resolution (7mm detector pitch) prevents the creation of a continuous distance-to-agreement (DTA) map from the measurement and the corresponding calculated fluence distribution, and the data sparsity hinders detection of small deviations from

expected field fluence. In this work, a convolutional neural network (CNN)-based method for error detection and classification is presented. **Methods:** Diode array measurements are simulated by retrospective undersampling of perturbed fluence maps, which are used as input training data for the CNN with the original calculated maps. Dropout is employed in the network architecture prior to classification to improve validation accuracy. The proposed CNN is evaluated on its ability to classify eight separate types of spatial error, including systematic leaf shift, source size, and single-leaf under- and over-travel. **Results:** While the precision and recall are poor for distinguishing source size errors from statistical noise, the network achieves better than 85% accuracy with an F1 score of 0.855, Matthews correlation coefficient of 0.827, Cohen kappa of 0.826. The highest recall and precision for individual features are 98.3% and 95.3% for systematic X bank shift and systematic Y shift, respectively. **Conclusion:** Diode array devices present singular utility in initial characterization of errors in IMRT. Though the sampling space is sparse, careful choice of interpolation modality provides a suitable training set for an NN – the modified Akima (makima) method was used in this work as it avoids large undulations which are not expected in the interior of most IMRT fields. Further refinement of learning parameters may increase training speed and performance.

PO-GePV-T-187

Validation of Rapid Arc Gating Technique for Lung and Liver Stereotactic Body Radiation Therapy (SBRT) with In-House 4D-Phantom

C Bhatt^{1*}, A Kumar², R Dobhal³, (1) Sarvoday Hospital and Research Center, Faridabad, HARYANA, IN, (2) Radiation Physicist Dept. Of Radiation Oncology Aiiims Rishikesh Uttarakhand, (3) Department of Radiation Oncology, S R Himalayan University, Dehradun, UK In

Purpose: In recent years, volumetric arc therapy combined with 4DCT for moving target, became more popular. It can be either performed by gating or tracking the tumour. The purpose of this dosimetric study to validate the rapid arc gating technique for lung and liver stereotactic body radiation therapy (SBRT) with an in-house made 4D wax phantom. **Methods:** 4DCT scan of the phantom with CC13 ion chamber inserted into the groove given, acquired using real-time position management system (RPM) (Varian Medical System, Palo Alto, CA) for respiratory motion monitoring. Appropriate phases were selected for delineation purpose, and the plan created in eclipse V13.5. The respiratory pattern of phantom recorded at the time of the 4DCT scan serves as a reference pattern during dose delivery. We took a gated cone-beam computed tomography (CBCT) scan for the setup verification before dose delivery. Quality assurance performed on in-house made 4D wax phantom having CC13 ion chamber inserted. Dosimetric validation of rapid arc gating technique has been performed for gated rapid arc plans created with 6MV, 6MV-FFF, 10MV, 10MV-FFF energies. **Results:** Dosimetric evaluation for gated rapid arc plans created with 6MV, 6MV-FFF, 10MV, 10MV-FFF energies showed $\leq 3\%$ variation for all the cases. Plans created for 6MV showed 0.50% and 1.00% variation, plans created for 6MV-FFF, 10MV, 10MV-FFF energies respectively showed the variation of 1.59%, 2.60%, 3.00%, additionally we have created conformal arc plan which showed variation within tolerance limit between the treatment planning system (TPS) dose and measured dose with ion chamber. **Conclusion:** This dosimetric study showed that the Point dose validation of a rapid arc gating technique carried out successfully using indigenous 4D wax phantom is well within tolerance limits compared to TPS calculated dose. So, Gated RapidArc can clinically be used to treat SBRT lung and liver.

A Convolutional neural Network Model for Predicting Gamma Passing Rate of 3D Array Detector-Based VMAT QA

T Matsuura^{1,2*}, D Kawahara², A Saito³, E Shiba⁴, K Yamada¹, S Ozawa^{1,2}, Y Nagata^{1,2}, (1) Hiroshima High-Precision Radiotherapy Cancer Center, Hiroshima, Japan, (2) Hiroshima University, Hiroshima, Japan, (3) Hiroshima University Hospital, Hiroshima, Japan, (4) Department of Radiation Oncology, Hospital of the University of Occupational and Environmental Health, Fukuoka, Japan

Purpose: The predicting models of gamma passing rate (GPR) via artificial intelligence have been proposed for improving the efficiency of the patient-specific quality assurance (QA) workloads. The current study aims to develop a convolution neural network (CNN) model for predicting GPR, and to propose a novel omitted workflow of prediction-based VMAT QA. **Methods:** Two hundred and twenty-five VMAT plans measured GPR by ArcCHECK were used in this study. The dose and DUP distribution on the detector element plane were used as input data for the predicting model. The DUP distribution was generated by accumulated field edges weighted by a segmental monitor unit. Our CNN model comprised nineteen layers and was trained for 200 epochs. 10-fold cross-validation was applied to verify the predicting performance. The GPR values were predicted for thirty-five test cases, and the difference between the measured and predicted GPR values was evaluated. The omission rate of the measurement was calculated for cases with GPR 2SD of prediction error higher or lower from 90% set as the action limit at 3%/3-mm and 3%/2-mm tolerances. **Results:** Mean absolute error (MAE) between measured GPR and predicted GPR in the CNN model using the dose distribution was 2.0% for 3%/3-mm, 3.1% for 3%/2-mm, and 6.6% for 2%/2-mm tolerances. By adding the DUP distribution to the CNN model, the MAE was improved to 1.8%, 3.0%, 6.0% for 3%/3-mm, 3%/2-mm, and 2%/2-mm tolerances, respectively. The effort of the measurements for patient-specific QA could reduce by 83% and 23% for 3%/3-mm and 3%/2-mm tolerances, respectively. **Conclusion:** The CNN model with the dose and DUP distributions on the detector enabled the prediction of GPR value with high accuracy. The proposed workflow with the CNN model could potentially help to omit the patient-specific QA workloads.

PO-GePV-T-189

Machine- and Site-Specific Analyses of TomoTherapy Patient-Specific QA Results Planned with Accuray Planning Station and RaySearch RayStation

P Hill^{*} and RA Bayliss, University of Wisconsin, Madison, WI

Purpose: To analyze treatment planning system calculation accuracy relative to patient-specific quality assurance (PSQA) measurements among two TomoTherapy treatment delivery systems and two treatment planning systems and evaluate any dependencies observed based on machine, planning system, or treatment site. **Methods:** Data were extracted from PSQA reports created from Delta4+ measurements on two TomoTherapy HDA units over more than two years, during which time treatment planning was transitioned from Accuray Planning Station (PS) to RaySearch RayStation (RS). Data points included the treatment site, the median of the planned-to-measured dose deviations over all detectors, and the proportions of detectors passing gamma calculation with a range of dose and distance to agreement criteria. These data were analyzed based on sorting by treatment machine, originating treatment planning system, and by treatment site. **Results:** Median dose deviation histograms considering all treatment sites revealed Gaussian probability distributions with mean values of -0.5% for PS and -0.3% for RS on Machine A, and -0.2% for PS and +0.3% for RS on Machine B. Welch's t-tests demonstrated that all these distributions were unique, indicating that despite their independent calibrations all delivery and treatment planning system combinations produced good agreement between dose prediction and delivery. Gamma pass rates pooling all treatment sites were 98-100% for 3%/3mm evaluation criteria, dropping to approximately 91-96% for 3%/2mm and 60-66% for 2%/2mm. **Conclusion:** Median dose deviation and gamma analysis both suggest similar dose calculation and delivery performance for both the Accuray and RaySearch treatment planning systems on two independent delivery systems. Because no clear dependence was observed based on generalized treatment site, future work is focused on investigating correlations with other plan characteristics such as target volume, machine parameters, and plan complexity.

PO-GePV-T-190

Quasi-3D Dosimetry System with Solid Polyurethane-Based Dosimeter

J Cho^{1,2,3*}, S Jung¹, J Son¹, H Jin^{1,2}, C Choi¹, J Park¹, J Kim¹, (1) Seoul National University Hospital, Seoul, KR, (2) Biomedical Research Institute, Seoul National University Hospital, Seoul, KR, (3) Yonsei University College of Medicine, Seoul, KR

Purpose: To evaluate a quasi-3D dosimetry system using a solid polyurethane-based dosimeter when conducting patient-specific quality assurances (QAs) in radiation therapy. **Methods:** The patient-specific QA is the procedure to verify the coincidence between measurement and calculated dose distribution for intensity-modulated radiotherapy (IMRT) and volumetric modulated arc therapy (VMAT) plans by using gamma analysis. A VMAT plan for a pancreas patient was analyzed with a criterion of both 2%/2 mm and 3%/3 mm, a threshold value of 10%, and a tolerance level of 90%. For the plan, the 2D gamma analysis was fulfilled with a MapCHECK2, and the 3D gamma analysis was performed using in-house solid polyurethane-based dosimeters and a quasi-3D phantom. The phantom was produced by drilling 25 holes of 9.4 mm in diameter and 56 mm in depth at even intervals, and it was made to be used by inserting a solid polyurethane-based dosimeter of the same size as the hole. A total of 9 solid polyurethane-based dosimeters were positioned according to the dose distribution of the plan. The 3D gamma analysis was performed on a region of interest of 5.5 mm in diameter and 35 mm in depth using a free platform for biomedical research, (3D) Slicer. **Results:** For the 3D gamma analysis, the average passing rates with 2%/2 mm and 3%/3 mm criteria for relative dose distribution were $91.6\% \pm 1.4\%$ and $99.4\% \pm 0.7\%$, respectively. For the 2D gamma analysis showed passing rates of 97.5%, 99.3% with 2%/2 mm and 3%/3 mm criteria, respectively. **Conclusion:** The quasi-3D dosimetry system was evaluated by performing patient-specific QAs with the solid polyurethane-based dosimeters and quasi-3D phantom. As the 3D gamma index for all solid polyurethane-based dosimeters showed more than 90% for 2%/2 mm criteria, this result means there was a possibility that the quasi-3D dosimetry system was clinically acceptable.

PO-GePV-T-191

Utilization of a Plan Quality Prediction Software to Investigate Patient Specific QA Passing Rates

P Irmen*, C Stambaugh, C Melhus, Tufts Medical Center, Boston, MA

Purpose: To investigate the use of a Plan Quality Prediction Software in improving patient specific quality assurance (PSQA) passing rates. **Methods:** Five prostate patients, whose clinical boost plans were generated using Pinnacle³ v16.2.1 (Philips, Amsterdam, Netherlands) and had failed institutional PSQA tolerances (95% passing at 3%/2mm, global gamma criteria), were investigated. PlanIQ (Sun Nuclear Corp., Melbourne, FL) was utilized to retroactively investigate the difference between the clinical DVH for the Bladder, Rectum, and Penile Bulb and the feasibility DVH. These differences were compared with five patients whose clinical QA passed institutional criteria. Three re-plans were created in Pinnacle³ v16.4.2 for each failing plan: 1.) pushing the DVHs to represent the DVHs of the clinical plan, 2.) using PlanIQ to set planning objectives, and 3.) using PlanIQ but restricting the minimum segment area. PSQA was measured for each re-plan and the relationship between plan passing rates was analyzed. **Results:** Comparing the failing and passing clinical plans, no significance was found in the difference between the clinical DVH and feasibility DVH for the Bladder or Rectum. However, at a feasibility score of 0.1, the difference between the clinical DVH and feasibility DVH for the Penile Bulb was found to be significant ($p=0.032$) with the failing plans exhibiting an average DVH difference of -2.23 ± 0.88 Gy and the passing plans exhibiting an average DVH difference of -0.57 ± 0.44 Gy. After re-planning these cases in v16.4.2, improved PSQA passing rates for failing plans were found when using PlanIQ, with average improvement of $1.1 \pm 2.5\%$. Combining PlanIQ with a restricted minimum segment area showed further improvement in PSQA passing rates, with average improvement of $2.6 \pm 1.7\%$. **Conclusion:** PSQA passing rates are influenced by many factors, but PlanIQ was shown to be a useful tool in improving PSQA passing rates for failing plans especially when combined with restricted segment areas.

PO-GePV-T-192

Design of a Respiratory Motion Quality Assurance System with Portal Dosimetry and Customizable Tumor Phantom

H Tan*, L Tan, C Koh, K Ang, S Park, National Cancer Centre Singapore, Singapore

Purpose: To design a high throughput respiratory motion QA system using portal dosimetry (PD) and customizable tumor with 3D printing. **Methods:** The design is divided into the stage control and tumor printing part. A closed-loop stages was assembled and the tumor was mounted on a rod attached to the stage and driven in the Sup-inf direction. The stage can be programmed to move with variable amplitude, period or according to patient's breathing curve. 3D printing was used to build customizable tumor to provide realistic representation of the treated tumor. Different PLA fill patterns and percentages were optimized to obtain a HU of close to zeros and the shortest printing time. The set-up was tested with an actual treatment plan comparing the static and moving phantom. Spherical tumors with 2 cm and 4 cm diameter were used for this testing. Gamma passing rate was used to quantify the dose agreement between static and moving phantom. **Results:** A linear pattern with 80% in-fill yields the shortest printing time and gives a HU closest to 0. A maximum HU of about 100 is achievable with PLA material. A moving phantom does blurs out the portal dose and causes a disagreement between the dose distribution between the static and moving phantom. A smaller tumor gives a gamma passing rate of 97% while a larger tumor gives a smaller passing rate of 94% with a 2%/2mm criteria. **Conclusion:** Appreciable dose difference between moving and static phantom with 4 cm and 2 cm water equivalent tumor phantom can be detected with portal dosimetry. Further work is underway to test the system with phase gating and determine the sensitivity of detecting breathing curve discrepancy and dose degradation due to motion interplay.

Automatic Plan Quality Assurance Using Knowledge-Based DVH Prediction for Head and Neck Cancer Patients

W Cao^{1*}, M Gronberg², A Olanrewaju³, C Cardenas⁴, B Beadle⁵, L Court⁶, (1) University of Texas MD Anderson Cancer Center, Houston, TX, (2) University of Texas MD Anderson Cancer Center, Houston, TX, (3) University of Texas MD Anderson Cancer Center, Houston, TX, (4) University of Texas MD Anderson Cancer Center, Houston, TX, (5) Stanford University, Stanford, CA, (6) University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: To investigate the use of knowledge-based planning to identify poor quality VMAT plans for head and neck cancer (HNC) patients. **Methods:** We used a commercial knowledge-based planning system (RapidPlan, Varian Medical Systems) to create two dose-volume histogram (DVH) prediction models using data from 25 HNC patients. One was trained by clinical plans (manual plans: MP); the other used automatically created plans (AP). 7 normal tissues and 2 automatically-generated standardized planning structures were included. DVHs were then predicted for an evaluation cohort of 25 patients (EC1) and compared with achieved DVHs of MP and AP plans. Next we predicted DVHs for 25 other patients (EC2) on which we intentionally generated plans with suboptimal normal tissue sparing while satisfying dose-volume limits of standard practice. These plans were also reviewed by one radiation oncologist when blinded to DVH predictions. Oncologist reviews on plan quality were analyzed together with the predicted DVHs. **Results:** Predicted DVH ranges (upper – lower predictions) were consistently wider for the MP model than the AP model for all structures. The average range of mean dose predictions among all structures was 9.9 Gy (MP model) and 3.4 Gy (AP model) for EC1 patients. RapidPlan models identified 7 MP plans as outliers according to mean dose or D1% on one of normal tissues while none of AP plans was flagged. For EC2 patients, 22 suboptimal plans were identified by prediction. While re-generated AP plans validated that these plans could be improved and pass RapidPlan QA, 19 out of 45 structures with predicted poor sparing were also identified by oncologist review for additional planning due to inadequate sparing. **Conclusion:** Our study shows that RapidPlan could provide accurate DVH prediction for HNC cancer patients. Agreement between prediction and oncologist review also shows promising use of knowledge-based DVH prediction for detecting poor quality plans.

PO-GePV-T-194

Estimation of Dosimetric Leaf Gap Correction Factor as Part of Commissioning a Log File Based QA System

U. Sreekala^{1*}, N.S. Shine¹, P. Raghukumar², (1) Banasthali Vidyapith, Jaipur, Rajasthan, INDIA(2) Regional Cancer Centre (RCC), Thiruvananthapuram, Kerala, India

Purpose: During the commissioning of the Mobius3D (M3D) QA software for TrueBeam (Varian Medical Systems Inc. Palo Alto, CA), an independent, log file-based QA system, it was observed that for more complex plans (IMRT/RapidArc) while performing dose comparison, the target volumes consistently came out as hot. This problem demanded a need for the determination of a Correction Factor (CF) for Dosimetric Leaf Gap (DLG). Even though DLG is a dosimetric parameter hardcoded in the M3D system to account for partial transmission through the rounded leaf ends on the MLC, provisions are incorporated within the software for its optimization by applying additional corrections. A Linear regression method recommended by the vendor was followed to overcome this scenario. This paper explains the steps performed to accomplish this task as part of M3D commissioning. **Methods:** The process for determining the DLG CF involved a spreadsheet for the calculation and a verification phantom (VP) provided by the vendor, subtracting MLC transmission contribution from ionization chamber measurements of multiple sweeping gap plans, plotting the resulting differences against the nominal gaps, and using linear regression to finding the optimal DLG CF. MFX, the value from the VP, is compared with the measured values to find the percentage deviation. Seven different plans, IMRT/RapidArc for various sites, were used in this process. **Results:** Dosimetric Leaf Gap (DLG) Correction Factor (CF) was determined for the energy 6MV and used these values to configure the M3D system. After the correction, the plan comparison for complex plans showed better results. **Conclusion:** This method proved to be very easy and reliable, which could be used as an essential tool for fine-tuning the Dosimetric Leaf Gap (DLG) Correction Factor (CF) for M3D commissioning. This method's approach and principles can be applied to any independent QA verification system's commissioning.

PO-GePV-T-195

Sensitivity of OSLD with Fully Filled Deep Electron/hole Traps in Kilovoltage Energy Range

M Chun^{1*}, H Jin¹, S Lee¹, O Kwon², CH Choi¹, JM Park¹, J Kim¹, (1) Seoul National University Hospital, Seoul, KR, (2) University of Wisconsin, Madison, WI

Purpose: To evaluate the sensitivity of optically stimulated luminescence dosimeters (OSLDs) in kilovoltage energy range with fully filled deep electron/hole traps. **Methods:** The experimental group was consisted of 24 OSLDs which were pre-irradiated greater than 5 kGy with Co-60 gamma ray source for fully filling deep electron/hole traps (OSLD(Full)), while the non-pre-irradiated 24 OSLDs were arranged as a control group (OSLD(Empty)). The bleaching device was equipped with 520 nm long-pass filter attached to light-emitting diode source, and the signal was read out with linear mode. For OSLD(Full) group, bleaching-and-readout cycle was repeated until the remained signal reached around background level. According to the in-phantom method in AAPM TG-61 reference dosimetry protocol, absorbed doses to water at 2 cm for 75, 80, 85, 90, 95, 100, and 105 kVp were measured. Due to the over-response to low energy X-ray of OSLDs, three dosimeters were calibrated with respect to the energy. For each energy, an exposure with 200 mA and 40 ms was defined as unit dose. To find an optimal bleaching time, bleaching-and-readout after fifty times of unit dose exposures was repeated until the signal reached low stable level. To investigate the sensitivity, exposures-readout-bleaching-readout cycle was repeated. The normalized sensitivity was defined as the signal counts divided by initial value. **Results:** For both OSLD(Empty) and OSLD(Full) group, 3.5 days were found as optimal for bleaching time with filtered bleaching device. In case of no cumulated dose, the average normalized sensitivities were improved as 11.7%, 13.6%, 14.8%, 7.9%, 15.8%, 20.1%, and 16.7% for 75, 80, 85, 90, 95, 100, and 105 kVp, respectively. Variations with cumulated dose were less than 7.8% for both OSLD(Empty) and OSLD(Full) group regardless of bleaching condition. **Conclusion:** Filling deep electron/hole traps in OSLDs can possibly increase the sensitivity in the kilovoltage energy range.

This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MSIT) (2019R1F1A1041944).

PO-GePV-T-196

Measuring Superficial Total Doses Delivered by Helical Tomotherapy using EPR Dosimetry

S Hoefel^{1*}, M Fix², M Drescher³, F Zwicker⁴, (1) University of Konstanz, Konstanz, DE, (2) Inselsptial - University Hospital Bern, Bern, BE, CH, (3) University of Konstanz, Konstanz, DE(4) German Cancer Research Center (DKFZ), Heidelberg, DE

Purpose: This phantom study investigates the applicability of Electron Paramagnetic Resonance (EPR) dosimetry for measuring superficial total doses delivered by helical tomotherapy treatments. **Methods:** For this purpose, eight EPR dosimeters were attached to distinct spots next to the surface of an anthropomorphic head phantom: i) within a superficial simultaneously integrated boost (SIB) volume, ii) near to organs at risk including the parotids and the lenses, iii) at the thyroid lying out-of-field. Each dosimeter consisted of two pellets: one lithium formate monohydrate (LFM) pellet and one L-alanine (ALA) pellet. A helical tomotherapy plan representing a realistic head and neck treatment was applied daily over a period of about 6 weeks (32 fractions). Planned total doses to the dosimeters ranged from about 2 Gy (lenses, thyroid) to 64 Gy (SIB volume). EPR read out was performed by means of a previously proposed EPR dosimetry system after all fractions were applied. The results were compared to thermoluminescence dosimeter (TLD) measurements and to planned total doses derived from the treatment planning system (TPS). **Results:** By taking uncertainties into account, EPR measurements were in agreement with TLD and the TPS. Exceptions occurred at the thyroid (out-of-field) and lenses (extreme sparing). Remarkably, each LFM and ALA pellet placed inside the SIB volume provided dose values that were within plus/minus 3% of the respective planned dose. LFM and ALA provided comparable results. However, LFM is preferable at lower doses due to lower measuring uncertainties. **Conclusion:** This study suggests that EPR dosimetry is a valuable tool for measuring superficial total doses in-vivo being applicable in a wide dose range and in various irradiation conditions.

PO-GePV-T-197

Evaluating the Accuracy of Different Methods for Estimating the Dose to An IMD (implanted Medical Device) of a TBI Patient, Treated at An Extended Distance with External Blocks

L Russell^{1*}, J Sillanpaa, Memorial Sloan-Kettering Cancer Center, New York, NY

Purpose: We treat TBI patients at an extended distance (440 SAD), with Cerrobend blocks approx. 5 cm from the patient. A CT scan in the treatment planning position is not possible (the MUs are determined by a hand calculation), making estimating the dose to an IMD challenging. We compare the accuracy of different methods for estimating the dose to the IMD. **Methods:** We estimated the dose using three different **Methods:** Eclipse calculations using AAA and Acuros algorithms, and ion chamber and OSLD measurements in solid water. The results were analyzed and compared to OSLD measurements from treatment. Four-7.5 cm thick blocks of different sizes were fabricated. Patient separation (16 cm) and depth of the IMD from the anterior surface (2.5 cm) were estimated from a CT scan. A 16*25*25 cm solid water phantom using an A12 ion chamber was used to perform measurements at IMD depth. NanoDot OSLDs, under 0.5 cm bolus, were used for measurements on the surface. A virtual water phantom of 16*25*25 cm, with a block 5 cm above the phantom, was used for the calculations. Measurements and calculations were performed to estimate the dose to the IMD, under the center of the block, for a single fraction in a 6 MV AP/PA treatment. A patient was treated using one of the blocks, and OSLD measurements were performed on the patient's skin during the treatment. **Results:** The OSLD and ion chamber measurements in solid water agree well: ion chamber 34 cGy, OSLD 35 cGy, Acuros 38 cGy, AAA 65 cGy. They also agree with OSLD measurement during treatment (34 cGy). **Conclusion:** Ion chamber and OSLD measurements in solid water predicted the results of the patient

measurements well. Acuros was accurate enough to provide a rough estimate, while AAA overestimated the dose to IMD significantly.

PO-GePV-T-198

Dosimetric Evaluation of Prostate VMAT Plans Optimized by the Photon and Progressive Resolution Optimization Algorithm

J Chow^{1*}, R Jiang², K Mamari³, (1) Princess Margaret Cancer Centre, Toronto, ON, CA, (2) Grand River Hospital, Kitchener, ON, CA, (3) Ryerson University, Toronto, ON, CA

Purpose: This study evaluated the dosimetry of prostate VMAT plans optimized by the photon optimization (PO) algorithm, which is introduced to replace the progressive resolution optimization (PRO) algorithm in the Varian Eclipse treatment planning system. **Methods:** The dosimetric evaluation was carried out by studying ten prostate patients with VMAT plans created by the 6 MV photon beams and dual-arc technique using the Eclipse treatment planning system. The prescription of the dose was equal to 78 Gy/39 fractions. For each patient, two plans optimized by the PO and PRO algorithm, as per the same dose-volume criteria for the target and organs-at-risk, were created. Dose-volume histograms (DVHs) for the planning target volume and critical organs, namely, rectum, bladder, left and right femur, were determined. From the DVHs, dose-volume index such as conformity (CI) and homogeneity index (HI) were calculated, together with radiobiological variables such as tumour control probability (TCP) and normal tissue complication probability (NTCP). **Results:** Comparing the dosimetry of VMAT plans optimized by the PO and PRO algorithm, it is found that the average CI values of plans optimized by the PO algorithm (0.912) was slightly higher than that by the PRO (0.908). On the other hand, the average rectal NTCP of plans using the PO algorithm was higher than that using the PRO (0.054 vs. 0.052). For the average HI and TCP of the prostate, both algorithms produced the same values of 0.054 and 0.955 from their VMAT plans, respectively. **Conclusion:** It is concluded that prostate VMAT plan optimized by the PO algorithm had a slightly higher average CI and rectal NTCP value compared to the PRO, with other plan dosimetry remaining almost the same. Considering other advantages of the PO algorithm, namely, less multileaf collimator aperture complexity and faster optimization speed, the PO algorithm is a good successor for the PRO.

PO-GePV-T-199

ADiar: Architecture of Dose-Image Agent Retrieval—an Architecture to Automatically Retrieve Similar Radiotherapy Plans

Y Shao*, Y Shao, Z Xu, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai, CN

Purpose: The design of treatment planning in radiation therapy (RT) represents the key to dosimetrists' experiences. This paper proposes an automated architecture using dose image as the agent to retrieve a similar treatment plan from a database and employing the optimization parameters from the retrieved plan to initialize the searching plan. **Methods:** From May 2018 to June 2019, 612 IMRT treatment plans of lung cancer patients were retrospectively selected. Architecture of Dose-image Agent Retrieval system consists of two parts separated by a firewall: one is the in-hospital workstation, and the other is the search engine in cloud. After the architecture is developed we did two studies. The first retrospective study is conducted to validate the percentage of fully automated plans generated by this architecture is qualified for clinical practice. 96 patients were involved in this study. The second comparison study is performed to validate whether this architecture (α Diar) may improve the quality of plan designing. Two dosimetrists are involved and design only one trial with and without α Diar. 26 patients were involved in this study. **Results:** The first study shows that 54.17% (52/96) of plans are qualified according to our department guideline. The second study shows that with the help of α Diar, the quality of treatment planning is improved for junior dosimetrists. **Conclusion:** With the help of α Diar, novel treatment planning systems may be developed, and a large part of treatment plans could be designed automatically, and those automated plans not qualified for clinical practice may also help improve the quality for plan designing.

PO-GePV-T-200

Deep Learning Dose Distribution Prediction Models for Cervical Cancer Volumetric Modulated Arc Therapy

Q Zhang*, P Bao², B Dong², R Yang¹ (1)Peking University Third Hospital, Beijing, CN, (2)Peking University, Beijing, CN

Purpose: To develop and test 2D and 3D-Unet dose prediction models to predict the three-dimensional dose distribution of volumetric modulated arc therapy (VMAT) for cervical cancer. **Methods:** 8 independent channels of contoured structures were input to the model, and the dose distribution was used as the output of the model. 2D and 3D-Unet prediction models were trained and validated on the training set (n=86) and validation set (n=11), respectively, and then tested using the test set (n=20). The study included 117 cases of cervical cancer patients treated with VMAT, with a prescribed dose of 50.4 Gy in 28 fractions. The results between clinical dose distribution and predicted dose distribution were compared in the following aspects: (a) the mean absolute error (MAE) within the body (b) the Dice similarity coefficients (DSCs) under different isodose volumes (c) the dose parameters include the mean dose (Dmean) and V40Gy (the volume of PTV receiving 40Gy dose) and PTV conformity index (CI) and homogeneity index (HI). (d) dose-volume histogram (DVH) **Results:** Both 2D and 3D-Unet dose prediction models can accurately predict the dose distribution of VMAT plans for cervical cancer. The overall average MAE of the 2D and the 3D-Unet model are $2.92 \pm 4.08\%$ and $2.43 \pm 3.17\%$ of the prescribed doses, respectively. The average DSCs are all greater than 0.9 in different isodose volumes, most of the dose parameters including Dmean, V40Gy, CI and HI are equivalent to those of clinical plans, and there is no statistically significant difference. The DVH of the two models is similar to the clinical plans. **Conclusion:** We have developed two dose prediction models, 2D-Unet and 3D-Unet, which can accurately predict the three-dimensional dose distribution of VMAT for cervical cancer. In terms of MAE and DSCs, the 3D-Unet model is better than the 2D-Unet model.

PO-GePV-T-201

Automated and Clinical-Criteria-Driven Planning for Locally Advanced Non-Small-Cell Lung Cancer Using the Expedited Constrained Hierarchical Optimization (ECHO) System

Q Huang, L Hong, Y Zhou*, G Jhanwar, J Yang, H Pham, E Yorke, L Cervino, J Deasy, M Zarepisheh, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: To develop and implement a fully automatic, clinical-criteria-driven treatment planning solution for locally advanced non-small-cell lung cancer (LA-NSCLC). **Methods:** 21 patients with LA-NSCLC of various tumor locations and sizes with prescription of 60Gy in 30 fractions were retrospectively included in this study. Clinical plans were created manually using static IMRT. Automated plans with the same beam arrangements were designed using in-house-developed automated planning system: ECHO. ECHO uses hierarchical constrained optimization technique and is integrated into Eclipse using API scripting. Department clinical criteria were separated into 2 categories: limits and guidelines. Limits were strictly enforced by ECHO as constraints, while guidelines were optimized as much as reasonably achievable in objective functions. Dosimetric metrics were evaluated for plans in terms of tumor coverage and normal tissue sparing. **Results:** Planning Target Volume (PTV) sizes ranged from 179cc to 1371cc. Planning time for ECHO averaged 59 minutes (range: 17min-107min). Both clinical and ECHO plans met all clinical criteria. Compared with clinical plans, ECHO plans were more consistent in target coverage and normal tissue sparing. Percentage dose to 95% of PTV for ECHO plans ranged 96.7%-100% (median 100%), compared to clinical plans with 87.1%-101.3% (median 100%). Median volume of total lungs excluding GTV receiving >5Gy and >20Gy for ECHO was 59.7% (46.9%-78.9%) and 31.8% (19.5%-36.9%), and for the clinical plans was 60.3% (42.7%-73.4%) and 33.3% (16.9%-36.3%) respectively. Doses to other organs at risk (OARs), including cord, esophagus and heart did not vary significantly between ECHO and clinical plans. **Conclusion:** We developed a flexible automated treatment planning system for LA-NSCLC, driven by modifiable constraints and planning limits/guidelines, and integrated with Eclipse. The automated ECHO plans met established

clinical criteria with better consistency for tumor coverage and OARs sparing. Use of ECHO saves time and effort while resulting in improved or non-inferior plans.

PO-GePV-T-202

Monitor Unit Efficient VMAT Treatment Planning Facilitated by the MU Objective Tool

M Ashenafi*, M Hare, C Rothfuss, H Zhang, University of Rochester, Rochester, NY

Purpose: Identify an MU-efficient treatment planning methodology that maintains the dosimetric quality of the treatment plan. **Methods:** Seventeen hypofractionated (7-18Gy/fx) and twenty-five conventional fractionated (1.8-3Gy/fx) volumetric modulated arc therapy (VMAT) treatment plans were selected utilizing the Varian Eclipse™ version AcurosXB_15.6. The treatment sites included H&N, lung, liver, and prostate. A base plan was created without utilizing the MU objective tool. Then, an MU-efficient plan was created by utilizing the MU objective tool with a strength setting of 70, a lower objective of zero, and an upper objective (MaxMU) of different values. Dosimetric quality and MU-efficient metrics were used to compare the base plan and the MU-efficient plan. The MaxMU parameter was identified for each treatment site that best reduced the total MU, but at the same time gave a similar to or better plan than the base plan by as determined by fulfilment of the dose constraint metrics. **Results:** For the hypofractionated lung and liver plans, a MaxMU of 1.25 times the prescription dose per fraction (1.25x) resulted in the total MU reduction by 24% and 25% respectively. For the hypo-fractionated prostate, a MaxMU of 2x resulted in the total MU reduction by 13%. For the conventional fractionated bilateral H&N and prostate with lymph nodes plans, a MaxMU of 600MU resulted in the total MU reduction by 19% and 15% respectively. For the conventional fractionated unilateral H&N and prostate minus lymph nodes plans, a MaxMU of 400MU resulted in the total MU reduction by 13% and 18% respectively. MU-efficient plans with the above-mentioned MaxMUs resulted in similar plans compared to the base plans, and in some cases, gave better dosimetric results for OARs. **Conclusion:** The MaxMU for four studied sites were identified that led to the optimum MU reduction without sacrificing target coverage or any other studied plan quality metrics.

PO-GePV-T-203

Evaluation of Performance of Static MLC Leaf-Sequencing Algorithms in IMRT

J Jing^{1,2*}, H Lin¹, J Chow², (1) Hefei University of Technology, Hefei, AH, CN, (2) Princess Margaret Cancer Centre, Toronto, ON, CA

Purpose: The aim of this study is to compare the performance of three multileaf collimator (MLC) leaf-sequencing algorithms, proposed by Engel et al, Bortfeld et al, and Kalinowski et al using megavoltage external radiation beams with various beam angles for lumbar vertebrae intensity modulated radiation therapy (IMRT). **Methods:** Different IMRT plans for lumbar vertebrae were created using the ARTS treatment planning system (TPS). The fluence maps for all photon beams were determined by the TPS after plan optimization. Three different MLC leaf-sequencing algorithms based on Engel et al, Bortfeld et al and Kalinowski et al were programmed to calculate the final beam segments and their monitor units. For comparison purpose, the matrices of fluence maps were kept constant in different plans. The number of beam segments and total number of monitor units were calculated for the three algorithms. **Results:** Although values of the number of beam segments and total number of monitor units calculated by the three algorithms varied with the lumbar vertebrae plans, it is found that the algorithm by Engel et al performed better with the lowest number of beam segments. Moreover, the algorithms by Kalinowski et al and Engel et al had larger total number of monitor units than that of Bortfeld et al. **Conclusion:** Although the performance of leaf-sequencing algorithms varied with different IMRT plans having different fluence maps, the best MLC field segmentation can be identified through comparisons among different algorithms for the calculated number of beam segments and monitor units. Our results suggested that ideally, a treatment planning system for IMRT should implement multiple algorithms for the MLC field segmentation.

Sparing Lung Tissue with Virtual Block Method in VMAT Planning for Locally Advanced Non-Small Cell Lung Cancer

J Chen*, J Dai, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CN

Purpose: Despite that VMAT technique has been widely used in the radiotherapy of non-small cell lung cancer, it may increase the low irradiation dose volume to lungs. This study aims to develop a new virtual block method for sparing the normal lung tissue in VMAT planning. **Methods:** A retrospectively VMAT planning study was performed and compared without and with virtual block method for 17 patients, named as non-block plan and block plan respectively. The identical initial optimization parameter for the non-block plans were designed by the mdaccAutoPlan system. The block plan adopted all optimization parameters in non-block plan for each patient, in addition of the maximum dose constraint for the virtual block. The two types of plans were compared with dosimetric indexes of targets and normal structures, and the results were statistically analyzed with Wilcoxon signed rank test. **Results:** Both block and non-block plans achieved sufficient dose coverage in target volume and similar conformity of target volume. For the structures, block plans have advantages in the following dosimetric metrics: 1) for total lungs, lower V5, V10 and mean dose, NTCP were observed ($p < 0.01$, respectively); 2) for the contralateral lung, significant reductions in V5 and V10 ($P < 0.001$, respectively); 3) decrease in the mean dose and V40 of heart; 4) decrease in esophagus V40; 4) significant reductions in mean dose, V5 and V10 of normal tissue. The quality scores of block plans were significantly higher than that of non-block plans (Mean: 82.51 ± 7.07 vs. 80.74 ± 7.22 , $P < 0.001$). **Conclusion:** The VMAT plans with the virtual block can significantly reduce the low irradiation dose volume of the lungs and the doses to other normal structures whereas keep similar conformity and homogeneity of targets. The block method might reduce the risk of radiation-related toxicity for patients.

PO-GePV-T-205

MLC Leaf Position Optimization for Direct Aperture Optimization Treatment Planning

D Wu^{1*}, A Eldib², Q Jiang³, L Chen⁴, C Ma⁵, (1) The People's Hospital of Guangxi Zhuang Autonomous Region, Nanning, Guangxi, CN, (2) Fox Chase Cancer Center, Philadelphia, PA, (3) The First Affiliated Hospital of Chongqing Medical University, Chongqing, CN, (4) Fox Chase Cancer Center, Philadelphia, PA, (5) Fox Chase Cancer Center, Philadelphia, PA

Purpose: Direct-aperture optimization (DAO) is an efficient optimization method that combines both dose optimization and leaf sequencing in the same process. Due to the random selection of aperture shapes it is often time-consuming to find optimal aperture shapes in DAO. This study investigates MLC leaf position optimization for DAO treatment planning. **Methods:** Fifteen patients were unarchived from our clinical database, who were previously planned using Eclipse TPS and treated on Clinac iX accelerators. These patients were re-planned using Prowess RT-Pro (Prowess, Concord, CA) using the same beam angles, dose constraints and optimization parameters. Manual MLC leaf position adjustment was performed for these Prowess plans to remove hot spots inside the target and cold spots near the target border. Plan quality was evaluated using the homogeneity index (HI), conformity index (CI), Dmax (D1%), and Dmin (D99%) for IMRT/VMAT, and R50% and D2cm for SBRT, and dose-volume and Dmean for organs at risk (OAR). **Results:** Treatment plan quality was

significantly improved after adjusting MLC leaf positions following very simple rules for Prowess plans generated using the DAO algorithm. The removal of hot spots inside the target and cold spots near the target border resulted in much improved CI, HI and OAR mean doses as well as OAR dose-volumes. However, the initial selection of aperture shape and monitor unit optimization played an important role in the critical structure sparing as shown in the bladder and rectum mean doses for prostate plans. **Conclusion:** Minor adjustment of aperture shapes and/or removal of invalid segments for DAO generated plans could significantly improve the plan quality to generate identical superior treatment plans using Eclipse and Prowess employing either DAO and/or beamlet-based approach. The method developed in this work can be further programmed as a post-optimization tool to improve DAO treatment planning efficiency.

PO-GePV-T-206

Using a Novel Leaf Sequencer and Segment Shape Optimization Algorithm to Reduce Treatment Session Times on the Elekta Unity

J Snyder*, J St-Aubin, S Yaddanapudi, S Strand, S Kruger, R Flynn, D Hyer, University of Iowa Hospitals and Clinics, Iowa City, IA

Purpose: A current limitation of MR-guided radiotherapy is extended treatment session times. This study evaluates a new Elekta developed research optimizer and leaf sequencing algorithm with respect to plan quality and the potential to reduce optimization as well as treatment delivery times for Elekta Unity patients. **Methods:** Three prostate, three oligometastases, two pancreatic, and two liver patients previously treated on the MR-linac were retrospectively evaluated. Reference plans for all ten patients were generated using the clinical Hyperion optimizer and leaf sequencer. These plans were then re-optimized using a novel Optimal Fluence Levels (OFL) leaf sequencing algorithm and Pseudo Gradient Descent optimization algorithm (OFL+PGD). Beam angles and IMRT objectives were held constant for clinical and research algorithm optimizations. All plans were normalized for equivalent PTV coverage. Optimization time, treatment delivery time, number of plan segments, total MU, and gamma passing rate were all evaluated. A paired t-test was used to determine statistical significance. Relative changes in plan quality were evaluated for the PTV and critical OAR's. **Results:** The PGD and OFL algorithms had a reduction in optimization time of $51.4 \pm 5.0\%$ and a reduction in treatment time of $10.6 \pm 7.5\%$ as compared to the Hyperion plans. The OFL+PGD plans used $5.6 \pm 9.1\%$ fewer MU, $13.0 \pm 12.4\%$ fewer plan segments, and had an average gamma passing rate of 99.1% compared to 99.2% for the Hyperion algorithm. Reductions in optimization time ($p=0.002$), delivery time ($p=0.005$), and number of plan segments ($p=0.009$) are statistically significant. The plan quality between the Hyperion and OFL+PGD algorithms was observed to be equivalent in terms of OAR sparing and PTV hotspot. **Conclusion:** The OFL+PGD generated plans optimized faster and had shorter delivery times while maintaining equivalent plan quality. These algorithms have the potential to decrease overall treatment session times for MR-guided radiotherapy.

Volumetric Dose Reconstruction for Iso-Dose Tuning

L Ma*, M Chen, X Gu, W Lu, University of Texas Southwestern Medical Center, Dallas, TX

Purpose: To develop a model to generate volumetric dose distribution from two isodose surfaces (iso-surfaces), and to interactively tune dose distribution by iso-surface dragging. **Methods:** We model volumetric dose distribution as analytical extension of two iso-surfaces with the extension variables as distances to iso-surfaces. We built a 3D lookup table (LUT) which are generated based on clinical dose distributions. Two LUT tables store the mean and standard deviation of voxel dose values of clinical doses and binned as distance to 100% iso-surface, reference iso-surface and reference dose level. The process of interactive tuning starts from a given base plan. A user drags iso-surface for a desired carving. Our method responds with tuned dose. The derivation of tuned dose follows two steps. Dose is extended from the two user-desired iso-surfaces (eg. 100% and 50%) to the whole patient volume by table lookup, using distances to two iso-surfaces and reference dose level as keys. Then we fine tune the extended dose by a correction strategy utilizing the information of base plan. **Results:** We validated this method on coplanar VMAT doses of post-operative prostate plans. The LUT was populated by dose distributions of 30 clinical plans. We optimized two plans with different rectum sparing for an independent case to mimic the process of dose tuning. The plan with less rectum sparing is set as base plan. The 50% iso-surface of the more-sparing plan is defined as the desired iso-surface input. The dose output by our method (expansion and correction) agrees with the more-sparing plan obtained by optimization, in terms of gamma (90%), DVH and profiles. The overall dose reconstruction time is within two seconds. **Conclusion:** We developed a distance-to-isosurface based volumetric dose reconstruction method, and applied it to interactive tuning with iso-surface dragging.

A Multi-Staged Treatment Planning Framework for Large-Volume Ventricular Tachycardia Stereotactic Ablative Radiotherapy

X Gu*, R Timmerman, J Daniels, R Wu, W Lu, The University of Texas Southwestern Medical Ctr, Dallas, TX

Purpose: Stereotactic ablative radiotherapy (SABR) is emerging as a non-invasive ventricular tachycardia (VT) ablation regimen and has attained initial success of reducing refractory VT. However, a single-fraction biological potent dose (25 Gy) ablating a large planning target volume (PTV, median 98.9cc, range 60.9–298.8cc in ENCORE-VT trial) has high risk of radiation toxicity. We propose consideration of an optimized, multi-stage treatment planning strategy to mitigate radiation risk to adjacent organs at risk (OARs). **Methods:** The rationale for multi-staged SABR-VT is to divide an otherwise very large single-fraction treatment volume into sub-volumes allowing adjacent normal tissues to experience more tolerable fractionated radiation thereby minimizing the overall OARs biological effective dose (BED) and toxicity. The N-staged planning problem is stated: given a set of sub-targets and their respective prescription doses, and treatment sequence, find treatment plans such that each plan delivers the prescription dose p to target T in a single treatment session, and the total dose of all plans satisfies the OAR dose constraints. We formulate this problem as a constrained optimization. The objective of the constrained optimization is to ensure PTV coverage at prescription dose and minimize the weighted sum of OARs' BED. We use alpha beta ratio as 2 to estimate OAR BED reduction. **Results:** One of the VT cases we treated has PTV of 188.2cc. In a 1-stage treatment plan, the maximum doses to stomach and esophagus are 20.46Gy and 21.57Gy, respectively. Under a 3-stage treatment strategy, the biologically-equivalent 1-stage doses to stomach and esophagus are estimated as 14.85Gy and 15.63Gy constituting 28 percent reduction. **Conclusion:** Clinical investigation is required to confirm our modelled predictions regarding toxicity reduction with multi-stage SABR-VT and characterize the success of the approach in controlling arrhythmia.

PO-GePV-T-209

An Evaluation of Complex Plan Quality Using RayStation's Collapsed Cone Convolution (CCC) Algorithm as a Function of Differing Hardware Given a Time Constraint

E DeLuca*, N Sperling, University of Toledo Medical Center, Sylvania, OH

Purpose: The introduction of graphical processing unit (GPU) acceleration for RayStation's collapsed cone convolution (CCC) algorithm saw tremendous increases in the speed of dose calculations, but these speed increases and their effect on plan quality has not been extensively documented. The complexity of the optimization problem provides no guarantee of reaching acceptable plan results in reasonable timeframes. This study investigates the impact of hardware

on radiation treatment plan quality, pertaining to time burdens and optimization setup. **Methods:** Several complicated treatment plans were developed in RayStation v8A SP1 with optimization criteria that produce clinically acceptable plans without additional user input. These criteria have been optimized using different sets of initializations and optimization steps (1x240, 2x120...). These were evaluated for speed of computation and plan quality under GPU acceleration. CPU optimized plans were created under time constraints matching the accelerated plans, and results were compared to evaluate the impact of acceleration on plan quality. **Results:** CCC calculations entail a five-fold increased runtime in the CPU-accelerated environment over GPU-accelerated. Total runtime increases quadratically for long, continuous optimization runs, with decreased differential returns on time invested. The 1x240 optimization resulted in a plan with the most volume exceeding Rx (58.7%), while the 4x60 optimization resulted in the least excess (6.92%). **Conclusion:** The combination of quadratically increasing runtime for long optimizations and the superior metrics of multi-initialized plans suggests that this strategy is best, but multi-initialized plans give more of their runtime to CCC. Given the same amount of runtime, GPU-accelerated optimizations can perform more iterations than CPU optimization by completing CCC evaluations efficiently – producing higher quality treatment plans. This suggests that clinics using RayStation's CCC algorithm with tight timeframes can produce better plans with improved hardware. Further study intends to investigate the effect of varying GPU hardware on plan quality and optimization times.

Automated Deliverable Plan Generation of Intensity Modulated Radiation Treatment Using Dose Distribution Predicted from Deep Learning

Z Sun*, W Hu, J Wang, J Fan, X Xia, J Zhao, I Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, China, 2 Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, CN

Purpose: Intensity-modulated radiotherapy(IMRT) is widely used to achieve higher target conformity and normal tissue sparing. This report developed automated treatment planning strategies for nasopharyngeal carcinoma(NPC) and rectal cancer, including 3D dose prediction based on deep learning and development of automatic optimization algorithm based on dose distribution. **Methods:** IMRT plans for 117 NPC patients and 200 patients with rectal cancer were enrolled in this study. A deep learning model based on U-Net was trained to predict dose distribution of new patients. Model input was composed of patients' CT images and clinically delineated PTV contour, and model output was three dimensional dose distribution of patients. An optimized algorithm composing MSE and DVH constraints was developed to achieve dose distribution-based plan optimization. Planning results were illustrated by comparing DVH curves and quality evaluation parameters of PTVs and OARs. **Results:** Dose distribution similar to the clinical executed plan can be obtained by deep learning method, and cross-sectional dose map comparison results show no significant difference between clinical and predicted dose distribution. Automatically generated plans using MSE-based optimization target meet the clinical evaluation criteria, meanwhile the maximum brainstem dose is reduced by 5.2 Gy. V30 of left and right parotid glands are declined by 10.5% and 9.2% respectively. The overall planning time of a single NPC patient was less than 5 minutes. **Conclusion:** This research developed a novel automated IMRT planning process. Report demonstrated this method's ability to predict IMRT dose distribution precisely, providing more information accounting for an individual patient's treatment planning. Furthermore, the use of innovative objective function composed of MSE & DVH objectives allowed a standardized planning process that showed clinical gains over existing manual IMRT planning.

PO-GePV-T-211

Dosimetric Differences of Plans Using Flattened 6MV Versus Flattening-Filter-Free 10MV Beams for the Treatment of Prostate with and Without Seminal Vesicles

M Ashenafi*, C Rothfuss, A Gray, H Zhang, University of Rochester, Rochester, NY

Purpose: To investigate the dosimetric differences in treatment plans for prostate with and without seminal vesicle using volumetric modulated arc therapy (VMAT) plans with flattened and flattening-filter-free (FFF) beams. **Methods:** Nine patients treated with 1.8-2.5Gy/tx and 6MV-flattened beam (6x) were identified. Each patient's VMAT plans were recalculated for 10MV FFF beams (10FFF). All of the optimization parameters were set to be identical for flattened and FFF beam plans. The maximum dose rate for 6x (600 MU/min) and for 10FFF (2400 MU/min) were allowed during optimization; however, the treatment planning system automatically optimized at a lower dose rate for FFF plans. Plans optimized with 10FFF beams were compared with the plans optimized and calculated with 6x beams. Various metrics of these two plans were evaluated in this study. Studied metrics included mean dose to rectum, bladder, bowel, body, target; maximum dose to femoral heads, and penile bulb; conformity index; target dose inhomogeneity; and Total MU. **Results:** All generated plans, regardless of the beam modality, met clinically accepted objectives. Both 6x and 10FFF beams provided similar target coverage and dose conformity. In comparison, 10FFF beam provided better solution in sparing rectum, bladder, bowel, femoral heads and penile bulb than 6x beam. Mean dose to the body decreased with 10FFF by 5.2%. Average maximum dose to the femoral heads also decreased with 10FFF by 4.2%. 10FFF increased target dose inhomogeneity. In most cases, failure after external beam radiation show that the area responsible for the local recurrence is the intraprostatic dominant nodule. Finally, total MU was lower in plans using 10FFF. **Conclusion:** Both treatment modalities provided clinically acceptable treatment plans. The results of this study indicated that 10FFF plans resulted in better plan quality metrics, with relatively shorter delivery times. FFF beam's target dose inhomogeneity may be used for a focal dose escalation.

PO-GePV-T-212

Evaluation of Elekta Unity IMRT Beam Complexity Using a Novel Leaf Sequencer and Shape Optimizer in the Monaco Treatment Planning System

J St-Aubin*, J Snyder, S Yaddanapudi, R Flynn, D Hyer, University of Iowa Hospitals and Clinics, Iowa City, IA

Purpose: During online adaptive planning with the Elekta Unity MR-Linac, new intensity modulated radiotherapy (IMRT) treatment plans are created for each patient immediately prior to treatment. To reduce both offline and online planning time, Elekta has developed a new Optimal Fluence Levels leaf sequencer and pseudo-gradient descent shape optimizer (OFL+PGD) in a research version of the Monaco treatment planning system. **Methods:** Unity MR-Linac Step-and-shoot IMRT beam complexity metrics were calculated for plans generated using Elekta's research OFL+PGD algorithms and Elekta's current optimizer and leaf sequencer (Hyperion). A total of 10 patients were included in this preliminary study (3 prostate, 2 pancreas, 3 oligometas, and 2 liver). Beam complexity metrics include plan averaged beam area normalized to PTV area (NPA), plan averaged beam irregularity (PI), plan normalized MU (PMU), and plan averaged beam modulation (PM). Total number of segments, and number of MLC subsegments (i.e. separated open areas within a segment) was also quantified. Statistical significance between the OFL+PGD and Hyperion algorithms results was assessed via student t-test and correlations through Spearman's rank test. **Results:** Differences in IMRT beam complexity metrics between OFL+PGD and Hyperion algorithms were determined as follows: $\Delta NPA = -0.004 \pm 0.025$, $\Delta PI = -0.2 \pm 0.5$, $\Delta PMU = -37.0 \pm 59.4$ MU, and $\Delta PM = -0.1 \pm 0.1$. OFL+PGD algorithms also produced fewer segments and subsegments (-10.1 ± 9.7 and -0.2 ± 0.2 respectively) compared to the Hyperion algorithm. The pairwise reduction in PM, number of segments, and number of subsegments was statistically significant ($p=0.004$, $p=0.009$, $p=0.02$ respectively). Additionally, PMU was found to be correlated to PM for both the OFL+PGD and Hyperion algorithms. **Conclusion:** For the 10 plans evaluated, the new OFL+PGD algorithm produced plans with reduced PM, number of segments, and number of subsegments compared with Hyperion. Differences in NPA, PI and PMU were not found to be statistically different between the two algorithms. For both Hyperion and OFL+PGD algorithms, PMU was correlated with PM.

Funding for this work was supplied through an industry grant from Elekta.

PO-GePV-T-213

Sub-Segmentation of Laryngopharynx Whole-Mean Dose Constraints for Reducing Intra-Organ Dose Variability

C Sample¹*, H Clark², (1) British Columbia Cancer Agency, Vancouver, BC, CA, (2) British Columbia Cancer Agency, Surrey, BC, CA

Purpose: QUANTEC recommends whole-mean radiotherapy dose constraints for various organs-at-risk, but mean dose constraints allow dose to concentrate in arbitrary regions of the constrained volume. Here we demonstrate a radiotherapy treatment planning method that uses sub-segmentation to improve spatial control of modulated dose distributions. **Methods:** An open-source binary plug-in script for Varian Eclipse™, “Plan n Check,” was developed for structure sub-segmentation, applying constraints, and automating Volume Modulated Arc Therapy (VMAT) plan optimization. Plan n Check was used on 6 head-and-neck VMAT patients (70Gy, 35 fractions) to divide laryngopharynx structures into 8 sub-structures of equal volume using nested segmentation. An institutional whole-mean dose constraint of 45Gy (adapted from QUANTEC) was imposed on each sub-structure in an effort to mitigate the concentration of dose to sub-regions of the laryngopharynx. Plans were optimized with Plan n Check using the Analytical Anisotropic Algorithm (AAA). In addition, a standard plan which did not apply sub-segment dose constraints was created for each patient as a control. The number of sub-structures violating the adopted dose constraint was compared for plans with and without sub-structure constraints. The standard deviation of mean dose within laryngopharynx sub-structures was also calculated for all plans to determine whether sub-structure optimization can reduce intra-structure dose variability. **Results:** The number of laryngopharynx sub-structures with dose violations was significantly reduced (mean: 2.2 to 0.33) when plans imposed sub-structure whole-mean constraints (Student’s $t(5) = 3.38$, $p < 0.02$). Imposing sub-structure constraints significantly reduced the standard deviation (8.2Gy to 4.1Gy) of mean laryngopharynx sub-structure doses ($t(5) = 2.58$, $p < 0.025$). This technique did not significantly impact other organ or target volume dose distributions. **Conclusion:** Mean dose constraints may in some cases insufficiently constrain organ doses. Imposing additional sub-segment constraints is a practical method for exerting greater spatial control and reducing intra-organ dose variability.

PO-GePV-T-214

Dosimetric Advantages of Split-Field Fixed-Jaw Intensity-Modulated Radiation Therapy On Lung Protection for T-Shaped Esophageal Cancer

H Chen*, Z Xu

Purpose: To evaluate the dosimetric characteristics of split-field fixed-jaw (SF-FJ) intensity modulated radiation therapy (IMRT) technique used in treating T-shaped esophageal cancer and the lung sparing, and assess the correlation between the lung tissue dose volumes reduced by this technique and the target vertical axis length. **Methods:** SF-FJ IMRT plans for Thirty T-shaped esophageal cancer patients were compared to jaw tracking (JT) plans and static jaw (SJ) plans. The dose distribution in target volumes, the protection of organs at risk (OARs), MU as well as the correlation between the lung irradiation volumes reduced by the SF-FJ plan and the length of the target vertical axis were evaluated. Wilcoxon signed-rank test and Pearson rank test ($p < 0.05$) were used as the verification methods. **Results:** The HI and CI of PTV-G in the JT and SJ plans were superior to those of the SF-FJ plan. Compared with the JT and SJ plan, the SF-FJ plan significantly reduced the V5, V10, V13, V15, V20 for lungs and the maximum dose for the spinal cord, but slightly increased the V30 of lungs. The SF-FJ plan delivered higher MU than the SJ plan, and lower MU than the JT plan. The correlation coefficients between $\Delta V5$ JT-FJ, $\Delta V10$ JT-FJ, $\Delta V13$ JT-FJ, $\Delta V15$ JT-FJ and the length of the target vertical axis were 0.718, 0.725, 0.717 and 0.599, respectively, and $\Delta V30$ JT-FJ was negatively correlated with the length of the target vertical axis, with correlation coefficient value 0.631. The correlation coefficients between $\Delta V10$ SJ-FJ, $\Delta V13$ SJ-FJ, $\Delta V15$ SJ-FJ and the length of the target vertical axis were 0.747, 0.743 and 0.776, respectively. **Conclusion:** SF-FJ IMRT planning could maximize the protection of lung tissues, and as the length of the target vertical axis was longer, the low-dose to lungs was further reduced.

PO-GePV-T-215

Evaluation of Planning for Upper Thoracic Esophageal Carcinoma Based on Auto-Planning

M Mingchang*, W Ma, R Zhang, The 4th Hospital of Hebei Medical University, Shijiazhuang, HebeiCN

Purpose: To evaluate the progressive optimization algorithm-based Auto-Planning module of Pinnacle3 9.10 treatment planning system (TPS) whether can effectively reduce the difference in the plan quality caused by the lack of experience of the dosimetrist compared with the manual plan for the upper thoracic esophageal carcinoma. **Methods:** Ten patients with upper thoracic esophageal carcinoma were selected, set the same initial conditions, and Manual-IMRT and Auto-IMRT were designed separately. Change the lung dose limit conditions to generate a new plan. The results obtained are normalized based on the results of the initial plan and compare the effects of different initial conditions on automatic and manual plans. **Results:** Compared with the Manual-IMRT plans, the V5, V20 of Auto-IMRT plans were no statistical difference ($P = 0.704$, 0.085), and the V30 significantly reduced by 0.23% ($P = 0.003$). The mean dose for the lung decreased 0.1 Gy ($P = 0.045$) by using Auto-Planning. Compared with Manual-IMRT plans, Auto-IMRT plans were more convergent with the change of lung dose restriction conditions. **Conclusion:** Auto-Planning module can effectively reduce the difference in the plan quality caused by the lack of experience of the dosimetrist and improve overall plan quality and consistency.

PO-GePV-T-216

Dosimetric Impact in GNP-Enhanced Radiotherapy Using the 10 MV FF and FFF Photon Beams: A Monte Carlo Depth Dose Study

J Chow¹*, (1) Princess Margaret Cancer Centre, Toronto, ON, CA

Purpose: This study investigated the effect of dose enhancement and beam attenuation on the depth dose, when gold nanoparticles (GNP) were added to the soft tissue, using the flattening filter-free (FFF) photon beams in GNP-enhanced radiotherapy. **Methods:** A cubic water phantom irradiated with the 10 MV FF and FFF photon beams (field size = 10×10 cm²) was used. GNPs with concentrations ranging from 3 to 40 mg/mL were added to water. The depth doses of the phantom were determined using Monte Carlo simulation under the macroscopic approach. The depth dose enhancement ratio (DDER), defined as the ratio of the dose with GNP addition at a depth to the dose without GNP addition at the same depth, was calculated for each GNP concentration. **Results:** When GNPs were added, the DDERs were found larger than one in the depth range of 4-6 and 4-8 cm for the 10 MV FF and FFF photon beams, respectively. However, when the depth was larger than 6 (FF beam) and 8 cm (FFF beam), the enhancement ratios were less than one. This shows that the presence of GNPs did not increase the dose beyond 6 and 8 cm, and it is because the GNP addition not only enhances the dose, but attenuates the beam along the depth. Comparing the FF and FFF photon beams with GNP concentration increased from 3 to 40 mg/mL, the DDERs were found increased from 1 to 1.004 (FF beam) and 1 to 1.015 (FFF beam). This is because the FFF beam contained more low-energy photons than the FF. **Conclusion:** When GNPs were added to the phantom, the dose enhancement decreased with depths deeper than 6 and 8 cm for the FF and FFF photon beams, respectively. In addition, the dose enhancement was found decreasing at a higher rate when the GNP concentration increased.

PO-GePV-T-217

A Study of Surface Dosimetry for Whole Breast Irradiation Geometry Using EBT3 Gafchromic Film and Monte Carlo Simulation

S Su¹*, E Carpentier², C Duzenli^{1,2}, (1) British Columbia Cancer Agency, Vancouver, BC, CA, (2) University of British Columbia, Vancouver, BC, CA

Purpose: This in-phantom study was performed to validate a film technique for measurement of surface dose in isocentric, tangential whole breast irradiation by comparison with Monte Carlo (MC) simulations. **Methods:** Solid water phantoms of 20 cm and 30 cm separation were irradiated at 100 cm SAD with lateral half-blocked 6 MV and 15 MV x-ray beams, on a Varian TrueBeam linac. Two centimetres beam clearance on the anterior and inferior phantom edges was used to simulate whole breast tangential field geometry, with a field length of 20 cm and asymmetric field width of 15 cm. Measurements were performed using EBT3 Gafchromic™ film on the phantom surface under 0.0 g/cm², 0.03 g/cm² and 0.0995 g/cm² buildup materials to simulate potential breast support devices on the entrance, exit and inferior surfaces of the phantom. Dose was normalized to the mid separation dose. Film calibrations were performed at SAD 100 cm, 10x10 cm² field size at depth of 10 cm for both energies. Surface dose was calculated in depth increments of 0.025 g/cm² from the surface to a depth of 0.1 g/cm² using EGSnrc using the following parameter settings: ECUT=0.521 MeV, PCUT=0.010 MeV, BCA EXACT with a skin depth of 3, ESA PRESTA-II. **Results:** Film measurements agreed with MC within 5% at the beam entrance and exit surfaces for both beam energies and all buildup materials. Agreement was within 10% at the inferior phantom surfaces receiving side scatter from the phantom. **Conclusion:** Investigations of this EBT3 film technique to measure surface dose are ongoing. Significant corrections appear not be required when measuring entrance or exit surface dose but further work is needed to improve agreement with MC simulation at the inferior phantom surface, where dose is primarily due to side scatter from the irradiated volume.

Dosimetric Considerations of Moldable Silicones for Radiotherapy Boluses and Phantoms

G Aldosary^{1,2*}, J Belec^{3,4}, C Footit^{3,4}, E Vandervoort^{1,3,4}, (1) Department of Physics, Carleton University, Ottawa, ON, CA, (2) Department of Oncology, King Abdulaziz Medical City, Riyadh, KSA, (3) The Ottawa Hospital Cancer Centre, Ottawa, ON, CA, (4) Department of Medicine, The University of Ottawa, ON, CA

Purpose: Due to their favourable characteristics, moldable silicones (MS) have gained popularity in medicine and recently, in radiotherapy. We investigate the dosimetric properties of MS in high-energy radiotherapy photon and electron beams and determine their suitability as water substitutes for constructing radiotherapy boluses and phantoms. **Methods:** Two MS types were used ($\rho=1.04$ and 1.07 g/cc). Various dosimetric properties were characterized (e.g., Z_{eff} , relative electron density, mass-energy absorption coefficients). For each type, two MS slabs were molded with a base of 16×16 cm², and 1.5 cm and 5.0 cm thicknesses. Two additional 5.0 cm thick slabs were molded to fit a Markus ionization chamber (IC) flush to the surface. For each MS type, the doses at 1.5 cm and 5.0 cm depths were measured with 5.0 cm Solid Water (SW) backscatter material (MS-SW), and with a full MS setup (MS-MS), then compared with doses at the same depths in a full SW setup (SW-SW). Relative doses were reported as MS-SW/SW-SW and MS-MS/SW-SW. Measurements were repeated using film. Experimental results were verified using Monaco Treatment Planning System (TPS) dose calculations and DOSXYZnrc Monte Carlo (MC) simulations. **Results:** Dose ratios varied according to MS and beam types. For photon beams, a bolus setup caused ~5% dose reduction (MS-SW/SW-SW). Using MS alone resulted in ~2% dose reduction (MS-MS/SW-SW). For electrons, up to 2% dose increase was observed for MS-SW and MS-MS relative to a full SW setup (SW-SW). **Conclusion:** MS compositions differ from water/SW's and vary between manufacturers. Accurate dosimetry using these materials requires consideration of these differences. Compared with dose in SW, an interface of MS-SW can cause relatively high differences. Using MS alone for phantom construction provides a more tissue-equivalent setup. However, it is important to characterize a particular MS's properties for a given beam quality prior to clinical use.

PO-GePV-T-219

Feasibility of 18-MV Grid Therapy from the View of Radiation Protection

AH Karimi¹, X Wang^{2*}, SF Mirian³, HR Vega-Carrillo⁴, M Mohiuddin², (1) Department of Medical Physics and Biomedical Engineering, School of Medicine, Tehran University of Medical Sciences, Tehran, Iran., (2) Advocate Aurora Health, Park Ridge, IL, (3) Department of Nuclear Engineering, University of Isfahan, Isfahan, Iran, (4) University Autonomous of Zacatecas, Zacatecas, Zac, Mexico

Purpose: In Spatially Fractionated Grid Radiation Therapy (SFGRT), the grid block in the collimation system modifies the neutron production, photon scattering, and electron contamination in and out of the radiation field. The main purpose of this study is to investigate the photoneutron production and the secondary cancer risk in SFGRT with 18-MV photons. **Methods:** Using the MCNPX code, three types of grid made of brass, cerrobend, and lead, located at the tray of an 18-MV medical linear accelerator, were simulated. Plans with different field sizes were generated to compare the neutron and electron contaminations. A revised female MIRD phantom with an 8-cm spherical tumor inside the liver was simulated to study the lifetime risks of fatal cancer due to neutrons and scattered photons using a 20-Gy SFGRT plan and a 40-Gy CFRT plan with a 9×9 cm² field size. **Results:** The neutron fluences per electron-history in SFGRT plans with brass, cerrobend and lead blocks are averagely 55%, 31% and 31% less than that of the CFRT plan, respectively. In both SFGRT and CFRT plans with a 9×9 cm² field size, the contribution of the primary and scattered photons to the fatal cancer risk is 2 times or more than the photoneutrons. The total risks from photons in SFGRT with brass, cerrobend, and lead blocks are 1.733, 1.374, and 1.260%, respectively. These values are significantly lower than the total photon-risk in CFRT (5.827%). **Conclusion:** In the brass, cerrobend, and lead grids, the attenuation of photoneutrons outweighs its photoneutron production in SFGRT. The total cancer risks in the SFGRT plan were less than the risk in the CFRT plan. The grids also decrease the amount of electron contamination.

PO-GePV-T-220

Impact of Depth-Induced Spectrum Change on the Dose Enhancement of Gold Nanoparticle Aided Radiotherapy at Megavoltage Energy

R Schmidt*, J Shi, J Ford, D Hara, N Dogan, A Pollack, University of Miami, Miami, FL

Purpose: The magnitude of dose enhancement ratio (DER) induced by GNPs is sensitive to the beam quality, such as particle type and energy spectrum - traversing matter changes the energy spectrum. Monte Carlo simulations were used to assess the impact of depth-induced spectrum change on the micro-dosimetry induced by GNPs irradiated using megavoltage (MV) beams. **Methods:** Simulations were carried out using TOPAS-nBio. The micro-dosimetry calculation was split into three distinct steps. Step one: a simulated 10648cm³ cubic water phantom was irradiated by 6 MV x-rays, and phase space data (PSD) of the particles passing through a 5cm² plane at different depths (0.25cm to 10cm) of phantom were recorded. Step 2: the recorded PSD was used as a source of GNP irradiation. For increasing interaction probability, the PSD acquired in the first step was shrunk to be nanoscopic (16nm²). Ejected secondary particles were recorded as spherical PSD around the GNP. Step 3: the spherical PSD recorded in the step two was used to calculate the dose distribution in nanoscale - utilizing track structure-based physics models within TOPAS-nBio. The dose was scored in bins of 1nm for from 0nm-100 nm from the GNP center, 10 nm from 100nm-1µm and 100 nm from 1µ-100µm. **Results:** Simulations were validated using known characteristics of 6 MV clinical beams in water and found to be accurate. The fraction of low energy particles (<500 keV) in the incident beam increased from 6.56% to 8.44% as depth increased from 0.25cm to 10 cm. GNP-mediated DER was very localized around the NP regardless of depth, however, a depth dependency is still apparent. **Conclusion:** The incident photon spectrum does show a depth dependency, which should be accounted for when considering clinical GNP aided radiation therapy. The optimal energy for GNP-mediated DER needs to be further refined before clinical use.

PO-GePV-T-221

Validation of the Monte Carlo Model of a Novel Biology-Guided Radiotherapy (BgRT) Linac

M Shi^{1*}, K Bush¹, C Chuang¹, D Zaks², L Xing¹, N Kovalchuk³, M Surucu⁴, B Han⁴, (1) Stanford University, Stanford, CA, (2) RefleXion Medical, Hayward, CA, (3) Stanford University Cancer Center, Palo Alto, CA, (4) Stanford University School of Medicine, Stanford, CA

Purpose: RefleXion is a novel radiotherapy machine that tracks tumor using real-time positron emission signals and delivers radiation through a binary multi-leaf collimation (MLC) system. A Monte Carlo (MC) model of the RefleXion Linac is validated against commissioning measurement in this study. **Methods:** The RefleXion Linac consists of a 6 MV FFF photon beam, a 64-leaf MLC system, and two pairs of y-jaws locating above and below the MLCs. The leaf side focuses on the source and each leaf provides a 0.625 cm opening along the x direction at 85 cm SAD, giving a total of 40 cm opening when all MLCs are retracted. The y-jaw pairs move simultaneously to open 1 or 2 cm at 85 cm SAD. The beam commissioning measurements were performed in a Blue Helix Phantom using a diode and a W2 scintillation detector for scanning and output factor acquisition, respectively. The MC model provided by the vendor includes phase space files above MLCs and detailed structures of MLC leaves and lower y-jaws. Beam characteristics of field sizes from 1.25 x 1 cm² to 40 x 2 cm², including percentage depth dose (PDD), beam profiles, and output factors were simulated using MC codes, BEAMnrc and GATE, and compared with measurement. The relative simulation uncertainty is approximately 0.6%. **Results:** The mean and maximum differences of %dd(10) between measurement and simulation are 0.31% and 0.82%, respectively. The inline FWHM shows a deviation of 0.47 mm on average and 0.58 mm at most. The crossline off-axis ratio of the central 80% of field size differs by 0.88% on average (std = 0.92%). The mean output factor disagreement is 0.93% (std = 0.72%). **Conclusion:** A complete and accurate MC model of RefleXion Linac has been validated. This model will help substantially in the upcoming dosimetric, imaging and quality assurance studies.

PO-GePV-T-222

Focal Spot Size Effect of the RefleXion X1 Radiotherapy Machine: A Monte Carlo Simulation Study

OM Oderinde*, D Zaks, C Huntzinger, SM Shirvani, T Laurence, M Lu, RefleXion Medical, Hayward, CA

Purpose: The RefleXion™ X1 radiotherapy machine is a novel combination of positron emission tomography (PET) and computed tomography (CT) subsystems in the same gantry with a 6MV linac, with the intent of delivering biology-guided radiotherapy treatment (BgRT). Small treatment beam penumbra is desirable for small clinical targets. This study evaluated the focal spot size influence on treatment beam penumbra using a Monte Carlo (MC) technique. **Methods:** A reference field of 10 cm x 2 cm at source to axis distance (SAD) of 85 cm was modeled and simulated using the BEAMnrc MC package. The electron beam incident on the X-ray target was empirically modeled with a Gaussian function and the FWHM of the beam for the linac head model was varied between 0.4 and 2.0 mm in steps of 0.2 mm. Dose distributions were calculated in a water phantom of 60 x 30 x 22 cm³ using the DOSXYZnrc MC code. The effect of X-ray beam spot size on percentage depth dose (PDD), penumbra width, and field width based on profiles at depth of 15 mm and profiles in the air at SAD=85 cm was evaluated. **Results:** The variation in X-ray beam spot size did not have a significant effect on the PDD, with an average difference < 0.34% for PDD at depth of 100 mm. Penumbra width increases as X-ray beam spot size increases (R=1, P<0.01), while the field width is not affected by the variation of X-ray beam spot size. **Conclusion:** The beam spot size has a sizeable effect on penumbra width. This study shows that a small X-ray beam spot is preferred for small treatment fields due to the resulting narrow penumbra width.

Evaluating Backscattered Radiation into the Dose Monitor Chamber in the RefleXion X1 Using Monte Carlo Simulation

OM Oderinde*, D Zaks, C Huntzinger, SM Shirvani, A Maniyedath, T Laurence, M Lu, RefleXion Medical, Hayward, CA

Purpose: The RefleXion™ X1 is a novel ring gantry system with a unique structural design made to accommodate both a linear accelerator (LINAC) and positron emission tomography (PET) detectors for biology-guided radiotherapy (BgRT). A dose monitor chamber (DMC) for measuring beam output from the LINAC is located between a fixed primary collimator and a movable secondary multi-leaf collimator (MLC). Backscattered radiation from the secondary collimator may contribute to the total charges collected in the DMC, may result in an artifact in the measurement. The present investigation utilized Monte Carlo (MC) simulation to characterize the impact of backscattered radiation to the DMC measurements. **Methods:** The EGSnrc Monte Carlo package was used to model the X1 LINAC output of a 6 MV photon beam in flattening filter-free mode with 521 keV global electron cutoff energy and spin-on for reasonable backscattering calculation. The backscatter effect from downstream LINAC components was quantified by calculating the contribution of forward-directed and backscattered radiation to the energy deposited in the DMC. Scenarios involving 2, 4, 8, and 16 open MLC leaves with 1, 2, and 3 cm jaw settings were computed. **Results:** A maximum backscatter contribution of 0.12%±0.1% was obtained for a simulated field of 10 cm (16 MLC leaves) with a 2 cm jaw opening. For a simulated field of 1.25 cm (2 MLC leaves), a maximum backscattering contribution of 0.27%±0.1% was recorded. On average, backscattering contribution decreased with an increase in the field size. Minimal variation in backscattering was observed for different jaw openings. **Conclusion:** For the X1 LINAC photon beam, the effect of backscattered radiation is minimal even with very small field sizes and is not correlated with jaw size. Therefore, correcting for field-size dependence of DMC output to account for backscatter is not necessary for the RefleXion X1 design.

PO-GePV-T-224

On the Determination of Source Parameter Probability Distribution Functions During the Monte Carlo Modeling of a CyberKnife M6 Unit

J Duchaine^{*1,2}, D Marke¹, H Bouchard^{1,2,3}, (1) Université de Montréal, Montréal, QC, CA, (2) Centre de recherche du Centre Hospitalier de l'Université de Montréal, Montréal, QC, CA, (3) Centre Hospitalier de l'Université de Montréal, Montréal, QC, CA

Purpose: As prescribed by the IAEA-AAPM nonstandard beam dosimetry formalism, specialized radiotherapy treatment units which cannot achieve reference conditions established by conventional dosimetry protocols require detector quality correction factors. Monte Carlo is recognized as an essential method for the evaluation of these correction factors, but requires an accurate modeling and source parametrization of the radiotherapy device of interest. The purpose of this study is to propose a new maximum likelihood estimation method for the fitting of the source parameters of a CyberKnife M6 stereotactic radiotherapy unit. **Methods:** Based on the approach of Francescon et al 2008, a formalism is developed to estimate the likelihood distributions of the energy and spot size of the electron beam incident on the target. A rigorous uncertainty budget, which includes detailed consideration of positioning uncertainties, is estimated. The EGSnrc code system is used to model: 1) the CyberKnife M6 unit and 2) four detectors recommended by the IAEA-AAPM protocol for relative dosimetry of small photon fields. Absorbed dose in the detectors' sensitive volume are simulated for two setups, output factors and tissue-phantom ratios, using phase-space files generated with the CyberKnife model as the beam source. Corresponding measurements are performed on the CyberKnife M6 unit. **Results:** The method is used to estimate the probability distribution functions of the electron energy and spot size. From these distributions, the parameters, and their respective uncertainties, are extracted using the solutions of maximum likelihood and the standard deviation of the obtained distributions. Results illustrate the agreement, using a coverage factor of 95%, between measured and simulated output factors and tissue-phantom ratios for most considered detectors and field sizes. **Conclusion:** The proposed method allows an accurate beam parameterization of a CyberKnife M6 unit and a rigorous evaluation of uncertainties on the

determined energy and spot size.

PO-GePV-T-225

KQ Calculations of the ZAP-X Radiosurgical Device

R Townson^{1*}, F Tessier¹, G Weidlich², D Pang³, V Simic², M McEwen¹, (1) National Research Council Canada, Ottawa, ON, CA, (2) ZAP Surgical Systems, San Carlos, CA, (3) Georgetown University Hospital, Washington, DC

Purpose: The purpose of this work is to characterize the ZAP-X (ZAP Surgical Systems, Inc., San Carlos, CA) radiosurgical device beam quality using EGSnrc Monte Carlo k(Q) calculations of several ionization chambers. The TG-51 and TRS-398 clinical dosimetry protocols require k(Q) factors for calibrating external radiotherapy beams. **Methods:** ZAP-X produces a 3 MV photon beam with varying narrow conical beam collimation settings. For the k(Q) calculations, the beam was collimated to a diameter of 25 mm at 45 cm SSD (source to surface distance). This is a small field set-up compared to reference calibration conditions of 10 x 10 cm² at 100 cm SSD, that were used for the reference Co-60 beam. No machine-specific reference field has yet been defined for the ZAP-X linac, so as a first step only an overall k(Q) factor was calculated, with the chamber measurement point set at 10 cm depth in a 30 x 30 x 30 cm³ tank of water. For the Co-60 beam, the chamber depth was 5 cm as usual. Three ionization chambers were considered: the PTW 31010, Exradin A28 and Exradin A1SL. The Monte Carlo models for these chambers were previously produced from detailed manufacturer specifications and validated. **Results:** The overall k(Q) factors for the PTW 31010, Exradin A28 and Exradin A1SL under the 3 MV ZAP-X beam were calculated. Machine-specific reference k(Q) factors were then investigated based on additional simulations for various set-up conditions. **Conclusion:** Beam quality of the ZAP-X radiosurgical device was investigated using EGSnrc Monte Carlo simulations. Despite the small field size and low beam energy, overall k(Q) factors seemed relatively insensitive to varying ionization chamber models, and machine-specific reference conditions are proposed for the new ZAP-X linac.

PO-GePV-T-226

Characterization of Phosphorescent Strontium Aluminate as a Real-Time Dosimeter

S Drehmel^{*}, D Mathew, E Ehler, University of Minnesota, Minneapolis, MN

Purpose: A novel dosimeter capable of displaying dose in real time would enable one to verify the distribution of dose on the surface of a patient during treatment. The purpose of this study was to characterize the response of phosphorescent strontium aluminate (SrAl₂(2)O(4):Eu²⁺Dy³⁺) to high energy x-rays and to subsequently determine how the signal decays with respect to time. The wide range of application and low cost makes it a promising and attractive alternative to relative dosimetry. **Methods:** Glass cuvettes were filled with phosphorescent strontium aluminate powder and individually irradiated by a 6 MV beam at 100 cm SSD with a 10x10cm(2) field size at 1.5 cm depth. Post-irradiated cuvettes were placed in a black box and remotely photographed using a Nikon DSLR camera 1.5 minutes after irradiation. The resultant images were analyzed in MATLAB. Using a dose rate of 600 MU/min, we irradiated samples with 25, 50, 100, 200 400, 600, 800, and 1000 MU's to test linearity. Signal decay over time was measured by irradiating a cuvette at 600 MU and obtaining images in 5-minute intervals. **Results:** Strontium Aluminate exhibited a linear relationship to an increase in dose, within a dynamic range of 400-1000 MU with an R-square of .9922. For the signal decay over time test, the signal decreased roughly by a factor of 5 within the first 5 minutes and gradually decayed for the remaining intervals. The decay in signal was best fit by a rational function to the first degree. **Conclusion:** Phosphorescent Strontium Aluminate showed a favorable response in its linearity trials with changing dose and could potentially be used as a real time dosimeter during treatment or for routine QA procedures. Future experiments will focus on solidifying its functionality as an alternative to the current and more expensive relative dosimeters in use.

PO-GePV-T-227

When to Use Flattening Filter Free(FFF) Mode for Elekta Versa HD Delivered with VMAT

R Zhang<sup>¹, W Zhang², Y Gao³, W Bai^{1*}, Z Dong⁴, B Wang⁵, H Zhang⁶, D Zhao⁷, (1) The 4th Hospital of Hebei Medical University, Shijiazhuang, Hebei, CN, (2) Shijin Irrigation District Affairs Center, Hebei Province, CN, (3) Hebei General Hospital, Shijiazhuang, CN, (4) Affiliated Hospital of Hebei University, CN, (5) Cangzhou Hospital of Integrated TCM-WMHebei, CN, (6) The First Hospital of Shijiazhuang Hebei, Shijiazhuang City, CN, (7) Yuanshi County Hospital, CN

Purpose: To compare and evaluate the performance of Elekta Versa HD with and without flattening filter two operating mode(FF and FFF)delivery with volumetric modulated arc therapy. **Methods:** Treatment plans were graded four(Low,Moderate,Moderate-High and High complexity)according to the complexity.This includes 1 low complexity(brain metastasis 20Gy single dose),2 moderate complexity(Lung and Liver 12 Gy fraction dose),1 Moderate-High complexity(prostate 2 Gy fration dose) and 1 high complexity (head and neck 1.8 Gy fration dose) cases.All cases were designed two VMAT plans,one with flattening filter (group A) and the other with flattening filter free (group B).All plans were done on Elekta Versa HD with Monaco treatment planning system. All plans were generated with 6 MV X-rays.Plans were evaluated based on the ability to meet the dose volume histogram, radiation conformity index, estimated radiation delivery time,dose homogeneity index(HI) and monitor units(MU) needed to deliver the prescribed dose. **Results:** Plans of group A achieved the best HI (1.06 Vs.1.07) at the low complexity cases while plans of group B were slightly better at the high complexity cases (1.15 Vs.1.13). Treatment time of group B reduction more pronounced with increasing fraction dose for moderate target complexity (Low complexity: 535 Vs.262s,Moderate complexity:247s Vs.132s, and 341s Vs.137s),especially for the liver case with paradigms delivered time can be decreased 60%.The more MU for group B than group A as plan complexity increased (Low complexity:3325 Vs.3263, Moderate complexity:2001 Vs.2888, Moderate-High complexity:765 Vs. 920,High complexity:637 Vs.1333).No significant changes were observed between the group B and group A plans in terms of the healthy tissue mean dose.Both plans respected the planning objective for all organs at risk. **Conclusion:** The study concludes that VMAT plans with flattening filter free can significant decrease the delivering time at the moderate complexity cases with hypofractionation dose,while a slight compromise in the MU increased should be noted.

PO-GePV-T-228

Evaluation of a Scripted Planning Technique in Lung SBRT

J Donaghue^{1*}, S Gajdos², L Muhieddine Mossolly³, (1) Cleveland Clinic Fairview, Cleveland, OH, (2) Cleveland Clinic Akron General, Akron, OH, (3) Cleveland Clinic, Strongsville, OH

Purpose: The efficacy of SBRT in thoracic lesions depends on the effective dose deposited in the lesions. To reduce plan variability between multiple planners, a semi-automated process was validated for consistency of CI and R50 while increasing ITV mean dose and centralizing the hot spot to the ITV. **Methods:** Twenty-two lesions were investigated for patients who received a five fraction SBRT regimen via VMAT. A two-step process included a python code where user selects a set of initial parameters which automates the creation of tuning ROIs, machine settings, and loads the optimizer with a consistent set of objectives. The tuning ROIs include sets of rings at certain distances from PTV, as well as overlap ROIs with nearby organs at risk. The process focuses primarily on dose falloff and PTV coverage and then, meeting nearby organ at risk dose tolerances. The clinically delivered plan, which was planned by experienced staff, was used for comparison. **Results:** For the clinical plans, the CI was 1.04±0.05; R50 was 4.07±0.597; and ITV Mean relative to prescription was 117%±6.4%. For the scripted plans, the CI was 1.01±0.03; R50 was 3.61±0.351; and ITV Mean relative to prescription was 123.8%±2.8%. The scripting process was successful in meeting 335/336 OAR metrics resulting in 21 of 22 successful plans. For the clinical plans, the hot spot was located in the ITV 77.3%, while this occurred

in 95.3% of scripted plans. **Conclusion:** Through programmatic planning, standard deviations can be reduced compared to plans from a multiuser environment. In addition, the CI improved with a decrease of R50 without violation of critical organ dose tolerances in majority of cases. This script allowed for more planned dose deposition to PTV while also maintaining a safe dose falloff and organ tolerance preservation. This technique's clinical implementation can improve consistency with minimal user interaction.

PO-GePV-T-229

Retrospective Study of a Novel Automated Software for the Evaluation of Hypofractionated Treatment Plans Using Conventional Constraints

D Baldassari*, C Esquivel, L Patton, A Tipton, T Roberts, Texas Oncology San Antonio, San Antonio, TX

Purpose: Assess the use of a novel automated software in the treatment planning system to evaluate hypofractionated plans using conventional constraints. **Methods:** Eighteen Eclipse(v15.5) hypofractionated treatment plans of varying sites and dose per fraction regimens were retrospectively reviewed using Radformation's plan check software, ClearCheck(v1.67). The hypofractionated doses were compared to conventional 2Gy constraints using Equivalent-Dose(EQD2) formula, $EQD2=TD[(d+\alpha/\beta)/(2+\alpha/\beta)]$, where the $\alpha/\beta=2$. Within each treatment plan, EQD2 doses from ClearCheck were evaluated for soundness, accuracy, and consistency. **Results:** Variation in values of EQD2 doses determined by ClearCheck, compared to calculated values for the 18 plans, ranged between ± 0.1 cGy. Software-reported values demonstrated accuracy in the calculation itself and consistency amongst plans. In one plan, hypofractionated doses were within the defined objectives in ClearCheck. Subsequent conversion to the EQD2 however, indicates values just slightly in excess of the tolerances in ClearCheck for two critical structures. In theory, EQD2 values should be greater than the doses from the hypofractionated treatment plan. Invalid EQD2 values were observed for structures that were receiving doses less than 2Gy per fraction. **Conclusion:** ClearCheck is a convenient tool in the evaluation of hypofractionated plans and the conversion to conventional 2Gy-fraction constraints. Along with the user's ability to modify the α/β ratio, there is an instantaneous assessment of EQD2. With control in the manner reported, a planner is also able to ensure critical structure constraints are expressed in terms of maximum dose, mean dose, or dose for a specified volume, all essential for the conversion of EQD2 doses. While the EQD2 values are accurately calculated within the software, opportunity for erroneously reported values does, however, exist. In these instances, such as with normal tissues objectives receiving less than 2Gy/fraction, a warning should be provided, alerting the user of the priority in verifying the validity of results.

PO-GePV-T-230

Individualized Planning Target Volume for Cervical Cancer Patients Treated with Intensity-Modulated Radiotherapy Based On Bladder Filling Change

J Zhang^{1*}, (1) Cancer Hospital of Shantou University Medical College, Shantou, CN

Purpose: To establish an individualized planning target volume (PTV) based on bladder filling. To investigate the value of individualized PTV in clinical application, through comparing individualized PTV and RTOG standard PTV in tumor coverage and dosimetry. **Methods:** Twenty patients received radical radiotherapy for cervical cancer were selected in this study. Each patient scanned the CT image during full bladder (FB) and empty bladder (EB), respectively. IMRT based on an individualized PTV(PTVi) covering the CTV (Clinical Target Volume) position variations from FB to EB status instead of a uniform CTV-PTV margin of 1.5 and 2.0 cm (PTVs-1.5 and PTVs-2.0) at FB position were given to each patient. The target volume coverage was evaluated for PTVi, PTVs-1.5 and PTVs-2.0. The dose volume histogram was used to evaluate the treatment planning and assess the dosimetric parameter of OARs. **Results:** Compared with PTVi, the target volume was increased by 32.9% and 58.6% for PTVs-1.5 and PTVs-2.0, and the CTV to PTV was increased by 71.8% and 127.8%, respectively. PTVi had better target coverage than PTVs-1.5 and PTVs-2.0. For the OARs, the pelvic bone received V25Gy was $73.5\% \pm 4.89\%$, $79.5\% \pm 4.34\%$ and $82.3\% \pm 4.12\%$ for PTVi, PTVs-1.5 and PTVs-2.0, respectively ($p < 0.05$); V40Gy was $20.7\% \pm 2.90\%$, $31.6\% \pm 4.07\%$, $40.1\% \pm 4.93\%$, respectively ($p < 0.05$). Small bowel received V45Gy was $131.8cc \pm 69.23cc$, $145.7cc \pm 76.61cc$, $157.0cc \pm 82.94cc$, respectively ($p < 0.05$). For rectum and bladder, PTVi showed significantly less radiation dose, compared with PTVs-1.5 and PTVs-2.0. **Conclusion:** Compared with PTVs-1.5 and PTVs-2.0, individualized PTV results in better target coverage and organ-at-risk sparing. An individualized PTV is desired choice of the cervical cancer for radiotherapy.

PO-GePV-T-231

An Evaluation of An EQD2 Conversion Via Commercially-Available Software for Hypofractionated Treatment Plan Tolerances: A Retrospective Study

D Baldassari*, L Patton, T Roberts, A Tipton, C Esquivel, Texas Oncology San Antonio, San Antonio, TX

Purpose: Assess the use of an automated software to evaluate hypofractionated plans using conventional constraints. **Methods:** Eighteen hypofractionated treatment plans were retrospectively reviewed using MIM's EQD2 Variation 1 of the LQ model. The hypofractionated doses were compared to conventional 2Gy constraints using Thames and Withers' 2Gy Equivalent Dose (EQD2) formula. Within each treatment plan, EQD2 doses were evaluated within MIM for accuracy and consistency. **Results:** The 18 patients plans excel-generated hand calculations and the MIM-converted EQD2 doses demonstrated less than 5% difference for structures receiving more than 2Gy per fraction. In theory, EQD2 values should be greater than the doses from the hypofractionated treatment plan. Variations were observed with critical structures receiving fractional doses < 2 Gy. There is also disparity ($> 1\%$) between the hand calculated and derived EQD2 maximum and mean values for critical structures with a small volume. The MIM EQD2 is calculated per voxel and its handling of voxels within contours contributes to the discrepancy. A small change to the volume contributes to the discrepancy due to the software's preferences set to use "nearest neighbor" interpolation for datasets. **Conclusion:** MIM is a robust tool in evaluating hypofractionated treatment plans by converting to EQD2 doses to critical structures using traditional 2Gy/fxn constraints. Assessment of dose accumulated from hypofractionated and conventional plans with reference to one dataset is achievable, and the software makes for an easy workflow and rapid evaluation. While the EQD2 values are accurately calculated within the software, the user must exercise caution in cases when the fractional dose to a structure is ≤ 2 Gy. Acquiring a more comprehensive understanding of the way in which the EQD2 is applied to the dose cloud would be of additional benefit and begs further investigation into the software's handling of the EQD2 conversion and whether order of conversion matters.

PO-GePV-T-232

Evaluation of Bladder Dosimetric Property for Localized Prostate Cancer Using Deformable Registration of Simulation CT

C Ma*, X Zhang, Y Zhang, N Yue, X Wang, Rutgers University, New Brunswick, NJ

Purpose: To evaluate the dosimetric consequence caused by the inter-fractional variations in bladder during the prostate radiation therapy using deformable registration of simulation CT to Daily Cone-Beam CT (CBCT). **Methods:** Four patients who underwent volumetric modulated arc therapy (VMAT) for localized prostate cancer under RTOG 0126 protocol were chosen in this study, with total prescription dose of 7920 cGy delivered in 44 fractions in two stages. Patients were under daily CBCT guidance through the treatment course. To simulate the effect on consistent bladder under-filling, nine daily CBCT instances with smaller bladder volumes were selected for each patient, with seven selected for initial plan, and two selected for boost plan. For each instance, the simulation CT was deformably registered to daily CBCT image. During the registration, the shape of prostate and target region was preserved to stabilize the original planning ISO-center. The deformed simulation CT was then used to generate fractional dose distribution using original beam configuration. Finally, dose distributions from all nine instances were then deformed to the original simulation CT and summed up to generate the final accumulated dose distribution

through the radiation course. **Results:** The average reduction of the bladder volume among the four patients was $39.9\% \pm 12\%$ when compared with simulation CT. An increase was observed for bladder dose-volume parameters: for bladder V65Gy, the increase was $17.2\% \pm 11.6\%$; for bladder V75Gy, the increase was $15.8\% \pm 13\%$. **Conclusion:** A workflow has been developed to evaluate the accumulative dose through treatment course accounting for inter-fractional organ shape and position variations. Inconsistent bladder filling leads to increased bladder doses. It can be used to evaluate the dose-volume parameters variation due to inter-fractional bladder volume change and has the potential to guide future analysis of dose-volume relationship for bladder toxicity.

PO-GePV-T-233

Dosimetric Comparison of VMAT Prostate Plans Designed with 10MV Vs 18MV Photon Beams

D Shvydka¹, M Hajduk^{2*}, (1) University of Toledo Health Science Campus, Toledo, OH, (2) , University of Toledo Health Science Campus, Toledo, OH

Purpose: To compare prostate volumetrically modulated arc therapy (VMAT) treatments planned with 10MV vs 18MV photon beams to determine the practicality of 18 MV VMAT treatments. Recent studies indicate significantly lower than previously reported neutron doses associated with high-energy photon beams. **Methods:** Clinically delivered prostate patient treatments planned using a 10MV photon VMAT technique were selected and re-planned with 18MV photon beams. Both sets of plans were made to meet the same clinical goals and follow the same optimization constraints. The resultant plans were then compared across various criteria such as modulation factor, 50% isodose volume, and average dose to OARs. All treatments were planned in RayStation v8 utilizing clinically accepted beam model data. **Results:** All selected plans had the same prescription, and were treated on the same treatment machine. On average, 18MV photon plans were delivered with a ~17% lower modulation factor than the corresponding 10MV plans. The average 50% isodose volume of 18MV plans was found to be ~10 % larger than that of the 10MV treatments and average doses to the bladder and rectum were also larger on average. It was consistently observed however that in plans designed to treat larger patients 18MV photon plans were more likely to outperform their 10MV counterparts. **Conclusion:** On average treatments planned with 10 MV photons proved to be superior in 50% isodose volume and OAR averages doses. For larger patients 18MV prostate treatments are likely to produce dosimetrically preferable plans. Criteria used to distinguish that patient population will be presented. Since high-energy intensity-modulated treatments for prostate therapy may not be as detrimental as previously estimated, their place in clinical radiation therapy has to be firmly established.

PO-GePV-T-234

Evaluation of Two Different Dose Calculations Algorithms Between Two Treatment Planning Systems

J Martinez*, H Soysal, C Yang, University of Mississippi Medical Center, Jackson, MS

Purpose: To determine if there is any significant difference between two different dose calculation algorithms of two different treatment planning systems. **Methods:** Five Head and Neck VMAT plans generated in RayStation (version 9A) using collapsed cone algorithm were exported to and recalculated in Monaco (version 5.11.02) treatment planning system using Monte Carlo dose calculation algorithm. The five plans consisted of two arcs and each were recalculated on a Delta 4 QA phantom (Delta 4) with a voxel size of 3 mm. These calculated plans were compared to measurements using Delta 4. RayStation and Monaco algorithms were commissioned for an Elekta Versa HD Linac with Agility MLC and for 6 MV and 6 MV FFF photon beams. Point-dose measurements using a CC13 ion chamber in a large water tank were also taken to compare RayStation and Monaco calculated values. **Results:** Using 1% for the dose difference and 2mm for the DTA, the gamma analysis for the composite fields using Monaco was 94.0%, while for the convoluted cone was 90.3%. The two-tailed P value equals 0.037, which is statistically significant. Increasing up to 3% in dose difference and 3 mm in DTA, there was no statistically significant difference between the two calculations compared to measurements. For the point-dose measurements, RayStation showed less than 0.3% for different points, while Monaco showed 0.6% for 6 MV. For 6 MV FFF, Raystation showed 0.05% and Monaco 0.20% agreement for 17 different fields. **Conclusion:** The beam models in Monaco and RayStation are comparable when compared to point dose measurements. Monaco may generate a better dose agreement with measurement when using a tighter QA passing criteria than RayStation. However, they do not show a statistically significant difference in agreement between calculation and measurement when using the common passing criteria of 3% and 3 mm.

PO-GePV-T-235

Can a Seven-Day Subset of CBCTs Be Representative of All CBCTs When Reconstructing the Dose Delivered Over the Entire Course of Treatment for Prostate Bed Radiotherapy?

D Soliman^{1*}, M Noy², M Karp³, A Dal Pra³, E Bossart³, (1) University of Miami, Coral Gables, FL, (2) Florida International University, Miami, FL, (3) University of Miami, Miami, FL

Purpose: To determine if, for prostate bed treatment, generating synthetic CTs (sCT) from one daily cone-beam CT (CBCT) per week represents the average dose delivered to the patient over the full course of treatment. **Methods:** The planning CT plus 34 daily CBCT scans of a post-operative prostate bed patient were anonymized and sCTs were generated. The planning and organ at risk (OAR) volumes were deformed to the new sCT and checked for consistency. The treatment plan was recalculated on each of sCT. Single fraction Dose Volume Histogram (DVH) data was recorded for AnoRectum, Bladder, Body, Bowel, Femoral Heads, and Planning Target Volumes including prostate bed and pelvic lymph nodes. DVH data for all 34 fractions sCTs were averaged to get the treatment average daily dose to targets and OARs. Average DVHs were calculated for subsets of the sCT DVH data including for the first 7 days, the last 7 days, and every fifth day starting at day 1, 2, 3, and 4. ANOVA tests used to determine if the subgroup averages differed significantly from the average over all 34 fractions. **Results:** According to the ANOVA tests, which compared the subgroup averages to the total daily averages, the subset are not statistically different than the total average. For each structure, the p value was greater than 0.64. **Conclusion:** The recalculated DVH data for any of the checked 7 day subsets of the 34 sCTs were not significantly different than the average of the entire 34 fractions, so a once weekly subset appears to be an acceptable alternative to using the whole data set.

PO-GePV-T-236

A Comparison Study of AI Contouring and the Effect of Organ Tolerances and Reducing Dose Toxicity

K Melville^{1*}, R Patel², A Scott³, (1) East Carolina University, Greenville, NC, (2) Vidant Radiation Oncology, Greenville, NC, (3) Vidant Radiation Oncology

Purpose: To compare the use of standard contouring and AI contouring systems for use in Eclipse (Varian Medical Systems, Palo Alto, CA) treatment planning systems. **Methods:** Using the structures created by dosimetry and Limbus (Limbus AI, London, UK) and Mvision (Mvision AI, Helsinki, Finland) AI Systems, a comparison was performed to determine the dose toxicity difference in three head and neck patients chosen at random. Using the approved treatment plan, each set was applied to the plan. A dose volume histogram was generated for the brain, brainstem, mandible, oral cavity, and left and right parotids. The percent difference of the minimum, mean, and maximum dose (Gray) from the treatment structures were calculated and compared to determine if the dose toxicity would decrease using AI contouring. **Results:** The brain contour difference for the treatment plan, Limbus, and Mvision was under 5% difference for the minimum and maximum dose, however the mean for both systems were over 20%. The brainstem contour and mandible were under 5% for Mvision while Limbus was 10%. The mandible contour using Limbus was under 5% for the mean and max dose but the minimum was almost 10% different. The oral cavity contour using Limbus was under 5% (min) and 10-45% different (mean and max) while Mvision produced under 5% difference (min and max) but 10% difference for the mean. The parotid contours for both systems yielded a mean difference of over 10%, a min difference of under 5%, but the Limbus had a

max difference equal to 25% and MVision was under 5%. **Conclusion:** The use of AI contouring systems can reduce treatment planning time for patients and reduce dose toxicity. The MVision produced more contours that were within 5% of the treatment planning structure set while Limbus produced large differences of 10- 45%.

PO-GePV-T-237

Overlapping Volume Histogram (OVH) as a Tool for OAR Delineation Outliers Detection and DVH Prediction

T Teo^{1*}, M Gopalakrishnan², D Cutright³, I Das⁴, (1) Northwestern Memorial Hospital, Chicago, IL, (2) Northwestern Memorial Hospital, Chicago, IL, (3) University of Chicago Medicine, Chicago, IL, (4) Northwestern Memorial Hospital, Northwestern University Feinberg School of Medicine, Chicago, IL

Purpose: In contrast to conventional usage of OVH to determine the lowest feasible dose to an organ-at-risk (OAR), this study examines the feasibility of using OVH in detecting outliers incurred in the delineation of OARs in treatment plans, and determining the optimal OVH (amongst a large cohort of patient OVH) in predicting dosimetric DVH properties. **Methods:** An OVH characterizing the spatial relationship between the planning-target-volume (PTV) and an OAR was implemented by iteratively expanding the PTV, and determining the volume of overlap between the OAR and the expanded PTV. The OVH was determined for a cohort of 71 head-and-neck cancer cases. In evaluating the use of OVH as a tool for detecting outliers in OAR delineation, the OVH was applied to the entire data set and mean and median OVH from the OARs to PTV-1, -2, and -3 were evaluated along with the 1-standard-deviation of the OVH of all patient plans. Properties derived from the mean and median OVH profile were evaluated for accuracy in DVH prediction. **Results:** A smaller spread in the OVH curves, and a closer spacing between the mean and median OVH curves are observed for the serial organs (e.g. spinal cord) vs the parallel OARS (e.g. right parotids). For parallel organs, the OVH is confounded by the laterality of the OAR with respect to the PTV. The median OVH, which has a steeper gradient and lies close to the center of the OVH distribution, is relatively insensitive to outliers. Larger differences in the predicted DVH was observed between using mean and median OVH features for parallel organs. **Conclusion:** New insights on the sensitivity and feasibility of using OVH as a tool in detecting outliers of target contours is presented. Prediction of DVH for serial OAR is sensitive to features extracted from the mean and median OVH.

PO-GePV-T-238

To Assess the Impact of Bowel Gas Override on Pelvis Treatment Plans: Case Studies

V Chaswal^{*}, S Davis, J Contreras, R Tolakanahalli, Miami Cancer Institute, Miami, FL

Purpose: To assess the impact of bowel gas override on pelvis treatment plans as a contributor to overall treatment delivery uncertainty. **Methods:** Two VMAT pelvis plans for cervical carcinoma, on cases with noticeable bowel gas (BG) volumes (P1, 11.3% and P2, 27.3% gas in bowel bag) were optimized with mass density override (DO) of 0, 0.5 and 1 g/cc to get clinically acceptable plans. Each optimization was re-calculated with remaining 2 BG-DO overrides to assess the robustness of the optimization on varying bowel-gas conditions in-vivo. PTV coverage metrics of V100%, Dmax(0.03cc) and Dmin(0.03cc) and OAR metrics of Bowel Dmax(0.03cc) and V40Gy and Sigmoid V45Gy were chosen for comparing the studies. **Results:** Impact of BG-DO on PTV (V100) was low - in the worst case scenario of no BGO at optimization and recalculated with DO of 1 g/cc, the coverage dropped 2.2% on P1 and 3.8% on P2. Plans optimized with BG-DO of 1 g/cc are least variant (~0.5%) to changes in bowel gas. Changes in bowel gas with DO of 0.5 g/cc resulted in [-4.6%- 1.3%] difference in MinD0.03cc within the PTV. Impact of DO had a maximum change of 2% on D0.03cc for bowel. On P2, all 3 optimizations resulted in 4-6% variation on V40Gy for bowel as compared to <1% on P1. Impact of BGO on sigmoid V45 was substantial on both plans resulting in >7% variation. However, Sigmoid V44Gy was less sensitive to changes in bowel gas. **Conclusion:** Impact of bowel gas in overall treatment delivery uncertainty is of the order of 2-4% on PTV coverage. It is <2% for bowel itself, and OARs overlapping with PTV and in-plane with bowel should be evaluated on less sensitive metrics for robust planning.

PO-GePV-T-239

API Driven Plan Scorecard Designer for the Evaluation of External Beam Planning Quality

M Schmidt^{1,3*}, M Folkerts², C Abraham¹, B Baumann¹, N Knutson¹, F Reynoso¹, E Pryser¹, E Sajo³, P Zygmanski⁴, M Jandel³, A Magliari², (1) Washington University School of Medicine in St. Louis, Saint Louis, MO, (2) Varian Medical Systems, Palo Alto, CA (3) University of Massachusetts Lowell, Lowell, MA, (4) Brigham & Women's Hospital, Boston, MA

Purpose: Treatment plan quality for external beam radiation therapy contains several quantifiable metrics that may assist the clinician in evaluating dosimetric plan quality. Metric points along the dose-volume histogram (DVH) curves and other calculated metrics can provide assessment to the normal tissue organ sparing and target coverage. A single quantifiable metric, the plan score, can be used to determine plan quality from multiple dose quality parameters and has shown efficacy in plan quality events such as planning competitions and knowledge-based DVH estimation algorithm refinement. **Methods:** An integrated planning scorecard tool, the Eclipse Plan Scorecard (EPS) allows for the generation of custom plan scorecard templates and the import of templates from commercial plan scoring software applications. EPS allows for users to generate evaluation structures automatically and graphically displays plan scoring metrics to the user. To evaluate the scoring functionality, the score for several plans were evaluated against a commercial plan evaluation tool with scorecard functionality. **Results:** The plan scores for 8 patients were extracted by generating scorecard templates within the EPS and comparing them to existing scorecards from ProKnow. The percentage difference across the 8 plans ranged from -3.16% to 2.42% with a mean percentage difference of -0.15% across all plans. Sampling differences between the DVH extracted with ESAPI and the DICOM dose file used by ProKnow leads to minor discrepancies in the reported plan score. **Conclusion:** Integrating a planning scorecard into the treatment planning system allows for the immediate extraction of dosimetric quality parameters and an overall score, thereby facilitating the immediate review of plan quality and improvement across planning iterations.

Mr. Schmidt reports teaching honoraria outside of the submitted work and personal consulting fees with Varian Medical Systems associated with the submitted work.

PO-GePV-T-240

The Use of Daily Transit Dosimetry to Monitor Anatomy Changes and Setup Errors in Prone Breast Radiotherapy

X Shen^{1*}, S Hsu^{1,2}, D Mynampati¹, P Brodin^{1,2}, A Basavatia¹, J Fox^{1,2}, W Tome^{1,2}, (1) Montefiore Medical Center, Bronx, NY, (2) Albert Einstein College of Medicine, Bronx, NY

Purpose: To investigate the use of daily transit dosimetry to monitor anatomy changes and setup errors in prone breast radiotherapy. **Methods:** Five breast cancer patients treated with 3D tangential fields were retrospectively studied. All patients were treated prone and received 42.4-Gy in 16 fractions to the whole breast. Transit dosimetry and kVCBCT were acquired at each fraction. Using the field border structure on planning CT, PTV_CBCT was generated for each fraction same way as clinical planning PTV. Plans were recalculated on CBCT scans and the mean doses to PTV_CBCT were recorded. A reference PTV_CBCT was selected from the first three fractions, and absolute mean dose difference (AMDD) was calculated for each fraction. Transit doses were compared to the reference fraction dose using mean absolute error (MAE) in percentage within a region of interest defined by the planning PTV with 3 cm expansion to account for the daily breast motion. The AMDD in PTV_CBCT was evaluated as a function of MAE in transit dosimetry. **Results:** The median AMDD from all fractions ranges from 0.8% to 6.2% for five cases. While one case overall has larger AMDD ranging from 1.1% to 9.6%, other cases have

AMDD within 3%. The median MAE for all cases ranges from 3.4% to 11.3%. The same case mentioned above also has the largest MAE with a range of 6.6% - 16.2%, when other cases have MAE within 11%. In general, AMDD increases as MAE increases with a R2 value of 0.6102 using a linear regression fitting on all cases. **Conclusion:** Our study demonstrated a potential of using daily transit dosimetry to track anatomy changes and setup errors in prone breast radiotherapy. Current results suggest a threshold of 10% in MAE indicates setup position check or adaptive planning. Future work will include more patients including supine breast cases.

PO-GePV-T-241

Evaluating Bladder and Rectum Doses for Cervical Cancer Based on Dose Guided Radiation Therapy Using Kilovoltage Cone-Beam Computed Tomography

C Deng*, J Zhang, Cancer Hospital of Shantou University Medical College, Shantou, CN

Purpose: The bladder and rectum filling change causes uncertainty in radiation doses for cervical cancer patients. To estimate the bladder and rectum doses for cervical cancer patients with dose guided radiation therapy (DGRT) using weekly kilovoltage cone-beam computed tomography (KV-CBCT). **Methods:** Six cervical cancer patients were included in this study. All patients were required to have a full bladder for the planning CT and weekly KV-CBCT scan. In our hospital, weekly three-dimensional images of patients in treatment position are acquired for image-guided radiation therapy with KV-CBCT. In each KV-CBCT study, the bladder and rectum volumes were delineated and matched to the planning CT scan to appraise the volume change. These images can be used for calculating the actual dose delivered to the patient during treatment. The histogram matching algorithm was used for calibrating the KV-CBCT images. The treatment plans were recalculated on the KV-CBCT scans. Dose volume histograms were used to analyze the dose distribution in the bladder and rectum during each KV-CBCT scan. **Results:** The mean volume of the bladder delineated on weekly CBCT image was 390.5 ± 154.9 cc (range 130.1-541.9cc), and the mean rectum volume was 30.9 ± 7.1 cc (range 25.7-43.3cc). There was a large variation in rectum and bladder volume based on the weekly KV-CBCT image. The bladder and rectum received V40Gy were $61.3 \pm 8.2\%$ (range 47.8-72.9%) and $33.2 \pm 8.8\%$ (range 19.7-41.9%), respectively; and V45Gy of the bladder and rectum were $47.8 \pm 6.2\%$ (range 41.5-57.8%) and $4.9 \pm 2.6\%$ (range 0.93-7.8%), respectively. **Conclusion:** Considering the large changes of bladder and rectum volumes in the inter-fractional treatment, it is strongly suggested to perform in-room bladder volume measurements, using a 3D ultrasound scanner. DGRT can be used to determine the actual dose in the bladder and rectum using weekly KV-CBCT scan.

PO-GePV-T-242

A Comparison of Modulated Planning Techniques for Whole Brain Hippocampal-Avoidance Radiotherapy

E Viviers*, P Johnson, University of Florida Health Proton Therapy Institute, Jacksonville, FL

Purpose: Whole brain radiotherapy is a widely utilized palliative option for patients with brain metastases. Despite improving overall survival, associated reductions in cognitive function have a significant impact on quality of life. Hippocampal avoidance whole brain radiotherapy can delay the onset of neurocognitive decline. A planning technique published in 2015 demonstrated a class solution by partitioning the brain into sub-volumes and utilizing a VMAT split arc technique. The current study investigates an application of this technique, with simplified sub-volumes, for five clinical cases, with a comparison to alternative modulated techniques. **Methods:** Five patients who previously received hippocampal avoidance whole brain radiotherapy were selected for this retrospective planning study. The hippocampal avoidance region (HA) was a 5mm expansion of the hippocampi. The planning target volume (PTV) was the whole brain minus the HA region. The PTV was partitioned into three volumes: superior; mid; and inferior to the HA. Raystation was used to generate plans using the split VMAT technique, VMAT coplanar arcs, VMAT non-coplanar arcs and IMRT. The optimization prioritized dose homogeneity on the superior and inferior volumes. Dose falloff adjacent to the hippocampi was prioritized in the PTV mid-volume. Dose metrics and DVH data were used to assess plan quality. VMAT plans were perturbed in orthogonal directions to assess robustness. **Results:** PTV partitioning and standardized optimization parameters were able to meet dosimetric goals. VMAT delivered a more homogenous dose to the brain than IMRT. The VMAT split field was able to provide superior hippocampal avoidance and homogeneity. This technique resulted in the most robust plans under simulated setup variations. **Conclusion:** A simple split field VMAT technique consistently produces plans with superior homogeneity and hippocampal sparing. This technique does not require couch rotation and is relatively robust, which results in a simple plan delivery to patients who are often medically compromised.

PO-GePV-T-243

Dosimetric Comparison of the New Pinnacle Evolution Versus Pinnacle Version 16.2

M Naessig*, N Kirby, B Brown, C Kalu, A Woodin, J Gonzales, N Reyes III, P Myers, UT Health San Antonio MD Anderson Cancer Center, San Antonio, TX

Purpose: To investigate the optimization performance of two different versions, v16.2 and v16.4.2, of the Pinnacle Treatment Planning System by evaluating treatment plans and analyzing their dosimetric difference. **Methods:** For 25 patients, two VMAT plans were generated with the same beam setup and optimization goals for the targets and OARs: one with Pinnacle v16.2 and one with Pinnacle v16.4.2. The patients were planned for the following sites: brain, lung, head and neck (HN), pelvis, and prostate with 5 patients per site. The optimization time was limited to one hour for each plan. After the plans were completed, both systems were adjusted to have the same V100 value for comparison. **Results:** Pinnacle v16.2 provided a better conformity index ($CI = TV_{PIV}/TV$) with a mean value of 1.1003 when considering all treatment sites compared to v16.4.2, which had a mean of 1.1335. The homogeneity index ($HI = I_{max}/I$) was closer to 1 for v16.4.2 with a mean value of 1.1213. The gradient index ($GI = V50\%/V100\%$) was superior for lung, HN, and prostate patients for v16.4.2 plans, however when all sites were evaluated the GI was better for v16.2 plans with a mean value of 4.3677 compared to 4.4158 for v16.4.2. When analyzing individual sites, the CI was closer to 1 in four out of five sites when the plan was created using v16.2. Pinnacle v16.4.2 allowed for a greater number of optimizations within the one hour time limit, but it was noted that a higher amount of dose constraints were not met for the v16.4.2 plans, specifically for prostate, brain, and lung patients. **Conclusion:** For multiple treatment sites, VMAT treatment plans optimized within 1 hour using Pinnacle TPS v16.2 and v16.2.4 consisting of the same setup were found to be reasonably comparable. Further investigations involving more data points and evaluating other plan quality metrics are in progress.

PO-GePV-T-244

Investigating the Differences Between PlanIQ and IPA Planning Tools for Plan Optimization in Head & Neck Cancers

C Kabat¹*, S Stathakis¹, H Parenica¹, N Papanikolaou¹, S Das², B Chera², P Mavroidis², (1) UT Health San Antonio MD Anderson Cancer Center, San Antonio, Texas, (2) University of North Carolina, Chapel Hill, NC

Purpose: To investigate treatment plan guidance for head and neck cancers via the feasibility tool PlanIQ (Sun Nuclear) and an open-source Ideal Planning Assistant (IPA) application. **Methods:** Three patients with oropharyngeal squamous cell carcinoma were used to generate two sets of DVH guidance values for simultaneous integrated boost (SIB) treatment plans. In each case, 60Gy and 54Gy were prescribed to the high and standard risk PTVs. The PlanIQ feasibility tool generated values for the feasibility of 0.0, 0.1, and 0.5 for each OAR. To obtain similar feasibility values in the IPA application each OAR structure was pushed to the 90% value, providing a comparable 0.1 feasibility. Both tools assumed a 100% coverage of the PTVs with the prescription doses. **Results:** At the regions of maximum doses and dose cutoffs (OAR - target overlap regions) both tools showed good agreement in predicting high difficulty of feasibility.

However, lower doses for PlanIQ demonstrated the potential for greater sparing. For example, for the left and right parotids, planIQ indicates an average D50% 10.2Gy vs. 23.1Gy of IPA and 10.2Gy vs. 21.1Gy, respectively. Also, for the constrictors, PlanIQ indicates an average mean dose 26.3Gy vs. 45.2Gy of IPA. Those deviations mainly stem from the fact that PlanIQ accounts only for the target volume and OAR correlation, while PlanIQ considers the target volume in addition to dose sparing on all other defined OARs. **Conclusion:** The comparison of PlanIQ and IPA showed good agreement in the high doses but significant differences in the middle and lower dose region. The results reflect their fundamental approaches since planIQ calculates its feasibility doses without considering any tradeoffs between the OARs, whereas IPA accounts for OAR to OAR dose tradeoffs to achieve a balanced sparing between organs.

PO-GePV-T-245

Preliminary Patient Specific Dose Constraints of Rectum for Prostate Cancer Treatment

J Zhang^{1*}, B Lee², W Inouye³, R Kwon³, W Lien¹, (1) Southern California Permanente Medical Group, Los Angeles, CA (2) 2. Loma Linda University Medical Center, Loma Linda, CA, (3) VA Long Beach Healthcare System, Long Beach, CA

Purpose: External beam radiation therapy has gained popularity in treating prostate tumors. This study aims to re-evaluate the rectum dose constraints from conventional prostate treatment plans. **Methods:** RTOG 0924 protocol has been used as the guideline for the treatment plan with dose prescription, rectum contour and dose constraints. There were 41 patients treated during the period from May 2016 to Feb 2018 following RTGO 0924 protocol. Assume the proctitis is related to the relative high dose area in the rectum wall during the prostate treatment. Three volumes were used for the dose constraints re-evaluation: PTV prostate, Rectum and Rectum wall (R-wall-5mm-3cm) defined as 5mm outer wall of rectum structure within 3cm from the PTV prostate. RTOG 0924 recommended the rectum dose constraints as relative volume dose constraints such as V70<15%. As individual prostate patient has different prostate volume (also different overlap length with rectum in SI direction) and different total rectum volume, patient-specific rectum dose constraints were made here and used for re-evaluation. For all 41 prostate patients, the volumes of PTV prostate, R-wall-5mm-3cm and Rectum are 146.10cc, 37.75cc and 99.41cc respectively. The ratio of R-wall-5mm-3cm and PTV prostate volume and ratio of rectum and PTV prostate volume were used for patient specific rectum dose constraints re-evaluation. **Results:** The ratio of R-wall-5mm-3cm and PTV prostate volume is 0.29±0.09. And the ratio of rectum and PTV prostate volume is 0.80±0.50. The second ratio is in a very large random range. Therefore, it's hard to predict the side effect based on the relative volume dose constraints. **Conclusion:** This study showed that, for prostate radiation therapy, 1) patient-specific dose constraints are vital for individual patients and 2) the organ at risk for the dose constraints need re-evaluation.

PO-GePV-T-246

Evaluation of An Angle Optimization Algorithm in Breast Cancer Treatment Planning

Y Guo*, Y Fang, J Wang, J Zhao, W Hu, Fudan University Shanghai Cancer Center, Shanghai, ShanghaiCN

Purpose: To evaluation a commercial automatic beam angle optimization (BAO) algorithm in breast cancer radiotherapy. **Methods:** Twenty-one patients who previously treated with radiotherapy and breast conserving surgery were enrolled in this study, including 10 patients with left breast cancer and 11 with right breast cancer. Among these patients, 11 were treated with prescription dose 48Gy, 10 were treated with prescription dose 50Gy. For each patient, two IMRT plans were developed with different set of beams angles. One set of beams angles was generated by an automatic beam angle optimization and the other was manually set by physicists. The algorithm was developed by United Image (Shanghai, China) which was based on a new Multi-stage optimization approach. The Method introduces Branch-and-Prune to generate a feasible solution in the first phase. A simplex method is applied to find a local optimal solution from the Phase I starting point in the second phase. Both two plans were generated on UIH TPS (United Imaging, Shanghai, China) and use same number of beams, prescription and optimization constraint objective. The maximum dose (Dmax), homogeneity and conformity Index (HI, CI) of PTV and mean doses of relevant organs-at-risk (OARs) were compared. **Results:** There were no significant different in PTV Dmax, HI and CI for two plans (p>0.05). In terms of OARs, BAO plans achieved less value in ipsilateral lung V5 (35.5%±5.6%) compared to manual beam angle plans (36.9%±4.3%, P=0.034). There were no significant different in ipsilateral lung V20 and heart mean dose (p>0.05). No significant different were observed for all contralateral lung and contralateral breast dose volume indices. **Conclusion:** The UIH automatic beam angle optimization algorithm can achieve comparable quality plans compared to manual beam angles plans.

PO-GePV-T-247

Planning Strategies for Whole Head-And-Neck Radiation with Robustness Against Shoulder Motion Using Volumetric-Modulated Arc Therapy

J Cammin^{1*}, T Bouton², E Chacko², B Zhang¹, S Chen¹, J Molitoris¹, B Yi¹, (1) University of Maryland, Baltimore, MD, (2) Maryland Proton Treatment Center, Baltimore, MD

Purpose: To investigate planning strategies for head-and-neck radiation using volumetric-modulated arc therapy with robustness against interfractional shoulder motion and to evaluate each approach for reduction of shoulder dose and planning efficiency. **Methods:** Ten patients were randomly selected for planning in RayStation v10A. Clinical plans served as base plans and had no mechanism for robustness against interfractional shoulder motion. Plan variations included the following: 'shoulder-protect': using a feature in the TPS that closes the MLC leaves over a selected structure to avoid entrance dose, and 'shoulder-PRV': adding shoulder-avoid structures to the optimizer. Two patients were also planned using 'skip-arcs': partial arcs which skip the segments around the shoulders, 'shifted-iso': shifting the isocenter and utilizing beam divergence to avoid beams passing through the shoulders, and 'couch-kicks': using couch rotations to avoid the shoulders. Plans were evaluated for target coverage, shoulder sparing, OAR doses and planning efficiency. **Results:** V95 target coverage for all variations was within 2% of the base plan. All variations achieved lower mean shoulder dose relative to the base plan: 73%(shoulder-protect), 71%(shoulder-PRV), 80%(skip-arcs), 94%(shifted-iso), 59%(couch-kicks); however, the dose to 1% of the shoulder structures (D1 shoulder) increased relative to the base plan: 113%(shoulder-protect), 107%(shoulder-PRV), 109%(skip-arcs), 103%(shifted-iso), 104%(couch-kicks). The complexity metric (ratio of MU's over prescription dose) remained similar, except for an increase for the 'shoulder-PRV' approach(109%) and a reduction with the 'couch-kick' approach(88%). Dose homogeneity increased for the 'shoulder-protect'(108%) and 'shoulder-PRV'(106%) variations and decreased for the 'skip-arcs'(90%), 'shifted-iso'(94%), and 'couch-kick'(99%) variations. The 'shoulder-PRV' variation required the least amount of manual adjustments and planning time. **Conclusion:** Adding shoulder-avoid structures directly to the optimizer was found to be the best compromise between increased plan robustness against interfractional shoulder motion and increased planning complexity. More cases will be studied in the future to confirm the statistical significance of the findings.

PO-GePV-T-248

Dosimetric Study for Spine SRT Plans with Carbon Fiber Stabilization Devices

H Lee*, J D. Palmer, A S. Ayan, Ohio State University, Columbus, OH

Purpose: Presence of metal stabilization devices causes several issues in radiotherapy including imaging artifacts, possible dosimetric discrepancy and beam energy limitation. Carbon-Fiber Reinforced Polyetherthetketone (CFR-PEEK) material has been a potential alternative fixation with its radiolucency, and strength comparable to commonly used titanium devices. Previous studies have only focused on the dosimetric comparison for the screws themselves which are only part of the fixations. In this study, we present the dosimetric comparisons between the plans and the measurements on radiochromic films using a bone phantom with the entire CFR-PEEK fixations. **Methods:** CT scans were obtained with a specially designed bone phantom with CFR-PEEK fixations under

water phantoms representing neck and abdomen. The bone phantom was designed to resemble the shape and the HU values of vertebrae and spinal cord inside. A bone density phantom was scanned with the bone phantom for calibration. The bone phantom consists of two pieces, between which a film was placed for dosimetry measurement. Three stereotactic radiation plans were generated with mock targets near the fixations (one for neck and two for abdomen) and delivered to the bone phantom and the fixations. Coronal dose profiles were acquired with radiochromic films to evaluate the dose differences. **Results:** CFR-PEEK fixations did not determine any HU artifacts on CT images resulting in better image quality and easier delineation. The coronal profiles compared between the plans and measurements showed a reasonable agreement. **Conclusion:** This work evaluated dosimetric profiles on plans and measurements on CFR-PEEK fixations with a bone phantom. It demonstrated that the fixations provide better image quality and reduced dose uncertainty in target near the fixations. Further comparison with metal fixations is warranted.

PO-GePV-T-249

The Feasibility Study of Using Light Detection and Ranging (LiDAR) Application for Total Body Irradiation (TBI)

B Yeager*, F Mostafaei, M Gagne, J Barrett, A Al-Basheer, Augusta University, Department of Radiation Oncology, Augusta, GA

Purpose: This study aims to evaluate the feasibility of obtaining TBI patient specific measurements from available technology, specifically, LiDAR, on Apple iOS hardware and software application. The off-axis distance, reference plane distance, and patient field separations were measured with different devices for various anatomical sites according to our institutions TBI policy to determine monitor units (MU) and compare the differences. **Methods:** A direct comparison between standard measurement devices, caliper or measuring tape, and the Apple iPhone® iOS application was performed. To test the capability of LiDAR application and the effect of room light on application's performance, a 30cm and 15.2cm lengths were evaluated using a measuring tape and a ruler in horizontal and vertical setups. Vertical measurements were used to determine the distance limit in one-meter increments. To remove inherent motion of the device being hand-held, and the effect of room light on the software's capability, a 3D printed stand, a linear motion slide (Accuride International, Santa Fe Springs, CA), and a digital lux meter (Dr. Meter, Union City, CA) were utilized in house. **Results:** Considering the LiDAR application limitations (+/-1 cm), positioning, and motion effect, LiDAR measurements showed reasonable agreement with standard measuring tools. (+/-1 cm). Although stationary measurement was accurate with +/-1 cm, the LiDAR application was unable to report sub-centimeter and unable to define a starting point for the 15.2cm ruler at 4 meters. By calculating MU using the off-axis distance, reference plane distance, and patient field separations measured from the volunteers, agreement within 5% difference were found (2133 MU using standard tape measure vs. 2245 MU using LiDAR application). However, there are always random uncertainties with measuring and positioning volunteers/patients. **Conclusion:** The feasibility of the iOS application accuracy as compared to the standard tape measure has been demonstrated. Comparable measurements were obtained but great care must be taken when utilizing LiDAR.

PO-GePV-T-250

Extending the Body Outline Out into the Air to Improve the Superficial Dose Evaluation Accuracy for Breast Cancer Intensity Modulated Radiotherapy

Q Jiang*, W Huang, X Yi, W Lu, H Cui, J Dang, Y Li, The First Affiliated Hospital of Chongqing Medical University, Chongqing, China

Purpose: The superficial dose for breast cancer patients are usually underestimated by the irradiation treatment planning system (TPS) due to ignore the dose contribution which come from out of the body outline. This research aims to explore a reasonable body contouring method to improve the superficial dose evaluation accuracy for breast cancer intensity modulated radiotherapy (IMRT). **Methods:** Twelve modified radical mastectomy cases were involved. Automatic contour the outline of body with threshold value -350HU, then add 1cm margin along the planning target volume (PTV) anterior edge. 7 fields IMRT plans were designed to meet the clinical requirement. Duplicate the plan and recontouring the body with the threshold value of -350HU, then keep the fields and fluence as the same as the previous one and recalculate the new plan. Analyze the dose coverage difference of the PTV and OARs between the two groups. For one typical modified radical mastectomy case, the automatic contouring threshold value was set as -350HU, -650HU, -650HU plus 1cm margin, respectively. The superficial dose change with different distance by incident and exiting directions was analyzed. Plans were designed by Varian Eclipse TPS version 13.5. **Results:** The dose difference under the skin is much smaller than in the air. The trend is more obvious in exiting direction than in incident direction. The 1cm margin group have a much better target dose coverage than -350HU group. The PTV dose parameter V95% (99.2%±1.14 vs 96.8%±3.26), V100% (94.8%±3.53 vs. 88.7%±5.87), D98% (46.7±0.84 vs 39.6±6.54, Gy), CI (0.78±0.06 vs 0.68±0.03), HI (0.12±0.02 vs. 0.26±0.13), all P<0.05. All the OARs irradiation dose has no difference. **Conclusion:** Add 1cm margin to the body outline could represent the real irradiation environment in TPS, as thus to improve the superficial dose evaluation accuracy for breast IMRT. Especially for the case which PTV was contoured align the body surface.

PO-GePV-T-251

Conformal Radiotherapy with Sequential Boost Versus Intensity-Modulated Radiation Therapy with a Simultaneously Integrated Boost

G Komisopoulou*, M Tolia², A Siountas¹, S Stathakis³, N Papanikolaou³, P Mavroidis⁴, (1) Laboratory of Medical Physics, School Of Medicine, Aristotle University Of Thessaloniki, Greece, (2) Department Of Radiation Therapy, University Of Crete, Herakleion, Greece, (3) UT Health San Antonio MD Anderson Cancer Center, San Antonio, Texas, (4) UT Health San Antonio MD Anderson Cancer Center, San Antonio, Texas, (6) University of North Carolina, Chapel Hill, NC

Purpose: The purpose of this study is to compare the dosimetric and radiobiological differences between conformal radiotherapy (CRT) to the whole breast with sequential boost to the primary tumor and intensity-modulated radiation therapy (IMRT) to the whole breast with simultaneously integrated boost to the primary tumor. **Methods:** This study included 5 primary left-sided breast cancer patients. In total 5 CRT plans and 5 IMRT plans were created. In the CRT plans the whole breast receives a dose of 50Gy in 25 fractions with a sequential boost to the primary tumour of 10Gy in 5 fractions. In the IMRT plans the whole breast receives 50Gy and the primary tumor 60Gy in 25 fractions. Each plan was evaluated in terms of PTV coverage, primary tumour conformity index, maximum plan dose, ipsilateral lung dose (mean, V20), heart dose (mean, V5), contralateral breast doses and spinal cord dose. The doses of the respective plans were compared between each other and against the clinical goals. Furthermore, the respective tumor control and normal tissues complication probabilities (TCP and NTCP) were calculated. **Results:** IMRT created more conformal plans in all cases, (conformity index: average CRT = 0.33, IMRT = 0.76). CRT plans delivered lower mean heart doses in all cases (average CRT = 2.2Gy, IMRT = 2.8Gy). CRT plans delivered higher mean ipsilateral lung doses in 4 of 5 cases (average CRT = 6.8Gy, IMRT = 6.3Gy) and V20Gy in 4 of 5 cases (average CRT = 11.0%, IMRT = 10.1%). The NTCP values of ipsilateral lung and heart were lower for IMRT than CRT (0.02% and 0.0% vs. 0.04% and 0.23%, respectively). **Conclusion:** IMRT produced plans of superior dose conformity, lower NTCP values and shorter treatment duration at the expense of slightly higher maximum doses to contralateral breast and spinal cord.

PO-GePV-T-252

Dosimetric Impact of Multi-Leaf Collimator Positional Errors on Standard-Fractionated and Hypofractionated Radiotherapy Using Flattened and Flattening Filter-Free Beams

H Enomoto^{1,3*}, Y Fujita², S Matsumoto¹, T Ebara⁴, A Tonari⁴, Y Maruyama¹, A Nakanishi¹ (1) Department of Radiology, Kyorin University Hospital, JP (2) Komazawa University, JP (3) Radiological Sciences, Graduate Division of Health Sciences, Komazawa University, JP (4) Department of Radiation Oncology, Kyorin University Hospital, JP

Purpose: This study investigated the dosimetric impact of multi-leaf collimator (MLC) positional errors and determined the desired MLC positional accuracy for flattened (FF) and flattening filter-free (FFF) beams in standard-fractionated and hypofractionated radiotherapy. **Methods:** Eighty patients (20 each for treatment site) with prostate cancer, lung cancer, brain metastases, or spinal metastases were evaluated. Standard-fractionated and hypofractionated (2 and 7.25, 2 and 13, 4.2 and 10, and 3 and 16 Gy per fraction for prostate, lung, brain metastases and spinal metastases, respectively) volumetric-modulated arc therapy (VMAT) plans were generated using FF and FFF beams. Systematic open/closed MLC positional errors (± 0.25 , 0.5 , 1.0 , and 2.0 mm in opposite directions) were introduced in the VMAT plans. The dosimetric impact for the targets and organs-at-risk (OARs) were evaluated based on the generalized equivalent uniform dose (gEUD). **Results:** The gEUD deviations with MLC errors of the target volumes were strongly dependent on treatment site (2.46 ± 0.38 , 4.47 ± 0.88 , 1.74 ± 0.46 and 6.61 ± 1.25 %/mm for prostate, lung, brain, and spine metastases, respectively). The beam modality and dose per fraction had less impact on the gEUD of the target volumes. Among OARs, the gEUD deviations with MLC errors were strongly dependent on the dose per fraction (average 1.28 ± 0.29 and 1.29 ± 0.30 %/mm in prostate and spinal metastases) except for lung and brain metastases (average 0.06 ± 0.03 , and 0.14 ± 0.17 Gy/mm, respectively). Maintaining the target to within 2% corresponded to within 0.63, 0.42, 0.81, and 0.27 mm for prostate, lung, spinal metastases, and brain metastases, respectively. **Conclusion:** Since the dose errors due to MLC positional errors for VMAT may depend on the treatment sites, beam modalities (FF and FFF beams), and doses per fraction, these should be considered for quality assurance.

PO-GePV-T-253

Treatment of Large-Size Prostate Cancer Patients On An O-Ring Linac with 6MV FFF: Plan Quality Comparison with a C-Arm Linac Using 10MV Or 15MV Photons

B Liu^{1*}, C Cheng¹, X Wang¹, J Zhu¹, R Parikh¹, K Nie¹, N Yue¹, Y Zhang¹, (1) Rutgers Cancer Institute of New Jersey, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ

Purpose: To evaluate the dosimetric performance of the Halcyon Linac equipped with 6MV FFF photon beam in planning for large-size prostate cancer patients, compared to TrueBeam with Millennium MLC using 10MV or 15MV photons. **Methods:** Eight large-size prostate cancer patients ($BMI = 27.7 \pm 2.2$ kg/m² and pelvis lateral separation = 36.3 ± 1.1 cm) were retrospectively included in the treatment planning study. The dose prescription (79.2Gy to prostate and proximal seminal vesicles in 44 fractions) and clinical planning objectives were defined as in RTOG 0126. Halcyon and TrueBeam plans were optimized using 3 full arcs. For each patient, three plans were developed: Halcyon plan with 6MV FFF (Hal), TrueBeam plan with 10MV (TB-10X), and TrueBeam plan with 15MV (TB-15X). The plans were normalized so that prescription isodose surface covers 98% of the PTV volume. **Results:** The dosimetric parameters of all plans are meeting RTOG 0126 objectives. The Dmax of all plans are below 107% of prescription dose, and no difference of Dmax was observed among Hal, TB-10X and TB-15X. The V75Gy, V70Gy, V65Gy, and V60Gy of rectum on Hal are: $11.5\% \pm 3.6\%$, $17.8\% \pm 5.5\%$, $23.9\% \pm 7.0\%$, and $30.8\% \pm 8.4\%$, respectively; on TB-10X are: $11.1\% \pm 3.7\%$, $17.1\% \pm 5.6\%$, $23.1\% \pm 7.3\%$, and $29.9\% \pm 8.9\%$, respectively; on TB-15X are: $11.2\% \pm 3.7\%$, $17.3\% \pm 5.6\%$, $23.5\% \pm 7.1\%$, and $30.6\% \pm 8.6\%$, respectively. The V80Gy, V75Gy, V70Gy, V65Gy of bladder on Hal are: $4.3\% \pm 3.6\%$, $8.4\% \pm 6.7\%$, $11.5\% \pm 8.9\%$, and $14.6\% \pm 11.0\%$, respectively; on TB-10X are: $4.2\% \pm 3.6\%$, $8.2\% \pm 6.7\%$, $11.2\% \pm 9.0\%$, and $14.2\% \pm 11.1\%$, respectively; and on TB-15X are: $4.2\% \pm 3.5\%$, $8.1\% \pm 6.8\%$, $11.2\% \pm 9.1\%$, and $14.2\% \pm 11.3\%$, respectively. The mean penile bulb doses are: $19.9\text{Gy} \pm 8.5\text{Gy}$, $16.2\text{Gy} \pm 6.7\text{Gy}$, and $16.3\text{Gy} \pm 7.0\text{Gy}$, respectively for Hal, TB-10X, and TB-15X. **Conclusion:** This retrospective treatment planning study, based on the dose constraints derived from RTOG 0126 protocol, suggested that the essential equivalence between Halcyon plan using 6MV FFF and TrueBeam plans using 10MV/15MV for the arc treatment of large-size prostate cancer patients.

PO-GePV-T-254

The Future Is Here: An Inter-Comparative Study of AI and Human-Generated Plans Using Dosimetric Indices as a Guide to Plan Efficacy

S Pokharel^{*}, A Pacheco, S Tanner, GenesisCare, Naples, FL

Purpose: The purpose of this study is to assess the efficacy of Artificial Intelligence (AI)-generated treatment plans using Varian Ethos system. **Methods:** Six large field pelvic/abdomen sites, treated with Varian Ethos v.2.0, were chosen for the present study. Ethos created 2 VMAT and 3 IMRT AI-driven plans for these cases, based on priority goals in the RT intent and the user chose the most optimal plan. For all cases, IMRT plans were dosimetrically superior to VMAT plans and were selected for treatment. Typically, these cases would have been treated using VMAT in Eclipse. Ethos VMAT plans were exported to Eclipse v.16.1 and optimized by an experienced dosimetrist, using the same treatment geometry. All plans were calculated for dose using AcurosXB and were normalized, such that, 95% of the PTV received 100% of the prescription dose. **Results:** Global maximum doses for Ethos vs. Eclipse plans were 114.6% vs. 114.1% , respectively. PTV indices (D98/D50/D2) for Ethos vs. Eclipse VMAT plans were 98.3% vs. 98.4% , 104.2% vs. 105.0% , and 108.3% vs. 109.4% , respectively. Conformity and Homogeneity indices for Ethos and Eclipse plans were 1.06 vs. 1.08 , and 0.10 vs. 0.10 , respectively. On average, total plan monitor units were 985.7 and 946.2 for Ethos and Eclipse plans, respectively. Based on RTOG criterion, specific to the organ in question, both sets of plans were deemed to be clinically acceptable. **Conclusion:** Varian AI-driven Ethos system creates highly-modulated IMRT plans that are comparable or superior to conventional IMRT plans generated by dosimetrists. VMAT plans from Ethos are not as good as their IMRT plans but comparable to typical VMAT plans created in Eclipse. The inferiority of Ethos VMAT plans seems to be systemic. It appears AI VMAT plans are not running sufficient iterations due to time constraints and, therefore, plans are being trapped in local minima.

PO-GePV-T-255

Are Auto-Generated Organ-At-Risk Contours Good Enough in Prostate Radiotherapy?

H Liu^{*}, B Sintay, D Wiant, Cone Health, Greensboro, NC

Purpose: Precision manual contouring is a time- and labor-intensive process for radiotherapy that is subject to inter- and intra-observer variabilities. Furthermore, contours drawn prior to treatment do not necessarily represent the real patient anatomy over an extended treatment course. This study investigates the impact of auto-generated organ-at-risk (OAR) contours on treatment outcome. **Methods:** Prostate, seminal vesicles (SV), bladder, and rectum were manually delineated on planning CT and daily CBCT images for 20 prostate patients. OARs were automatically generated with atlas-based segmentation algorithms on planning CTs. Treatment plans were created via a novel automated planning application accessing a knowledge-based planning solution for both auto-generated OARs (aOAR-plan) and manual OARs (mOAR-plan). Both low-risk patients (LRP, CTV=Prostate) and intermediate-risk patients (IRP, CTV=Prostate+SV) were studied. Calculated doses were transferred from planning CT to daily CBCTs based on clinical shifts, then contour-based deformable registrations were used to obtain the cumulative doses. Differences in cumulative dose for the bladder and rectum were used as an indicator of the agreement between auto-plans and manual-plans. Furthermore, 5 patients were selected to test the difference between obtaining cumulative dose from transferred doses versus doses recalculated on CBCT. Maximum dose, V55, V60, V65, V70 and V75 were used for the dosimetric evaluation. **Results:** For both LRP and IRP groups, good dosimetric agreement between the aOAR-plans and mOAR-plans was observed. The dose differences were within 2.5% for bladder and within 4% for rectum, respectively. No significant dose differences between the transferred and recalculated doses were observed for both the bladder and rectum. **Conclusion:** Manually drawn precision contours are used to represent patient anatomy that often fluctuate by multiple millimeters on a daily basis, thereby making the time and effort questionable. Automated contouring tools offer improvement in contour consistency, and provide acceptable delivered doses compared with precision contours.

This research was supported by a grant from Varian Medical Systems, Palo Alto, CA.

Dosimetric Effects Due to Inter-Observer Variability of Organ Contouring When Utilizing a Knowledge-Based Planning System for Prostate Cancer
H Liu*, C Amaloo, B Sintay, D Wiant, Cone Health, Greensboro, NC

Purpose: Radiotherapy is a widely accepted standard of care for early stage prostate cancer, and it is believed that the plan quality and treatment outcome are associated with contour accuracy of both the target and organs-at-risk (OAR). The purposes of this study are to: (1) assess geometric and dosimetric uncertainties due to inter-observer contour variabilities and (2) evaluate the effectiveness of geometric indicators to predict target dosimetry in prostate radiotherapy. **Methods:** Twenty prostate patients were selected for this retrospective study. Five experienced clinicians created unique structure sets containing prostate, seminal vesicles, bladder, and rectum for each patient. A fully automated script and knowledge-based planning routine was utilized to create standardized and unbiased plans that could be used to evaluate changes in isodose distributions due to inter-observer variability in structure segmentation. Plans were created on a “gold-standard” structure set, as well as on each of the user defined structure sets. The correlation between geometric and dosimetric indices was evaluated using R2 statistics for plans generated with different combination of structure sets. **Results:** Inter-observer variability of contours during structure segmentation was very low for clearly defined organs such as the bladder but increased for organs without well-defined borders (prostate, seminal vesicles and rectum). For plans generated with the user defined structure sets, strong / moderate correlations (correlation coefficient $0.4 < |r| < 1$) were observed between the geometric indicators for target structure agreement and target coverage for both low-risk and intermediate risk patient groups, while OAR indicators showed no correlation ($|r| < 0.2$) to final dosimetry. **Conclusion:** Level of target delineation accuracy is crucial in order to maintain adequate dosimetric coverage regardless of the associated inter-observer uncertainties in OAR contours that had limited impact upon final dosimetry.

This research was supported by a grant from Varian Medical Systems, Palo Alto, CA.

PO-GePV-T-257

A Single Institution Evaluation of a Machine Learning Based Decision Support Software for Head and Neck Radiotherapy

L Zhuang^{1*}, E Bowers¹, M Pankuch², M Posner¹, (1) Northwestern Lake Forest Hospital, Lake Forest, IL, (2)Northwestern Medicine Chicago Proton Center, Warrenville, IL

Purpose: To evaluate the performance of a machine learning (ML) based decision support software (InsightRT, Siris Medical, CA) for head and neck (H&N) radiation therapy. **Methods:** Twenty-two sets of H&N patients' data were retrospectively evaluated in this study. All patients were treated with volumetric modulated arc therapy and planned using the Monaco treatment planning system (Elekta Inc.). Three simultaneous integrated boost (SIB) treatment schemes were prescribed including PTV60/54-59.3/53.9 (11 patients), PTV69.96/59.4-63/54-59.3/53.9 (5 patients) and PTV66/59.4-63/54-59.3/53.9 (6 patients). The H&N prediction model of InsightRT was built upon a total of 813 patients with the aforementioned three Rx schemes. D95 for all PTVs (PTV69.96, PTV66, PTV60, PTV<59.3) and organ at risk (OAR) constraints including cord max (CM), mandible max (MM), left parotid mean (LPM) and right parotid mean (RPM) were compared between planned and predicted data through a paired t-test. Software running time was also evaluated to assess the efficiency of the clinical workflow. **Results:** Statistically, there was no significant difference between planned value and predicted value for D95 of PTVs (pPTV69.96=0.45, pPTV66=0.3, pPTV60=0.07, pPTV<59.3=0.38) and OAR constraints (pCM=0.49, pMM=0.09, pLPM=0.46, pRPM=0.28). Prediction could be performed in less than 5 seconds for each individual case, and structures could be automatically associated provided the structure labeling followed pre-defined rules, thus demonstrating a robust algorithm. In addition, matched patient data used for prediction were provided to assist dosimetric tradeoff decisions during the planning process. **Conclusion:** InsightRT could provide plan result prediction in good agreement with clinically approved plans for H&N radiotherapy in a rapidly produced and automated fashion. Predicted plan results and matched patient data could assist with dosimetric tradeoff decisions during the planning process and help prevent unnecessary plan modifications or replanning cycles.

PO-GePV-T-258

An Unsupervised Method for Error Detection of Treatment Plan in Radiotherapy

Z Song*, H Yan, J Dai, Department of Radiation Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CN

Purpose: An unsupervised machine learning method, autoencoder (AE), was applied to error detection of treatment plans in radiotherapy. **Methods:** Treatment plans of more than 500 breast cancer patients between 2010 and 2020 were collected from MOSAIQ system and analyzed retrospectively. Those plans were hybrid intensity-modulated radiotherapy (IMRT) plans with two tangential conformal fields and two tangential intensity-modulated fields. The most important 9 parameters were extracted from plan for each patient. A classical autoencoder (AE) method was used to encode the original features to fewer features and then reconstruct the original features from the encoded features. The average mean-square error (MSE) between the reconstructed features and the original features for all training data was calculated and set as baseline for error detection. For a new patient, the 9 features were extracted from treatment plan and fed into trained AE model. The reconstruction MSE was then calculated by AE and compared to the baseline value for the difference. If the difference is more than a threshold value, this treatment plan is considered as an outlier and need further checking. In addition, errors in various levels were purposely introduced to each parameter in testing dataset. The resulting error detection rates were used to evaluate the sensitivity of AE model. **Results:** AE model detected all errors with 100% detection rate in testing dataset. For sensitivity analysis, 1 parameter was not affected as its value always fixed to two constants. 4 parameters were less sensitive to errors and another 4 parameters were more sensitive to errors. For all tested parameters, the false positive rate is about 0.01%. **Conclusion:** AE method provides a novel way for automatic treatment plans checking, which is more efficient and robust.

PO-GePV-T-259

The Effect of Dimensionality-Reduction Algorithms on Parameter Checking of Treatment Plan in Radiotherapy

P Huang*, Z Song, J Dai, Department of Radiation Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CN

Purpose: Dimensionality reduction is important for clustering method in detecting error of radiotherapy treatment plan. The traditional method is principal component analysis (PCA) which is linear representation of high-dimensional features and might be failed for data with non-linear relationship. In this study, the non-linear components contained in high-dimensional feature space were extracted by an autoencoder (AE) method for more effective clustering capability. **Methods:** Treatment plans of more than 500 breast cancer patients between 2010 and 2020 were analyzed retrospectively. Those plans were hybrid intensity-modulated radiotherapy (IMRT) plans with two tangential conformal fields and two tangential intensity-modulated fields. The most important nine parameters were extracted from plan for each patient. First, the input feature vectors in nine dimensions were reduced to three components by PCA and AE methods, respectively. Then the feature vectors in three dimensions were assigned to different groups using K-means clustering algorithm. Next, the outliers were detected by a distance threshold value. Finally, the effects of two dimensionality-reduction methods on the clustering performance were evaluated by silhouette coefficient index. **Results:** The performance of error detection by AE-based method is better than that by PCA-based method according to the values of precision rate and recall rate. The performance of clustering resulted by AE-based method is higher than that of PCA-based method according to the silhouette coefficient index. **Conclusion:** AE-based feature vectors show higher clustering capability than those of PCA-based feature vectors. It provides an effective

dimensionality-reduction method for error detection of treatment plan in radiotherapy.

Patient Treatment Transferability Between Unmatched Medical Linacs

J Foy*, S Kucuker Dogan, I Das, Northwestern Memorial Hospital, Northwestern University Feinberg School of Medicine, Chicago, IL

Purpose: Linacs with unmatched beam characteristics create operational challenges. The feasibility of transferring patients between unmatched Linacs was investigated for a limited number of treatment fractions. **Methods:** Twenty 4-field 3DCRT and 20 VMAT prostate plans were evaluated on unmatched Elekta Infinity and Versa Linacs using Pinnacle TPS. With MUs held constant, the mean dose to four OARs (rectum, right femur, left femur, and bladder), PTV, and prescription point were evaluated. Differences in mean dose were assessed with paired t-tests ($p < 0.05$). Relative differences in mean dose were calculated. The number of interchangeable fractions allowable before surpassing a 5% difference in dose to the prescription point was determined as recommended by ICRU-50. VMAT plans were delivered on both Linacs for QA with ArcCheck. Measured dose distributions were compared with distributions calculated on the Infinity. Gamma analysis passing rates were compared between machines using 2.0%/2.0mm criteria. **Results:** The mean dose to the PTV and prescription point was greater for all 3DCRT plans calculated on the Versa and reduced for 17 and 16 out of 20 VMAT plans, respectively. The averaged mean dose difference for the rectum, right femur, left femur, bladder, and PTV were 0.9%, 1.3%, 5.5%, 0.6%, and 0.9% among 3DCRT plans, and 2.9%, 0.9%, 1.4%, 2.8%, and 0.6% among VMAT plans, respectively. Mean dose significantly differed between Linacs for all OARs, PTV, and prescription point. The relative difference to the prescription point ranged from 0.75%-1.35% (mean: 0.96%) among 3DCRT plans and 0.06%-1.40% (mean: 0.43%) among VMAT plans resulting in an average of 5 (range: 4-7) and 11 (range: 4-90) allowable interchangeable fractions between Linacs, respectively. Among VMAT plans, gamma passing rates differed by 0.0%-3.0% (mean: 0.18%). **Conclusion:** Despite small differences in calculated dose, transferring patients between unmatched machines for a limited number of fractions (<5) is possible to improve clinical flexibility.

PO-GePV-T-261

Development of a Progressive Plan Quality Evaluation Solution

J Neylon*, J Hegde, S Mcloskey, J Lamb, University of California, Los Angeles, Los Angeles, CA

Purpose: Plan quality assessments have become a ubiquitous component of plan evaluation in radiotherapy. The typical methodology assesses dose-volume histogram (DVH) constraints and applies a binary pass/fail evaluation. In this work, a framework was developed to continuously accumulate plan quality data and provide additional context during plan assessment by comparing the current plan results to the past patient population. **Methods:** At our institution, a third party commercial software is utilized to maintain a database of plan quality constraint templates, categorized by treatment site, technique, prescription dose and fractionation. This software does not have the capability of storing plan evaluations in their database, but is capable of exporting the individual patient reports in JavaScript Object Notation (JSON) format. A reactive web application was developed to parse this data, calculate statistics, compile a patient database, present the results for comparison and evaluation, and print plan quality reports for inclusion in the patient chart. **Results:** Initial development focused on external beam radiotherapy of the breast, which has well established plan constraints and a large population of treated patients. The data for 111 patients have been collected so far. Plan quality reports can now display the current plan performance overlaid on a boxplot of the past patient population. Each subsequent patient can then be added to the population database. **Conclusion:** A framework for continuous accumulation of plan quality data and feedback to the planner has been implemented. Further study is needed, but this framework is expected to lead to improvements in overall plan quality for two reasons: (1) evaluation that looks beyond pass/fail DVH constraints with the context of past patients to see where a plan may improve; and (2) the objectives currently in use can be evaluated against what has been historically achievable and adjusted accordingly to improve their efficacy.

PO-GePV-T-262

A Retrospective Study to Establish Recommendations for Plan Quality Metrics in Linac Lung SBRT

S Taghizadehghahremanloo, F Akbari*, D Pearson, University of Toledo, Toledo, OH

Purpose: The quality of planned dose distributions in lung SBRT was evaluated by characterizing dose distributions for conformity, homogeneity, and gradient parameters using an in-house script. The goal of this study was to establish size-dependent recommendation for achievable values of these plan quality metrics. **Methods:** Sixty-nine patients (73 lesions) treated with lung SBRT during the period 2017- 2020 were retrospectively reviewed for this study. Included patients had been treated on the Varian Edge and have a prescription of 50-60 Gy in 5 fractions. All cases were classified based on the lesion size into four groups, very small ($V < 5cc$), small ($5 < V < 10cc$), medium ($10 < V < 30cc$), and large ($V > 30cc$). Plans were generated in RayStation treatment planning system using the collapsed cone algorithm with a computation grid size of 2 mm. Plans were retrospectively evaluated using dosimetric indices from respective RTOG and ICRU protocols. **Results:** Our recommendations for the acceptable values for the plan quality metrics, HI, GI, CI and PCI is shown in table 1 of the supporting documents. These are based on clinically approved plans, after removing statistical outliers that we would not have approved if the metrics had been calculated. Additionally, we observed that a sharper dose fall-off and a more homogeneous plan were found using 6FFF compared to 10FFF energy. **Conclusion:** Using various dosimetric indices to characterize dose distributions in lung SBRT is a powerful tool to assess plan quality. The plan recommendations are now being used in our clinics. We recommend that these values be calculated for all plans, utilizing a script or program so as to improve clinical workflow. Our retrospective analysis identified 9 out of 73 plans that would have been rejected. Also, we recommend using the 6FFF beam for lung SBRT treatment planning based on our institutional data evaluation.

PO-GePV-T-263

Evaluation of Treatment Plan Uncertainties for VMAT TBI

I Duarte*, P Galavis, N Gerber, D Barbee, J Teruel, NYU Langone Health, New York, NY

Purpose: To investigate the effect of patient positioning in Volumetric Modulated Arc Therapy (VMAT) for Total Body Irradiation (TBI) given the use of multiple isocenters, by simulating offsets in patient positioning and evaluating changes to planned dose distributions. **Methods:** VMAT treatment plans for seven TBI patients treated as part of a prospective stage II clinical trial were evaluated. Plan uncertainties were calculated by introducing 5mm and 10mm translational shifts to the plans' isocenters in the lateral (x), vertical (y), and longitudinal (z) directions. Dose distributions were then re-calculated in the treatment planning system (Eclipse), in order to evaluate dosimetric robustness to one global imaging shift at treatment. Differences in target volume (PTV) coverage and doses to organs at risk were evaluated based on four parameters: lung mean dose, PTV-V100%, PTV-D98%, and kidney mean doses. **Results:** Lung mean dose increased an average of 8.2cGy, 4.4cGy, and 3.3cGy when shifted 5mm in the x,y,z directions (respectively) across seven patients; 33.2cGy, 18.5cGy, 18.3cGy for 10mm shifts in x,y,z. Target coverage V100% decreased an average of 0.3%, 0.03%, 0.1% for 5mm shifts, and 1.1%, 0.8%, 0.4% for 10mm shifts in x,y,z. D98% decreased 0.9%, 0.3%, 0.3% when shifted 5mm; 3.5%, 2.1%, 1.0% when shifted 10mm in x,y,z. Mean dose to the left kidney increased 6.6cGy, 9.7cGy, 2.8cGy for 5mm, and 28.1cGy, 32.7cGy, 18.0cGy for 10mm shifts in x,y,z. Right kidney mean dose increased 11.9cGy, 8.9cGy, 3.1cGy for 5mm, and 36.5, 30.5, 19.8cGy for 10mm. **Conclusion:** Though small in relation to total dose, the largest increase in mean lung dose and decrease in coverage was seen with lateral shifts as compared to vertical or longitudinal shifts. These results support the use of an approach with preferential alignment to the chest region (lung-sparing), as long as residual imaging alignment outside the chest is kept below 10mm.

Jose Teruel has received honorarium from Varian Medical Systems.

PO-GePV-T-264

Three-Year Experience with Active Breathing Coordinator Device Used in Reducing Radiation Dose to the Heart in Left-Sided Whole Breast Cancer Patients

R Gupta*, M Huq, UPMC Hillman Cancer Center and University of Pittsburgh School of Medicine, Pittsburgh, PA

Purpose: Radiation dose to the heart during breast radiotherapy (RT) has been associated with increased risk of ischemic heart diseases. In our clinic about three years ago, we started deep inspiration breath hold (DIBH) technique using Active Breathing Coordinator (ABC) device for reducing mean heart dose (MHD) in suitable left-sided breast cancer (LBC) patients. **Methods:** Out of 120 LBC patients treated with 3D/field-in-field plans during the last three years, 80 were found suitable candidates for using ABC. These patients underwent training with the ABC device (Elekta Oncology, Stockholm, Sweden), during which lung capacity, optimal breath hold duration and level, patient comfort and compliance were assessed. Out of these 80 patients, 12 patients declined using ABC; 33 patients did not require DIBH/ABC use due to a negligible volume of heart within the treatment fields as determined via a free-breathing (FB) CT scan and remaining 35 patients underwent CT simulation with both FB and ABC for comparison of dosimetry. The median prescription dose was 42.56Gy plus 10Gy boost. All 35 patients were treated using ABC on Elekta Infinity via automated response gating interface. **Results:** Out of 80 eligible patients, 35 patients received RT using ABC, corresponding to 44% procedural success. Use of ABC in LBC patient's RT course reduced MHD by 20% or greater when compared with MHD from FB based planning. The median values for absolute and relative reduction in MHD were 1.4 Gy and 65%, respectively. **Conclusion:** ABC device during RT should be considered to reduce MHD and hence the risk of ischemic heart disease in left-sided breast patients. However, high proportion of the LBC patients were ineligible due to poor tolerability of the device. DIBH with the ABC device remains preferred approach for cardiac sparing. Data for additional patients treated with ABC device will be added to this analysis

PO-GePV-T-265

Investigating the Level of Dose Trade-Offs Between Left Lung and Heart in Lung Cancer Cases to Identify Optimal Sparing

K Pant^{1*}, G Komisopoulos², J Dooley¹, K Wang¹, A Weiner¹, S Das¹, P Mavroidis¹, (1) Department of Radiation Oncology, UNC at Chapel Hill, NC, (2) Laboratory Of Medical Physics, School Of Medicine, Aristotle University Of Thessaloniki, Greece

Purpose: To identify the current state of dose trade-offs between ipsilateral lung and heart as a function of PTV size and target distance from heart. This study will investigate whether one organ should be systematically spared over the other, with the potential to investigate different levels of dose trade-offs between ipsilateral lung and heart. **Methods:** The dosimetric data of 118 consecutive patients, who were treated for lung cancer with IMRT/VMAT or SBRT were retrospectively collected. The dose volume histograms of heart and left lung were obtained from each patient and used to calculate the corresponding normal tissue control probability (NTCP) values. The Relative Seriality model was used to calculate NTCP values. The mean lung dose (MLD), mean heart dose (MHD), lung V20, and heart V5 were also obtained from each patient treatment plan. The minimum distance from target to heart was measured directly on the planning CT. **Results:** The median PTV volume was 93cc and the mean minimum distance between the target and heart was 3.5cm, respectively. The patients with PTV > 93cc had an average lung NTCP value of 11.6%, which is much larger than the average heart NTCP of 3.0% (p=0.001). For PTV < 93cc the corresponding NTCP values are almost equivalent (0.2% vs 0.1%, respectively). Regarding the target to heart distance for both cut-offs with the average lung and heart NTCP values being 9.6% vs 2.5%, respectively for the 3cm cut-off and 8.2% vs 2.1%, respectively for the 5cm cut-off. **Conclusion:** Our results show that there is an unbalanced level of sparing between left lung and heart, which varies based on the minimum target to heart distance and PTV size. Using NTCP metrics for heart and lung would help in finding better levels of sparing.

PO-GePV-T-266

Automated and Clinical-Criteria-Driven IMRT Planning for Prostate Using Expedited Constrained Hierarchical Optimization (ECHO)

Y Zhou*, L Hong, Q Huang, G Jhanwar, J Yang, H Pham, L Happersett, A Damato, L Cervino, J Deasy, M Zarepisheh, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: To report our initial clinical experience with automated IMRT planning for prostate radiotherapy plans using ECHO. ECHO is a home-grown independent optimization engine based on hierarchical constrained optimization, integrated with Eclipse® system through application program interface. ECHO does not use Eclipse optimization engine and the optimal fluence map generated by ECHO is imported into Eclipse for leaf sequencing and final dose calculation. **Methods:** ECHO was released to clinical use at our institution starting from Dec.2019 for prostate post-brachy SBRT (25Gy in 5fractions) and moderate hypofractionation prostate radiotherapy (MODHYPO) (70.2Gy in 26fractions) without nodal involvement. Prior to clinical release, training was performed on randomly selected 10 SBRT and 8 MODHYPO cases to fine-tune the ECHO parameters, and validated retrospectively on 50 cases (21 SBRT, 29 MODHYPO). We performed a comparison study with the manually generated clinical plans for all dose metrics used for prostate SBRT and MODHYPO patients in our clinic. Over a 14 months period of ECHO clinical implementation, ECHO has generated 152 clinical plans (130 SBRT and 22 MODHYPO) using 9 coplanar beams IMRT. **Results:** In pre-clinical validation, ECHO plans met all the clinical criteria and had high quality with less variability compared with manually generated clinical plans. After clinical implementation, the average time to produce an ECHO plan was 28 minutes (range 16-39). All ECHO plans were produced by one single run. They all met or were better than the institutional clinical criteria. All ECHO plans were delivered after passing institutional quality assurance process. **Conclusion:** ECHO required only few patients for training and produced high-quality plan within short time consistently for post-brachytherapy and moderate hypofractionation prostate radiotherapy. It streamlined the clinical planning workflow, improved the plan quality on average and consistency, and shortened planning time by one day from simulation to treatment in our clinic.

PO-GePV-T-267

Auxiliary Structures-Assisted Plan Optimization for Advanced Left Breast Cancer Radiotherapy

R Lei*, X Zhang, R Yang

Purpose: To evaluate the IMRT and VMAT treatment plan quality of auxiliary structures (ASs)-assisted plan optimization in advanced left breast cancer radiotherapy when using the ASs to spare the regions with aorta, pulmonary artery, superior vena cava and contralateral tissue of upper chest and neck, and the regions with cardia and fundus of the stomach, left liver lobe and splenic flexure where there are no intact delineated structures. **Methods:** A total of 20 left-sided advanced breast cancer patients' planning CT data were selected. The ASs were created separately in the regions of the aorta, pulmonary artery, superior vena cava and contralateral tissue of upper chest and neck, and in the regions of cardia and fundus of the stomach, left liver lobe and splenic flexure. Using these two ASs during optimization, the two kinds of plans, IMRT and VMAT were created for each study case. Dosimetric parameters for the target and OARs were compared for the two kinds of plans. **Results:** With the use of ASs, both the IMRT and VMAT plans were clinically acceptable and deliverable. The ASs significantly realized the dose sparing for the regions and bring a better conformity index from 0.70 to 0.79 (p < 0.05) and homogeneity index from 1.12 to 1.08 (p < 0.05) in VMAT plans. Besides, the volume receiving at least 20 Gy (V20) for the heart (4.5% vs 5.4%, p < 0.05), the V40 for the left lung (7.9% vs

9.2%, $p < 0.05$), and the V40 for the axillary-lateral thoracic vessel juncture (ALTJ) region (27.22% vs 41.04%, $p < 0.05$) were all lower in VMAT plans. **Conclusion:** The use of the defined auxiliary structures in VMAT was more effective than that in the IMRT in improving the target dose distribution as well as sparing OARs for advanced left breast cancer radiotherapy.

PO-GePV-T-268

Evaluation of Initial Planning Techniques in Ethos for Adaptive Head and Neck Patients

N Nasser^{1,2*}, J Caudell², E Moros², V Feygelman², G Redler², (1) University of South Florida, Tampa, FL, (2) H. Lee Moffitt Cancer Center, Tampa, FL

Purpose: Initial planning techniques and plan quality with the novel Ethos CBCT-guided ring-gantry adaptive radiotherapy system are evaluated for head and neck(H&N) patients. **Methods:** Clinical data(planning CT/structures) are used to replan previously treated H&N patients(n=9). The Ethos Intelligent Optimization Engine generates 5 plans(7/9/12 fixed-field IMRT and 2/3 full-arc VMAT) based on clinical goal prioritization (rather than cost function parameter inputs). Four priority levels exist (P4-P1) with fine-tuning provided by ordering clinical goals within each level. Planning target volume(PTV) goals and critical organ-at-risk(OAR) Dmax are assigned higher priority(P1-P2), while other OAR goals are assigned lower priority(P3-P4). Within this paradigm, different planning techniques are assessed: utilization of physician goals; PTV coverage preference ignoring overlapping OARs; clinical goals applied to OARs cropped from PTVs. Generic helper structures for isodose shaping and hot-spot control are evaluated. Dosimetric comparison of Ethos(AcurossXB) and clinical(Collapsed-cone-convolution superposition(n=8); Monte Carlo(n=1)) plans is based on NRG guidelines. **Results:** The first two planning techniques result in under-covered PTVs, unacceptable PTV heterogeneity, and high dose to OARs intersecting PTVs. The third technique, with the use of helper structures, provides the most comparable results to clinical plans. These Ethos versus clinical plan PTV average D99%, D95%, and Dmax are within the NRG guidelines: 103.6% vs. 100.5%, 102.2 vs. 100.9%, and 108.8% vs. 105.5%, respectively. Average global hot-spot is 110.5% in ethos(occasionally outside of PTVs) and 105.6% in clinical plans (potentially due to dose calculation algorithm differences). Most OAR doses are within NRG guidelines for both plans(with lower doses in Ethos) except for larynx, pharynx and submandibular glands (with higher doses in Ethos) due to PTV proximity. **Conclusion:** Ethos generates clinically comparable initial H&N plans with better PTV coverage and OAR sparing. However, care must be taken to precisely evaluate the magnitude and location of hot-spots in the produced plans to ensure clinical acceptability.

Analyzing Performance of Atlas-Based and Deep Learning-Based Auto-Segmentation in Breast Cancer Patients

M Weiland^{1*}, K Kisling¹, (1) UC San Diego, La Jolla, CA

Purpose: Auto-segmentation has become more widespread for contouring, saving time and decreasing inter-observer variability. In this study we analyzed the performance of both an atlas- and a deep learning-based auto-segmentation of patients undergoing breast radiation. **Methods:** The atlas-based segmentation was built using 12 patients from our clinic in MIM v6.9.3. The model for the deep learning-based auto-segmentation (MIM Contour ProtégéAI) was provided by the vendor. CT scans of 12 unique patients were used for testing, and contours were manually delineated for four different structures (heart, left lung, right lung, and left breast) to be used as reference structures. The 12 test patients were then auto-segmented using the atlas and the deep learning-based methods. Three geometrical metrics were then used to quantitatively evaluate the auto-contours: the Dice similarity coefficient (DSC), the mean absolute distance (MAD), and the Hausdorff distance (HD). **Results:** The mean DSC for the heart and the lungs were greater than 0.90 for both the atlas and deep learning techniques. For the breast, which was only available via atlas-based segmentation, the DSC value was 0.83 ± 0.04 (mean $\pm$ standard deviation). The mean MAD for the lungs, heart, and breast were all less than 0.4cm for both techniques. The HD for atlas and deep learning techniques were 2.4 ± 0.8 cm and 3.1 ± 0.6 cm for the lungs, and 1.8 ± 0.8 cm and 1.4 ± 0.4 cm for the heart, respectively. The atlas resulted in HD of 3.6 ± 0.7 cm for the breast. The largest discrepancies seen were in the lung and breast where the auto-contours tapered off at the inferior and superior edges. **Conclusion:** Based on these results, we conclude that both auto-segmentation methods were sufficient for clinical use for heart and lungs, and the atlas-based segmentation will be implemented in our clinical workflow this year. The breast auto-segmentation will be used to facilitate automated beam setup for tangent fields.

PO-GePV-T-270

Gamma Analysis to Validate Dose Calculation Algorithms in a Lung Phantom: AAA Vs AcurosXB

B Rudek, T Chen, D Barbee, H Wang, A Rea, J Xue*, NYU Langone Health, New York, NY

Purpose: This study investigated the accuracy of two dose calculation algorithms (AAA version 15.6.05 and AcurosXB (AXB) version 15.6.05) in lung, fat, and bone regions of a lung phantom using 2D Gamma analysis. **Methods:** A commercial thorax phantom (CIRS) was marked and CT simulated with 1.5 mm slice thickness then planned in Eclipse v15.6 (Varian) using an oblique 3x3 cm field traversing soft tissue, lung, and spine regions. Dose was calculated using AAA and AXB algorithms at 1.0 mm resolution for four different beam energies with the same number of monitor units: 6X, 6X-FFF, 10X and 10X-FFF. Each field was separately delivered to the phantom with Gafchromic EBT3 film placed in the axial plane through the beam isocenter. Film alignment was performed using built-in phantom pins as registration marks. Gamma analysis was performed in SNC Patient 8.2 (Sun Nuclear Corp.) software using distance-to-agreement (DTA) to compare AAA and AXB calculated doses against one another and against measured dose. **Results:** Considerable dosimetric differences occurred between AAA and AXB especially at tissue interfaces and in the beam penumbra within the lung. About 10% and 30% of analyzed points had dose differences larger than 3% for 6X and 10X, respectively. The differences were a few percentages smaller for non-flattened beams. In comparison of calculation with measurement, the 3%/2mm-DTA passing rate for AAA was 3.7% higher than AXB for the 6X beam (3.9% for 6X-FFF), but -15.9% lower for 10X (-24.9% for 10X-FFF). **Conclusion:** Dose calculation algorithm accuracy was assessed in a heterogeneous thorax phantom using 2D gamma analysis and Gafchromic film. Large differences in the passing rate, especially at 10X(FFF), suggest to verify that clinical plan evaluation metrics such as coverage and dose constraints are not compromised by the choice of dose calculation algorithm.

PO-GePV-T-271

Clinical Implementation of Automated Treatment Planning for Rectum Intensity-Modulated Radiotherapy on UIH Using Voxel-Based Dose Prediction and Clinical Optimization Strategies

Y Zhong*, J Wang, W Hu, 1 Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, China, 2 Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, China, Shanghai

Purpose: This study aims to demonstrate the feasibility of clinical implementation of automated treatment planning (ATP) for rectum cancer combining a deep learning based three-dimensional (3D) dose prediction and clinical optimization strategies on UIH (TPS; United Image, Shanghai, China) for rectum cancer. **Methods:** 160 previous treated rectum cancer cases were enrolled in this study including 140 cases for training, 10 for validation and 10 for testing. Using data of CT images, planning target volumes and contours delineation the organs at risk as input and 3D dose distribution as output, a DL model was developed for predicting a 3D dose distribution for new patients. Based on these 3D dose prediction automated IMRT plans were then generated through two optimization objective functions: MSE and MSE plus more clinical optimization strategies, which include complex clinical dose target metrics, such as high priority of

target, HI and CN improving, OARs protection, target hot point control and low dose area adaptive control. To evaluate the performance of the proposed ATP model, the DVH parameters of OARs and PTV and the 3D dose distributions of plan were compared with manual plans. **Results:** By combining clinical optimization strategies, the automatically generated treatment plan can achieve better homogeneous PTV coverage and dose sparing for OARs except mean dose for femoral-head. Compared with manual plan, no statistically significant differences were found on HI, CN and global maximum dose. The manual plan outperforms slightly better in other dosimetric indexes, but our proposed clinical optimization strategies still can obtain clinically acceptable plan. **Conclusion:** With the help of these clinical intelligent optimization strategies, the proposed new automated treatment planning solution can be used to improve the quality and consistency of the treatment plans for intensity modulated rectal cancer radiation therapy.

PO-GePV-T-272

Implementation of An Automated Workflow for Planning Tangential Breast Radiotherapy

T Keiper*, D Hoffman, K Kisling, UC San Diego, La Jolla, CA

Purpose: Automated planning for breast radiotherapy can improve efficiency and consistency for one of the most commonly treated disease sites. While several in-house solutions have been proposed, few have been translated to other clinical practices. This work aims to implement a previously developed auto-planning workflow for tangential breast radiation in an independent clinic. **Methods:** Each step of planning is automated, including the beam geometry. The contours are generated via atlas-based auto-segmentation in MIM. The posterior border of the tangents and thus the beam geometry is determined with a support vector machine in MATLAB. Eclipse scripts create the plan in the TPS, and EZFluence optimizes the dose distribution. Breast plans were generated for 12 patients, 4 to tune the beam generation parameters and 8 for independent testing. Auto-plan quality was compared to the clinical plan using DVH metrics. Beam geometry similarity and treatment coverage were assessed with the 50% and 90% isodose overlap, respectively, using the Dice similarity coefficients (DSC) and mean absolute distance (MAD). **Results:** All DVH parameters were comparable to the clinical plans. On average, the heart mean dose changed by 0 ± 13 cGy, the lung V20Gy by $+1.4 \pm 3.8\%$, and D95% of the tumor bed by $+1.0 \pm 1.2\%$ of prescription. The average maximum dose was $+0.5 \pm 1.0\%$ and the homogeneity (V105%/V95%) was 0.02 ± 0.04 . We confirmed similarity of beam geometry and coverage with DSC averaging 0.91(50%: ± 0.06 , 90%: ± 0.07) and MAD averaging 0.27cm(50%: ± 0.23 cm, 90%: ± 0.21 cm). **Conclusion:** We successfully integrated a suite of commercial and in-house tools for breast auto-planning at our institution. The methodology for determining beam geometry, first developed at an outside institution, was implemented in our workflow, showing the generalized applicability of this approach. Automated plans were comparable to clinical plans. Next, we will implement this automated workflow in our clinic and assess the efficiency gains.

PO-GePV-T-273

Adequacy of Target Volume Drawn Based On "slow" CT Scan for SBRT Lung Treatment in Helical TomoTherapy

S Awan¹*, R Badkul², S Gupta-burt³, A Meigooni⁴, (1) University of Kansas Hospital, Lawrence, KS, (2) University of Kansas Medical Center, Kansas City, KS, (3) Kumc, (4) University of Nevada Las Vegas, Las Vegas, NV

Purpose: In this project, we investigated adequacy of "slow" CT for Stereotactic Body Radiation Therapy (SBRT) utilizing helical TomoTherapy treatment technique and confirmation of dose delivered to the moving target volume. **Methods:** Presently various CT simulation techniques such as slow CT, fast CT, four-dimensional CT(4DCT) and breath-hold(BH) are employed for treatment planning and delivery of radiation therapy treatment to account for tumor motion in chest and abdominal area. Due to limitations of Hi Art TomoTherapy systems, only slow scan CT scan technique can be employed to account for tumor motion. Hi Art TomoTherapy systems are equipped with MVCT that not only provide means to localize tumor volume, but can also be used for adaptive planning to confirm dose delivered to the target volume. Four patients with lung lesions were prescribed SBRT treatment and were gone through CT simulations employing "Slow CT Scan" technique in conjunction with planning CT on Siemens Biograph PET/CT. CT images were imported in Pinnacle treatment planning system. CT/Slow CT images were used to draw GTV/PTV and other critical structures volumes. All patients have gone through MVCT imaging prior to each treatment delivery. Shifts were employed based on MVCT/Planning CT fusion prior to the treatment delivery. Latter MVCT acquired for localization prior to each treatment delivery was utilized to compute dose utilizing the TomoTherapy Planned Adaptive application. **Results:** TomoTherapy Planned Adaptive application enabled calculation of actual dose delivered to the patient during each treatment fraction utilizing the pretreatment megavoltage computed tomography (MVCT). Dose coverage to PTV, GTV, and D2cm computed for each fraction were compared to the values obtained per approved treatment plan. **Conclusion:** Results of our investigations show that tumor volumes drawn based on slow CT scan appropriately account for tumor motion and enables to provide adequate coverage to the target volumes during high dose treatment.

PO-GePV-T-274

Interpolation of Dose Planes for Use in the Optimization of Multi-Leaf Collimator Dosimetric Leaf Gap and Transmission

Dominic J. DiCostanzo* and Ahmet S. Ayan, The Ohio State University, Columbus, OH

Purpose: To develop computationally efficient and fast process of plan generation for use in the optimization of multi-leaf collimator dosimetric leaf gap and transmission. **Methods:** Eighteen sliding window intensity modulated radiotherapy treatment plans with varying number of fields, collimator angles, and monitor units were selected. The planar doses corresponding to a set of transmission and dosimetric leaf gaps were calculated using the treatment planning system. Each pixel value in these series of planar doses was fit with an independent linear function for transmission and dosimetric leaf gap. The interpolated dose planes within the bounding values of DLG and transmission were compared to the calculated dose planes from the treatment planning system. Mean absolute difference (MAE), mean squared difference (MSE), and structure similarity metric (SSM) were used to compare the interpolated dose planes to the TPS generated and exported dose planes. **Results:** The interpolation method produced 116,688 dose planes in 2.5×10^5 seconds, or 2.16s per dose plane, as opposed to 13s per dose plane when calculating in the treatment planning system (without accounting for read-write operations required to export the dose plane). The use of multivariate linear interpolation to calculate dose planes produces nearly identical results to the dose planes calculated in the treatment planning system with MAE of 0.0207 ± 0.0286 cGy, MSE of 0.0484 ± 0.1768 cGy², and SSM of 0.9999 ± 0.0001 . **Conclusion:** Using multivariate linear interpolation provides an accurate and time efficient process for generating dose planes required for optimization of dosimetric leaf gap and transmission.

PO-GePV-T-275

Accounting for Dose Accumulation Uncertainty in Spine Reirradiation

J Mechalakos, L Zhang, N Shah, Y Hu, P Zhang, A Ballangrud, L KUO*, J Deasy, L Cervino, Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: To estimate dosimetric uncertainty in registration-based dose accumulation for spine reirradiation and propose a novel method to account for this uncertainty. **Methods:** Dose accumulation was performed for 3 SBRT spine reirradiation patients using 3 methods. First, a rigid vertebral registration between primary and secondary scans was used. Second, the rigid registration was independently perturbed 2-3 mm in the superior, inferior, anterior, posterior, left and right directions to estimate the effect of registration uncertainty on results. Third, an in-house API script (Radiotherapy Dose Accumulation Routine, RADAR) was used. RADAR accounts for registration uncertainty by associating with each dose voxel in the secondary scan the maximum dose within a small search

space of user specified dimensions centered on that voxel. The RADAR search dimensions were set equal to the perturbations from method 2 for comparison purposes. Results of the 3 methods were compared using maximum spinal cord (patients 1 and 2) or cauda (patient 3) dose (Dmax). RADAR was run for 2 use cases: “unrestricted”, where the entire search space was considered for each secondary voxel and “restricted”, where the search space for each voxel was limited to the portion within the cord/cauda contours. **Results:** Dmax for each patient respectively was 3790/2463/3548 cGy using method 1. Dmax increased to 4062/2555/3787 cGy (SI perturbation), 4904/3808/3773 cGy (LR perturbation), and 4955/3538/3735 cGy (AP perturbation) using method 2. Using RADAR, Dmax was 4163/2595/3802 cGy (SI), 4878/3723/3751 cGy (LR), and 4878/3477/3777 cGy (AP) for the unrestricted use case and 3947/2496/3704 cGy (SI), 4846/2496/3633 cGy (LR), and 4575/2496/3777 cGy (AP) for the restricted use case. Typical computation times for RADAR were ~2-4 minutes. **Conclusion:** RADAR provides an automated solution for incorporating registration uncertainty into dose accumulation for spine reirradiation. RADAR can be applied to other disease sites with adjustments to search radii, which are structure specific.

PO-GePV-T-276

Determining the Optimal Assigned Density for Various High-Density Prostheses Calculated with AcurosXB and AAA

H Genco*, S de Boer, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Purpose: To investigate Acuros®XB and AAA algorithms with the presence of high-density prostheses commonly found in the body and to determine the optimal material and density assigned in treatment planning system (TPS). **Methods:** Prosthetic devices (hip, knee, and dental implants) were utilized to develop patient-like phantoms. Prostheses were contoured in the TPS and divided into regions with assigned appropriate materials and densities. An iterative process determined the optimal assigned materials/densities for each phantom in the TPS. All treatment plans were computed using both algorithms to compare with the measured data. For the first hip prosthesis phantom two plans were generated, a single field plan and a clinical VMAT plan. The measured data were acquired using Sun Nuclear (SNC) ArcCHECK® with prothesis inside the central cavity. Measurement data for a second hip prosthesis phantom were acquired utilizing SNC MapCHECK® along with two pieces of Gafchromic film at two additional depths. The doses to the knee and dental phantoms were measured with Gafchromic film. **Results:** The two hip prostheses phantoms yielded same optimal assigned materials, despite their different sizes. For the femoral head and acetabular components, optimal assigned material/density were Stainless Steel (7.24 g/cm³) and Aluminum (2.6113 g/cm³), respectively. The femoral stem was assigned Titanium Alloy. When the femoral stem was contoured to separate the “neck” and “body” regions the optimal assigned densities of the “neck” was 4.31g/cm³ and the “body” was 4.4001g/cm³. The optimal material/density for the “metal” of the knee prosthesis was Titanium Alloy (4.6144 g/cm³) and its “plastic liner” was PMMA (1.19 g/cm³). The dental fillings were assigned Stainless Steel (8.0 g/cm³). **Conclusion:** This work indicates the advantage of contouring a prosthesis into regions to reflect the actual materials present and by assigning the appropriate densities to each region. The two algorithms yielded comparable pass rate results.

PO-GePV-T-277

Implementing Recommendations of TG 329

E Sudentas*, L Fu, C Teng, Mount Sinai West, New York, NY

Purpose: To implement recommendations of TG 329 for dose-to-tissue corrections **Methods:** Traditionally, our department reported dose as dose-to-water. We have undertaken the task of changing the reporting to dose-to-tissue, following the guidance of TG 329. Our department is using Varian Eclipse treatment planning system for external beam therapy plans, with AAA algorithm for photon beams and eMC for electron beams. For both algorithms, TG 329 recommends applying 0.99 correction factor to reference calibration dose in water. We have applied this correction factor and then recalculated the models. Verification of this change was then performed. This included both phantom plans as well as selected patient plans. We have compared Monitor Units, isodose distributions, dose profiles, and dose-volume histograms of plans done before the change and after the dose-to-tissue corrections were applied. **Results:** For photon beams, plan recalculation after adjusting reference calibration dose leads to different Monitor Units but the same isodose distribution when static MLC is used. In case of VMAT plans (that have not been re-optimized) MUs stay the same, but there is a change of isodose distribution. For both such scenarios, we verified that the 0.99 factor is correctly reflected in the isodose distribution and MUs. For electron beams, due to the stochastic nature of Monte Carlo algorithm, in order to verify the expected 1% change, we had to reduce statistical uncertainty below the level used clinically. **Conclusion:** A change to dose-to-tissue reporting was successfully implemented in our clinic.

PO-GePV-T-278

A Hybrid Full-Body Image Set Generation for TBI Using Both CT and 3D Optical Imaging

H Jung*, S Kim, Virginia Commonwealth University, Richmond, VA

Purpose: To implement TBI-VMAT, we developed a technology that can obtain 3D whole-body information using both CT and 3D optical surface imaging and bring it to a treatment planning system (TPS). **Methods:** This process consists of 5 steps. Step1: Take a CT scan, only the upper body (i.e., head to pelvis). Step2: Take a surface image for the lower body using a handheld 3D scanner while keeping the same position as CT scanning. At this time, reference markers are placed on the body surface and that part of the body is overlapped in both image sets for proper alignment later. Step3: Convert the surface image to the “.stl” format to get the lower body outline. Step4: Expand the field-of-view of the CT image and assign a density equivalent to air. Merge both the expanded CT and the lower body outline utilizing the overlapped area and markers. Then it is saved as a new CT DICOM set. Step5: Import the new DICOM set to the TPS (Eclipse) and assign water density inside the lower body. Finally, organ-at-risk structures in the upper body including the pelvis are delineated. The feasibility of the proposed method was tested using a Rando phantom and a cost-effective Structure Sensor 3D scanner (Occipital, Inc., USA). **Results:** Image registration accuracy between CT and the 3D surface image was within 3 mm on average. The time required for surface imaging was about 5 minutes. The process of image alignment and registration took about 30 minutes. A treatment plan with homogeneous dose distribution in the whole body while effectively reducing the dose to normal organs was successfully obtained without compensators/shields. **Conclusion:** It was demonstrated that a whole-body image set for modern TBI treatment planning could be obtained in a single setup by using both CT and 3D surface imaging.

PO-GePV-T-279

PenMRT: A Multi-Scale Dose Calculation Engine for Microbeam Radiation Therapy

S KESHMIRI*, S Brocard, N Rosuel, R Serduc, J Adam, INSERM UA 7 STROBE, Grenoble, France

Purpose: Microbeam radiation therapy (MRT) is a treatment modality based on high flux, synchrotron generated x-rays. The negligible beam divergence together with the high x-ray source coherence gives the possibility of spatial fractionation of the radiation beam in a micrometric array to push the dose-volume effect towards its theoretical limits. So far, the most advanced MRT treatment planning system (hybrid dose calculation algorithm) is limited to a macroscopic rendering of the dose and do not account for the special features of MRT. For this reason, a pure Monte Carlo dose calculation engine with micrometric resolution is currently been developed for MRT (penMRT). **Methods:** PenMRT, is based on the PENELOPE (2018) Monte Carlo code, modified to take into account the voxelised geometry of the patients (CT-scans) and offering an adaptive micrometric dose calculation grid. To further improve the speed, parallelization using MPI was added together with an optional source replication protocol. The performance of penMRT is compared to its original version (penmain) for a 2x2 cm² incident broad beam and for a 50m x 2cm single microbeam, in terms of dose distribution assessment in a water equivalent phantom.

The so-called peak to valley dose ratio (PVDR) obtained in a 2x2 cm² MRT field using penMRT were also compared to the literature. **Results:** A good agreement was observed between penmain and penMRT with a maximum relative difference of $\pm 0.05\%$ and $\pm 0.2\%$ in the irradiation field and out-off field, respectively. PVDR values obtained using a spectrum with an average energy of 99 keV are in coherence with the ones found in literature. **Conclusion:** This study shows the performances and reliability of penMRT to provide micrometric dose maps for MRT treatments using synchrotron generated x-ray microbeams arrays. The code is now in experimental validation phase using Gafchromic films and microdiamonds detectors.

PO-GePV-T-280

Evaluation of Beam Data Correspondence for Five TrueBeam Linear Accelerators

S Gardner*, C Smith, B Miller, N Wen, I Chetty, Dept. of Radiation Oncology, Henry Ford Cancer Institute, Henry Ford Health System, Detroit, MI

Purpose: To evaluate consistency in beam-data for a group of TrueBeam linacs. **Methods:** Five TrueBeam linacs were installed between 2010 and 2018 at our institution. For each linac, beam-data was measured for input into TPS, including scanning data (PDD, crossline profile, diagonal profile) acquired using one of two scanning chamber types (0.04cc volume and 0.13cc volume) and output factors (0.13cc chamber volume). From the full dataset, an average dataset ("consensus") was generated for analysis, and variation of each machine dataset was evaluated relative to consensus data. For scanning data, field sizes larger than 4x4cm² were included for analysis, ranging from 6x6cm² to 40x40cm² (6 field sizes in total). For output-factor data, field sizes 3x3cm² and larger were included for analysis. The data was evaluated as follows: (1) output factors – relative-st.dev. is reported, (2) PDD – average dose difference magnitude and overall max dose difference for depths beyond dmax are reported, (3) crossline/diagonal profiles – average dose difference magnitude and overall max dose difference within the inner field (defined as inner 80% of field). **Results:** For output-factor comparison, the average relative-st.dev. was 0.15% and largest relative-st.dev. was 0.37%. For PDD measurements, range in average dose difference magnitude was [0.18%, 0.26%] and range in overall max dose difference was [0.25%, 0.83%]. For crossline profiles (field sizes of 30x30cm² and smaller), the range in average dose difference magnitude was [0.06%, 0.19%], and range in overall max dose difference was [0.52%, 0.65%]. For 40x40cm² field size, overall max dose differences were slightly larger, with range of [0.64%, 1.17%]. For diagonal profiles, range in average dose difference magnitude was [0.19%, 0.37%] and range in overall max dose difference was [0.55%, 1.29%]. **Conclusion:** For field sizes ranging from 6x6cm² to 30x30cm², our results indicate a level of agreement well within 1% for all measurements. For largest field size (40x40cm²), our results indicate a level of agreement within 1.5% for all measurements. Overall, our results suggest that average beam-data set may be used to model the broad-beam-data for TrueBeam linacs.

PO-GePV-T-281

Solving Beam Orientation Optimization (BOO) of IMRT Treatment Plan Using Tree Embedded Reinforcement Learning for Prostate Cancer

A Sadeghnejad Barkousaraie*, A Balagopal, G Bohara, S Jiang, D Nguyen, UT Southwestern Medical Center, Dallas, TX

Purpose: To propose a method to solve BOO problem in a matter of seconds without dose-influence matrices information available. We compare the proposed method with the state of the art column generation method (CG) to show its capability in solving BOO problem. **Methods:** A tree search embedded reinforcement learning method (RL) is proposed to solve beam orientation optimization problem (BOO) in IMRT treatment planning for patients with prostate cancer. This method uses a pre-trained deep neural learning (DNN) model introduced in [1] and improves on it by adding a tree-search algorithm during the training of the model. During clinical use, after the model is trained, it can suggest a set of beams for treatment planning in less than one second with only patient anatomical information as input. The same set of patients previously used to train and validate the DNN model is used here and a separate independent set of data is used for testing. **Results:** Although the model is still in training stages, because of the complex and memory intensive training steps, initial results are promising. In about 50% of the cases, RL successfully surpassed CG, and in the rest, although it may not surpass CG, the model will be able to find a solution as good as or better than the DNN model. In all cases, the beam selection process takes 1 seconds to propose five beams for each patient. **Conclusion:** A fast method for solving BOO problem that uses only anatomical features of the patient and can perform better compared to DNN model and CG.

This work was sponsored by NIH grant No. R01CA237269 and Cancer Prevention and Research Institute of Texas (CPRIT) (IIRA RP150485, MIRA RP160661).

PO-GePV-T-282

Clinical Impact of the Dose Calculation Engine for Vestibular Schwannoma Treatments on Cyberknife

E Ali*, E Vandervoort, The Ottawa Hospital Cancer Centre, Ottawa, Ontario, CA

Purpose: Historically for Cyberknife, long computation time was a barrier to using Monte Carlo (MC) instead of Ray Tracing (RT) for repeat and final dose calculations during plan optimization. With current computing power, MC can be used during optimization for more accurate dose calculations. In this study, the impact of changing the primary engine from RT to MC was evaluated for radiosurgery treatment planning of vestibular schwannoma with varying target sizes. **Methods:** Retrospective analysis was performed in Precision v2.0.1.1 for 23 vestibular schwannoma patients treated at our institution to an Rx of 18Gy in 3 fractions. The mean GTV volume was 2.6 +/- 3.7cc. From the MC and RT calculations for each patient, we extracted the minimum dose to the GTV, the percent PTV volume receiving the full Rx, and the maximum dose to the PRV of the ipsilateral cochlea. Results were evaluated against 3 GTV sizes: >5cc, 1.5-5cc, and <1.5cc. **Results:** For the minimum dose to the GTV, MC vs RT results showed minimal sensitivity to target sizes >5cc. For the second (1.5-5cc) and third (<1.5cc) bins, MC was higher by an average of 2% and 3.5%, respectively. This implies that with MC-based optimization that maintains the nominal Rx, future patients will, on average, receive a lower actual dose to the GTV by the amounts above. Dose to the neighboring OARs will be lower (an aside: for the PRV of the ipsilateral cochlea, MC results were higher by 1%, 2.5% and 5% for the above bins, respectively). The change in the percent PTV receiving full Rx changed by -1.0 +/- 3.3%, implying the need for a small scaling in either direction with MC-based optimization. **Conclusion:** Switching from RT- to MC-based optimization is not expected to affect the continuity of historical clinical outcomes for vestibular schwannoma patients, including small targets.

PO-GePV-T-283

Improved Dose Prediction Performance with Data Clustering and Transfer Learning On H&N Cancer Patients

D Nguyen*, T Bai, A Sadeghnejad Barkousaraie, R McBeth, A Balagopal, S Jiang, Medical Artificial Intelligence and Automation (MAIA) Laboratory, UT Southwestern Medical Center, Dallas, TX

Purpose: We propose a deep learning (DL)-based clustering and Transfer Learning technique for improved model performance and test it on dose prediction of head and neck (H&N) cancer patients. **Methods:** We used H&N cancer patient data available from the OpenKBP Challenge, consisting of 200 training, 40 validation, and 100 testing. This includes CTs, planning target volumes (PTV) and organs-at-risk (OAR) masks, 3D dose distributions. The dose distribution was generated from a 9 beam equidistant IMRT setup with 6 MV fields. As baseline, we trained a U-net style architecture model on all of the training data to take the patient anatomy as input to predict the dose distribution. For the clustering method, we first utilized an encoder-decoder style model and trained it to take the anatomy as input to predict the dose distribution, and then used the encoder to transform all the data into the latent space. A TSNE calculation is made on the data in the latent space, and clusters of data are determined. Models of the same U-net style architecture as the baseline are then trained to predict the dose distribution in one of two ways: 1) training from scratch on each data cluster or 2) Transfer Learning (TL) from the baseline model to each data cluster.

Results: Compared to the ground truth data, the Cluster+TL method performed the best in regard to minimizing the error in structure mean and max doses, dose coverage, and isodose similarities between its prediction and the ground truth dose data. Training from scratch on each cluster without TL performed similarly to the baseline model likely due to tradeoff between data quantity and precision. **Conclusion:** We show that our method of Clustering+TL can further improve the result from baseline. Clustering without TL may require more data before it can outperform the baseline model.

This study was supported by the National Institutes of Health (NIH) R01CA237269 and the Cancer Prevention & Research Institute of Texas (CPRIT) IIRA RP150485.

Feasibility Study of a Novel and Efficient Treatment Planning Technique for Total Body Irradiation and Total Marrow Irradiation On Conventional Linacs

C Han*, S Dandapani, J Wong, A Liu, City of Hope Medical Center, Duarte, CA

Purpose: We evaluated the feasibility of using a novel treatment planning technique for total body irradiation (TBI) using modern VMAT fields on conventional linacs with the aim of improving planning efficiency and minimizing dose variation in field junction regions. **Methods:** Two clinical TBI cases were used in this study. The head-in upper body CT simulation and feet-in lower-extremity CT simulation for each case were registered and concatenated to form a whole-body simulation from the top of skull to toes. A treatment plan was optimized to treat the whole-body target volume for 13.2 Gy total in 8 fractions, in which nine arc fields were used to treat the upper body and three wide aperture arc fields were used to treat lower extremities from the mid-thigh level. The optimized plan was separated into an upper-body and a lower-extremity plan. An in-house software program converted the lower-extremity plan into a new plan with the feet-in position by re-arranging control points and rotating field apertures at every control point. The converted lower extremity plan was re-imported into the TPS for recalculation and validation and the total dose was verified by an independent calculation algorithm. **Results:** In both the whole-body TBI plans the mean lung dose was < 8 Gy with the upper-body and lower-extremity targets receiving the prescribed dose to at least 85% volume. With the feet-in patient position, the re-calculated lower-extremity plans showed identical dose distribution to the original plans. Both the upper-body and lower-extremity plans showed a linear dose gradient in the mid-thigh junction region with an average drop-off of 30 cGy/mm. **Conclusion:** Using this planning technique, VMAT TBI plans can be generated efficiently with homogeneous dose in the junction region while minimizing dose variation from setup uncertainties. Our clinical experience showed that this takes similar time and resources as conventional TBI.

PO-GePV-T-285

Generalizability Study On a Deep Learning-Based Dose Conversion Model

X Zhong*, Y Xing, M Lin, S Jiang, Y Zhang, UT Southwestern Medical Center, Dallas, TX

Purpose: Recently a deep-learning model was proposed to boost the accuracy of AAA doses to the level of AcurosXB doses (AXB). A robustness study was performed to evaluate the model on plans across different sites, planning techniques, and machine models to examine its generalizability. **Methods:** In total 66 AAA plans of 5 sites from the same institution were recalculated using the AXB dose engine, and the resulting AAA-AXB dose pairs were used as the testing cohort. A prior deep-learning model trained and validated using VMAT lung plans on Elekta LINACs (VersaHD) was deployed on the testing cohort to derive deep-learning-boosted doses (DLB-AAA) from original AAA doses. The DLB-AAA doses were evaluated using gamma passing rates with the calculated AXB doses as reference. The testing cases were grouped into VMAT-only, same machine model-only, and VMAT & same machine model-only to evaluate the effects of planning techniques and machine models on the deep-learning model accuracy. **Results:** When comparing the gamma passing rates for all testing cases, the DLB-AAA doses do not show better match to AXB doses than the original AAA doses, indicating overall limited model generalizability. However, when restricting the evaluation plans to VMAT-only, the DLB-AAA doses are significantly closer to AXB doses than the original AAA doses across all sites except for head-and-neck (HN), potentially due to the substantial difference in modulation factors between HN and lung VMAT plans. To improve the generalizability of the model, we propose to include plans from all sites and planning techniques for training, with potential fine-tuning through transfer learning warranted. **Conclusion:** Our DL-based AAA-AXB dose conversion model shows robustness towards machine models and treatment sites (except for HN), while lacks robustness towards different planning techniques (VMAT vs. IMRT vs. 3D). Transfer learning or a more generalized model is needed to further improve its robustness.

The study was partially supported by funding from the National Institutes of Health (R01CA240808) and from the University of Texas Southwestern Medical Center

PO-GePV-T-286

Dosimetric Evaluation of Dose Accumulation in MIM and Pinnacle System

I Khaferllari^{1*}, M Liu¹, J Liang², D Lack¹, M Snyder², (1) Beaumont Health System, Troy, MI, (2) Beaumont Health System, Royal Oak, MI

Purpose: Imaging solutions such as MIM Software are commonly utilized to perform dose accumulation for previous treatment. The purpose of this study was to evaluate the dosimetry of dose accumulation performed using algorithms in MIM and Pinnacle treatment planning system (TPS). **Methods:** Six SBRT NSCLC patients with a previous SBRT lung treatment were retrospectively analyzed in this study. The new treatment planning CT was used as the primary dataset. Rigid image registration was performed in Pinnacle TPS. In the first technique, a Pinnacle host script was used to transfer and recompute the previous treatment beams to the new CT; and then summed with the dose from the current treatment beams. The image registration, original RT dose files, original CT datasets, and the new RT structures were exported to MIM software. In the second technique, MIM utilized the imported image registration from Pinnacle to transfer the original old dose from the old CT to the new CT followed by a second dose accumulation generated in MIM. To remove sampling grid bias, both MIM and Pinnacle generated dose accumulations were evaluated in MIM. Dosimetric analysis was performed based on clinical OAR dose limitations. **Results:** The OAR doses in the composite plans were similar between the two software. For the Dmax(0.1cc) constraints for spinal cord, heart, esophagus, etc, the mean and standard deviation of the absolute difference between the two methods were 0.24 ± 0.28 Gy (range: 0 to 1.31 Gy). A significant statistical difference was not observed ($p > 0.5$). The difference between the two methods for the volumetric dose constraints were within 0.36%. Neither was statistically significant. **Conclusion:** Minimal dose differences were observed between the dose accumulation generated from Pinnacle recalculation method and MIM direct summation. These differences are not clinically nor statistically significant. Either methods of dose accumulation can be clinically implemented.

PO-GePV-T-287

Knowledge-Based Planning Assisted Automatic Prostate Cancer Radiation Treatment Planning

L Chen*, Z Xiong, A Godley, S Jiang, M Lin, UT Southwestern Medical Center, Dallas, TX

Purpose: For modern radiation therapy (RT), a human planner needs to adjust planning objectives and constraints in the treatment planning system (TPS) to define the optimization problem for plan generation. Such a process is often tedious and time-consuming, while the plan quality can be affected by many factors, such as the planner's experience and available planning time. To address this issue, we developed a RapidPlan assisted automatic scheme to improve

treatment planning efficiency and quality. **Methods:** The proposed scheme has two stages: Firstly, RapidPlan is employed to define the planning objectives and constraints in TPS to generate an intermediate plan. Secondly, the intermediate plan was evaluated by a set of planning criteria consisting of the safety limits and pre-defined physician's objectives. If the intermediate plan fails to meet all the planning criteria, a set of rules summarized corresponding to the criteria are applied to adjust the objectives and constraints to improve the plan quality. This step can be repeatedly executed until a clinically acceptable plan is obtained. In this study, we considered the prostate-cancer-SBRT (4500cGy in 5 fractions) and prostate-Post-Operative-VMAT (7020cGy in 39 fractions) as two testbeds. 10 patient cases were employed for each type to evaluate the performance of the proposed scheme. **Results:** For 7 of the 10 prostate SBRT, plans generated directly by RapidPlan achieved similar or better plan quality compared to clinical plans. The other three needed to proceed with the second stage, and clinically acceptable plans were successfully generated. Similar results were observed for Post-Operative VMAT planning with 6 of 10 going through the second stage. **Conclusion:** The proposed Rapidplan assisted automatic TPS is effective to generate high-quality plans for prostate SBRT and Post-Operative VMAT. It can be useful for other planning tasks, and has the potential to serve as a tool for training new planners.

PO-GePV-T-288

Dose Evaluation of Deep Inspiration Breath-Hold On the Left Anterior Descending Coronary Artery for Left-Sided Breast Irradiation

A Kwag^{1*}, J Jung², (1) Vanderbilt University, Nashville, TN, (2) East Carolina Univ, Greenville, NC

Purpose: To evaluate the radiation dose of the left anterior descending coronary artery (LADA) for the patients treated with deep inspiration breath-hold (DIBH) technique. In routine clinical treatment planning for the left breast cancer patients, the dose-volume histogram (DVH) analysis of the LADA is not commonly evaluated because its dose constraint information is not enough to analyze clinical toxicities in terms of a critical volume with total dose in number of fractions. **Methods:** Ten left breast patients with various tumor sizes and positions previously treated with field-in-field tangential beam and DIBH were randomly selected. The LADAs were manually contoured. DIBH based on 4DCT (4-dimensional computer tomography) was used for each patient to minimize the heart irradiation. For treatment planning, the prescription dose was 42.6 Gy in 16 fractions. Organs at risk (OAR) included LADA, heart, lumpectomy cavity and lungs. **Results:** The volume of LADA from this study was measured to be 0.25 ± 0.07 cm³. There was not a difference to the sizes, but the positions were changed by the patients' anatomic structure. The dose to LADA were affected by these. The mean, minimum and maximum dose of LADA were 5.37 ± 1.94 , 2.03 ± 0.87 , and 13.15 ± 8.20 , while the mean, minimum and maximum dose of heart were 1.31 ± 0.36 , 0.13 ± 0.04 , and 18.16 ± 11.99 , respectively. The mean dose ratio of LADA to heart was 4.1. **Conclusion:** Our evaluation of the LADA dose demonstrated lower mean dose and standard deviation than other institutions. More clinical evaluations are required from this study in terms of the discrepancy of LADA delineation among the planners and inclusion of the dose effect from electron boost.

PO-GePV-T-289

Discrepancies in Out-Of-Field Dose Prediction Between Treatment Planning Systems

T Tyson^{*}, M Mistro, A Kubli, A Harrison, K Mooney, Thomas Jefferson University Hospital, Philadelphia, PA

Purpose: Physicians routinely rely on dosimetric parameters for organs outside of the treatment field to make clinical decisions regarding plan quality. The purpose of this study is to quantify variance in predicted out-of-field dose by the TPS for relevant OAR constraints in a simple treatment plan. **Methods:** This investigation compared dosimetric data from a simple breast tangent plan prescribed to 4005 cGy in 15 fractions with open jaw-based rectangular fields calculated using different beam models and calculation algorithms within several software systems. The plan parameters such as energy, field size, gantry angle, collimator angle, MU, and isocenter were kept consistent throughout all iterations and the same CT and structure set was utilized. The plan was evaluated on a Varian Truebeam, Varian Edge, Varian Trilogy and Elekta Synergy with an Agility head (Elekta-SA) modeled in various treatment planning systems: Eclipse using AAA, Xio using CCC, and Monaco using Monte Carlo. **Results:** The mean heart dose was recorded for each iteration of this plan as well as the Lung V20. The mean heart doses ranged from 44.7 cGy (Trilogy, Eclipse AAA) to 98.3 cGy (Elekta-SA, Eclipse AAA), the standard deviation was 19.58 cGy. This research also found a 29% difference in the calculated mean heart dose for the same plan on the same machine that had been modeled in two different TPS. Total Lung V20 did not change significantly with distinct beam model, ranging from 12.2% to 12.5%. **Conclusion:** The research reinforces that out-of-field dose cannot be quantified with consistent accuracy across treatment planning systems. The relationship between out-of-field dose predicted by a particular beam model and absolute dose being delivered to that area is not well characterized and necessitates further investigation. This calls into question the strength with which physicians should weigh dosimetric values outside of the treatment field.

PO-GePV-T-290

Investigation of the Dosimetric Effects of An SBRT Positioning System

D Baldassari^{*}, C Esquivel, K Andrews, L Patton, Texas Oncology San Antonio, San Antonio, TX

Purpose: Investigate the potential dosimetric impact of the Bionix SBRT system on the patient. **Methods:** The Bionix RT-4500 Omni-V SBRT system was investigated for the potential dosimetric influence on patients. Structures not unaccounted for during planning may result in inaccurate skin dose and dose coverage. Skin dose measurements acquired using Varian 21iX and 6MV beam. The Edge diode-detector was placed at 100cm SAD, adjacent to each component, for varying field sizes (10x10, 6x6, 4x4, 2x2cm²). The components included the compression belt (with and without insert), chest compression plate (thickest and thinnest part) of the Turner Arch, and the body support vacuum cushion (2, 5, 10cm thicknesses). For attenuation effects, the diode detector was placed at 100cm SAD and 10cm depth in solid water (90cm SSD) for the same field sizes. The SecureFit Bar (center and lock tab), side-rail belt-attachment, Turner Arch, and the base of the SBRT system were placed on top of the phantom. **Results:** With the Eclipse TPS, anything outside the body contour is not considered dosimetrically. Components of the immobilization system must be scrutinized and appropriately considered. Oversight of a device can result in increased surface dose or reduced coverage of the target due to attenuation. Skin dose increases as the field size increases. For attenuation effects, there is a slight decrease of the radiation dose as the field size decreases. **Conclusion:** Measurements traversing various components of the Bionix SBRT system have been reported for user reference within the radiation oncology community. Apart from the T-Vac Cushion on which the patient lies, most components can be knowingly avoided within the treatment planning process. While minimal attenuation of the beam through parts of the device may be observed, unintended skin dose may be significant.

PO-GePV-T-291

The Impact of Treatment Planning System Errors on Patient Dose Delivery

F Brooks^{1*}, M Glenn², J Pollard-Larkin¹, R Howell¹, C Peterson¹, C Nelson¹, C Clark³, S Kry¹, (1) MD Anderson Cancer Center, Houston, TX, (2) University of Washington, Seattle, WA, (3) UCLH, London, SRY, GB

Purpose: To evaluate the impact of different beam modeling errors within the treatment planning system (TPS) on patient care. **Methods:** The Imaging Radiation Oncology Core (IROC) recently conducted a study to understand suboptimal TPS beam modeling that was associated with IROC phantom failures. The resultant dataset describes TPS parameter selection in the radiotherapy community. The current study evaluated the impact of this spread in TPS parameters on clinical treatment plans. The following parameters were modified in RayStation: multi-leaf collimator offset (MLC(O)), transmission (MLC(T)), gain (MLC(G)), curvature (MLC(C)), source size (SS), leaf tip width (LTW) and tongue and groove (T&G). Each parameter was independently modified to match

the community data at the 2.5, 25, 75 and 97.5 percentile levels. The impact of these modifications was evaluated on fifteen patient cases, including prostate, lung and brain plans, generating a total of four hundred and twenty perturbations. The difference in the mean dose delivered to the clinical target volume (CTV) and parallel organs at risk (OAR), and the maximum dose to the serial OAR, were evaluated with respect to the dose delivered using 50-percentile parameter values. **Results:** Variation in the MLC(O) and MLC(T) parameters resulted in the greatest dose difference, relative to the 50-percentile level, for all anatomical sites. For the MLC(O) parameter, the greatest impact to the mean CTV and OAR dose was 5.5% and 14.6%, respectively, at the 97.5-percentile. For MLC(T), the greatest CTV and OAR dose perturbations were -2.8% and -26.7%, respectively, at the 2.5-percentile. **Conclusion:** MLC(O) and MLC(T) beam modeling parameters play a substantial role in patient dose calculations. Extreme values for these parameters (e.g., 2.5 and 97.5 percentile values), which have previously been associated with failing the IROC phantom, negatively impact the quality of patient care. Careful attention should be given to these beam modeling parameters.

This work was supported by Public Health Service Grants CA180803 and CA214526, awarded by the National Cancer Institute, United States Department of Health and Human Services.

PO-GePV-T-292

Dose Prediction Using Three-Dimensional Convolutional Neural Network for Nasopharyngeal Carcinoma with Tomotherapy

Y Liu^{1*}, G Zhang¹, Z Chen², J Wang³, X Wang³, B Qu^{3,4}, S Xu^{3,4}, (1) Beihang University, Beijing, BJ, CN, (2) Manteia Medical Technologies, Xiamen, CN, (3) PLA General Hospital, Beijing, BJ, CN, (4) Beijing Advanced Innovation Center for Big Data-Based Precision Medicine, School of Medicine and Engineering, Beihang University, Beijing, 100191, China; and Key Laboratory of Big Data-Based Precision Medicine (Beihang University), Ministry of Industry and Information Technology

Purpose: To accurately predict 3D dose distribution based on the patient-specific gap between organs at risk (OARs) and PTVs, and small OARs for nasopharyngeal carcinoma (NPC) with Tomotherapy. **Methods:** 3D matrix for a deep learning model of dose prediction was trained to learn more about the relationship between dose distribution and patient anatomical information by increasing the height of training matrix. And 3D HD U-net was used as model. 127 NPC patients treated with Tomotherapy were enrolled in this study, including 84 for training and 43 for testing. The multi-channel 3D input matrix including CT and ROIs, dose array was used as the output matrix. A comparative experiment was done between the training matrix height of 48 (Model I) and 16 (Model II). Mean absolute error (MAE) was taken as the loss function. The models' performance was evaluated by the comparison and statistical analysis. **Results:** The corresponding errors were calculated by comparing the predicted dose with ground truth dose. The deviations among the mean and maximum dose of planning target volumes (PTVs) and OARs were within 4.37%. Error for max dose of optic nerves-L in Model I were $4.05 \pm 3.49\%$, comparing with $7.11 \pm 5.10\%$ in Model II ($p=0.002$). The gamma passing rates of body and PTV for 3%/3mm criteria were $76.5 \pm 10.7\%$ and $83.8 \pm 5.4\%$ in Model I, comparing with $43.3 \pm 5.4\%$ and $73.6 \pm 6.6\%$ in Model II ($p<0.001$). The prediction error of D95 for PTV was $0.48 \pm 0.33\%$ in model I, comparing with $2.72 \pm 1.28\%$ in Model II ($p<0.001$). **Conclusion:** It is important for deep learning dose prediction model to learn the distance of OARs and PTV. We found that large height of training matrix could improve the accuracy of dose prediction. Our dose prediction methods provide a milestone to build automatic Tomotherapy planning.

This work was partially supported by a grant from Medical big data and AI R&D project (No. 2019MBD-043).

PO-GePV-T-293

ROI Contour Based Deep Learning AAA Dose Improvement Method

Z Wang^{1*}, Q Zhou², Y Liu³, Z Chen², B Yang¹, J Qiu¹, (1) Peking Union Medical College Hospital, Beijing, China (2) Manteia Technologies Co., Ltd (3) Department of Physics, Beihang University, Beijing, China

Purpose: Deep learning methods have been explored to accelerate speed and boost accuracy of dose calculation, which of great significance in improving radiotherapy efficiency, by converting fast AAA dose calculation results to much slower but more accurate AXB dose calculation results. In this study we aim to develop a new deep learning scheme, by incorporating ROI contours into the training structure, to improve the performance of dose conversion from AAA dose to AXB dose. **Methods:** We developed a 3D HD U-NET to convert AAA dose to AXB dose. In this deep learning scheme ROI contour binary masks were able to be incorporated as input data in the network structure, as well as the CT and AAA dose. Corresponding AXB dose were calculated using AXB algorithm as the ground-truth. 95 VMAT female pelvic cancer cases were selected for the research, where 76 cases were for training, and 19 cases were for testing. MSE is the loss function. Decay learning rate ranged from 10-4 to 10-6. The training process is stopped when the loss and learning rate stopped to decrease. The comparison study used only CT and AAA dose as input data. **Results:** We calculated the Gamma passing rate (1 mm / 1%, 10% threshold) to evaluate our method using corresponding AXB dose calculation as comparison reference. The Gamma passing rate of original AAA dose and converted AXB dose are $73.64 \pm 3.46\%$ and $95.57 \pm 1.06\%$, respectively. Time consumed for the conversion is 3.06 ± 1.78 s. Compared to deep learning schemes using only CT and AAA dose as input data, Gamma passing rate of our newly devised method increased by 1.1% (TTest, $p=0.004$). **Conclusion:** Deep learning method performs well in converting AAA dose to AXB dose in VMAT female pelvic cancer cases. Adding ROI contour as training data can improve the accuracy of dose conversion.

PO-GePV-T-294

The Effect of Contrast Agents On Dose Calculations in Volumetric Radiotherapy for Critical Structures

S Almohsen^{*}, A Elawadi, M Alshanqity, H Allassaf, R ELGENDY, H Allazkani, R Mohamed, King Fahad Medical City, Riyadh, Saudi Arabia, Mansoura University, Faculty of Medicine, Oncology and Nuclear Medicine Dept., Egypt

Purpose: Accuracy of radiotherapy dose calculation requires high quality CT imaging while tissue delineation may require the use of Contrast Agents (CA). It is widely accepted practice to acquire two sets of CT images in radiotherapy CT simulators, one with contrast and another with no contrast. This study aims to evaluate the effect of CA on the dose calculations in critical structures and planning target volumes (PTV). **Methods:** Two hundred and twenty-six patients' Volumetric Modulated Arc Therapy (VMAT) plans of different cancer sites (Brain, Head and Neck (H&N), Chest, Abdomen, and Pelvis) were evaluated in this study. Selection criteria included all VMAT patients that had planning CT with contrast (CCT) and non-contrast CT (NCCT) at the same time. Approved treatment plans were recalculated using CCT without any further changes, then compared to NCCT. The variation in Hounsfield Units (HU) and dose distributions for critical structures and PTV's were analyzed using absolute HU values, relative dose values, D2%, D98%, and 3D-gamma analysis. **Results:** HU variation due to CA were statistically significant ($p\text{-value}<0.05$) for the majority of critical structures and PTVs. However, this was not clinically significant as the variation in HU values was within 40 HU. Variation in PTV D2% and D98% values was insignificant for all sites except in Brain and Nasopharynx. Relative dose maximum difference was $\leq 2\%$ for the majority of critical structures. Minimum, maximum, mean, and median values for D2% and D98% were within 1.5%. Gamma analysis results revealed that 202 and 18 patients passed with 2%/2mm, 3%/3mm, criteria respectively, other 6 patients failed. **Conclusion:** CCT could be acquired for VMAT radiotherapy planning purposes instead of NCCT, since there is no clinically significant difference between dose calculations based on either image set.

PO-GePV-T-295

A Simple Method for Accurate Multi-Target Winston-Lutz Testing

G Gilson*, Abbott Northwestern Hospital, Minneapolis, MN

Purpose: Treatment modalities such as Varian's HyperArc allow convenient and efficient treatment of multiple stereotactic targets in a single isocenter. Confirming geometric accuracy of the mechanical, radiation, and imaging systems for off-axis targets is crucial for these treatments, but centering an MLC field on an off-axis target poses a significant challenge due to geometric offsets in the source-target direction and fixed MLC leaf width. While methods have been proposed to perform Winston-Lutz testing of off-axis targets relative to baseline measurements, this work aims to provide a simple solution for multi-target Winston-Lutz testing that is absolute, efficient, and reproducible. **Methods:** The VisionRT Cube phantom was used, which includes five 7.5mm ceramic spheres, including 4 targets offset in three dimensions from a central target. Total distances vary from 2.3cm to 4.1cm. Eight fields were planned which included gantry, collimator, and table rotations. Within each field, 1.5cm MLC openings were centered on three targets including the central target. Exact MLC locations for centering on each target in the leaf motion direction, as well as known target offsets in the interleaf direction, were calculated from simple beam divergence projections. These known offsets were then subtracted from the Winston-Lutz results for each field. This test was repeated on five occasions to confirm reproducibility. **Results:** Initial results showed a maximum isocenter offset of 1.35mm. After applying offset corrections, all targets for all fields showed accurate results with the largest offset being 1.03mm. The average offsets ranged from 0.32mm to 0.54mm for the various targets, while standard deviations ranged from 0.15mm to 0.21mm. **Conclusion:** This proposed multi-target Winston-Lutz method provides an accurate and reproducible means to characterize off-center targeting performance. The process can be utilized during commissioning of a single isocenter multi-target SRS program and is simple enough to perform routinely.

PO-GePV-T-296

Physics Quality Assurance: A Pilot Survey of Global Needs

A Yorke*, V Williams E Ford, University of Washington, Seattle, WA

Purpose: To assess physics QA and quality management in low- and middle-income countries (LMIC). An exploratory preliminary study was conducted to investigate the relationships between physics QA needs and the economic factors in the radiotherapy centers surveyed. **Methods:** A survey was conducted amongst 13 centers in 6 countries. 3 LMIC and 10 upper middle-income countries (UMIC). Questions covered education and training, recognition of medical physics as a profession, the nature and type of external beam equipment, patient workload on Linac/Co-60, HDR and LDR brachytherapy and, physics QA needs and practices. **Results:** The survey response rate was 92%. In countries with lower gross domestic product per capita (GDPpc) there were a higher number of patients treated per year and higher linac workloads. In terms of staff workload on average there were 360 patients/year/physicist and 210 patients/year/radiation oncologist (or therapist). This workload is comparable to other surveys in Eastern Europe and other regions. In lower GDPpc countries there were more QA needs, including: film/array detectors, independent dose calculation software, calibration of ion chambers, diodes, TLDs, phantoms for verification, TPS test phantoms, imaging test phantoms and film dosimeters education and training. The study also revealed centers follow AAPM (75%), IAEA (66.7%) and other international guidelines (20%) for their QA practices. **Conclusion:** Our study shows the relation between QA needs and RT centers in low GDP regions. Though centers follow international QA guidelines, they lack recommended devices and infrastructure to execute these protocols. These results support the need to further investigate current physics QA practices in these centers and develop collaborations to build comprehensive local QA programs.

PO-GePV-T-297

Accelerator Beam Data Variability with Detectors

S Kucuker Dogan*, M Gopalakrishnan, I Das, Northwestern Memorial Hospital, Northwestern University Feinberg School of Medicine, Chicago, IL

Purpose: Accurate beam parameters (percent depth dose-PDD and profiles) are essential for treatment planning and dose calculations that are acquired during machine commissioning. However, these are dependent on the selection of a detector. The suitability of modern detectors for a wide range of field sizes and beam energies are investigated. **Methods:** Beam parameters are measured using IBA blue phantom scanning water tank on a Varian TrueBeam machine with 6, 10, 18MV, 6FFF and 10FFF energies for field sizes ranging from 1x1 cm² to 30x30 cm². Modern detectors such as IBA CC-01, CC-04, Scanditronix SFD, PFD, microDiamond (PTW-60017), microSilicon (PTW-60023) and Standard imaging-W2 plastic scintillator detector (PSD) were used with recommended bias (300V and 0V). IBA Stealth chamber and Scanditronix RFD were used as the reference chambers for small to intermediate and large fields, respectively. IBA CC-04 was treated as a reference detector for 5x5cm² to 30x30cm² and W2 for 1x1cm² for PDD and profile analysis and comparisons. **Results:** The PDD and profiles varies significantly among the detectors, field size and beam energies. The average variation in PDD beyond buildup region, among detector was $\pm 1\%$, $\pm 2\%$ and $\pm 5\%$ for 1x1cm², 10x10 cm² and 30x30 cm², respectively but nearly independent ($\pm 2\%$) on beam energy. The variation in profiles at 10 cm depth was $\pm 5\%$, $\pm 4.5\%$ and $\pm 3\%$ for 1x1cm², 10x10cm² and 30x30cm² for 6MV and slightly larger ($\pm 1\%$) for 18MV but mainly in penumbral region. Differences are pronounced with beam energy and field sizes due to μ_{en}/ρ variation associated with photon spectrum. **Conclusion:** Selection of detector is critical for acquiring accurate PDD and profile for various energies and field sizes. It is concluded that PSD W2 and small volume ion chamber are preferred for field sizes from 1x1-5x5cm² and 3x3-30x30cm² respectively.

PO-GePV-T-298

Deep Learning for Patient-Specific Quality Assurance : Predicting Gamma Passing Rates for IMRT Based Log File

Y Huang*, Y Huang, Z Xu, Shanghai Chest Hospital, Shanghai, 31CN

Purpose: To propose a deep learning-based approach to predict IMRT QA gamma passing rates using log files. **Methods:** 112 IMRT plans for thoracic tumors, including 584 fields, were planned and delivered with portal dosimetry on TrueBeam LINAC. Then the machine recorded log files data were collected. Gamma passing rates for 3%/3 mm, 2%/3mm, 3%/2mm, 2%/2mm local dose/distance-to-agreement (DTA) were analyzed and recorded. The CNN based learning model was trained using log files as inputs and gamma passing rates of four different criteria as output. Fivefold cross-validation was utilized to tune the model and prevent "overfitting" and MSE was used for loss function. Model performance for both validation set and test set were assessed using MAE, RMSE, Spearman rank correlation coefficients and Determination coefficient were analyzed between measured and predicted GPR values. **Results:** In test set, the MAE of prediction model were 0.402, 0.511, 1.724, 2.530, the RMSE were 0.800, 0.993, 2.580, 3.083, the Sr were 0.643, 0.684, 0.821, 0.824 (P<0.001) and the R2 were 0.4110, 0.4666, 0.6677, 0.6769 for 3%/3mm, 3%/2 mm, 2%/3 mm, 2%/2 mm, respectively. The accuracy of the prediction model decreased with stricter gamma criteria while the Sr and R2 between measured and predicted GPR values increased. **Conclusion:** The CNN prediction model based on log files could accurately IMRT QA passing rates for different gamma criteria. It could reduce QA workload and improve efficiency in pre-treatment and on-treatment dose verification. Our results suggest that CNN prediction model based on log files may be a promising tool for gamma evaluation of IMRT QA.

PO-GePV-T-299

Toward Ending the Manual Annual: Lessons Learned From the Expansion of An Automated Output Quality Assurance Technique to Outside Institutions

L LeMerise^{1*}, E Morris², B Loughery¹, (1) Wayne State University, Detroit, MI, (2) UCLA Health, Los Angeles, CA

Purpose: To adapt a single-setup in-house linac QA automation method to outside institutions. **Methods:** Annual output quality assurance was automated in previous work for our Varian TrueBeam through the SAGE tool, TrueBeam Developer Mode, and the PTW UNIDOSwebline electrometer with in-house software. We adapted this work to 2 outside institutions based on their 2020 annual output QA procedures. Crucially, we hypothesized that outside institutions would see a strong hysteresis effect depending on the length of the beam off time between irradiations. Extensive scripts were created to address the tradeoff between short scripts and hysteresis across a hypothesized 140 measurements over 30 minutes. **Results:** The expansion of our automation method to an outside institution highlighted the implicit clinic-specific assumptions that were made in the original Developer Mode scripts. Adaptation required adjustment of each beam to the energies, test parameters, and measurement repetition used in each clinic. Also, our in-house analysis program needed to be adjusted to accept the output file format from a Standard Imaging SuperMAX electrometer. Furthermore, the MLC model needed to be switched from HD to standard. It is essential that clinics using our technique are able to create their own scripts in a user-friendly manner. Our early emphasis on minimizing the time between irradiations while optimizing the inherent tradeoff with hysteresis was misplaced. The contributing clinics required only 53% of the measurements of our own clinic. Minimizing the duration of beam-off pauses yielded a small gain for the outside institutions. A 5-second beam off time after each irradiation was measured to be sufficient to reduce hysteresis to within 0.5% over 100 irradiations. **Conclusion:** Widespread adaptation of the work will help to determine the appropriateness of digital electrometers and their analysis software for automation. Generalization is necessary to enable customization of this work to any cancer center.

PO-GePV-T-300

An Innovative Water-Equivalent Solid Device for Beam Scanning to Replace Computerized 3D Water Scanning Systems

K Xie*, D Shvydka, N Sperling, E Parsai, University of Toledo Medical Center, Toledo, OH

Purpose: To develop a solid phantom that is capable of replacing the computerized water scanning system in its entirety. This phantom is designed such that it is easy to install at the head of the gantry and within a few minutes of data collection, the user can extract profiles and percent depth dose (PDD) data quickly through the software associated with this device. **Methods:** Using Monte Carlo package MCNP5 we modeled our LINAC (Varian Edge 6FFF), and confirmed that simulated PDD ($10 \times 10 \text{ cm}^2$) and profiles at different depths agree favorably with measured data acquired in a 3D water tank ($40 \times 40 \times 40 \text{ cm}^3$). We then created a virtual solid device placed at 60cm source to surface distance (SSD) on modeled Linac, which is near closest distance to gantry head. The device modeled in MCNP consists of two new phantoms that interlock and are modeled using published data for solid water material and a detector grid with much smaller volume and special geometrical shape to accommodate acquisition of data for PDD and profiles. Scoring points were placed in virtual phantom representing arrays of diodes for future prototype for the measurements of PDD and profiles. New data are acquired through simulation and compared with data from the 3D water tank to demonstrate the feasibility of this new device. **Results:** Simulated PDD and profiles in new designed solid water phantoms agree favorably with data from a 3D water tank (<1% error). The effective mass of the prototype phantom for profiles is 9% of 3D water tank while the phantom for PDD is only 1%, indicating much easier handling and setup. **Conclusion:** Monte Carlo simulations show the feasibility of our new solid phantoms to replace 3D scanning water tank from the points of saving time in data acquisition, accurate dosimetry evaluation and convenience of equipment setup.

PO-GePV-T-301

Energy Dependence And dosimetric Stability of EPIDs Used for Linac QA

C Raman*, Y Hao, B Gu, M Schmidt, T Zhao, B Sun, Washington University in St. Louis, St. Louis, MO

Purpose: Electronic portal imaging devices (EPIDs) have been widely used for linac QA. The purpose of this study is to determine the energy dependence and long-term stability of EPID pixel response. **Methods:** Six Varian Truebeam linacs (3 equipped aS1200 and 3 equipped aS1000 EPID panel) with different ages (1 to 10 years) were included in this study. Since the vendor-provided flood-field calibration method cannot separate beam response and pixel gain, we generated a pixel sensitivity map (PSM) independent of the beam profile to quantify the pixel response. PSM was derived by applying a recursive algorithm from five EPID images acquired in different imager locations. All the pixel responses were normalized to the central pixel. PSM measurements were performed for 6 MV and 10 MV consecutively from 8-25 weeks for different imagers. The pixel response of EPID was compared for 6MV and 10 MV. The time-dependent response of EPID pixels was evaluated to determine long-term stability. **Results:** Central axis response changes for the six machines were as follows: 0.24% (Tr5-aS1000), 0.31% (Tr7-aS1000), 0.23% (Tr14-aS1000), 0.23% (Tr15-aS1200), 0.24% (CHNW TB1-aS1200), 0.18% (BJSP TB2-aS1200). The mean absolute changes of pixel response for the entire panel during the study period were: 0.48% (Tr5-aS1000), 0.76% (Tr7-aS1000), 0.45% (Tr14-aS1000), 0.98% (Tr15-aS1200), 0.59% (CHNW TB1-aS1200), 0.51% (BJSP TB2-aS1200). The mean difference of EPID response for 6MV and 10 MV was: 1.10% (Tr5-aS1000), 0.89% (Tr7-aS1000), 0.83% (Tr14-aS1000), 0.65% (Tr15-aS1200), 0.66% (CHNW TB1-aS1200), 0.57% (BJSP TB2-aS1200). **Conclusion:** The PSM corrected images enable the evaluation of pixel response independent beam profile. EPID Pixel response has a small dependence on energy. Overall, the EPID pixel response was found to be very stable over a relatively long period.

PO-GePV-T-302

API Assisted Treatment Planning System Validation for Medical Linear Accelerators

M Schmidt^{1, 2*}, N Knutson¹, B Sun¹, E Sajo², P Zygmanski³, M Jandel², J Kavanaugh¹, G Hugo¹, F Reynoso¹, (1) Washington University School of Medicine in St. Louis, Saint Louis, MO, (2) University of Massachusetts Lowell, Lowell, MA, (3) Brigham & Women's Hospital, Boston, MA

Purpose: The characterization of the dosimetric properties of a medical linear accelerator (linac) in radiation therapy is a critical physics task prior to the linac's clinical use. Vendor provided application programming interface (API) access can assist in the efficient collection of validation data. **Methods:** Over the past year, two linear accelerators, TB1 and TB2, were commissioned with the aid of custom software assistance. The beam data validation was assisted by a software application that accesses calculated treatment planning system (TPS) percent-depth-dose (PDD) and profile data for electron and photon beam qualities. Data was also collected and analyzed for stereotactic conical collimators (SRS CC) and electronic portal imaging device images. **Results:** Gamma pass rates of scanned beam commissioning data were above 94% using a 1% dose-difference (DD) and a 1mm distance-to-agreement (DTA) for PDD and 2% DD and 2mm DTA for profiles for photon beams. Electron pass rates for PDD and profile data were above 98% for TB1 and 92% for TB2 using 2%/2mm and 3%/3mm for DD/DTA for PDD and profiles, respectively. SRS CC output factors for all cone sizes were within 2% for all cone sizes and tissue maximum ratio point data were within 3% for TB1. Validation of image prediction algorithms were performed with a 2D gamma image comparison with 2%/2mm DD/DTA and an average pass rate of 99.42% for over 42 acquired images. **Conclusion:** API driven analysis tools can assist commissioning physicists in the efficient and precise collection of beam scan data, calculated dose volumes, and dosimetric images. Thousands of data points and dozens of images can be analyzed while simultaneously measuring other energies and fluence modes. From the experience of commissioning two linacs throughout the past year, TPS validation scripts assist in gathering the dosimetric data needed to confidently release a linac into clinical service.

PO-GePV-T-303

Independent Evaluation of MPC Using Winston-Lutz Test

W Luo*, M Halfman, University of Kentucky, Lexington, KY

Purpose: The Varian Machine Performance Check (MPC) system is a QA tool used to quickly test the functions and performance of the Varian TrueBeam and Halcyon. This study was to evaluate MPC with geometry test independently using the Winston-Lutz test. **Methods:** MPC was performed on the Varian TrueBeam using an IsoCal phantom sitting on the six-degree-freedom treatment couch. Beam isocenter size/location, Isocenter coincidence, collimator rotation offset, gantry position accuracy, couch accuracy, MLC leaf position (inner leaves), and Jaw position are checked by MPC. The Winston-Lutz test (WL) was conducted with a 10x10x10cm³ plastic cube. A small metal ball (BB) sits in the center of the cube. The cube was set on the couch with the BB located at the isocenter. The WL results were analyzed using the Pylinac Winston-Lutz program. **Results:** MPC performed six tests with the IsoCal phantom aligned with the isocenter, and three tests with the IsoCal phantom off the isocenter. Correspondingly, nine WL tests were performed. The average isocenter diameter measured by WL was 0.33 mm, and 0.35 mm by MPC with the IsoCal phantom aligned with the isocenter, and the difference was 0.02 mm. With the phantom off isocenter, the isocenter diameter was 0.32 mm in average for both WL and MPC. **Conclusion:** MPC tests of the isocenter and couch are highly accurate. The accuracy of tests are not affected by phantom setup uncertainty and thus reliable. It is comparable with WL test in accuracy for isocenter test and also a convenient and efficient tool for SRS/SBRT QA.

PO-GePV-T-304

Quantification of Peripheral Dose in the New Ring-Gantry RefleXion X1 Radiotherapy Machine

OM Oderinde*, S Khan, M Narayanan, A Maniyedath, SM Shirvani, G Kuduvalli, RefleXion Medical, Hayward, CA

Purpose: In radiation treatment delivery, scattering and secondary particles exist far from the treatment target region, contributing unaccounted doses to the patient. This study aims to quantify the peripheral dose in the RefleXion™ X1 radiotherapy machine. **Methods:** Measurements were carried out with an Exradin-A14SL microchamber inside a solid-water phantom in the RefleXion X1 machine under the conditions of a flattening filter-free 6MV photon beam. Peripheral dose was measured at 5 points (2, 4, 6, 8, and 10 cm) from the edge of the fields in the IEC-X direction at 85 cm SSD for 10,000 MU. The fraction of dose was calculated using the CAX measurement as a reference. In addition, the dose was measured at 1.5, 5, and 10 cm depths in the solid-water phantom for beam segments defined with a 2 cm fixed jaw opening in the IEC-Y direction and 2.5, 5, 7.5, and 10 cm multi-leaf collimator (MLC) opening in the IEC-X direction. **Results:** Peripheral dose for the RefleXion X1 machine was 0.39%, 0.55%, 0.69%, and 0.79% of the CAX dose, respectively, for the corresponding 2.5, 5, 7.5, and 10 cm MLC openings at a 1.5 cm depth in the phantom at a 2 cm extended distance from the field edge. The peripheral dose increased with depth from 75 cGy at 1.5 cm to 146.24 cGy at 10 cm depth for 10 cm MLC x 2 cm jaw field size. Also, radiation dose decreased with larger extended distances from the field edge: At 10 cm off-axis from the field edge, the ion chamber measurement was 0.11%±0.02%, 0.17%±0.07%, 0.20%±0.06%, and 0.23%±0.08% of the CAX measurement for the corresponding 2.5, 5, 7.5 and 10 cm MLC openings, respectively. **Conclusion:** This study demonstrates that the RefleXion X1 machine's peripheral dose is low, even in scenarios where the scattering effect is pronounced.

Efficient Beam Modeling of a Linear Accelerator with the Reference Data Set to Enable a Faster Clinical Go-Live

Y Zhong*, Y Yang, J Zhao, W Hu, 1 Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, China, 2 Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, China, Shanghai

Purpose: An ultraefficient program that optimizes linac commissioning and beam modeling times to enable a faster clinical go-live using golden beam data (GBD) is proposed. The aim of this paper is to address this issue and quantify the dose variation using commissioning data. **Methods:** Two Elekta Infinity linacs with agility heads were installed and matched with the reference data set in our institution. Then, a customer acceptance test (CAT) and model validations were performed on measured percent depth doses (PDDs) and profiles for open-field point-doses in a 3D water phantom. Gamma analysis was used to assess the agreement for these two machines. Before clinical use, intensity modulated radiation therapy (IMRT) and volumetric modulated arc therapy (VMAT) plans were used to test the validity of the two beam models. **Results:** For comparing Monaco-calculated PDDs and profiles with measured data, gamma index values greater than 93.3% above 1 were observed for both beam models. A total of 96.8% and 97.2% open field point doses of TPS calculations were within the 2% tolerance for linac 1 and linac 2, respectively. Electron beam TPS calculations of R50 and R90 in a homogenous water phantom yielded results that were within 3 mm at all evaluated points. Output factors derived from TPS-calculated dose values for field sizes greater than 6 × 6 cm² agreed to within 3% for all energies, cones, and cutout sizes tested. Comparisons between TPS calculated plans and Delta4 measurements and gamma analysis at 3% and 3 mm yielded passing rates of greater than 90% for all plans measured. Point-dose agreement was within 3% for all plans. **Conclusion:** The proposed method has the potential to provide treatment flexibility and to simplify the linac commissioning procedure, save time and manpower and increase the accuracy of the commissioning and annual QA processes.

PO-GePV-T-306

Streamline the Annual Relative Dosimetry QA Check with MapCheck

M Zhang*, D Lovelock, H Zhang, L Voros, Y Song, Department of Medical Physics, Memorial Sloan Kettering Cancer Center, Ny, NY

Purpose: The study goal is to streamline the annual relative dosimetry QA checks to increase efficiency while maintain precision. The performance of MapCheck was evaluated against ion chamber (IC) and razor diode for various measurements. **Methods:** The scope of annual Linac QA requires the checking of a large number of beam parameters. The possible use of a MapCheck diode array to perform multiple annual tests was investigated in order to determine if time required to perform the tests could be reduced, and that results of the tests were consistent with those obtained using a single ionization chamber and a razor diode. **Results:** The relative standard deviation from repetitive MapCheck point dose measurements across all beams was 0.08% on average with the maximum of 0.79%. In photon checks, MapCheck provided the same measurement uncertainty as IC for dose linearity, dose rate linearity, output factor for ≥3x3cm field, and enhanced dynamic wedge output. MapCheck measured output factor for small field was <2% different from a razor diode for 3x3cm down to 1x1cm square field. The beam flatness measured by MapCheck yielded >2% error comparing to IC. For electron beams, cone factors measured by MapCheck had upto 1.42% uncertainty. Based on such observations, four QA plans were designed to cover all annual relative dosimetry checks: plan 1: photon beam measured by MapCheck; plan 2: photon beam measured by IC; plan 3: electron beam measured by IC; and plan 4: electron beam measured by MapCheck. Comparing to doing QAs in service mode with IC, it can potentially reduce the total QA time by half. **Conclusion:** MapCheck demonstrated good quality as an IC substitute for relative dosimetry QA task except for absolute beam flatness and electron cone factor measurements. A streamlined QA scheme was

developed by combining MapCheck and IC to achieve high efficiency.

PO-GePV-T-307

Validation of Non-Isocentric Delivery and Analysis of VMAT QA Plans Using ArcCHECK

G Cui*, N Walls, N Eclow, J Duan, Duke University Medical Center, Raleigh, NC

Purpose: To validate non-isocentric delivery and analysis of VMAT QA plans using ArcCHECK. **Methods:** ArcCHECK (Sun Nuclear Corp., Melbourne, FL) is routinely used in rotational delivery for patient pre-treatment QA. A CavityPlug insert with ion chamber is used for isocenter dose measurement. Plans with high dose targets not at isocenter typically require one delivery with isocentric setup for gamma analysis and another with ArcCHECK shifted to position the ion chamber at a high dose region for dose measurement only. The shifted non-isocentric ArcCHECK measurements, particularly in transverse directions, are not standard and not recommended by the manufacture for gamma analysis. In this study, we demonstrated and validated non-isocentric delivery and analysis of VMAT QA plans using ArcCHECK. Ten clinical VMAT plans with the isocenter outside high dose targets were used for the study. All plans were generated in Varian Eclipse TPS with HD120 and Millennium 120 MLCs using 6FFF, 6X, 10FFF and 10X photon energies. For each clinical plan, two QA plans were created, one without and one with shifts from the ArcCHECK isocenter. QA plans delivered without shifts were used for gamma analysis as baseline. QA plans delivered with shifts were used for both absolute dose measurement and gamma analysis. The average gamma passing rates for non-isocentric delivery were compared with the corresponding results of isocentric delivery. **Results:** With 10% threshold and local 3%/3mm passing criteria, the average gamma passing rate for non-isocentric and isocentric deliveries were $(98.7 \pm 1.4)\%$ vs. $(97.0 \pm 2.4)\%$, respectively. With 3%/2mm passing criteria, they were $(95.2 \pm 4.0)\%$ vs. $(90.2 \pm 5.7)\%$, respectively. The absolute dose measurements of the non-isocentric deliveries were all within $\pm 3\%$ of the calculated dose. **Conclusion:** The non-isocentric delivery and analysis of VMAT QA plans using ArcCHECK were demonstrated and validated for patient pre-treatment QA.

PO-GePV-T-308

On the Performance of LINAC Annual Quality Assurance Without the Need for a 3D Water Tank

H Kadji¹*, B Lewis¹, R Teboh Forbang^{1, 2}, (1) Hackensack Meridian Health at Mountainside Medical Center, Montclair, NJ, (2) Hackensack Meridian Health at Hackensack University Medical Center, Hackensack, NJ

Purpose: 3D water tanks are utilized to acquire data as part of the annual quality assurance on linear accelerators. A 1D water tank alone or in combination with a modern array detector may offer an attractive alternative in terms of cost and expeditious results. In this work, we compared aspects of our annual QA acquired with and without the use of a 3D water tank. **Methods:** The 3D water tank used was Standard Imaging's DoseView 3D and the alternate equipment was Sun Nuclear's 1D Scanner as well as the Ion Chamber (IC) profiler. With the IC profiler's inherent depth of 0.9cm, additional water slabs were used as needed to acquire profiles for photons (6MV, 6FFF, 10MV, 10FFF, 15MV), and electron energies (6e, 9e, 12e, 15e, 18e) for different field sizes and different depths. Furthermore, by irradiating the 1D tank from the side, that is a gantry of 90 (or 270) with the tank atop the couch at 100cm SSD to the side, we also acquired profiles using the 1D tank alone. These results were compared with those acquired using the 3D water tank. **Results:** We observed excellent agreement between the 3D tank versus the IC profiler with a measured discrepancy within 1% for all photons/electrons profile flatness and symmetry and within 2% for all electron flatness. The calculated Beam Profile Constancy for the 6MV, 10MV and 15MV beams between the 3D and 1D water tank were excellent, observing 0.49%, 0.44% and 0.79% respectively for the 10x10cm field and correspondingly 0.38%, 0.54% and 0.62% for the 20x20cm field. **Conclusion:** A 1D scanner and a detector array produce comparable profile results vis-a-vis a 3D scanner and therefore offer an attractive alternative. The limitation is with the maximum field size attainable as well as the range of depths achievable using a 1D scanner.

PO-GePV-T-309

Small Field Dosimetry of a Novel Biology-Guided Radiotherapy System

B Han*, N Kovalchuk, M Shi, K Bush, D Capaldi, D Breikreutz, E Simiele, L Xing, M Surucu, C Chuang, Stanford University, Department of Radiation Oncology, Stanford, CA

Purpose: A biology-guided radiotherapy (BgRT) system - Reflexion™ X1 was developed and equipped with PET imaging. This study reports the small field measurement results of the first clinical BgRT machine at Stanford. **Methods:** The X1 linac produces 6MV flattening filter free beam and consists of a binary multi-leaf collimator (MLC) system with sixty-four 6.25mm-thick leaves and y-jaws switching between 1cm and 2cm. All clinical beams are delivered with the narrow longitudinal beam geometry which resulted in a lack of charged particle equilibrium. Therefore, it is critical to ensure the accuracy of small field dosimetry for the system. We performed profile scans and relative output factor measurements of field sizes from 1.25x1cm² to 40x2cm² using a diode detector in a 3D water tank during the commissioning process. Subsequently, we repeated the tests using diode, film, and tissue-equivalent W2 scintillator in plastic water focusing on small fields down to 0.625x1cm². **Results:** For the fields with 2cm Jaw, the mean differences of relative output factors measured using diode and scintillator were 0.57% and a maximum of 2.79% for the 0.625x2cm² field. The film results agreed better with the scintillator, with mean and max differences of 0.2% and 0.7%. For the fields with 1cm Jaw, the mean differences of relative output factors measured using diode and scintillator were 1.35% and a maximum of 3.15% for the 0.625x1cm² field. The film results maintained good agreements to the scintillator with mean and max differences of 0.44% and 0.99%. The FWHM differences calculated from the longitudinal and transverse profiles measured with diode and film were within 0.5mm across the depth from 1.5cm to 20cm. **Conclusion:** This evaluation represents the first small field dosimetry of the clinical BgRT system serving as a future reference.

PO-GePV-T-310

A Novel Method to Verify Deformable Dose Accumulation for Patients Treated with Helical Tomotherapy

H Zhong*, J Garcia Alvarez, K Kainz, G Chen, A Tai, E Ahunbay, X Li, Medical College of Wisconsin, Milwaukee, WI

Purpose: To develop an independent dose mapping program for verification of adaptive radiotherapy (ART) for patients treated with helical tomotherapy. **Methods:** An in-house developed ART platform (Hertz) was adapted to verify dose accumulations performed in a commercial ART system (PreciseART, Accuracy Inc.). Specifically, in PreciseART, deformable image registrations were performed from daily MV-CTs to a planning kV-CT. The resultant displacement vector fields (DVF) were used to map doses from the MV-CTs to the kV-CT. All the CTs, doses and DVFs were exported to Hertz. In Hertz, HU-to-mass density tables for kV and MV-CTs were used to convert HU and dose to mass density and energy. DVFs were used to generate their pseudo-inverse DVFs. An energy-and-mass congruent mapping (EMCM) method was implemented to reconstruct the deformed doses on the planning CT using the pseudo-inverse DVFs. The doses reconstructed by the two methods were compared to verify the accuracy of dose accumulation in PreciseART. The doses reconstructed by EMCM and PreciseART were converted to energy using the mass densities of the daily MV-CT and planning kV-CT, respectively. Energy distributions derived from the planned, delivered, and reconstructed doses were compared with each other to detect potential DVF errors, mass changes or imaging artifacts in each organ. The program was tested with the data acquired from three tomotherapy patients. **Results:** The dose and energy reconstructed by PreciseART and Hertz were compared within six representative structures. The dose difference averaged over all the structures is $2.7 \pm 1.7\%$ and energy difference is $5.4 \pm 0.8\%$. Compared to the energy on the daily images, the reconstructed energy on the planning images changed by $4.1 \pm 0.4\%$ for Hertz and $8.4 \pm 0.0\%$ for PreciseART. **Conclusion:** An independent dose reconstruction program has been developed to verify dose accumulations in PreciseART. This program may also help calculate energy distributions within each organ for root cause analysis.

This project was funded in part by NIH/NIBIB R01-EB028324.

PO-GePV-T-311

Evaluation of Out-Of-Field Dose Calculation Accuracy of Monaco Treatment Planning System for a 1.5T MR-Linac

Y Zhang^{1,2*}, S Yan^{2,3}, Z Li², B Li², H Quan¹, J Zhu², (1) Wuhan University, Wuhan, CN (2) Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, CN (3) University of South China, Hengyang, CN

Purpose: To evaluate the accuracy of the out-of-field dose calculation for a 1.5T MR-Linac using a Monte Carlo fast dose algorithm in the Monaco treatment planning system. **Methods:** Using optically stimulated luminescence dosimeters, 25 checkpoints were measured on surfaces (20 checkpoints) and internal organs (5 checkpoints) of the anthropomorphic phantom for square radiation fields, with similar prescribed doses for the head, thoracic, and pelvic sites. Each measurement was repeated five times, and the average was compared with the calculated dose values of the Monaco treatment planning system. The inverse of the function that describes the out-of-field dose with respect to the isocentric distance from the radiation field was fitted. In addition, the relationship between the dose evaluation error of the treatment planning system and the variation in the isocentric distance from the radiation field is described. **Results:** Among the 25 checkpoints, the thyroid gland received the highest dose. However, the measured dose did not exceed 1.45% of the prescribed dose. The dose measured both on the surface and internal checkpoints of the anthropomorphic phantom for plans with different sites, followed an exponential function of dose reduction over a distance of 10–90 cm from the isocenter of the plan. Compared with the measured data, the results of the Monte Carlo dose calculation algorithm in the Monaco treatment planning system underestimated the out-of-field checkpoints dose by 0–35% in an isodose area between 2% and 5% and overestimated the out-of-field checkpoint dose by 0–270% in an isodose area between 0% and 2%. **Conclusion:** In an isodose area below 5%, the out-of-field dose evaluated through the fast Monte Carlo algorithm in the Monaco treatment planning system deviates from the measured dose, and the deviation increases as the distance from the target volume increases.

PO-GePV-T-312

Cross Dose Engine Transformation Based Fast Dose Calculation for Online MR-Guided Adaptive Radiotherapy

T Song^{1*}, L Zhou², Y Li³, (1) School of Biomedical Engineering, Southern Medical University, Guangzhou, CN (2) Department of Radiation Therapy, SYSU Cancer Center, Guangzhou, CN

Purpose: To propose a novel magnetic field dose calculation method based on transformation from pencil beam to monte carlo distribution. **Methods:** The novel magnetic field dose calculation algorithm is established by a pencil beam dose engine and a magnetic field influence correction network. The correction network is constructed by a Res-UNet framework, including a residual module and an encoding-decoding path. Beam dose calculated by pencil beam engine without considering magnetic field and by Monte Carlo with magnetic field are generated and enhanced respectively to train the network. 100 clinical treated static beam IMRT plans were collected, including brain, head and neck, lung, and abdominal cancer cases. 80% of them are used to train the model and the other 20% to test. By comparing the predicted dose distribution with the original input PB dose and the corresponding MC dose, the feasibility and effectiveness of the method is evaluated. **Results:** Results of both lung and HN cases show that the predicted dose distribution from the cross-dose engine transformation is very close to MC results, and the profiles are basically consistent, compared to PB dose VS. MC. The average voxel absolute dose error could decrease from 4.2% (PB to MC) to 0.9% (predicted value to MC), and the Gamma pass rate increase from 48.8% to 99.2%. The PB calculation and transformation process can be completed in ms. **Conclusion:** We have successfully proposed a fast and precise magnetic field dose calculation algorithm, with the capability to perform accurate and real-time dose calculation during optimization process for MR-guided adaptive radiotherapy.

Second Dosimetry Check with Deep DoseNet

P Dong*, L Xing, Stanford University, Stanford, CA

Purpose: We propose a second dosimetry check framework based on data collected from model-based calculations or measured beam doses, from which a convolution neural network is trained to perform dose calculation with high accuracy and speed. **Methods:** We first estimate the dose from primary photon transport using the cross-axis profile of field size 40 cm and the PDD for 100 cm SSD and 10 cm beam size corrected by Mayneord factor using radiological distances calculated from raytracing at the 5 mm voxel size. The network, named as Deep DoseNet (DDN), takes the estimated 3D doses and corresponding CT scans as the input and outputs up sampled final doses at 2.5 mm. DDN uses Residual in Residual Dense Block as the backbone where local features learned at each layer are sent to all subsequent layers to promote feature reuse, which is widely used and the state of art in the image super resolution field. For the training, we generated 2000 beams at 6 MV in Eclipse TPS on 20 patient CT scans. The beam isocenter, gantry angle, collimator angle, jaw position and MLC position are all randomly generated. The doses are calculated with the Acuros algorithm at 2.5x2.5x2.5 mm. The mean square error of the DDN converges after training for ~20 epochs using the ADAM optimization algorithm with an initial learning rate of 10^{-4} . **Results:** For 11 randomly selected vmat arc fields on patient CTs which the network hasn't seen before, the average 3D gamma passing rate for 1%1mm is 74.8% (58.6%-88.3%), 2%2mm is 96.5% (93.9%-99.1%) and 3%3mm is 99.5% (98.5%-99.8%). The average calculation time is ~30 seconds with one Nvidia V100 GPU card. **Conclusion:** DDN successfully generalizes from limited training dataset. It can serve as an independent, fast and accurate second dosimetry check tool for VMAT treatments.

PO-GePV-T-314

Validation of ClearCalc Photon Secondary Check Dose Calculation Algorithm

J Wong^{1*}, Y Lei¹, S Wisnoskie¹, A Granatowicz², S Wang¹, A Besemer¹, M Hyun¹, S Zhou¹, C Enke¹, Q Fan³, (1) University of Nebraska Medical Center, Omaha, NE, (2) Nebraska Medicine, Omaha, NE, (3) Memorial Sloan Kettering Cancer Center, Commack, NY

Purpose: ClearCalc (RADformation, NY) is an independent dose calculation software and has increasingly gained popularity for secondary dose check. This work aims to validate its photon dose calculation algorithm. **Methods:** We first created a 10x10 cm² open-field plan irradiating a 30x30x30 cm³ solid water phantom (SW) in Eclipse treatment planning system (TPS, v15.6), with and without a Styrofoam insert. Both the central-axis and off-axis point doses at dmax, 5cm and 10cm depths were measured with pinpoint ion chamber and compared with those from TPS and ClearCalc, respectively. Subsequently, we replaced the above open-field plan with 20 clinical treatment plans, then measured the isocenter doses with ion chamber, and compared the measurements with the corresponding point doses in ClearCalc. Lastly, we randomly selected 91 clinical plans (25 brain, 10 head&neck, 13 breast, 10 lung, 12 abdomen, 11 pelvis, 10 prostate) and retrospectively compared the calculation point doses between TPS and ClearCalc. **Results:** In the SW, the average central-axis point dose difference between ClearCalc and measurement for the open-field plans was $-0.99\% \pm 0.89\%$ (without the insert) and $-1.21\% \pm 1.34\%$ (with the insert), respectively. The ranges span from -2.41% to 0.34% and from -4.01% to 0.04%, respectively. As to the 20 clinical plans, the average isocenter dose difference between ClearCalc and measurement was $-1.27\% \pm 7.22\%$ with the range spanning from -13.8% to 18.6%. Additionally, 13 out of 20 plans had agreement within 5%. For 91 clinical plans, the average difference between TPS and ClearCalc was $-1.16\% \pm 0.43\%$ and the difference range is (-1.46%, 8.76%). Specifically for each individual treatment sites, the difference was $-0.22\% \pm 0.39\%$ (SRS cone plans), $-0.05\% \pm 1.26\%$ (brain), $0.52\% \pm 1.95\%$ (head&neck),

0.49%±2.59% (breast), 1.90%±1.64% (lung), -0.12%±1.17% (abdomen), 1.14%±1.17% (pelvis), and -0.10%±2.35% (prostate). **Conclusion:** ClearCalc photon dose calculations corroborate relatively well with both the treatment planning system and measurement in most cases.

PO-GePV-T-315

Comparison of Secondary MU Calculation Softwares for Clinical Use: RadCalc and ClearCalc

H Lee*, A Pompos, M Lin, UT Southwestern, Dallas, TX

Purpose: To compare two MU calculation softwares in their calculation accuracy and automation workflow for secondary MU check of AAA and AcurosXB calculated plans. **Methods:** ClearCalc is an API-based software that integrates to the treatment planning system (TPS). RadCalc is a standalone software equipped with two modes of heterogeneity correction: one based on path length and one performs the correction based on the structure contours (RadCalc-ROI). We developed an API script to eliminate the manual plan export/import and carry over the SSDs and effective-path-length information to RadCalc. The arrival of DICOM files to RadCalc triggers its own automatic calculation and reporting workflow. A total of 30 plans covering various sites were analyzed to test the MU calculation accuracy and workflow. Both AAA and AXB plans were created for each case to evaluate the accuracy of the secondary MU calculation for different algorithms. Planner's user experience survey was performed to score the software/workflow design of the two software. **Results:** The results are similar between AAA and AXB plans. With the finite-sized pencil beam (FSPB) algorithm and patient's CT information, ClearCalc exhibited a better calculation accuracy in general. The frequency distribution of calculation failure (>5%) demonstrated that the RadCalc-ROI module improves the calculation accuracy to a comparable level as ClearCalc. For the lung site, all methods failed with very large difference (40-80%) which evidences that these softwares are not best suited for lung SBRT plans. ClearCalc provides an intuitive user interface and seamless process to switch calculation point while RadCalc offers automatic report printing and the calculation failure warning/stop-sign to prevent users from blindly passing a failed plan. **Conclusion:** Both systems offer accurate secondary MU calculation. The integration with TPS via API minimizes the manual steps and ensures a safe workflow.

PO-GePV-T-316

Modulation Area Index (MAI): A Plan-Specific Metric for Quantifying VMAT Modulation Complexity

B Wu*, R Gonzales, J Qian, L Lin, J Yu, H Li, S Han-Oh, Johns Hopkins University, Baltimore, MD

Purpose: The constraint on a minimum segment area in VMAT optimization is utilized to restrain small MLC apertures due to limited accuracy on TPS's small-field output factor modeling. Since this constraint is applied to a total MLC aperture area per control point (CP), it does not effectively prevent small island apertures, e.g., island aperture area<1cm². We quantify the amount of these apertures in clinical plans as the first step for investigating their dosimetric and delivery impact. **Methods:** 21 head-and-neck, 21 pelvis-node, and 21 prostate-bed clinical VMAT plans are selected, which are optimized with Elekta Agility MLC in Pinnacle³. Each DICOM RT-plan is exported from TPS for analysis. A CP may have multiple unconnected, island apertures. A table is created for every CP to record the MLC parameters of each island aperture: index of leaf pair(s) forming the aperture, leaf positions, and aperture area. The process is performed for all CPs. Finally, Modulation Area Index, MAI(r), is defined as a cumulative histogram of these island-aperture areas, r, calculated from all CPs and normalized by the total MLC opening area. The MAI(r) quantifies as a percentage of the island aperture for r<0.1cm², r<0.8cm², and r<0.6cm². **Results:** Average MAI(r<1cm²) is 3.4%, 1.3%, and 0.3% with maximal 8.22%, 2.67% and 1.6% for the head-and-neck, prostate-node, and prostate-bed plans; for r<0.8cm², average MAI is reduced to 2.3%, 0.8%, and 0.2%; when r is further decreased to <0.6cm², MAI is still non-zero as 0.6%, 0.1%, and 0.1%. Statistical significance, p<0.05, is observed with the three disease sites. **Conclusion:** We propose a plan-specific metric quantifying VMAT modulation complexity: optimization for head-and-neck produces the most island apertures, while prostate-bed produces the least. Future study is to investigate the impact of these apertures on the passing rates of patient-specific QA and TPS's dose calculation accuracy on target coverage.

PO-GePV-T-317

The Impact of Flattening Filter Free on Remaining Volume at Risk in Lung Cases for VMAT and IMRT Techniques

M Alfshawy*, (1) International Medical Center, Cairo, EG

Purpose: Flattening filter free beam is a modern modality used in new radiotherapy machines, especially in SBRT cases to consuming treatment time. The remaining volume at risk (RVR) is known as undefined normal tissue, and it assists in evaluating very late effects like carcinogenesis. The present study is aimed to compare between the effect of flattening and unflattening 6MV beams on (RVR) in the lung cases that treated by conventional dose for volumetric modulated arc therapy (VMAT) and Intensity modulated radiation therapy IMRT. **Methods:** Eleven lung cancer cases with prescribed dose 60Gy in 30 fractions were selected retrospectively for this study. Four plans were generated for each case (VMAT FF, VMAT FFF, IMRT FF and IMRT FFF plan). Plans are developed using Eclipse treatment planning system and Truebeam linear accelerator HD MLC. Two arcs for VMAT plan and five coplanar fields are selected according to lesion volume and location for IMRT plans. RVR mean dose, V15Gy, V10Gy and V5Gy are introduced in this study as RVR evaluation parameters. **Results:** The study revealed that the variance percentage comparison between FFF and FF for the RVR evaluation parameters are (2.95, 1.1, 1.95 and 2.6), (1.95, 0.9, 1.6 and 2.15) for VMAT and IMRT respectively. However, for the comparison between VMAT and IMRT in RVR evaluation parameters study shows that variance percentage is (1.74, 2.06, -7.8 and -4.8), (2.86, 2.28, -7.2 and -4.4) for FF and FFF respectively. **Conclusion:** The study present that using FFF is clinically benefit than FF for all RVR evaluation parameters in addition to consuming time. On the other hand VMAT is preferred in RVR mean dose and V15Gy while oppositely in the V10Gy and 5Gy.

PO-GePV-T-318

Field Junction Technique for Total Body Irradiation Using Tomotherapy with TomoDirect Mode

Y Suetsugu¹*, N Higashi², Y Fukuyama³, K Inoue¹, K Matsumoto⁴, H Terashima², T Sasaki¹, (1) Kyushu Univ., Fukuoka-shi, Fukuoka-ken, JP, (2) Harasanshin Hosp., Fukuoka-shi, Fukuoka-ken, JP, (3) Fukuoka Tokushukai Hosp., Kasuga-shi, Fukuoka-ken, JP, (4) Kurume Univ. Hosp., Kurume-shi, Fukuoka-ken, JP

Purpose: The present study aims to verify the dose distribution of the field junction region using a volumetric gradient matching technique (VGMT) with TomoDirect (TD) mode. **Methods:** Two planning CT image sets were acquired with the head first position (HFP) and feet first position (FFP) using two solid water phantoms mimicked the thighs. Planning target volume was divided into upper, lower and gradient volumes. The junction region was comprised of one 2.5 cm and four 2 cm thick gradient volumes to create descending slope dose distribution. TD plans were generated with 12 and 4 ports for HFP and FFP plans, respectively. Gafchromic film placed at the central coronal plane and measured dose profile was obtained. Dose verification, especially in the junction area, was performed by shifting deliberately the position of the FFP plan by 0.5, 1.0, and 1.5 cm in the superior and inferior direction. Absolute dose measurements were performed at 3 points for respectively HFP and FFP plans using ionization chamber at the matching plane. **Results:** The TD plans produced a linear gradient in junction region. An optimum alignment of both HFP and FFP leads to a relatively constant dose profile. Relative dose deviations via film dosimetry of 6.5%, 11.1%, 17.2% and 11.7%, 15.1%, 16.9% were observed for 0.5, 1.0, and 1.5 cm setup errors in the superior and inferior direction, respectively. The absolute measured dose showed a good correlation with the calculated dose in the gradient junction except for 1 out of 6 measured points. The average percent difference (±SD) in five points was +1.9 ± 2.1%. **Conclusion:** VGMT with TD enables to create a linear dose gradient across the junction region and reduce the impact of longitudinal setup error on dose distribution.

PO-GePV-T-319

Commissioning and Clinical Implementation of Pseudo 4Pi On An MR-Guided Radiotherapy (MRgRT) Linac

J McCulloch^{1,2*}, A Gutierrez^{1,2}, T Romaguera^{1,2}, D Alvarez^{1,2}, K Mittauer^{1,2}, (1) Miami Cancer Institute, Baptist Health South Florida, Miami, FL, (2) Florida International University, Herbert Wertheim College of Medicine, Miami, FL

Purpose: The maximum field size on a commercial MR linac is 27x24cm. In the event that a treatment volume exceeds the field dimensions, a multi-isocenter technique can be employed to elongate the total treatment coverage area. We commissioned and clinically implemented a Pseudo 4Pi workflow on an MRgRT linac. **Methods:** An eight-coplanar beam, dual isocenter step-and-shoot IMRT plan with 6cm displacement of isocenters across the IEC-Y axis was created. The plan was delivered to a 3D IMRT diode array phantom. In order to treat each isocenter, the treatment couch moves between the isocenters during the treatment workflow. A second plan was developed to perform an end-to-end validation in treatment workflow on a cylindrical water phantom with an A1SL ion chamber in the region of the field junction. The chamber dose was compared between the calculated TPS (i.e., mean dose of A1SL active volume ROI) and the measured dose. Additionally, treatment interrupts with IGRT shifts were performed to validate the couch localization accuracy in the Pseudo 4Pi workflow. **Results:** The gamma analysis using 3%/2mm criteria resulted in a passing result of 98%. There was no observed overlap or separation at the dosimetric junction on the diode array measured dose profiles. For the ionization chamber absolute dose measurement, the difference between the measured (10.21±0.06Gy) and calculated (10.10±0.20Gy) dose was 1.04%. The treatment time was twice as long due to the doubling of treatment beams for the two isocenter approach. The couch localized within ±0.1mm during interrupts irrespective of positioned isocenter at respective delivery. **Conclusion:** There was no overlap visible in the measured profiles and the difference between the expected and measured dose to the ion chamber was less than 5%. The accuracy of Pseudo 4Pi planning and execution make it a clinically acceptable technique when target volumes exceed the field size dimensions.

PO-GePV-T-320

Dosimetric Analysis of ElastoGel Bolus

M Pacella*, M Webster, S Tanny, University of Rochester, Rochester, NY

Purpose: ElastoGel Bolus has been gaining increasing popularity. It has a density of 1.2g/cm³, instead of the traditional 1.0g/cm³. This difference in density will have an effect on treatment beams traversing the bolus, especially electron beams. This study aims to quantify the difference for typical electron beam energies. **Methods:** Two methods were used to quantify the dose difference caused by the higher density of ElastoGel. First, solid water phantoms were scanned with ElastoGel and Superflab boluses with thicknesses of 0.3, 0.5, and 1.0cm. Treatment plans with a 10x10cm² field, 100MUs and 100cm SSD to the bolus surface were calculated for 6, 9, 12, 16, and 20MeV electron beams. A dose profile was taken from these beams along the central axis and 2cm off-axis. Second, 9 plans, previously treated using ElastoGel were retroactively analyzed. The bolus depths included 0.3, 0.5, and 1.0cm. The electron energies were 6, 6 and 9, 9, 12, and 16MeV. For each plan, the patient was scanned with no bolus and the bolus was then added in the treatment planning software. To simulate Superflab, the bolus was assigned a Hounsfield Unit of 0. For the purposes of this study, a PTV was created to match the 90% isodose volume for the plan. The bolus was then changed to simulate ElastoGel, with 300HU. PTV coverage was compared using mean dose, D_{max}, V5, V20, V80, V90, V95, and V100. **Results:** The largest difference was seen for 6MeV with 1cm of bolus. For the solid water plans, past the buildup within the bolus, this combination had a dose difference of 0.3%. For patients, V95 and V100 changed by up to 4.2%. All other metrics changed by less than 1%. **Conclusion:** ElastoGel Bolus presents little dosimetric influence and is not a risk if the density is assigned incorrectly.

PO-GePV-T-321

Validation of Spatial Fractionated GRID Treatment Planning Using Volumetric Modulated Arc Therapy (VMAT)

C Collins*, M Schwer, M Keefe, D Wazer, G Cardarelli, Rhode Island Hospital / Warren Alpert Medical School at Brown University, Providence, RI

Purpose: To validate a novel and practical volumetric modulated arc therapy (VMAT) planning method for Biology Spatial Fractionated (SF) therapy (GRID). **Methods:** Spherical contours measuring 1.5 cm in diameter are distributed in a bulky tumor ranging in sizes from 500 to 3000 cm³. Each contour must be at least 3 cm apart, center to center and at least 1 cm from any organ at risk (OAR). The spheres are then grouped together and planned as one target. Three concentric ring structures (0.5, 1 and 3 cm) are created to optimize the dose to the center of the spheres and minimize the dose surrounding the spheres. The result is alternating regions of high and low dose to the tumor and minimal dose to the OAR's. The number of spheres varied from 12 to 30 depending on the size of the tumor. High dose rate filter-free (FFF) beams are used to deliver the entire treatment, typically in less than 20 minutes. **Results:** The validation is performed on 5 previously treated bulky liver or stomach patients using anonymized data. The spheres were placed by expanding the ROI size to 3 cm arranging them to not overlap, until the tumor was completely filled. Once the tumor was filled, the sphere size was reduced to 1.5cm diameter. The planning was optimized using similar objectives as other VMAT multi-target SRS planning techniques and then delivered on a Varian TrueBeam STX. Dose measurements were collected using a standard multidetector planar array. The treatments varied from 2-8 arcs. All five treatment plans passed 95% gamma at 3%/3mm 10% threshold. **Conclusion:** We have validated a novel approach to planning GRID therapy patients. VMAT can be used to treat bulky tumors in a SF approach both as a single treatment or as a boost, without sacrificing dose to surrounding tissue.

PO-GePV-T-322

Treatment Planning and Verification for Radiodynamic Therapy Using 45 MV Beams

A Eldib*, J Liu, C Ma, Fox Chase Cancer Center, Philadelphia, PA

Purpose: Radio-dynamic therapy (RDT) uses a combination of high-energy photon beams and photo/radio-sensitizers to kill cancer cells. RDT treatment plans were generated following our institutional protocol for a phase I study on RDT. In this work, we present the experimental and theoretical studies that were conducted to insure accurate dose delivery for RDT. **Methods:** A LA45 RaceTrack Microtron was commissioned for RDT. LA45 uses scanning electron beams to produce uniform photon dose distributions and a purging magnet to remove the contaminant electrons. Purging efficiency was tested as it could influence machine calibration. The Eclipse system was used for treatment planning. Monte Carlo simulation was used to model 45 MV beams to serve as a second check for RDT. Matrixx 2d array was used treatment plan QA check. Initial trials of portal imaging with the 45MV beam using humanoid phantom showed blurry images, which was attributed to scattered electrons generated by the patient. A 5-mm copper build-up plate was therefore used to insure optimal image contrast and film exposure. **Results:** Purging magnet was found to be functional as was seen by the comparison between percentage depth curves of a 10cm x10cm field with and without the purging magnet. The machine was calibrated following TG51. A comparison between the calculated and measured dose distributions was made resulting in 95% of pixels analyzed passing our acceptance criteria. This was achieved with our phantom studies as well as with patients treated in the phase I trial. Portal images using 45 MV photons showed better image quality compared to lower energies with the copper buildup. **Conclusion:** Treatment plans for RDT were designed to facilitate post treatment PET imaging, which were used to dose delivery verification and treatment assessment, and were successfully delivered to patients.

PO-GePV-T-323

Dosimetric Impact of Materials Override of Hydrogel Spacer in Stereotactic Body Proton Therapy (SBPT) for Locally Advanced Pancreas Cancer (LAPC)

D Han^{1*}, H Hooshangnejad², W Yao³, J Jatzak⁴, K Ding⁵, (1) University of Maryland, Baltimore, MD, (2) Johns Hopkins University, School of Medicine, Biomedical Engineering, Baltimore, MD, (3) University of Maryland School of Medicine, Baltimore, MD, (4) University of Maryland, (5) Johns Hopkins University, Baltimore, MD

Purpose: To quantitatively assess the dosimetric impact of three materials override methods for injectable iodinated hydrogel spacer utilized in stereotactic body proton therapy (SBPT) for pancreatic cancer. **Methods:** TraceIT is an absorbable, iodinated polyethylene glycol (PEG) hydrogel for tissue marking and spacing. A patient diagnosed with locally advanced pancreas cancer (LAPC) underwent endoscopic hydrogel injection and CT simulation with breath-hold. The CT with patient and spacer contours was imported to Raystation 9B for proton pencil beam scanning (PBS) planning. The patient was prescribed with 3300 cGy (RBE) in 5 fractions to the GTV. Two posterior beams were used, one of which has a distal end close to the spacer. The ground truth of the spacer composition was calculated based on previous publication and imported to the Raystation. SBPT plans with the same beam but different material override methods for spacer were recalculated with Monte Carlo algorithm: 1) HC plan assigning spacer with ground truth material; 2) W plan with spacer assigned with water; and 3) CT plan with CT Hounsfield Units of spacer used in planning. The target and organs-at-risk doses and Gamma index of 2 mm / 2% were used to quantify the dosimetric differences. **Results:** All three plans achieve the same target coverage with D98 around 3316 cGy (RBE). The mean doses to the duodenum are 1364 cGy (RBE), 1359 cGy (RBE), and 1364 cGy (RBE) for plan 1), 2) and 3), respectively. For stomach, the mean dose is 256 cGy (RBE), 249 cGy (RBE) and 255 cGy (RBE), respectively. The Gamma index analysis confirms the plan differences for plans 1) and 2), and plans 1) and 3) are minimal. **Conclusion:** With TraceIT as a spacer for proton dose planning, we found no significant dosimetric difference existing among the plans using three override methods

Quantifying the Dosimetric effect of Tumor Treating Fields (TTF) Transducer Arrays: Is a Correction Needed?

K Kelly*, I Alecu, N Papanikolaou, N Kirby, P Myers, D Saenz, S Stathakis, K Rasmussen, UT Health San Antonio MD Anderson Cancer Center, San Antonio, TX

Purpose: Current studies report the protocol for the use of TTF in treatment of glioblastoma as CT simulation using a foam pad as a surrogate for the high-density TTF transducer array followed by the delivery of external beam radiotherapy with the array in place. This work assesses the need for a dosimetric correction factor using these conditions. **Methods:** Measurements were taken on an Elekta VersaHD accelerator with and without the transducer array for depths of 0–20 cm using solid water slabs for the following energies: 6 MV, 10 MV, 18 MV, 6 MV FFF, and 10 MV FFF. Surface measurements were taken with OSLDs, measurements up to 1 cm were taken with a parallel plate chamber, and measurements 1 cm and greater were taken with a cylindrical chamber. For each depth and energy, 100 MU was delivered with a 10x10 cm² open field at 100 cm SAD, and ratios of the readings with the array to readings without the array were determined. **Results:** Ratios ranged from 0.96–2.35 for 6 MV, 0.97–3.34 for 10 MV, 0.97–4.08 for 18 MV, 0.96–2.43 for 6 MV FFF, and 0.96–2.87 for 10 MV FFF. The deviations between readings with and without the transducer array were greatest for shallow depths for each energy. The ratios decreased with increasing depth throughout the build-up region before stabilizing near d_{max} for each energy. **Conclusion:** Utilizing lower energy beams for radiation treatments with TTF transducer arrays will reduce the discrepancies in the build-up region between dose calculated without the array and dose delivered with the array in place. It is recommended to apply a correction factor for targets located at shallow depths, as differences for measurements taken with and without the transducer arrays were most pronounced for depths shallower than d_{max} for each energy.

PO-GePV-T-325

Reducing Delivery Time of 3D DIBH Breast Treatments Using a Sliding Window Technique Over Step and Shoot Field in Field

A Lee*, D Pearson, J Seekamp, University of Toledo, Toledo, OH

Purpose: A concern over the time taken to deliver DIBH left breast tangent treatments warranted us to investigate methods to reduce delivery times by switching from a field in field delivery to a sliding window technique. **Methods:** DIBH left breast patients treated with static tangents using a step-and-shoot, field in field, forward planned technique were retrospectively replanned and compared using the sliding window tangents. For an accurate comparison of the difference in delivery times, the replanned treatments were created to the same clinical quality as the original plans. Beam energy, gantry, collimator and blocks were not changed when the plans were redesigned using sliding window. Both the original and new plans for each patient were then delivered on the machine with no gating and the delivery times were compared. **Results:** From the delivery time statistics gathered, initial results suggest that a sliding window delivery may reduce delivery times by 10% or more over field in field for breast treatments due to not having to stop the beam while the MLCs move. It was found though that the sliding window plans have slightly more 105% dose in the breast as well, but that may be simply an issue of plan quality which could be improved by replanning again, rather than a significant difference between the two different delivery techniques. **Conclusion:** Given that sliding window delivery takes less time than step and shoot field in field, this indicates that sliding window may be the preferred method specifically for DIBH left breast patients. Many patients have difficulty holding their breath for an extended period of time, so any reduction in delivery time will greatly increase comfort for these patients. This should also come with no detriment to the patient as it seems plans of nearly identical quality can be produced with either method.

PO-GePV-T-326

An Investigation into the Dosimetric Properties of a Three-Dimensional (3D) Printing Material for Potential Use in Radiation Therapy

K Bittinger*, N Sperling, University of Toledo Medical Center, Toledo, OH

Purpose: To measure and evaluate the dosimetric properties of a three-dimensional (3D) printing material, polylactic acid (PLA), for use in radiation therapy. This study evaluates the effect of several different infill percentages as well as the effect of infill pattern on the dose delivered to a phantom to establish reasonable guidelines for 3D printed bolus usage. **Methods:** Six slabs of PLA, each with dimensions 5x5x1 cm³, were designed and printed. The cubic infill pattern was used for five slabs with infill percentages of 25%, 50%, 67%, 75%, and 100%. One slab with 50% infill and the tri-hexagonal pattern was printed. Preliminary dose calculations were made in RayStation, using two dose specification points, one at the surface between the slab and the backscatter material, and one at a depth of 1.5 cm into the backscatter material. The dose at each point was recorded from delivering 100 monitor units (MUs) to each slab material and density, with each photon energy, and for both 5x5 cm² and 10x10 cm² field sizes. **Results:** The results present the ratios of calculated dose under the PLA bolus material to the dose with either no bolus (for data at 1.5 cm depth) or a water bolus (for data at the surface). The results show that the dose was consistent at 1.5 cm depth for multiple slabs with 10 MV energy, while 100% and 75% infill slabs were consistently similar to the water bolus. **Conclusion:** PLA is an adequate replacement for traditional bolus material, and 3D printed, patient specific bolus materials could significantly improve patient outcomes. Additional studying of how the measured dose and the spatial dose distribution are affected by the choice of infill, as well as the effect on electron dose distribution, are ongoing.

PO-GePV-T-327

Volumetric Axillary Boost (VMAB): Novel Planning for Nodal Coverage in Breast/Chestwall Patients

W Duggar*, B Eske, D Deng, H Soysal, C Yang, University of Mississippi Med. Center, Jackson, MS

Purpose: To demonstrate the superior quality of the dose distribution given by a novel axillary boost planning technique for nodal coverage during breast/chestwall radiotherapy. **Methods:** Six breast cancer patients previously planned with the traditional monoisocentric posterior axillary boost (PAB) technique were replanned with a volumetric axillary boost (VMAB) to complement the current 3D tangent and supraclavicular (SCLV) fields. The at-risk nodal volumes had been delineated during the planning process as well. The dose distributions were then compared for major differences with the key endpoints being the nodal region dose volume histograms (DVH), ipsilateral lung DVHs, and maximum dose hotspot within the plan. The original PAB plans were designed balancing the tradeoff of nodal dose coverage and overall hotspot while the VMAB plans optimized both. The ideal hotspot was considered < 110% of the whole breast/cw dose and the ideal nodal coverage was considered D95 = 95-100% of 45-50 Gy depending on the original patient prescription. **Results:** Due to the limited sample size, no statistically significant differences were observed between the traditional 3D PAB technique and VMAB. Two statistically significant differences ($p < 0.05$) were observed for lymph node dose coverage for level 1 V95% and level 2 V100%, where the VMAB increased coverage by a mean value of 14.9% and 30.3%, respectively. Level 2 V95%, was not significant ($p = 0.053$) with a mean increase of 20.7%, but may become significant with a higher sample size. Differences in maximum dose, level 3 lymph node dose coverage, and lung doses were not found to be close to significance. **Conclusion:** This novel planning technique, VMAB, results in significantly improved dose coverage of nodal regions while avoiding increase of undesirable hotspots and/or lung dose. Though implemented clinically, future work will confirm these findings with a larger sample size to discern true statistical certainty.

PO-GePV-T-328

Development of a Collision Prediction Tool Between Gantry and Table Using Blender

G Guyer^{1*}, Y Wyss¹, J Bertholet¹, P-H Mackeprang¹, H Loebner¹, M K Fix¹, P Manser¹, M F M Stämpfli², S Mueller¹, (1) Division of Medical Radiation Physics and Department of Radiation Oncology, Inselspital, Bern University Hospital and University Of Bern, Bern, CH, (2) Institute for Biomedical Engineering, University of Zurich & Swiss Federal Institute of Technology, Zurich, CH

Purpose: Non-coplanar treatment techniques such as dynamic trajectory radiotherapy (DTRT) have the potential to improve treatment plan quality in comparison to conventional volumetric modulated arc therapy. However, collision avoidance must be considered during treatment plan creation. In this work, we developed a detailed collision-prediction tool for gantry and table-top or table-base, considering possible six degree of freedom (DoF) set-up table correction. **Methods:** A virtual linac model was created using blender, a free and open-source 3D computer graphics software toolset, that can be accessed via an integrated python API. DTRT plans described with XML files can be simulated on the virtual linac and tested for possible collisions between gantry and table for a given table position. If an additional tolerance table is provided, all combinations of maximal setup shifts given in the tolerance table are tested for potential collision interlocks. Collision prediction was verified experimentally by setting the gantry to a certain angle and then translating or rotating the table until a collision interlock occurred. The resulting table angles and positions were compared to the predicted values. This was repeated with additional 3° pitch and roll rotations in order to verify the model for setup correction. **Results:** For collision due to table angle, the mean difference between predicted and measured table angles leading to collision interlock of the gantry with table-top or table-base were 2.1° and 4.2°, respectively, with 70% of the values within 2° difference. For collision due to table translations with and without setup correction, the mean difference between predicted and measured table positions between gantry and table-top was 0.7 cm with 97% of the values within 2 cm difference. **Conclusion:** Using blender, a collision prediction framework between gantry and table capable of considering patient shifts with a 6 DoF table was successfully developed and verified with measurements.

This work was funded by the Swiss National Science Foundation

PO-GePV-T-329

Preliminary Treatment Planning System Commissioning Results for the First Clinical Biology-Guided Radiotherapy Machine

N Kovalchuk^{1*}, B Han¹, E Simiele¹, D Capaldi¹, D Breikreutz¹, T Yeung², J White², D Zaks², M Owens², S Maganti², A Purwar², L Vitzthum¹, D Chang¹, L Xing¹, M Surucu¹, (1) Stanford Radiation Oncology, Stanford, CA (2) Reflexion Medical, Inc

Purpose: To report the preliminary treatment planning system (TPS) commissioning results for the first clinical installation of Reflexion X1- biology-guided radiotherapy (BgRT) system. Reflexion TPS generates IMRT/SBRT plans using the gradient-descent-optimization and Collapsed-Cone-Convolution algorithm (2.1mm grid) for 6MV-FFF beam delivered axially via 50 firing positions with couch advancing every 2.1mm. **Methods:** CT images of multiple phantoms were acquired and transferred to Reflexion TPS to test the accuracy of data acquisition, anatomical modeling, plan evaluation and dose calculation. Dosimetric parameters for various open static fields and SADs were evaluated in water and heterogeneous slabs phantoms. TG-119 and representative clinical IMRT/SBRT cases were planned and verified with ion chamber, film and ArcCheck (gamma:3%/2mm). End-to-end (E2E) testing was performed using anthropomorphic head and lung phantoms. **Results:** The maximum difference between Reflexion TPS and known CT numbers was 10.3±6.0HU, maximum difference in the structure volume was 20.2±4.8cc(Eclipse) and 2.93±0.6cc(MIM); maximum difference in the structure dose was 5.0±1.2Gy(Eclipse) and 1.7±0.4Gy(MIM). For static fields, PDD10 matched between TPS and measurement within 0.8%, crossline profiles matched within 1.6% in 80% from CAX for all fields≥2.5cm, and inline profiles agreed within 0.5mm FWHM. Output factors matched scintillator measurements within 1% for all fields. Dose in heterogeneous slab phantoms agreed within 3.5%. Lung phantom verification with film passed with gamma≥98.6%. The ion chamber measurements for TG-119 plans were within 2.9%; and ArcCheck QA passed>90% for all plans. E2E film analysis showed 0.8mm total targeting error for isocentric and 1.1mm for off-axis treatments. Iterations to the beam model are in progress to further improve the passing rate for smaller targets≤3cm. **Conclusion:** In this current preliminary report, the test results agreed within the tolerances specified by TG-53, MPPG 5.a, TG-119, TG244, and TG-148. A subset of the commissioning tests has been identified as a baseline data for an ongoing QA program.

PO-GePV-T-330

Capacity Assessment of African Clinics to Conduct Hypofractionated Radiotherapy Clinical Trials for Localized Prostate Cancer

W Swanson^{1*}, M Lavelle¹, V Ainsworth¹, N Bih², D Seymour³, W Ngwa⁴, (1) University of Massachusetts Lowell, Lowell, MA, (2) Dana Farber Cancer Institute, Boston, MA, (3) Bio Ventures for Global Health, Wellesley, MA, (4) Brigham and Women's Hospital, Boston, MA

Purpose: Recent developing work has demonstrated the efficacy and benefits of adopting hypofractionated radiotherapy (HFRT) for prostate cancer in low- and middle-income countries. Adopting HFRT in limited-resource countries, such as those in sub-Saharan Africa, can reduce treatment costs and increase treatment access where cancer burden is great. Before HFRT can be fully implemented, clinical trials on African populations are necessary. Clinics in these regions are significantly under-represented in radiotherapy clinical trial participation. In this work, we assess the capacity of African cancer centers to participate in radiotherapy clinical trials in terms of capability and quality assurance. **Methods:** 14 African radiotherapy clinics with linear accelerators were invited to participate in a survey inquiring about past clinical trial experience, available resources, and relevant infrastructure. Survey items included experience in specific clinical trial phases, facility accreditation and documentation, specialist personnel on-site, and quality assurance methods. These reports were tabulated and compared to determine missing critical items required to participate in cancer clinical trials. **Results:** Among surveyed cancer centers; 36%, 93%, 93%, and

79% of clinics have reported capability to participate in clinical trials of Phase I, II, III, and IV, respectively. Specialist on-site personnel varied greatly from 57% to 93%. Specialists included roles such as research coordinators, pathologists, and biostatisticians. All surveyed clinics reported to have computed tomography imaging. **Conclusion:** While most of the surveyed clinics have the resources and accreditation for clinical trial participation, preliminary analysis shows that most sites are missing a number of specialist personnel which may be necessary for HFRT clinical trials. Additionally, only a handful of our surveyed clinics report to have Phase-I clinical trial capability. This could be due to lack of quality assurance necessary for Phase-I, lack of investment, or cultural stigma. Further investigation is required to determine the influence on the lack of Phase-I participation.

PO-GePV-T-331

Photoelectric Dose-Enhancement Using FDA-Approved Materials

W Swanson^{1*}, Y Hao², W Ngwa³, (1) University of Massachusetts Lowell, Lowell, MA, (2) Washington University School of Medicine, St. Louis, MO, (3) Brigham and Women's Hospital, Boston, MA

Purpose: Photoelectric dose enhancement using metallic biomaterials continues gaining popularity among methods of radiotherapy (RT) improvement. High-Z materials such as gold, platinum, or gadolinium are commonly attached to targeting proteins or formed into colloid nanoparticles which eject photoelectrons while under low-energy x-rays. When these biomaterials are introduced to the tumor microenvironment, typical external beam RT can deliver increased local dose by this method. Already existing FDA-approved metallic biomaterials such as specific chemotherapy drugs or MRI contrast agents could be implemented with multiple functions by providing RT dose enhancement in addition to their primary function. In this work, we estimate the potential dose enhancement provided by FDA-approved materials. **Methods:** Dose enhancement estimations were determined by a Monte Carlo-simulated fluence from a 6MV clinical LINAC directed to a homogeneous metallic biomaterial distribution at 20cm depth (10cm x 10cm field) in an infinite slab tissue-equivalent phantom. Photoelectron dose was calculated corresponding to the fluence energy spectrum, concentration of metallic biomaterial, and the metallic photoelectric absorption coefficients. This was repeated for gadolinium and platinum nanoparticles; gadolinium-based contrast agents; and platinum-based chemotherapy drugs. **Results:** To achieve a clinically significant dose-enhancement factor (DEF) of 1.2, the metallic biomaterial concentrations were estimated as 6mg/ml for Gd and 4.9mg/ml for Pt. Using FDA-approved intravenous delivery, this translates to 1%ID/ml of Omniscan or 0.5%ID/ml of Magnevist contrast agents; or 2%ID/ml of Carboplatin or 0.5%ID/ml of Cisplatin chemotherapy drugs. If 100%ID were to localize to the cancer site, the DEF would be 20,38,11, and 40 for Omniscan, Magnevist, Carboplatin, and Cisplatin, respectively. **Conclusion:** Preliminary estimations showed that FDA-approved biomaterials could potentially deliver clinically significant DEF at reasonably achievable concentrations. In future work, we seek to investigate local delivery or protein-targeting of these biomaterials to improve localization and increase the DEF.

PO-GePV-T-332

Comparing Ideal and Realistic Surrogate Motions with the Radixact Synchrony System

K Jeong*, L Goddard, W Tome, Montefiore Medical Center, Bronx, NY

Purpose: To evaluate the effect of the surrogate motion on the target motion modelling for Radixact Synchrony system. **Methods:** A modified version of Delta4 from Scandidos was used to test Accuray Synchrony motion tracking. A 3D printed cube with density close to that of tissue containing a cylindrical high-density material was used to simulate the tumor inside the lung. High density material was delineated as target and planned with Lung with Respiratory motion tracking option in Accuray Precision planning software. A Delta4 HexaMotion platform was used to simulate the patient breathing motion. Four motion traces provided for AAPM MATCH Challenge were used to simulate respiration. All motions were delivered twice (1) with surrogate LEDs attached to the phantom in which case the surrogate motion is the same as target motion (2) with surrogate LEDs on the cardboard that was placed on top of the Delta4 such that the surrogate motion is closely related with the target motion but not exactly the same. Accuray delivery raw files were analyzed to compare the modelled motion traces and HexaMotion driving traces. **Results:** Average shift of the modelled target traces in x, y, z directions were -0.22 mm, -0.57 mm, -0.56 mm for cases (1) and -0.40 mm, -0.62 mm, -0.58 mm for cases (2). These corresponds to setup uncertainty. The tracking accuracy can be estimated with standard deviation of the difference between driving traces and modelled traces. The average value of the standard deviation in x, y, z directions were 0.34 mm, 0.30 mm, 0.31 mm for cases (1) and 0.63 mm, 0.46 mm, 0.63 mm for cases (2). **Conclusion:** This test showed that Synchrony system can accurately model the target motion with submillimeter precision even if the surrogate motion is not the same as target motion.

The authors have researched a grant from Accuray

PO-GePV-T-333

End-To-End Testing of Hybrid VMAT-Based Total Body Irradiation Technique: Simulation, Planning and Delivery Verifications

S Ahmed*, T Gray, L Lu, P Xia, B Guo, Cleveland Clinic Foundation, Cleveland, OH

Purpose: To conduct an end-to-end verification for VMAT based total body irradiation. **Methods:** Total body irradiation (TBI) is traditionally delivered using anterior and posterior (AP/PA) beams. Recently a VMAT based hybrid planning technique was developed at our institution to improve the target coverage and patient comfort while sparing the critical organs. To validate this technique, an end-to-end test was conducted using an anthropomorphic phantom, including simulation, planning and treatment delivery following the clinical procedures of VMAT-TBI. The CT images were acquired at 5mm slice thickness and whole-body CT was generated. Planning was done in Pinnacle TPS prescribing 13.2 Gy in 8 fractions. The goals were to achieve >85% of PTV receiving the prescription dose while reducing the mean dose to lungs <80% and mean dose to kidneys <50% of the prescription dose. Hotspots were limited between 110-120% of the prescription dose. Treatment was delivered on rando phantom in HFS orientation for upper body and in FFS orientation for lower body under image guidance. Measurements were performed with MOSFET dosimeter at four locations (central and lateral thorax, abdomen and pelvis) and two transverse EBT3 films at the lung and pelvis at the junction region between the head first and feet first treatment. **Results:** The 88.5% of PTV received prescription dose. Mean lung dose and mean kidney dose were 10.4Gy and 6.3Gy meeting the planning constraints. A good agreement was achieved between the measured and calculated dose. The mean dose difference for both films at lungs and pelvis were 5.1 ± 14.9 cGy and 11.8 ± 6.6 cGy respectively. The average dose difference for MOSFET dosimeters was 4.1%. **Conclusion:** The hybrid VMAT based TBI planning technique was capable of delivering uniform dose to the whole body and spare critical structures such as lungs and kidneys. End-to-End test proved that the workflow of VMAT-TBI achieves accurate dose delivery.

PO-GePV-T-334

Pre-Treatment 4DCT Fiducial Marker Combination Selection for Robotic Lung SBRT

W Belcher*, A Ju, J Jung, East Carolina Univ, Greenville, NC

Purpose: This study aims to make recommendations for fiducial marker selection that optimizes lung tumor tracking in SBRT patients. It is rare that all fiducials are tracked during treatment delivery and the selection is currently based on proximity to the GTV. **Methods:** 10 patients were retrospectively reviewed. Each patient had 4 fiducials placed via bronchoscopy per manufacturer recommendations. The gross tumor volume (GTV) and each fiducial were contoured in each of the 10 phases from a simulation 4DCT. The center of mass (COM) was calculated for each fiducial and the GTV in every phase using a Matlab program with post-processing to eliminate noise. The centroid of every fiducial combination was found and compared to determine which centroid

combination was closest to the GTV's COM and which centroid's motion was most like the GTV's. **Results:** 8 of the 10 patients had the centroid tracked that was not the centroid closest to the GTV's COM and 1 patient had the centroid that matched the tumors motion the best tracked. The centroid that was closest to the GTV's COM was closer than the tracked centroid on average by 8.5 mm and the centroid that kept the most consistent distance was more consistent on average by 0.3 mm. **Conclusion:** The fiducials that are tracked during robotic SBRT delivery per usual clinical practice are not always the fiducials that are closest to the GTV's COM, or that best correlate with GTV COM motion during breathing. An analysis of GTV and fiducial motion on 4DCT using the technique described here, along with machine data during clinical simulation on how well different fiducial combinations are tracked, can improve tumor tracking during SBRT delivery or inform the treating physician on the expansions needed to create the PTV that would minimize the risk of marginal tumor recurrence.

PO-GePV-T-335

Prediction of Fiducial Marker Positions in Robotic SBRT Using 4D-CTs at Different Treatment Dates

J Jung^{1*}, W Belcher¹, K Patel¹, E Patel¹, K Yang², S Sharma², A Ju², (1) East Carolina University, Greenville, NC, (2) Medical School of East Carolina University, Greenville, NC

Purpose: To predict the marker positions using deformation vectors from the registration of 4D-CTs of patients who may have had multiple tumors treated over different dates and compare the predicted positions with the reference positions **Methods:** Two sets of 4D-CTs were acquired from a patient receiving robotic SBRT for separate lung tumors in 2017 and 2019. Deformation vector fields (DVF) were acquired by B-spline registration between the expiration phases in 2017 and 2019, and the expiration and the inspiration phase in 2017. Two hypothetical markers were inserted in the 4D-CTs in 2017 to the positions acquired from the registration of 4D-CTs in 2019 and the 4D-CTs of 2017 were deformed using the DVFs acquired above. A scaling factor was applied to compensate the difference between the breathing amplitudes in 2017 and 2019 and it was determined iteratively. The center of masses of the predicted markers from 2017 and the reference markers from 2019 were identified and the Euclidean distances between two points were calculated and compared. **Results:** The 4D-CTs were reconstructed using the DVFs and the positions of hypothetical markers were acquired. The average distance between the center of masses of prediction markers and reference markers was 7.8 mm (Marker A: 7.5 mm, Marker B: 8.0 mm). After a scaling factor was applied, the distance was reduced to 2.0 mm (Marker A: 1.1 mm, Marker B: 2.9 mm). **Conclusion:** The data would suggest that the position discrepancy can be no more than 3.0 mm. However, more research is needed to validate this approach with more cases. Several uncertainties can be associated with these results such as registration accuracy, image quality of 4D-CTs, and DVFs variations with and without tumors and markers. This data can be very helpful when planning the fiducial marker placement for a clinical or research application.

PO-GePV-T-336

The 4D Composite Dose Study of the Breath Motion Effect During the Lung Stereotactic Body Radiotherapy (SBRT)

Z Xia^{*}, F Wang, Y Xu, J Xu, Kansas University Medical Center, Kansas City, KS

Purpose: Tumor motion due to the breathing cycle affects the dosimetry of the lung treatment especially for SBRT cases. We retrospectively studied the correlation between the dose coverage and the tumor motion including rigid motion and deformable motion for SBRT lung treatment. **Methods:** Six patients are enrolled into this study. Simulation 4D-CT is acquired and divided to 10 individual phases. The gross tumor volume (GTV) is contoured on each phase of the breathing cycle. The original treatment plan is generated on the average phase. This plan is copied to each individual phase CT and recalculated with same beams orientation and with a weighting factor of 10% prescription dose. The dose on each phase is transformed back to the average phase based on the deformable registration. A 4D dose is then determined by combining the weighted dose from all 10 phases. The displacement of the GTV centroid is used as the index of rigid motion; and the GTV volume change is used as the index of the deformable motion. **Results:** The 4D composite dose is compared with the clinical plan. With rigid motion from 0.22 cm to 1.89 cm, the 4D PTV dose coverage dropped by up to 20% from the clinical plan. The PTV coverage loss gets higher while the tumor motion is higher, on the order of ~10% for 1 cm rigid motion and R2 coefficient is 0.93. When the tumor has similar rigid motion, the tumor with higher deformable motion gets worse dose coverage, with ~3% PTV coverage loss for 20% GTV volume change. **Conclusion:** For SBRT lung cases, breath motion causes worse dose coverage and lower maximum dose. Rigid motion plays a dominant factor for motion effect on dose coverage. Deformable motion can change the dose coverage too at a smaller scale.

PO-GePV-T-337

Effect of Target Positioning Error on Tumor Control Probability in Stereotactic Radiosurgery for Metastatic Brain Tumors Using the CyberKnife M6

T Takizawa^{1,2*}, S Tanabe³, H Nakano³, S Utsunomiya⁴, M Sakai³, K Maruyama¹, S Takeuchi⁵, T Nakano², A Ohta³, M Kaidu², H Ishikawa², K Onda⁵, (1) Department of Radiation Oncology, Niigata Neurosurgical Hospital, Niigata, JP, (2) Department of Radiology and Radiation Oncology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, JP, (3) Department of Radiation Oncology, Niigata University Medical and Dental Hospital, Niigata, JP, (4) Department of Radiological Technology, Niigata University Graduate School of Health Sciences, Niigata, JP, (5) Department of Neurosurgery, Niigata Neurosurgical Hospital, Niigata, JP

Purpose: The purpose of this study was to evaluate the effect of target positioning error (TPE) on dose distribution and tumor control probability (TCP) in stereotactic radiosurgery (SRS) plans for metastatic brain tumors of different sizes using the CyberKnife M6. **Methods:** The reference plans in SRS were created using the circular cone of the CyberKnife M6 for each spherical planning target volume (PTV) with diameters (Φ) of 5, 10, 15, and 20 mm, contoured on CT images of a head phantom. The dose of 20 Gy per single fraction was prescribed to the 70% isodose lines, covering 95% of the PTV. Subsequently, TPE plans were created by shifting the beam center by 0.1–2.0 mm in three dimensions relative to the reference plans, using the same monitor units and beam arrangements. Dosimetric parameters such as V20Gy of the PTV, conformity index (CI) and generalized equivalent uniform dose (gEUD)-based TCP estimates were evaluated for each plan. Shifts corresponding to the TCP reduction rate of 3% were also evaluated for each PTV size. **Results:** The V20Gy, CI and TCP values of the reference plans for Φ 5-mm PTV were 95.1%, 0.90 and 81.4%, respectively. The corresponding values for TPE plans with 0.5-mm, 1.0-mm, and 2.0-mm shifts were 79.0%, 0.62 and 79.6%, 62.9%, 0.40 and 72.3%, and 34.2%, 0.12 and 19.5%, respectively, all of which decreased as TPE values increased. The TCP values for TPE plans with 2-mm shifts were 19.5% for Φ 5-mm PTV, 68.9% for Φ 10-mm PTV, 74.3% for Φ 15-mm PTV, and 79.0% for Φ 20-mm PTV. Shifts corresponding to the TCP reduction rate of 3% were 0.6, 1.1, 1.2, and 1.6 mm, respectively. **Conclusion:** The TPE had a significant effect on target dose coverage and TCP in SRS for metastatic brain tumors using the CyberKnife M6, in particular, for small PTV.

Predicting the Effect of Indirect Cell Kill for Radiosurgery of Multiple Brain Metastases Via Single-Isocenter/Multi-Target Volumetric Modulated Arc Therapy (SMT-VMAT)

A Palmiero^{*}, D Fabian, M Randall, W St Clair, D Pokhrel, University of Kentucky, Lexington, KY

Purpose: Patient setup errors are of major concern for stereotactic radiosurgery (SRS) of multiple brain metastases (m-bm) when using SIMT-VMAT treatments. However, recent clinical outcome studies show high rates of tumor local control for SIMT-VMAT. This could be from contributions of both direct cell kill (DCK) and indirect cell kill (ICK) via devascularization for a single-dose of 15Gy or more. This study quantifies the role of ICK in dosimetric errors as a function of spatial patient setup uncertainty. **Methods:** Nine patients with 2-16 metastases (61 total) were planned using SIMT-VMAT with HyperArc planning geometry using a 10MV-FFF beam with a 20Gy prescription to each lesion. Isocenter was placed at the geometric center of all tumors with an average distance to isocenter of 5.4 cm (2.2-8.9cm). Plans were recalculated with clinically realistic patient setup errors [± 2 mm, $\pm 2^\circ$] in all 6-directions. Boolean structures were generated to calculate the effect of DCK as 20Gy isodose volume (IDV) and ICK as 15Gy minus 20Gy IDV. Contributions of DCK and ICK to PTV coverage were analyzed along with brain toxicity. Induced uncertainty and minimum dose covering the entire PTV were analyzed to determine the maximum acceptable patient setup errors to utilize ICK for SIMT-VMAT. **Results:** Patient setup errors of 1.3mm/1.3° in all 6-directions must be maintained to achieve PTV coverage of 15Gy for ICK with SIMT-VMAT. Setup errors of 2mm/2° showed clinically unacceptable loss of PTV coverage of 29.4 $\pm$ 14.6% even accounting for ICK—suggesting repositioning the patient. However, no significant effect on normal brain toxicity was observed. **Conclusion:** SRS of m-bm using SIMT-VMAT treatments have shown positive outcomes even with patient setup errors. These clinical outcomes, while largely due to DCK, are also due to ICK. Mechanisms, such as devascularization, should be explored to provide better understanding of the radiobiological response of SRS of m-bm using SIMT-VMAT.

PO-GePV-T-339

Treating Vestibular Schwannomas Abutting the Brainstem with SRS/fSRS Alone

M Keohane^{1*}, Z Whiting¹, D Koffler², E Calugaru², A Goenka², J Chang² (1) Hofstra University, New York, NY, (2) Northwell Health, Lake Success, NY

Purpose: To present our experience in treating large vestibular schwannomas abutting the brainstem with stereotactic radiosurgery (SRS) or fractionated stereotactic radiosurgery (fSRS) alone without surgery. **Methods:** At our institution, we have increasingly performed Gamma Knife (GK) SRS/fSRS alone for patients clinically diagnosed as having a Koos Grade 3 or 4 acoustic neuroma. In this study, we retrospectively reviewed the treatment plans of 23 patients treated with this approach from 3/2014-1/2021, and reported the dosimetric indexes and treatment outcomes. All patients were prescribed a dose of 12Gyx1 or 6Gyx5 fractions, planned using the Leksell GammaPlan (LGP), and treated with the GK Perfexion (before 5/2018) or ICON system (after 6/2018) of our institution. Dosimetric indexes collected included gradient index (GI), Paddick Conformity Index (CI), and maximal dose and V10/23Gy (per TG101 dose constraints) of the brainstem. To measure changes in tumor volume, post-treatment imaging was imported into LGP and the index lesion was individually contoured. **Results:** All treatments demonstrated excellent local control with limited toxicity. All except 2 treated targets touched the brainstem. The mean $\pm$ standard deviation for the CI is 1.23 $\pm$ 0.08 and for the GI is 3.00 $\pm$ 0.24. For the brainstem, the mean maximal dose and V10Gy are respectively 12.20 $\pm$ 3.77 Gy and 0.097 $\pm$ 0.097 cm³ for 12Gyx1 fractionation. The mean maximal dose and V23Gy are respectively 26.53 $\pm$ 1.078 Gy and 0.096 $\pm$ 0.130 cm³ for 6Gyx5 fractionation. The majority of the follow-up scans showed increased tumor volumes at 6 months and decreased/stabilized volume in the 18-month plan. **Conclusion:** Large vestibular schwannomas can be safely treated with SRS/fSRS alone. The brainstem constraints in TG101 for single and five fractions can be met. This treatment approach is proven effective based on the follow-up scans. Further data is also needed to appropriately compare hypofractionated vs single-fractionated SRS in this population.

PO-GePV-T-340

Evaluation of Three Dosimeters on Output Factor Measurement of the New Aktina SRS Cone System

L Zhuang^{1*}, M Gao², M Pankuch², M Xu³, G Pixton¹, C Breit¹, (1) Northwestern Lake Forest Hospital, Lake Forest, IL, (2) Northwestern Medicine Chicago Proton Center, Warrenville, IL, (3) Northwestern Medicine Delnor hospital, Geneva, IL

Purpose: To evaluate the performance of three dosimeters on output factor(OF) measurement of the newest Aktina SRS Cone system attached to Elekta VersaHD LINAC using 6FFF beam. **Methods:** The Aktina SRS cone system is equipped with cone sizes of 5mm, 7mm, 9mm, 11mm, 13mm and 15mm. OF for each cone defined as the cone output at 10 cm depth divided by the output of open field of size 10cm at 90cm SSD was measured. A daisy chain correction factor was applied to calculate the final OF value using field size of 3cm. Dosimeters evaluated in this study include EBT3 Gafchromic film, EDGE detector, and Exradin A16 Micro chamber. EDGE & A16 measurements were performed in water tank, while EBT3 film was conducted in solid water. EDGE & A16 OF were also corrected based on published small field output correction factors for comparison purpose. In addition, IROC SRS OF phantom was utilized to independently verify the OF for cone size of 15mm. **Results:** The OFs measured with EBT3 were 0.502, 0.609, 0.664, 0.720, 0.761 and 0.783 respectively. OFs measured by EDGE were 0.550, 0.645, 0.705, 0.746, 0.773 and 0.795 respectively which were consistently higher (mean diff= 2.9%) than EBT3 measurements. A16 measurements were consistently lower than EBT3 measurements (mean diff= -2.4%) which were 0.455, 0.574, 0.651, 0.703, 0.743 and 0.770 respectively. EBT3 OFs, corrected EDGE OFs and corrected A16 OFs on average were within $\pm 1\%$ of each other. IROC results showed a satisfactory independent check of OF for cone size of 15mm (TLD/Inst=0.96 at 1.5cm & TLD/Inst= 0.97 at 7.5cm). **Conclusion:** Overall, EDGE over-responded to small field measurement and A16 Chamber under-responded to small field measurement due to volume averaging. OFs measured by EBT3 were found to be in good agreement with corrected EDGE and A16 OFs.

PO-GePV-T-341

A Multi-Clinic Validation of An End-To-End Procedure for MLC-Based Stereotactic Radiosurgery with a Novel Phantom

T Brown^{1*}, J Fagerstrom², C Beck³, C Holloway⁴, J Kerns⁵, D Kaurin⁶, K Kieler⁷, (1) Northwest Medical Physics Center, Lynnwood, WA, (2) Northwest Medical Physics Center, Lynnwood, WA, (3) Northwest Medical Physics Center, Lynnwood, WA, (4) Northwest Medical Physics Center, Lynnwood, WA, (5) Varian Medical Systems, Palo Alto, CA, (6) Northwest Medical Physics Center, Lynnwood, WA, (7) Varian Medical Systems, Palo Alto, CA

Purpose: An end-to-end procedure for a new anthropomorphic phantom was developed for MLC-based SRS commissioning on a linear accelerator. This procedure was developed and tested by Northwest Medical Physics Center at three independent clinical sites with Varian Edge and TrueBeam accelerators, following local standards for MLC-based SRS planning. **Methods:** The end-to-end procedure uses a novel anthropomorphic SRS phantom recently developed by Varian Medical Systems. This phantom was used to verify isocenter coincidence, targeting accuracy, treatment modulation and absolute dosimetry for dose delivery to a single target and single-isocenter, multitarget geometries. Testing was performed at three clinical sites in an all-Varian environment consisting of ARIA, Eclipse treatment planning, and TrueBeam/Edge machines with Millennium and HD-MLCs. CT simulation and treatment delivery was performed using Qfix Encompass and Brainlab mask systems. Treatment plans were developed for RapidArc and dynamic conformal arcs at 6FFF and 10FFF. Consistent planning criteria was applied across all three clinical sites. A nominal dose of 16 Gy was prescribed for each plan using a sites' standard beam geometry for SRS cases. **Results:** Pinpoint ion chamber readings showed agreement with the planned dose to within 3% for treatment delivery to a 2-cm target. DoseLab software was used to perform relative gamma analysis of the film dose planes compared to extracted data from the treatment planning system. Most single and multitarget treatment plans showed gamma passing rates >90% for 3% and 1 mm after auto-registration shifts ≤ 1 mm in any direction. **Conclusion:** Validation of the end-to-end procedure at three independent clinical sites indicates that it is acceptable for the commissioning of MLC-based SRS treatments. Data is now being acquired at additional clinical sites for the purposes of establishing acceptance criteria for end-to-end measurements performed on TrueBeam and Edge machines.

This work received financial support from Varian Medical Systems.

PO-GePV-T-342

Consistency in Response Between Two Copies of a High-Resolution Diode Array for SRS Dosimetry

B Barraclough^{1*}, (1) University of Wisconsin, Madison, WI

Purpose: To evaluate variability in response between two copies of SunNuclear's SRS MapCHECK diode array. **Methods:** Measurements suitable for device commissioning were collected with each copy of the SRS MapCHECK. The irradiations tested the devices' dependencies on beam angle, pulse repetition rate (PRR), dose per pulse (DPP), total dose, and field size for flattened and unflattened 6MV and 10MV beams. Angular dependence was tested with both axial and vertex beams. DPP was varied by changing SDD. Additionally, three treatment plans (lung SBRT, spine SBRT, 3D conformal SRS) for each energy were delivered to each device. Measurements were collected on one Varian TrueBeam on the same day to reduce variability of linac behavior. Differences in dependence on each variable were compared between the two devices. **Results:** Differences in dependence on beam angle were less than 1% for angles >10° from parallel with the array for axial and vertex orientations. Changing PRR and DPP resulted in differences between devices of less than 0.5% across the available range of PRR, less than 0.8% across the range of DPP, and within 0.4% for all but the highest DPP. Dose linearity varied by <0.2% between the two devices from 10 to 3500 cGy. Variability in field size dependence was <0.5% for all field sizes except for the 10FFF 1cmx1cm field, where the greatest difference was 0.9%. Finally, passing rates from each device were at least 94.8% and within 3% of each other using a 1%/1mm gamma comparison (lung SBRT and 3D SRS, all energies) and >89% and within 4.3% of each other with 2%/2mm criteria for the spine SBRT plans. **Conclusion:** The two diode arrays responded similarly across a wide range of tests. Only small differences in dependence to various conditions were observed. Gamma passing rates matched closely with more stringent criteria than used clinically.

PO-GePV-T-343

Evaluation of a New Diode Detector for Beam Data Measurements

S Stathakis*, C Kabat, M Naessig, Mays Cancer Center - MD Anderson Cancer Center, San Antonio, TX

Purpose: The purpose of this study is to evaluate a new semiconductor detector for photon beam dosimetry. Especially consideration was given to the narrow field dosimetry. **Methods:** The PTW MicrosiliconX diode is being evaluated for its application in measurements for beam data collection. An ELEKTA VersaHD linac and the PTW BEAMSCAN water tank were used for the measurements. We used 6MV, 10MV, 18MV, 6MV FFF and 10MV FFF energies for all measurements and field sizes ranging from 0.5x0.5cm² to 30x30cm². We measured profiles at 5,10, 20cm depths, percent depth dose curves, and output factors. The same measurements were collected for fields with the motorized wedge in place. Finally, all measurements were repeated using the SNC Edge detector and the PTW Photon Diode 61016P detector. The dose per pulse dependency was also checked for all detectors. **Results:** The dose per pulse dependency was acceptable for all detectors. The MicrosiliconX and 61016P detector had the lowest and the SNC edge had the highest dose per pulse dependency. The SNC Edge is also the most aged detector amongst them. The dose per pulse was 0.29%, 0.31%, 1.15% for the MicroSiliconX, 61016P and SNC Edge detectors. There was less than a 2% difference in all output factors. PDDs and profiles had small differences between them. The SNC Edge detector showed higher PDD values past 15cm depths but that the difference was within 1-2%. The profile penumbras were very similar. The PTW detectors had less noise in the measurements of PDDs and profiles. **Conclusion:** The new PTW MicrosiliconX detector was compared against established detectors for photon beam measurements. The detector performed similarly to the other ones and had less noise in the PDD and profile scans which in turn requires less data smoothing and less time for processing while obtaining reliable measurements.

PO-GePV-T-344

A Comparison of Field Output Correction Factors for a Diode Detector Among Various Measurement Setups and Among Various Energies for Stereotactic Cones

Y Lee^{1*}, Y Kim², (1) Miami Cancer Institute, Miami, FL, (2) Duke University, Durham, NC

Purpose: Diode detectors over-respond in small fields and their over-response needs to be corrected for field output factors (FOFs). The goal of this study is to compare field output correction factors (FOCFs) for the Sun Nuclear Edge detector among various measurement setups and among four different energies for stereotactic cones. **Methods:** FOCFs for Varian stereotactic cones (4, 5, 7.5, 10, 12.5, 15 and 17.5 mm in diameter) (Varian Medical Systems, Palo Alto, CA) referenced to a field size of 10 × 10 cm² were measured on Varian TrueBeam STx using a plastic scintillation detector (W2, Standard Imaging Inc., Middleton, WI) and the Sun Nuclear Edge detector (Sun Nuclear Corp., Melbourne, FL). Measurements were performed for four different energies (6MV, 6MV flattening filter free (FFF), 10MV and 10MV FFF) at depths of 1.5 cm, 5 cm and 10 cm in source-to-skin distance (SSD) and source-to-axis distance (SAD) setups. The daisy-chain method was used only for the Edge. FOCFs were determined by taking a ratio of FOFs for the W2 to those for the Edge. **Results:** First, absolute differences in FOCFs among three depths range from 0.002 to 0.011 (6MV), from 0.001 to 0.008 (6MV FFF), from 0 to 0.004 (10MV) and from 0.01 to 0.013 (10MV FFF) for the SSD setup and from 0.002 to 0.004 (6MV), from 0.002 to 0.006 (6MV FFF), from 0.001 to 0.003 (10MV) and from 0.012 to 0.02 (10MV FFF) for the SAD setup. Second, FOCFs for the SAD setup are usually larger than for the SSD setup and differences are largest for the 4 mm cone. Third, FOCFs for 6MV FFF are largest in both setups. **Conclusion:** FOCFs for the Edge detector can be different depending on the measurement setup and energy. Therefore, FOCFs for each setup and energy should be considered for accurate FOFs.

PO-GePV-T-345

A Method for Estimating the Geometrical Accuracy for Single-ISO Multiple-Target Treatment

H Li*, N Wen, I Chetty, Henry Ford Health System, Detroit, MI

Purpose: To present a method for estimating the geometrical targeting accuracy in single-ISO multiple-target (SIMT) linac-based stereotactic radiosurgery. **Methods:** Seven BBs (4 mm diameter) were inserted into a Rando head phantom, with CT image acquired. A treatment plan was created to irradiate the BBs with SIMT. Plan contained 69 static beams, 1.5x1.5cm field size (MLC-shaped), with various couch, gantry and collimator angles. Each beam irradiated one BB only. MLC aperture was designed to align BB and field centers as closely as possible. Distances from ISO to BB centers ranged from 0 to 7.5 cm. Before irradiation, the phantom was aligned to the planned position with CBCT guidance so that the final positional mismatch was ≤0.1 mm (translation) and ≤0.2 degree (rotation). During irradiation, EPID MV imager was used to capture exit field images of the BBs and 1.5x1.5cm fields. Distance between the BB centers on the exit MV image against DRR was measured, revealing the inaccuracy intrinsic to target alignment, and the uncertainty of the MV imager and the couch. Distance of the field centers on the MV image versus the DRR was measured, revealing the inaccuracy due to the MV imager, MLC leaf positioning, gantry sag, and collimator rotation. Distances between BB and field centers on the MV image and the corresponding values on the DRR were measured and compared to distinguish various inaccuracy sources. **Results:** For our Varian Edge System, the distance of the BB center on MV image against DRR was 0.4±0.2mm (max=0.7 mm). The distance of the field center on MV image against DRR was 0.3±0.1mm (max=0.6 mm). The difference of the BB center relative to field center on MV image against DRR was 0.5±0.2mm (max=1.0 mm). **Conclusion:** Our method confirmed that our Varian Edge System can deliver SIMT treatment with submillimeter geometrical targeting accuracy.

PO-GePV-T-346

Optimal Frequency of Winston-Lutz Test for Stereotactic Radiosurgery Treatment: A Five-Year Clinical Experience

J Qian*, R Gonzales, Johns Hopkins University, Baltimore, MD

Purpose: To determine optimal frequency of Winston-Lutz(WL) test in our clinic that assures the integrity of linac radiation isocentricity for stereotactic radiosurgery(SRS) treatment while effectively detecting abnormal deviations at minimum cost of clinical machine time. **Methods:** An Elekta Versa HD linac equipped with Agility MLC and Aktina cone system is used for MLC- or cone-based SRS. WL test is done with Elekta BB phantom and MV imager and analyzed with in-house software. After our SRS program commissioning in 2015, WL test is implemented in three phases with different frequencies: phase I(2015-2017) -on every day that had SRS treatment, phase II(2018) -bimonthly/monthly, and phase III(2019 to date) -on weekly basis if that week has SRS treatment, or after an isocentricity-affecting event, i.e. beam tuning, etc. Individual and average deviations of BB-cone/MLC field centers in MV images are calculated and compared. 2D distribution of those deviations is evaluated by beam-eye-view(BEV) plots. **Results:** The isocentricity of our SRS system is overall stable across all three phases of WL test frequencies. Average BB-cone field center deviations are $0.71 \pm 0.35 \text{ mm}$ ($n=54$), $0.75 \pm 0.35 \text{ mm}$ ($n=14$) and $0.73 \pm 0.40 \text{ mm}$ ($n=35$) for phase I,II and III, respectively. For MLC-based case, average deviations are $0.88 \pm 0.31 \text{ mm}$ ($n=23$), $0.83 \pm 0.31 \text{ mm}$ ($n=15$) and $0.69 \pm 0.37 \text{ mm}$ ($n=23$), respectively. The trend of average MLC-based field center deviation has relatively large fluctuation ($0.49\text{--}1.33 \text{ mm}$), compared to that of cone-based case ($0.61\text{--}1.03 \text{ mm}$). Weekly WL did help to catch abnormal average deviations (tolerance $< 1.2 \text{ mm}$) due to beam tuning and drifting. BEV plots indicate that MLC-based field centers (mean coordinates $(-0.41 \text{ mm}, -0.27 \text{ mm})$), are relatively more off isocenter than cone-based ones $(-0.08 \text{ mm}, -0.38 \text{ mm})$. **Conclusion:** Given an SRS system with historical stability in isocentricity and that daily WL could be machine time-demanding and monthly WL could miss opportunity identifying possible issue, it appears that weekly WL QA may promptly assure the integrity of SRS system isocentricity while being temporally practical in our clinic.

PO-GePV-T-347

Dosimetrical Verification of Output of Small Cones in a Radiosurgery Device

L Jin*, S Hayes, C Ma, Fox Chase Cancer Center, Philadelphia, PA

Purpose: Dosimetry for small fields presented a challenge for determining output factors for small-sized cones, so the accuracy delivered by small-sized cones could be affected if there are some errors in output factors. This work designed a method to verify the dose accuracy for small cones used in a Cyberknife. **Methods:** A "a large uniform dose area" plan using 5 mm cone was generated for a prostate (60 mm lesion size) and a brain case with a large lesion (35 mm in size), and then recalculated with a phantom. A point dose (placed at a uniform dose area) was measured with a pinpoint ion chamber (0.015cc) for each phantom plan. The method to measure the point dose actually has been practiced in our routine clinical QA for plans that have a large uniform dose area, which has been approved correct. To compare, plans for these two cases are also generated with large cones (35 mm for the brain case and 60 mm for the prostate case), and their point doses for phantom plans were also measured. **Results:** The average of three repeated measurements were taken as the measured dose. For plans using 5 mm cone, the measured dose is larger than the plan dose by 2.71% for the brain case while the prostate case shows that the measured dose is smaller than the plan dose by 3.8%. For the plan using large cones (35 mm above), the differences between the measured and plan doses are 1.41% and 0.8%, respectively for the brain and prostate case. **Conclusion:** With acknowledging the method used for a point dose measurement is correct for a large uniform dose area, this work showed that the output for small cones in our Cyberknife are correct within about 3%.

PO-GePV-T-348

A Simple Method for Quantifying and Reducing Lateral Response Artifact of Flatbed Scanner for Film Dosimetry

X Du^{1*}, B Rasmussen², (1) Northwest Medical Physics Center, Seattle, WA, (2) Marquette General Hospital, Marquette, MI

Purpose: To quantify radiochromic film flatbed scanner's lateral response artifact in a technically simple manner and to determine the region of the flatbed scanner where the lateral response is minimized, reducing or eliminating the need for correction factors. **Methods:** The scanning area ($30 \times 45 \text{ cm}^2$) of the expression 12000XL photo scanner is virtually divided into a matrix of $5 \times 5 \text{ cm}^2$ squares. A single piece of $3 \times 3 \text{ cm}^2$ EBT3 film is irradiated, then scanned separately at the center of each "square" location 72 hrs later using a ROI of $5 \times 5 \text{ cm}^2$. The center $2 \times 2 \text{ cm}^2$ ROI of each image is analyzed with red channel in RIT, and the average pixel value is converted into dose. Film calibration is generated from $3 \times 3 \text{ cm}^2$ film pieces from the same sheet, irradiated to known dose quantity, and scanned at the center of the flatbed. The regions with similar pixel values and low ROI standard deviation is determined to be the area on the scanner for which correction factors for clinical dosimetry is not needed. **Results:** Dose response of the single piece of $3 \times 3 \text{ cm}^2$ film is not observed from excessive scanning. The pixel value of all analyzed ROI ranges from 17317 to 19628, which corresponds to a dose range of 6.3 Gy to 8.5 Gy. The regions where lateral response artifact is minimized is approximately 10 cm from the scanner glass edge in each direction except on the right side ($\sim 5 \text{ cm}$ from the edge). In this region the pixel value ranges from 18557 to 18645 (dose range between 7.13 Gy to 7.21 Gy), and the standard deviation is < 131 pixels. **Conclusion:** This work describes a straightforward method to identify regions of a flatbed scanner where the lateral response artifact is minimal, which can improve the outcome quantitative film dosimetry.

PO-GePV-T-349

Thresholding Gamma Analysis On SRS Anthropomorphic Phantoms

A Molineu*, L Acuna Scafati, S Kry, UT MD Anderson Cancer Center, Houston, TX

Purpose: To calculate gamma results for SRS anthropomorphic phantoms using different thresholding methods and compare to the standard IROC region of interest method. **Methods:** The SRS anthropomorphic phantoms have a 1.9 cm target that houses two TLD and radiochromic film in the sagittal and coronal planes. It is mailed to institutions that create a plan treating the center of the target to 30 Gy with target coverage per institutional protocol. They irradiate and return the phantom and submit the plan in DICOM format. TLD are read and a 5%/3mm gamma analysis is done on the film. A newly commissioned in-house software addition includes the ability to use dose thresholding techniques to define the area used in the gamma analysis. Prior versions only allowed the area to be defined by as a rectangle relative to the target and was chosen to be a 2.9 cm square centered on the target. 28 recent SRS phantom results were recalculated using 10%, 20% and 30% of maximum dose thresholds as well as using a 10 Gy limit. Results were compared to the original regions of interest. **Results:** Analyzed phantoms had a pass rate of 86% using all methods except the 10 Gy threshold measurement. This method created one more failure making a pass rate of 82%. The average changes in the gamma results were 0% for each percent thresholds and 1% for the 10 Gy threshold with maximum changes of 2%, 3%, 5% and 14% respectively. **Conclusion:** The new ability of the software allows more flexibility in setting the area on the film use for gamma analysis. It will be further tested results of other phantoms before our methods are changed.

This work received funding from the NIH/NCI grants #CA180803

PO-GePV-T-350

An End-To-End, Low-Cost, Universal Winston-Lutz Type Quality Assurance Procedure for Hypofractionated Image-Guided Stereotactic Radiosurgery

L Ma^{1*}, W Hu², T Nano¹, L Wang³, C Chuang³, (1) University of California, San Francisco, San Francisco, CA, (2) Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, China (3) Stanford University, Stanford, CA

Purpose: Image-guided stereotactic radiosurgery (SRS) is rapidly disseminating worldwide. A robust low-cost and universally accessible QA method is critically needed for its safe implementation and global collaborations. In this study, we developed a low-cost, universal, end-to-end Winston-Lutz method to address such a need. **Methods:** After surveying the state-of-the-art SRS phantoms and QA strategies on the market, a simple two-piece detachable plastic film slab was created and specifically implemented for isocentric and off-center Winston-Lutz measurements. The phantom is constructed similar to the OSLD slabs shipped from IROC for Gamma Knife units. To conduct off-center Winston-Lutz testing, the user was instructed to cut a 0.3-mm solder wire into small bits (~0.5 mm). These fiducial bits were then randomly taped onto a radiochromic film (~250 cm²). The film was then needle-pricked on its back side at central positions of the taped fiducial bits. The film was then sandwich pressed between the two slabs. Treatment plan was created to deliver a near-spherical dose toward individual fiducials via online imaging guidance. The film and RTDose file were collected and analyzed centrally, a process similar to IROC workflow. **Results:** The initial measurements with the method yielded excellent results, showing submillimeter matching in mechanical-vs-radiological isocenters and peripheral isodose lines. Most excitingly, the technique for CBCT-guided trigeminal neuralgia treatments yielded <0.5 mm isocenter deviation that cemented clinical workflow. Additional benefits of our technique is its low cost and ease of implementation with the consumable cost estimated to be \$10.20. Since final dose distribution associated with different phantom constructs was embedded into the DICOM RTDose file, no special restrictions were placed for the film slabs if made locally. **Conclusion:** A low-cost, high-functional, end-to-end test procedure is developed and demonstrated for the first time. Implementations of the technique across modalities including carbon machines are underway with results forthcoming.

PO-GePV-T-351

Evaluation of Delivery Quality Assurance of Cyberknife Stereotactic Radiosurgery

J Li^{*}, X Zhang, H Zhuang, R Yang, Peking University Third Hospital, Beijing, Beijing, CN

Purpose: The purpose of this study is to establish and assess a practical delivery quality assurance method for stereotactic radiosurgery with Cyberknife by analyzing the geometric and dosimetric accuracies obtained using a PTW31016 PinPoint ionization chamber and EBT3 films. **Methods:** 150 cases of delivery quality assurance plans were performed on Cyberknife for assessing point dose and planar dose distribution respectively using a PTW31016 PinPoint ionization chamber and Gafchromic EBT3 films. The measured chamber doses were compared with the planned mean doses in the sensitive volume of the chamber, and the measured planar doses were compared with the calculated dose distribution using gamma index analysis. The gamma passing rates were evaluated using criteria of 3%/1 mm and 2%/2 mm. **Results:** For point dose comparison, the averaged dose differences ($\pm$ standard deviations) were $1.6 \pm 0.73\%$ for all the cases. For planar dose distribution, the mean gamma passing rate for 3%/1 mm, and 2%/2 mm evaluation criteria were $94.26\% \pm 1.89\%$, and $93.86\% \pm 2.16\%$, respectively. The gamma passing rates were higher than 90% for all the delivery quality assurance plans with the criteria of 3%/1 mm and 2%/2 mm. **Conclusion:** PTW31016 PinPoint ionization chamber and EBT3 film can be used for routine Cyberknife delivery quality assurance. The point dose difference should be within 3%. The gamma passing rate should be higher than 90% for the criteria of 3%/1 mm and 2%/2 mm.

PO-GePV-T-352

Comparison of SRS QA Tools On IROC Head Phantom Plan

C Teng^{1*}, N Vassell², E Sudentas¹, T Nguyen³, Y Lo⁴, (1) Mount Sinai West, New York, NY, (2) Mount Sinai Chelsea, New York, NY, (3) MD Anderson Cancer Center, Houston, (4) Mount Sinai Health System, New York, NY

Purpose: Intracranial stereotactic radiosurgery (SRS) requires high positional and dosimetric accuracy. This study evaluated three different SRS QA tools for IROC SRS phantom test. **Methods:** Portal dosimetry (PD), SunNuclear SRS MapCHECK, and IROC film/TLD were used to evaluate the agreement between delivered and planned dose for IROC SRS phantom test plan QA. Gamma Index for each of the three SRS QA methods was computed for a combination of criteria from 1-3mm distance-to-agreement (DTA), and 1%-5% dose difference (DD) for all detector points measured > 10% threshold. A VMAT plan consisting of 6-field non-coplanar beams of 6MV FFF was delivered to a 1.9 cm diameter target using TrueBeam V2.7 and 120 Millennium MLC. Plan was calculated by Eclipse AAA (Version 15.6.03) in 1mm calculation grid. **Results:** PD, MapCheck and film/TLD all are good tools for SRS QA. For tightest tolerance of 1%/1 mm, the Gamma passing rate were 95.4%/92.5% for PD/MapCheck, respectively. For clinical use 2%/2mm tolerance, the passing rates were 99.6%/98.2%/94.7% for PD/Mapcheck/film, respectively. We found that PD had slightly higher passing rate than MapCHECK QA in all combination of DTA and DD criteria, with the largest difference at the tightest bound of 1mm/1%. Gamma Index difference was reduced to <1.5% at 2mm/2%, and <1% at 2mm/3%. **Conclusion:** Portal dosimetry does not require the use of a specialized phantom, provides sub-millimeter detector resolution, and is convenient to use. However, due to the fixed geometry of the portal imager with the gantry, the PD QA does not simulate couch walk, and hence does not represent the true delivered dose distribution. Before an institution commissions the protocol for patient-specific QA using PD, it is recommended to use multiple SRS QA tools and determine a machine specific gamma passing criteria adequate for an accurate SRS treatment delivery.

PO-GePV-T-353

Implementing a QA Phantom to Test Discrepancies in Stereotactic Space Definition for Gamma Knife ICON

J Caron^{*}, S Ahmad, Y Chen, University of Oklahoma Health Sciences Center, Oklahoma City, OK

Purpose: To develop a QA phantom that can quantitatively evaluate stereotactic spaces defined among MRI, CT, and Cone Beam CT (CBCT). Variations in stereotactic space definition have been an issue when acquiring imaging with different modalities for gamma knife SRS patients. These discrepancies dispute the systematic integrity and are especially significant since variation in object localization may result in lack of prescribed dose to the target with additional radiation being absorbed by parenchyma. **Methods:** A Leksell Gamma Knife dosimetry phantom was placed in the immobilized stereotactic frame so it can be locked in position when being imaged across multiple modalities. A total of 12 CT and 4 MRI spot markers were placed inside and around the phantom. These markers were used as the means of comparison among different modalities. The phantom was imaged in CT and MRI with dedicated localizer box and a CBCT image was also taken using on board imager from a Gamma Knife ICON machine. All coordinates for the markers were determined in Gamma plan with different stereotactic space definition accordingly. The coordinates from CT and MRI were compared with that of CBCT and a translational shift was calculated by a taking vector magnitude between the two stereotactic space coordinates. **Results:** Minimum, median, and maximum total translational shifts of 0.65, 1.24, and 1.85mm, respectively were obtained for CT compared to CBCT. Interior markers were more susceptible to shifts compared to exterior. The MRI to CBCT comparison resulted in similar total translational shifts, with minimum, median, and maximum values of 0.64, 1.17, and 1.41mm. The 3 markers used for this comparison were on the phantom exterior. **Conclusion:** With the magnitude of most of the shifts being close to 1mm, this experiment suggests that further investigation may need for systematic error when co-registering images from different modalities.

PO-GePV-T-354

Evaluation of a New Winston Lutz Tool for the Treatment of Multiple Brain Metastases for Mono-Isocentric Beams

A Perez-Andujar*, Y Mutaf, G Klein, J Chen, Kaiser Permanente, Dublin, CA

Purpose: To evaluate the use of a new Winston Lutz tool for the treatment of multiple brain metastases for mono-isocentric beams. **Methods:** The Winston Lutz phantom has 5 built in BBs positioned at different distances from isocenter including off axis positions. The phantom was imaged before delivering the plan to ensure setup position. In total, twenty-one Winston Lutz tests were performed. Each test included eight different gantry, couch, and collimator configurations. The actual position of the phantom and each BB was also calculated for all the measurements. **Results:** The average position of the phantom ranged from 0.08-0.19 mm in the x,y, z direction and 0.1 degrees for the pitch, roll and yaw positions. Target 4 (5.8 cm from isocenter) and Target 5 (7 cm from isocenter) had the largest number of Winston Lutz test with a maximum 2D deviation between the BBs and the field center of 0.75 mm and 1 mm for a configuration with the gantry, couch and collimator at 0 degrees. The same targets showed a larger percent of times with a Winston Lutz > 1 mm. Overall target 5 showed 3% of the time a value ≥ 1.0 . **Conclusion:** Winston Lutz tests were performed for a total of 168 beam arrangements for a phantom aligned within our clinical tolerances < 0.5 mm and < 0.5°. Overall targets 4 and 5, the targets further from isocenter, had the largest number of Winston Lutz > 1 mm among all shifts and all gantry combinations. Longitudinal shifts seemed to affect the overall results the most. Nevertheless, a Winston Lutz < 0.75 mm seems to be achievable for most circumstances. Our result might be an indication that careful consideration should be taken for those targets further away from isocenter even when tight setup constraints are used during treatment.

PO-GePV-T-355

Simple and Reliable Calibration Fields for OrthoChromic Film Dosimetry Protocol

W Feng^{1*}, C Shi², J Zhou³, A Chu⁴, L Zhou¹, J Sakellakis¹, A Grann¹, (1) Saint Barnabas Medical Center, Tenafly, NJ, (2) New York Proton Center, New York, NY, (3) Rutgers - Cancer Institute of New Jersey, New Brunswick, NJ, (4) Montefiore Medical Center, Stony Brook, NY

Purpose: To demonstrate various calibration fields for the newly introduced OrthoChromic Film Dosimetry Protocol to optimize dose accuracy in order to deliver stable film dosimetry results over a wide dose range. **Methods:** The OrthoChromic OC-1 film was tested using Eclipse v15.6 with Truebeam and MultiPlan v5.3 with Cyberknife M6, respectively. The films were scanned in reflection mode on an Epson flatbed scanner with 48bit at 75dpi. A glass plate was used to flatten films on the scanner. OrthoChromic protocol requires a calibration film exposed to a calibration plan with multiple dose levels in scan direction and uniform dose in lateral direction, and a QA film exposed to patient specific QA plan. When the two films are scanned together in parallel in scan direction, the possible dose errors caused by lateral effect from scanner sensors and film coating variations are corrected. OrthoChrome Pro software was used to register films with corresponding plans, calculate delivered dose from film, and compare delivered dose to planned dose. Quality of QA film compared with planned dose were determined by gamma analysis at 2% and 2mm. **Results:** (1) Truebeam jaw can generate a step wedge calibration field that provides reliable dosimetric results, with over 95% gamma passing rate. (2) Cyberknife MLC can generate calibration field comparable to the Truebeam 8-level step wedge, with over 95% gamma passing rate. (3) Using overlapping circular fields generated by Cyberknife Cone, an equally reliable calibration field can be generated, with over 95% gamma passing rate. (4) An actual patient treatment case QA was performed with the overlapping cone calibration. The reliability of this dosimetric method was confirmed with over 95% gamma passing rate. **Conclusion:** There are many ways to design reliable calibration fields to obtain accurate dosimetric results using the newly introduced OrthoChromic Film Dosimetry Protocol.

PO-GePV-T-356

The Effect of Collimator Setting on Small Photon Field Output in a Commercial Treatment Planning System

S Zhang*, D Du, C Han, A Liu, City of Hope Medical Center, Duarte, CA

Purpose: More than one third of SBRT/SRS fields treated in our clinic were less than 5 mm in size. Due to limitation of linear accelerator collimator jaw positioning accuracy (Y: +/- 2 mm, X: +/- 1 mm, manufacture specification) the effect of the collimator setting on small photon field output needs to be studied. **Methods:** A commercially available treatment planning system (Eclipse TPS, Version 15.5.11, Varian Medical System) was used in this study. The outputs of small photon fields of collimator setting in 10 x 10 mm and 20 x 20 mm were first calculated to validate the accuracy of small field dose calculation accuracy of our treatment planning system. A number of treatment plans were then created with a small photon MLC field of 5 x 5 mm in size with various X and Y jaw collimator settings. The calculated outputs of the small photon fields were compared, as well as to that of 100 x 100 mm reference field. **Results:** The outputs for 10 x 10 mm and 20 x 20 mm photon field shown comparable results with publishing results in the literature, validating the dose calculation accuracy of our dose calculation algorithm. The outputs of the same field size of 5 x 5 mm with various collimator setting from 5 x 5 mm to 20 x 20 mm shown a difference up to 24.9%. For the same collimator setting 5 x 20 mm, by interchanging X, Y jaw settings the output also shown 4% difference. **Conclusion:** There was significant difference among plans with the same MLC field size but different collimator jaw settings, which would be verified by measurement with plastic scintillation detector. Recently we have adopted new planning guideline to have fixed jaws of 20 x 20 mm for all small field conformal arc plans,

PO-GePV-T-357

Comparison of Commercial Pre-Treatment QA Devices for Stereotactic Radiotherapy Plans

S James^{1, 2*}, A Al-Basheer¹, E Elder^{2, 3}, J Barrett¹, F Mostafaei¹, (1) Augusta University, Augusta, GA, (2) Georgia Institute of Technology (3) Emory University

Purpose: The goal of this research is to compare commercial quality assurance (QA) devices to the EBTXD film dosimetry method for pre-treatment evaluation of stereotactic body radiation therapy (SBRT) & Intracranial stereotactic radiosurgery (SRS) treatment plans. **Methods:** SBRT & SRS plans were created using IMRT or VMAT technique with varying target volumes (smallest volume of 11.98cc and largest of 40.01 cc) were created using Eclipse 15.6 treatment planning system. Plans were delivered using a Varian Edge LINAC and measured on QA devices at beam energies of 6 MV and 10 MV with and without flattening filter. The QA plans measured using EBTXD film on a 15cm solid water phantom and a A1SL ion chamber, SNC ArcCHECK (0.64mm² detector area with 10mm spacing) and Varian DMI EPID. Results analyzed at 3%/3mm, 2%/2mm, 2%/1mm, and 1%/1mm for each QA method. **Results:** EBTXD films were scanned using an Epson10000XL flatbed scanner and analyzed using RIT software and had average gamma analysis passing rates of 97.42%, 93.42%, 84.52%, and 76.07% for 3%/3mm, 2%/2mm, 2%/1mm, and 1%/1mm gamma criteria, respectively. The Varian DMI EPID produced an average gamma analysis passing rates of 99.46%, 99.90%, 99.29%, and 97.92% for 3%/3mm, 2%/2mm, 2%/1mm, and 1%/1mm gamma criteria, respectively. The SNC ArcCHECK produced an average gamma analysis passing rates of 96.82%, 90.84%, 78.18%, and 70.80% for 3%/3mm, 2%/2mm, 2%/1mm, and 1%/1mm gamma criteria, respectively. **Conclusion:** Passing rates decreased for all devices as gamma criteria becomes stricter. EBTXD film and ArcCHECK show agreement within 3.5% for 3%/3mm and 2%/2mm gamma criteria and begin to diverge from agreement as criteria becomes more stringent. In contrast, the EPID system resulted in high pass rates regardless of target size, modulation factor, and gamma criteria. To further study this topic, an SNC SRS MapCheck and IBA myQA SRS will also be used in the comparison.

PO-GePV-T-358

On the Optimal Number of Dose-Limiting Shells in the SBRT Auto-Planning Design for Peripheral Lung Cancer

Y Duan*, Z Xu

Purpose: The number of dose limiting shells in the optimization process is one of the key factors determining the quality of stereotactic body radiotherapy (SBRT) auto-planning. This study attempted to derive the optimal number of shells by evaluating the auto-plans designed with different number of shells for peripheral lung cancer patients treated with SBRT. **Methods:** Identical treatment technique, optimization process, constraints, and dose calculation algorithm were retrospectively applied to fifty peripheral lung cancer patients who underwent SBRT in our center. For each of the patients, auto treatment plans were optimized based on 2 shells, 3 shells, 4 shells, 5 shells, 6 shells, 7 shells, 8 shells, respectively. The optimal number of shells for the SBRT auto-planning was derived through the evaluations and comparisons of various dosimetric parameters of planning target volume (PTV) and organs at risk (OARs), monitor units (MU) and optimization time of the plans. **Results:** The conformity index (CI) and the gradient index (GI) of PTV, the maximum dose outside the 2cm of PTV (D2cm), Dmax of Spinal Cord (SCmax), the percentage of volume of total lung excluding ITV receiving 20Gy (V20) and 10Gy (V10), and the mean lung dose (MLD) were improved when the number of shell increased, but the improvement became not significant as the number of shell reached 6. The monitor units (MUs) varied little among different plans where no statistical differences were found. However, as the number of shell increased, the auto plan optimization time increased significantly. **Conclusion:** It appears that for peripheral lung SBRT auto planning using 6 shells can yield satisfactory plan quality with acceptable beam MUs and optimization time.

PO-GePV-T-359

Volume-Staged Stereotactic Radiosurgery (VS-SRS) Treatment of Large Arteriovenous Malformation AVM: Volumetric Modulated Arc Therapy Approach

D Soultan*, H Jiang, N Demez, F Wang, Kansas University Medical Center, Kansas City, KS

Purpose: Volume-staged SRS downsizes treated volume per stage which allows tolerating higher SRS dose to target's sub-volumes and reducing risk of brain necrosis. However, meeting SRS treatment plans quality matrix in VS-SRS plans is challenging given the angioarchitecture of staged-volumes and total volume, delivery technique and modality limitations. We present a VMAT VS-SRS planning approach for large AVM treated with VS-SRS to three sub-volumes of nidus. **Methods:** A patient with large AVM (16.5cc) in the right parietal lobe was simulated with Brainlab SRS-mask and 1 mm CT slice thickness were obtained and imported into Varian Eclipse TPSV15.6 and registered to MRA images data-sets and Angio-CBCT scans for contouring AMV nidus which was divided to feeding nidus (8 cc), draining-superior (4.25 cc) and draining-inferior (4.0cc) for geometric optimization purposes. 20 Gy was prescribed to the entire nidus volume and portions of total dose were delivered to sub volumes with interval of 2-4 weeks. VMAT plans were generated for each volume/iso center using non-coplanar arcs delivered on HDMLC Novalis-Tx. Collimator and arc angles were configured to minimize dose spillage between staged volumes. Planning objectives including generalized uniform equivalent dose gEUD were assigned to planning volumes and OARs. Normal tissue objective was enabled, structure resolution was set to 1.25mm, and AAA calculation grid was set to 1mm. Individual and composite plans isodoses and DVHs were examined. All individual sub-volume plans passed IMRT QA. **Results:** V95% was >95% and D95% was >95% and minimum dose was >93.5% for all three sub volumes and total volume in composite plan. CI was 0.63, PTV was 1.57, R50 was 4.36 while GI was 2.77, V12 was 52.9cc (3.9%). **Conclusion:** VMAT VS-SRS meets SRS plans quality parameters when compared with published literature covering VS-SRS delivery with different treatment modalities and techniques such as Cyberknife and GammaKnife, DCA and IMRT.

PO-GePV-T-360

Clinical Evaluation of a Novel Automatic Inverse Planning System in Gamma Knife Lightning

T Cui*, K Nie, J Zhu, D Shabbar, J Weiner, A Chundury, N Ohri, Y Zhang, I Vergalasova, N Yue, X Wang, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ

Purpose: To evaluate the dosimetric qualities of plans generated using a novel automatic inverse planning system for Gamma Knife stereotactic radiosurgery (GKSRS). **Methods:** Patients treated with GKSRS for pituitary adenoma (PA), vestibular schwannoma (VS), and post-operative brain metastases (pBM) at a single institute were randomly selected. The original clinical plans were manually generated and reviewed prior to treatment. Each case was re-planned by two independent planners using the inverse planning (IP) system in Gamma Knife Lightning. The planning goal was to achieve at least 99% prescription dose coverage to targets, while minimizing beam-on time and dose to organs at risk (OARs), if any. The beam-on time, scaled by plan dose rate, and dosimetric metrics were compared among three plans. Statistical analyses were performed using the ANOVA and Tukey tests. **Results:** Thirty GKSRS patients were identified with 10 in each diagnosis type. At least 99% target coverages were achieved in the IPs, comparable to those in the clinical ones. There were no significant differences in the Paddick Conformity Index. Whereas the Gradient Indices were equivalent among the plans for PA and VS, the GIs in the IPs for pBM were significantly lower ($p < 0.01$) due to the relatively large targets. Similar dosimetric metrics of OARs were also observed between the IPs and clinical plans. The average beam-on times in the IPs were reduced by 25 minutes for PA ($p < 0.01$) and by 10 minutes for VS ($p = 0.60$), but unchanged for pBM. However, the reductions in the IPs for PA and VS were offset by the increased numbers of shots used to control the dose to OARs, resulting in comparable total treatment durations. **Conclusion:** Inverse planning in GK Lightning allows planners to generate GKSRS plans of equivalent plan qualities compared to manual planning. The automation accelerates GKSRS planning and therefore improves the clinical workflow.

PO-GePV-T-361

Dose Gradient Improvement for SBRT Lung Plans During Optimization

T Li*, B Mowbray, P Vadnais, A Mendez, C Geraghty, B Hasson, Anne Arundel Medical Center, Annapolis, MD

Purpose: In this work, as a preliminary study and proof of concept, patient specific normal tissue objective (NTO) based on PTV volumes is applied during the optimization process to improve dose gradient R50% (ratio of the 50% isodose volume/PTV volume). **Methods:** Assuming PTV as a sphere, the radius can be derived from simple geometric formula. The desired 50% isodose volume can be obtained from the PTV volume times the R50% constraint from RTOG 0813 protocol, thus the radius of 50% isodose volume can be derived. The difference of the radius of these two spheres (the distance from PTV edge to 50% isodose line) is an indication of dose falloff. This distance (DNTO) is calculated according to PTV volumes and incorporated in the normal tissue objective (NTO) module of Eclipse TPS's photon optimizer. The setting is set to achieve the distance from PTV edge to the 50% isodose line be equal to DNTO. Retrospectively 5 lung SBRT patients are re-planned utilizing the NTO module, while maintaining other OAR constraints. The R50%, CI (Conformity index) and V20 (percent lung volume receiving 20 Gy) for each plan are then compared with previously treated clinical plans where NTO objectives were not used. **Results:** CI remains unchanged as expected. R50% is reduced for all plans, ranging from 1.2% to 7.7%, with an average of 4.4% when patient specific NTO are used. V20 are also reduced, ranging from 2.8-6.8%, with an average of 5.4% utilizing NTO. Further reduction is possible if more aggressive NTO setting is employed, which is under current investigation. **Conclusion:** R50% can be effectively reduced using patient specific NTO settings based on PTV sizes. V20 can also be improved utilizing NTO. The correlation of R50% reduction and potential better clinical outcomes is also manifested in the improved V20 values.

PO-GePV-T-362

Investigation of Treatment Planning Strategies for Multi-Isocenter Intracranial stereotactic Radiosurgery

I Rusu*, J Roeske, S Gros, A Solanki, H Kang, Loyola University Medical Center, Maywood, IL

Purpose: To assess the impact of utilizing avoidance structures versus avoidance sectors on dosimetric performance, planning efficiency and patient-specific quality assurance (PSQA) of multi-isocenter frameless stereotactic radiosurgery (SRS). **Methods:** Five patients each with 4 to 6 lesions were included in this study. Three VMAT plans were generated for each patient, to treat one target and avoid the remaining lesions. While the treatment geometry was identical between the three plans, the first VMAT plan employed avoidance sectors (SRS-AvS) to minimize the dose to the untargeted lesions. The second and third plans designated the untargeted lesions as avoidance structures and prohibited "Entrance and Exit" of the beam through them for the second plan (SRS-NEE) and only "Entrance" for the third plan (SRS-NE). The three plans were evaluated using commonly employed dose-volumes and plan quality indices (Paddick Conformity Index [CIPaddik], Homogeneity Index [HI], normal brain [V12Gy], maximum dose to OARs and untargeted lesions) and total number of monitor units (MUs). PSQA was performed for the SRS-AvS and SRS-NEE plans and evaluated for gamma passing rate of 3%/3mm. **Results:** All three plans achieved similar target coverage, CIPaddik, HI, V12Gy and sparing of OARs and untargeted lesions. On average, the SRS-AvS plans resulted in 44% and 17% reduction in the total MUs when compared to SRS-NEE and SRS-NE plans, respectively. The greater the overlap between the targeted lesion and avoidance structures, the larger the reduction in total MUs offered by SRS-AvS plans. Regarding PSQA, two of the SRS-NEE plans that resulted in highest increase in total MUs did not satisfy the clinical criteria of 95% passing rate. **Conclusion:** Although the use of avoidance structures improves planning efficiency by eliminating the need of identifying avoidance sectors in the VMAT arcs it could potentially result in substantial increase in MUs and ultimately beam-on time.

PO-GePV-T-363

Validation and Clinical Implementation of VMAT Liver SBRT on 6MV-FFF O-Ring Halcyon Linac

T Tackett*, A Webster, M Bernard, M Kudrimoti, D Pokhrel, University of Kentucky, Lexington, KY

Purpose: Evaluate the plan quality, delivery efficiency, and accuracy of VMAT liver SBRT on 6MV-FFF O-ring Halcyon. **Methods:** Eight liver cancer patients received VMAT-SBRT, delivering 30-50 Gy in 5 fractions, prescribed to 80% isodose line on Halcyon. Mean PTV volume was 167.4±70.88 cc (range, 71.7-304.1cc). VMAT liver SBRT plans were generated with full RTOG-1112 compliance, advanced AcurosXB algorithm for heterogeneity corrections with Halcyon couch and SBRT board insert. Patients were treated every other day using 2-4 partial/full arc geometry with 6X-FFF beams including fast 15-second kV-iCBCT imaging for set up corrections. For comparison, clinical Halcyon plans were retrospectively reoptimized on TrueBeam Linac with identical geometry and optimization parameters. Plan quality, organs-at-risk (OAR) and treatment delivery parameters were compared after identical target normalization. For clinical Halcyon plans, quality assurance and couch corrections results are reported. **Results:** Halcyon and TrueBeam plans showed similar conformity index, total monitor units, modulation factors and maximal dose fall-off at 2cm away from the PTV. Mean PTV dose was 106.0±2.4% and 105.9±1.8% of the prescribed dose for Halcyon and TrueBeam, respectively. RTOG volumetric doses for OAR were similar: 8.7Gy vs 8.3 Gy (0.5cc of duodenum); 13.1Gy vs 12.9Gy (0.5cc of stomach); 9.6 Gy vs 9.9 Gy (0.5cc of small bowel) and 4.4 Gy vs 4.1 Gy (30cc of heart) for Halcyon vs TrueBeam plans. Halcyon pre-treatment portal-dosimetry QA result was 98.7%, on average for 2%/2mm gamma passing criteria. The 3D radial couch correction was 0.65±0.47cm (0.41–0.95cm). Mean beam-on time was 3.4±1.2min (2.0–5.7min). Overall treatment time on Halcyon was <15 min. **Conclusion:** For select patients, SBRT of liver cancer on Halcyon is safe, feasible, efficient and dosimetrically similar to TrueBeam Linac. Faster overall liver SBRT treatment on Halcyon may increase patient compliance, reduce intra-fraction movement and improve clinic workflow. Clinical follow up of these patients is underway.

This work is partially supported by Varian Medical Systems.

PO-GePV-T-364

Retrospective Characteristic Analysis of New Exponential Dosimetric Variable, Dose Dropping Speed (DDS) in the Treatment Plans of Arteriovenous Malformations (AVM) to Evaluate Dose Fall-Off

H Kaur^{1*}, S Hazarika³, J Ninan⁴, Dr. Aditya Gupta⁵, Dr. S C Pande⁶, (1) Artemis Hospitals, Gurugram, HR, IN, (2) Artemis Hospitals, Gurugram, HR, IN, (3) Artemis Hospitals, Gurugram, HR, IN, (4) Artemis Hospitals, Gurugram, HR, IN, (5) Artemis Hospitals, (6) Artemis Hospitals

Purpose: The purpose of this study is to analyze the trend of Exponential dosimetric variable Dose Dropping Speed (DDS) in the treatment planning of Arteriovenous Malformations (AVM) to evaluate dose fall-off and normal tissue sparing. **Methods:** A total of 30 patients of Arteriovenous Malformations (AVM) of volume ranging 0.03 cc-9.775 cc, Prescription Dose-ranging 14 Gy-25 Gy were included in this study. Treatment Plans were done using Iris or Fixed collimators depending upon the volume of the target. The DDS included two decay co-efficient: one which is in the vicinity of Gross Tumor Volume (GTV) named greater decay coefficient (b1) and another at a distance from GTV named lesser decay coefficient (b2). For performance evaluation of DDS, various equally situated ring-like shells were generated around the GTVs, and the mean dose in each shell was noted. Further, curve fitting was done using the exponential decay function of second-order and two different decay coefficients were obtained. **Results:** Prescription line for all the cases were in the range of 60%-80%. The Conformity Index (CI), New Conformity Index (nCI), Homogeneity Index (HI) and equivalent diameter of GTVs were 1.23±0.20, 1.29±0.20, 1.43±0.12 and 1.49±0.63. The average value of Decay co-efficient b1 and b2 were 0.33±0.10 and 0.21±0.12. The maximum and minimum difference between b1 and b2 was 0.3455 and -0.307. **Conclusion:** It was observed that 90% of the cases were having a larger value of b1 as compared to b2 which concluded that dose fall off near the GTVs was more and compared to dose fall away from the GTVs. A higher b2 value in 10% of the cases was observed where nCI was more. DDS shall be included in the Treatment Plan evaluation process. Furthermore, Institutional decay coefficient values can be standardized depending upon the tumor volume.

PO-GePV-T-365

Evaluation of Model-Based Dose Algorithms Using HU as a Density Surrogate for FFF-SBRT of Island Lung Lesions

B Bismack*, S Devpura, I Chetty, Henry Ford Health System, Detroit, MI

Purpose: To investigate dosimetric parameters of 4 algorithms for lung cancer patients treated with flattening filter free stereotactic body radiotherapy using HU as a surrogate for PTV density. **Methods:** We studied 15 lung cancer patients treated with SBRT using 6xFFF. Dose regimen was 12 Gy/fx in 4 fractions. Treatment plans were created using the pencil beam convolution in iPlan with IMRT and recalculated using identical parameters with iPlan's Monte Carlo Algorithm (MC), Analytical Anisotropic Algorithm (AAA), AcurosXB (AXB), and a collapsed cone convolution algorithm (Sun Nuclear Dose Check (SDC)). These lung-island tumors had ITV volumes of 12.44 ± 13.90 cm³. Data sets were indexed by average PTV density and several dosimetric indices for the target and normal lung tissue were evaluated. % difference relative to MC calculation is reported. **Results:** Average tumor densities were -594.3 ± 146.7 (-828.9 to -189.9 HU). The ΔD95 was -8.35 ± 3.22% (-13.00% to -2.99%), 1.16 ± 2.85% (6.47% to -1.93%), and -1.52 ± 1.55% (-4.58% to 1.44%) for SDC, AAA, and AXB respectively across all densities. Agreement with MC was moderately (0.576 ≤ r ≤ 0.713) correlated with density with a p < 0.05. A threshold for clinical agreement between the algorithms was noted around -450 HU. Below -600 HU ΔD95 was -11.39 ± 1.63%, 3.25 ± 3.29%, and -1.41 ± 1.71% for SDC, AAA, and AXB respectively. Of note, AAA and AXB were closer to MC than SDC but AXB and SDC both predicted under coverage relative to MC with AAA predicting over coverage. Lung V20 and V5 showed a tight spread with max difference within 2.0% of MC. **Conclusion:** Preliminary results suggest that target

coverage agreement has moderate correlation with target density and a threshold for clinical agreement might be established. Lung V20 and V5 showed a much tighter spread of agreement.

PO-GePV-T-366

Evaluation of Parameters Affecting Gamma Passing Rate in Patient-Specific QA's for Multiple Brain Lesions IMRS Treatments

E Salari*, D Shvydka, E Parsai, University of Toledo Medical Center, Toledo, OH

Purpose: Using single isocenter for treatment of multiple brain lesions with Intensity Modulated Radiosurgery (IMRS) have gained acceptance in recent years. One of the challenges of this technique is conducting a patient-specific quality assurance (QA), involving accurate gamma passing rate (GPR) calculations for small and wide spread-out targets. We evaluated effects of parameters such as dose grid and energy on GPR using our clinical IMRS plans. **Methods:** 10 patients with total of 40 volumetric modulated arc therapy (VMAT) plans were created in Raystation(V.8A) treatment planning system (TPS) for the Varian Edge Linac using 6 and 10 Flattening Filter-Free (FFF) beams and planned dose grids of 1mm and 2mm resulting in 4 plans with 6 to 10 targets per patient. All parameters and objectives except dose grid and energy were kept the same in all plans. Next, patient specific QA's were measured evaluating GPR with 10% threshold, 3%/3mm objective, and an acceptance criterion of 95%. Modulation factors (MF) and confidence intervals were calculated. Two modes of measurements, standard density (SD) and high density (HD) were used. **Results:** 1mm planned dose grid has higher GPR's than 2mm dose grid. The GPR's of 6FFF plans were higher than those of 10FFF. GPR showed no noticeable difference between HD and SD measurements. No correlation between MF and GPR was observed. The SD pass rates fall within the confidence interval of HD. **Conclusion:** Calculated dose grid should be less than or equal to 1/3 of distance to agreement, thus 1mm planned dose grid is recommended to reduce artifacts in gamma calculation. GPR of SD and HD measurement modes is almost the same which indicates SD mode is clinically preferable for performing patient specific QAs. According to our results using 6FFF with 1mm planned dose grid is more accurate and reliable for dose calculation of IMRS plans.

PO-GePV-T-367

Gamma Knife Thalamotomy – Imaging Verification of the Isocenter Location

C Yang*, Y Chen, Monmouth Medical Center, Long Branch, NJ

Purpose: As functional treatment of essential tremor (ET) becomes a popular protocol for Gamma knife radiosurgery, the geometrical location of the isocenter was determined based on the anatomical formula to identify the Ventral intermediate (thalamic) nucleus (VIM). Registered MRI allows for lesion positioning/localization, as well as guidance for GK isocenter placement, verification of this location from the post-MR was accomplished. **Methods:** Distortion or mis-registration of the MR introduces the uncertainties of target localization. The standard formula for determining the core of VIM was challenging. A Series of treated ET images were studied to identify the actual treatment location, 130 Gy prescription of dmax with 4 mm collimator was prescribed and the necrosis is observed to identify the margin accuracy. Image fusion analysis was performed to analyze the geometrical accuracy, the distance was measured with the necrosis ring with image fusion to show the 11 mm lateral to the midline of third ventricle was accurately correlated. MR fusion was performed. **Results:** With typical intracranial image fusion of pre/post treatment datasets of same patient, a case study has shown that post treatment MR verification of treated isocenter. Framed based GK radiosurgery has recommended that the lateral distance for the core should be half of the 3rd ventricle width plus 11 mm lateral shift, as this patient with 14 mm lateral shift to correlate the observable lesion was confirmed. Image fusion using frame has demonstrated that the target has been achieved with T1 necrosis with ring, which addressed radiation dose of ET thalamotomy was successfully delivered with proper OAR avoidance. **Conclusion:** Frame based GK thalamotomy with current formula to identify the core of Vim is accurate enough to generate necrosis with proper margin, which caused the noticeable clinical outcome for ET. The core of Vim was properly identified and delivered dose as planned.

PO-GePV-T-368

To Determine the Impact of Rotational Uncertainties On Dosimetric Coverage of Distant Targets Using VMAT Planning and a TPS Tool to Measure Plan Uncertainty

G Klein*, Y Mutaf, Kaiser Permanente, Dublin, CA

Purpose: To determine the impact of rotational uncertainties on dosimetric coverage of distant targets using VMAT planning and a TPS tool to measure plan uncertainty. **Methods:** VMAT plans containing a spherical 8 mm GTV with uniform 1 mm PTV expansion at 5 cm from isocenter were generated in a phantom. Similar plans were also generated for a target at 6 cm to assess differential impact based on distance. All plans were normalized such that V100% > 98% for each PTV; CI ranged from 1.23-1.32. As the TPS tool for assessing plan uncertainty uses translational shifts only, shifts were calculated to represent the location of the target after rotations of 0.4 and 0.5 degrees. PTV and GTV dosimetric coverage was then analyzed to determine the impact of each rotation in pitch, roll, and yaw individually. The impact of positive versus negative roll was also evaluated to determine sensitivity to rotational direction at each distance. **Results:** GTV coverage remained at 100% for all tests. In no case did the d=5 target coverage fall below 93%, whereas in 2/6 cases the d=6 target did. Worst-case coverage for the d=5 target was 93.0% versus 88.3% for the d=6 target. Dosimetric impact was found to be sensitive to rotational direction for the d=6 target, with coverage suffering more with roll in one direction versus the other. **Conclusion:** Rotational deviation reduced PTV coverage at both distances evaluated. The effect was larger for greater degrees of rotation and was more variable at greater distance. Despite decreased PTV coverage, the 1 mm GTV to PTV margin ensured that GTV coverage remained at 100%. This data demonstrates that target coverage may be sensitive to uncorrected rotation. The potential impact of rotational deviations should be considered when evaluating targets far from isocenter with a specific GTV to PTV margin.

PO-GePV-T-369

Feasibility of Skull Base Stereotactic Radiotherapy on Elekta MR-Linac

H Wang*, J Yang, J Phan, E Han, T Lim, P Castillo, X Wang, MD Anderson Cancer Center, Houston, TX

Purpose: Reirradiation of skull base lesions is often challenging due to the high dose gradient required to spare previously-treated nearby structures. This study investigates the feasibility of stereotactic radiotherapy for skull base lesions on Elekta MR-Linac. **Methods:** Two patients with locally-recurrent skull base lesions were treated with stereotactic radiotherapy in 2020. IMRT plans(mIMRT) were re-generated in Monaco for MR-Linac and compared to clinical RayStation VMAT plans(rVMAT) for Varian TrueBeam sTx. Simulation MR images were registered with planning CT images, and then manually shifted 2mm and 4mm individually in each of the lateral, anterior-posterior, and superior-inferior(SI) directions to simulate and test the online adapt-to-position(ATP) daily planning workflow. The quality of daily adaptive plans(dIMRT) was evaluated in terms of target coverage and dose to organ-at-risks(OARs). **Results:** Patient-1 had a smaller CTV1(1.4cm³) and a more irregular CTV2(17.4cm³) compared with Patient-2 larger CTV1(21.6cm³) and CTV2(34.3cm³). The mean registration error in Monaco was 0.3mm(range: 0.0 – 0.7mm). mIMRT plans achieved comparable target coverage and uniformity to rVMAT plans. Conformity and dose gradient were superior for rVMAT plans. All clinical goals were met in mIMRT plans for non-adjacent OARs, however mean doses of these OARs were inferior to rVMAT. Volumes enclosed by 50% prescription isodose line were larger in mIMRT plans. dIMRT plans achieved same clinical goals that used in corresponding mIMRT plans on simulated 2mm shift images but not on all 4mm images. This reflects the features of current MR-Linac with coplanar beams, sagittal MLCs, and 7mm MLC width. All ATP plans were concluded within 3-minutes. Brainstem and cochlea goals were not met for Patient-1 with 4mm lateral shift and required an Adapt-to-Shape plan(>20-minutes). **Conclusion:** MR-Linac has the potential for stereotactic radiotherapy to treat aggressive

tumors in the skull base region. Daily adaptive planning can track lesion changes while maintaining nearby critical structure dose constraints.

PO-GePV-T-370

Impact of MLC Uncertainty in Single Isocenter Multiple-Lesions SRS VMAT Plans

J Xu*, E Chacko, B Zhang, M MacFarlane, K Jiang, M Mishra, M Guerrero, S Chen, University of Maryland School of Medicine, Baltimore, MD

Purpose: To evaluate the dosimetric impact of multiple-leaf collimator (MLC) positional uncertainties (including systematic and random errors) in single-isocenter multiple lesions stereotactic radiosurgery (SRS) with volumetric modulated arc therapy (VMAT). And we also explore the impact on dose distributions due to MLC positional uncertainties in different lesion volumes. **Methods:** Five single-isocenter multi-lesion SRS VMAT plans with planning target volumes (PTVs) of varying size (<0.2 cc to >10 cc) are selected to introduce simulated MLC leaf position errors in RayStation. There are two types of systematic errors, MLC banks shift in the same direction and in opposite directions are simulated for magnitudes of 0.5 and 1 mm. For random errors, MLC leaf position offsets follow normal distributions and uniform distributions are simulated for magnitude of 0.5 and 1 mm standard deviations and bounds. The resultant dose distributions re-calculated in RayStation using the same Monitor Units (MUs) as in original plans for all control points are compared with original dose distributions of PTVs. **Results:** With both systematic and random MLC optional errors, small volume lesions (<0.2 cc), the percentage dose differences between modified plans and the original ones at D98 and D95 are much higher than those of lesions in relative larger volume (~ 0.5 to 1 cc). For hot spots in plans, the percentage dose differences at D2 randomly fluctuate with lesion volumes which are smaller than 3 cc. For the lesion with large volume (>10 cc), the percentage dose differences at both D95 and D2 are just change slightly with systematic and random MLC errors. **Conclusion:** Data demonstrates that both systematic and random MLC uncertainties have an effect on D2, D95, and D98 of single isocenter multiple-lesion SRS VMAT plans. The MLC positional uncertainties' impact on dose is dependent on lesion volumes--more pronounced effect for lesions with small volumes.

PO-GePV-T-371

Use Monte-Carlo Simulation to Determine the Coverage-Based PTV Margin

L Huang*, J Chang, Northwell Health, Lake Success, NY

Purpose: To determine the PTV margins required to achieve a desired reliability (e.g., 95% of the time) for covering a specified percentage (e.g., at least 95%) of the CTV. **Methods:** Monte Carlo simulation was performed to simulate the CTV motion, assuming changes in CTV position follow an independent normal distribution, $N(0, \mu)$ in each of the three motion axes. We also limited the CTV to be perfectly spherical. Applying circular symmetry, the three-dimensional random motion was simplified to a one-dimensional random motion in the radius direction following the Chi-square distribution ($k=3$). For each simulated motion, the percentage of CTV covered by PTV was calculated. The simulation was run for 1 million times for each combination of CTV radius and PTV margin, from which the histogram of percent CTV coverage (by PTV) was obtained. **Results:** The reliability function for percent CTV coverage was plotted for CTVs of radius from 1μ to 30μ and PTV margins (M) from 0 to 3μ . We found that the PTV margin required to achieve a desired reliability for covering a specified percentage of the CTV is significantly affected by the CTV dimension. If the clinical goal is at least 95% CTV coverage 95% of the time, a smaller CTV will require a larger PTV margin to achieve this goal, e.g., $M=1.97\mu$ for $r=5\mu$, and $M=1.19\mu$ for $r=15\mu$. If $M=0$, only 59.1% of a CTV with $r=5\mu$ can be reliably covered by PTV 95% of the time, while it is 86% for $r=15\mu$. An exponential equation was derived to relate the CTV radius to the required PTV margin, $M = 2.72 \cdot \exp(-r/19.78) - 0.11$ for achieving this clinical goal. **Conclusion:** This study demonstrated a size dependence for coverage-based PTV margin. A useful equation was developed for quick assessment of the required PTV margin for a given CTV radius.

PO-GePV-T-372

Assessment of Dosimetric Robustness Against Manually-Introduced Tumor Positional Shifts Among Lung SBRT Patients

J Joo*, P Qi, P Xia, The Cleveland Clinic Foundation, Cleveland, OH

Purpose: The lung tumor lesions were occasionally displaced from planned positions in reference to the bony anatomy during the treatment course. Due to the uncertainties in the dosimetric effects of tumor positional shifts on the quality of lung SBRT plan, the patient treatment was oftentimes interrupted or postponed for re-planning. The purpose of this work is to assess the dosimetric consequences of the "would-be" tumor positional shifts. **Methods:** We selected one lung SBRT patient and "manually" shifted the original target contours and the isocenter along six different orthogonal directions up to 6 cm. Both original and shifted target densities were overridden with either lung density or soft-tissue density to account for the changes. For each shifted plan, the dose was re-calculated with the same beam arrangement and MU as the original plan. The dose-volume histogram (DVH) of the internal/planning target volumes (ITV/PTV) and organs-at-risk (OAR) was assessed, including ITV V98%[%], PTV V95%[%], Ipsilateral Lung V10.5Gy[cc], Heart D0.035cc[Gy], Esophagus D0.035cc[Gy], and Cord D0.035cc[Gy]. **Results:** For lateral shift up to 3cm, PTV V95% decreased by 3% and the max percent increase of cord D0.035cc was 50%. For inferior shift up to 4cm, PTV V95% changed only by 0.4% while the max percent increase of lung V10.5Gy was 15%. For superior shift up to 2cm, PTV V95% decreased by 4% (the most percent change among all directions) while DVH percent changes of all OAR were less than 6%. For anterior-posterior shifts up to 6 cm, PTV V95% decreased by 2% whereas the max percent increase of heart D0.035cc was 40%. For all directional shifts, ITV V98% was 100%. **Conclusion:** Target coverage was robust against all directional tumor displacements. The DVH percent change of OAR were sensitive to both shift direction and magnitude, particularly lateral shift.

PO-GePV-T-373

Dosimetric Impact of Anatomical Changes Between Photon and Proton Stereotactic Body Radiation Therapy for Lung Cancer

C Liu^{1*}, T Ma², T Gray³, S Ahmed⁴, N Yu⁵, K Stephens⁶, G Videtic⁷, P Xia⁸, (1) Cleveland Clinic, Cleveland, OH, (2) Medstar Georgetown University Hospital, Midlothian, VA, (3) Cleveland Clinic, Cleveland, OH, (4) Cleveland Clinic, Cleveland, OH, (5) Cleveland Clinic, Cleveland, OH, (6) Cleveland Clinic, Cleveland, OH, (7) Cleveland Clinic, Cleveland, OH, (8) Cleveland Clinic, Cleveland, OH

Purpose: To investigate the impact of tumor displacement (TD) on target coverage in photon and proton stereotactic body radiation therapy (SBRT) treatments for lung cancer patients under daily IGRT. **Methods:** For patients treated with photon SBRT for lung cancer in 2017-2019 in our institution, 16 fractions from 16 patients with daily iso-center shifts >1.5 cm in any directions were identified according to kV-cone-beam CT (kV-CBCT) guidance. TDs of these fractions were identified by the difference between the iso-center shifts of bony alignment and tumor alignment. Eight fractions from eight patients had TDs in any directions >3 mm. For each of these eight patients, one photon plan with VMAT technique and one proton plan with IMPT were generated retrospectively. Photon and proton plans were optimized to achieve $>95\%$ of the PTV and $>98\%$ of the ITV receiving the prescription dose, respectively. For dose recalculation with TD, we shifted the tumor contours according to the corresponding TD on the patient specific planning CT. HU override was applied to shifted ITV (0.7 g/cm³) and original ITV (0.26 g/cm³). We evaluated dosimetric impact of TD with the percentage volume of GTV and ITV receiving the prescription dose (V100%). **Results:** The range of TDs was 3.58–12.18 mm, where the translational shifts was 0.24–4.45 mm in ML direction, 0.11–11.69 mm in AP direction and 0.9–10.57 mm in SI direction, respectively. For photon SBRT, all fractions had V100% of the GTV $\geq 99\%$ and V100% of the ITV $\geq 98\%$. For proton SBRT, V100% of the GTV and ITV had a range of 12.60%–96.21% and 34.17%–83.75%, respectively. **Conclusion:** Adequate target coverage was achieved in photon SBRT plans. TD had greater impact in proton SBRT plans, leading to target underdosage and adaptive planning was needed to provide adequate tumor dose coverage.

The Dosimetric Effect of Using a Titanium Material Assignment Versus Limited Hounsfield Units for SBRT Spine Patients with Hardware

Z Richards*, D Christ, D DiCostanzo, K Dibs, D Blakaj, Ohio State University Wexner Medical Center, Columbus, OH

Purpose: To evaluate the dosimetric differences observed in spine SBRT patients when assigning a material to contoured spine hardware as compared to utilizing the Hounsfield units (HU) obtained during computed tomography simulation. **Methods:** Forty-five spine SBRT patients with titanium hardware were retrospectively analyzed. The clinical plan was re-calculated with AcurosXB (version 15.6.05) set to report dose-to-medium with the spine hardware set to 3071 HU. A duplicate of the clinical plan was calculated with the material of the hardware contour set to titanium (density of 4.42 g/cm³ and 8610 HU) via the physical materials table available. A planning target volume for evaluation (PTVeval) was created by subtracting the hardware from the clinical PTV. Dosimetric statistics for PTVeval, spinal cord, cauda equina, and esophagus were computed and analyzed. The PTVeval was used for comparison purposes as dose within the rods is not clinically significant. **Results:** The compared PTVs displayed average percentage differences for maximum dose, mean dose, minimum dose, median dose, and dose to 95% of the volume (D95) of 1.95%, -0.18%, -0.44%, -0.16%, and -0.86%, respectively. Whereby a positive percent difference means that the plans with titanium assigned show higher dose. The average percent difference for the spinal cord, cauda equina, and the esophagus are 0.04%, -0.14%, and -0.22%. When the hardware encompassed more than 10% of the PTV volume, the average percentage differences for maximum dose, mean dose, minimum dose, median dose, and D95 were 2.90%, -0.34%, -0.74%, -0.30%, and -1.41%, respectively. **Conclusion:** The largest observed dosimetric difference for the D95 was -3.5%, representing a decrease in coverage when assigning titanium material versus 3071 HU. Additionally, no dosimetric differences for the organ at risk metrics exceeded 2.5% when assigning titanium material versus 3071 HU.

PO-GePV-T-375

Quantitative Assessment of Inter-Fractional Anatomy Change On Dose Delivery of Prostate SBRT

C Cheng*, X Zhang, B Liu, N Yue, R Parikh, Y Zhang, X Wang, Rutgers University, New Brunswick, NJ

Purpose: Target coverage and OAR sparing deficiency may be more prone to inter-fractional anatomy change due to the fewer fraction nature of hypofractionation. This study quantifies inter-fractional anatomy variations and evaluates their dosimetric impact during prostate SBRT using image deformation technique. **Methods:** Ten patients diagnosed with favorable intermediate risk prostate cancer were retrospectively included in this study. Total dose was prescribed to 36.25Gy in 5 fractions. Following guidelines from RTOG 0938, a CTV to PTV expansion of 5mm in all directions except for 4mm posteriorly were used. Patients were instructed to maintain a full bladder and empty rectum prior to CT simulation and each treatment. Localization was achieved through aligning to 3 fiducial markers in the prostate on daily CBCT. To evaluate the dosimetric impact from inter-fractional anatomy change on actual delivery, the body and OARs (bladder, rectum, penile bulb, femurs) were deformed to daily CBCT before performing forward dose calculations on each deformed CT. Inverse vector-field deformation was applied before creating a 5-fraction composite back onto the planning CT. **Results:** A 4.32%±32.32%(4.58cc±81.28cc) inter-fraction volume variation was observed for bladder, and -4.06%±4.86%(-2.02cc±2.41cc) for rectum. Discrepancy was noted between fiducial marker/CTV-focused versus pelvic bone-focused rigid registrations. The translation misalignment ranged from 0.05mm-9.38mm, and rotational angles from 0.0°-3.71°. CTV coverage from the composite dose remained comparable, with D95% at 100.73%±1.29% of the prescription dose(Rx) for the original plan and 100.31%±1.48%Rx for the delivery. The dosimetric parameters of OARs, including D0.03cc, D3cc, D90%, D80%, and D50% of rectum, and D0.03cc, D90%, and D50% of bladder remained comparable to those in treatment plan. **Conclusion:** In spite of the inter-fractional anatomical change (including, but not limited to, bladder filling, rectal emptying and bony anatomy change), the CTV coverage, the rectum and bladder sparing of the overall course of delivery remained similar to the planned condition.

PO-GePV-T-376

Analysis of Plan Quality for Intensity-Modulated Proton Therapy Vs. Photon Stereotactic Radiosurgery for Brain Metastases

T Gray, C Liu, P Xia, T Gray*, The Cleveland Clinic Foundation, Cleveland, OH

Purpose: The purpose of this work was to quantify the difference in plan quality between intensity- modulated proton therapy (IMPT) and photon-based stereotactic radiosurgery (SRS) treatment planning for multiple brain metastases. **Methods:** Twenty-two brain lesions from six patients, were planned using scanning beam proton and compared against photon-based SRS plans. Proton plans were optimized and evaluated using the Monte Carlo algorithm and photon plans were optimized using a collapsed cone convolution algorithm. Dose coverage to each lesion was set to 99% of the target volume receiving the prescription dose for all plans. Conformity index (CI), gradient index (GI), total V4.5Gy, mean brain dose and V12Gy for each lesion, were used to compare plan quality between the proton and photon plans using dose-volume histograms (DVHs) generated from each plan. **Results:** Both average CI and GI across all lesions were generally lower than the proton plans than those from the photon plans, but both were comparable, with a mean CI of 2.29 ± 1.47 and 2.48 ± 2.48 for protons and photons, respectively, with p>0.05. Mean GI was 4.58 ± 3.13 and 5.18 ± 2.60 for protons and photons respectively, with p>0.05. Mean V4.5Gy was 59.3 ± 35.7 cm³ and 203.8 ± 121.9 cm³ for proton plans and photon plans, respectively, with p<0.05. Mean brain dose was 36.7 ± 25.8 cm³ and 135.2 ± 47.5 cm³ for protons and photons, respectively, with p<0.05. **Conclusion:** We quantified the plan quality for both IMPT treatment plans and photon SRS plans for brain metastases. Proton therapy for brain lesions offers a good alternative to photon-based SRS treatment, with a lower average CI and GI, V4.5Gy and mean brain dose, and can significantly increase preservation of normal brain tissue.

PO-GePV-T-377

Robustness of AI Treatment Planning to Account for Inter-Fractional Changes in Targets and OARs

T Gray^{1*}, W Wang², C Liu³, D LaHurd¹, E Balagamwala¹, A Vassil¹, J Wu², P Xia², (1) Cleveland Clinic, (2) Duke University, Durham, NC

Purpose: To evaluate robustness of an AI model developed from a different institution to create adaptive plans for our pancreas patients to account for inter-fractional changes in the targets and organs-at-risk during a course of radiation therapy for pancreatic cancer. **Methods:** Fifteen patient CTs, including planning and daily CTs, were contoured using an image analysis software. Major organs-at-risk contoured include the duodenum, stomach, small bowel and colon, along with a GTV and PTV. Treatment plans for each patient CT were planned using an artificial intelligence model developed for pancreas patients. These fifteen patient CTs were not used for the model development. Prescription dose was 33 Gy and 25 Gy to the GTV and PTV, respectively. DVHs were generated and evaluated for each GTV, PTV and each major organ-at-risk. Dosimetric constraints for each organ-at-risk include dose at 0.03 cc < 33 Gy, 0.5 cc < 30 Gy and 5 cc < 25 Gy. Target volumes were evaluated for dose at 95% volume and percent volume at 95% dose. **Results:** Overall, the AI model was successful to create adaptive plans with adequate dose coverage to all targets. Most OAR constraints were also met. Average PTV percent volume at 95% dose for the AI model was 96.29 ± 5.20%. Average dose at 95% volume PTVs was 32.21 ± 0.68 Gy. **Conclusion:** This study demonstrates that the AI model developed from another institution is robust and can be applied to our patient images for daily adaptive planning.

PO-GePV-T-378

Selection of Single-Isocenter for Multiple Targets Based On Simulated Annealing Algorithm

J Miao, J Dai*, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CN

Purpose: Treating multiple targets with a single isocenter improves efficiency but requires margins to account for rotation which is related with target-to-isocenter distance. A method to select the isocenter position for multiple targets that minimizes the total volume of expanded target is presented. **Methods:** A statistical model was developed considering both the conventional setup error and the additional rotational uncertainty. Both translational and rotational uncertainties are assumed to follow the three-dimensional independent normal distribution with a zero mean, and standard deviations of σ_s and σ_R respectively. The relationship between margin of each target point and the distance d (from isocenter to target point), setup uncertainties, and significance level was established. In order to find the optimal iso-center position quickly, simulated annealing optimization algorithm was used. This method was implemented in the Pinnacle3 treatment planning system and compared with isocenters at the center-of-mass (COM) and center-of-surface-area (CSA). Spherical tumors and ten multiple brain metastases targets were chosen for evaluation. **Results:** For multiple brain metastases targets, isocenter placement at the optimal location, COM, and CSA, reduced the total margin volume versus an isocenter at geometric center up to 18.9%, 17.5%, and 18.6%, respectively. CSA provide useful approximations to select the optimal isocenter for multi-target. Simulated annealing algorithm can find the optimal isocenter for multiple targets within five minutes. The result has nothing to do with the position of the initial point used in simulated annealing algorithm. This method is not only suitable for two targets, but also can be used for dozens of targets. **Conclusion:** Optimal treatment isocenter selection for multiple targets of large size differences can significantly reduce total margin volume. This method could be used for clinical margin determination and might be useful for the protection of risk organs.

PO-GePV-T-379

Dosimetric Comparison of ZAP-X and CyberKnife Stereotactic Radiosurgery for Single Brain Metastasis

J Wang¹, L Pan², B Qu¹, M Bodduluri³, X Dai¹, Z Ju¹, C Wang¹, J Bai¹, S Xu^{1*}, (1) Department of Radiation Oncology, the First Medical Center of PLA General Hospital, Beijing, BJ, CN, (2) Department of Neurosurgery, the First Medical Center of PLA General Hospital, Beijing, BJ, CN, (3) Zap Surgical Systems, Inc. San Carlos, CA

Purpose: To evaluate the dosimetric characteristics of ZAP-X and CyberKnife (CK) G4 stereotactic radiosurgery (SRS) for single brain metastasis. **Methods:** Ten patients with single brain metastasis treated with CK were re-planned in the ZAP-X planning system using the same prescribed dose. The prescribed dose of planning target volume (PTV) was 20-24Gy for 1-3 fractions. The PTV volumes ranged from 0.68-11.52 cm³. The same target and organs at risk (OARs) constraints were used, and the prescription dose of PTV was normalized to 70% for both ZAP-X and CK. The dosimetric parameters and total MUs, treatment time (TT) were evaluated for PTV and normal structures. A paired t-test was performed to show the significance of difference. **Results:** For coverage, CK is significantly higher than ZAP-X (98.89±0.89% vs 97.69±1.54%, $p<0.01$), but ZAP-X shows a higher conformity index (0.80 ±0.05 vs 0.77±0.08), and a lower Paddick gradient index (2.97±0.26 vs 3.04±0.24) than CK. Because all the prescribed doses of PTV are normalized to 70%, the plans have the same HI. The total MUs of ZAP-X are significantly lower than CK (12159.9 ±5423.0 vs 25940.1 ±2752.3, $p<0.01$) and shows shorter TT than ZAP-X (25.67 ±6.67 vs 37.89 ±4.94 min) ($p<0.01$). For V2-V21 and Dmean of brain tissues, there are no significant differences between two modalities, but ZAP-X have a little lower than CK. But CK may have a certain advantage for the target close to OARs, such as lens, due to no function of avoiding certain organs in ZAP-X. **Conclusion:** For SRS treating single brain metastasis, ZAP-X can provide a high quality plan equivalent to or even better than CK, especially reducing the treatment time. ZAP-X may become a new SRS platform for the treatment of brain metastasis.

PO-GePV-T-380

Direct Dosimetric Comparison of LINAC Vs GK FSRT for Large Brain Tumors

Z Whiting*, E Calugaru², D Ma², B Garcia¹, M Keohane¹, A Goenka², J Chang², (1) Hofstra University, Hempstead, Ny, (2) Northwell Health, Lake Success, NY

Purpose: To directly compare the plan quality of Gamma Knife (GK)- vs linear accelerator (LINAC)-based delivery techniques for fractionated stereotactic radiotherapy (fSRT) of large brain metastases. **Methods:** For 15 patients with >10cc clinical target volumes (CTVs), comparative plans were run for 9Gy×3 fractions utilizing Eclipse vs Leksell GammaPlan (LGP) treatment planning system (TPS). Each GK plan was first developed using LGP's automatic planning initially, followed by manual adjustment/refinement. The same MRI and structures (CTV+OARs) were then DICOM-transferred to Eclipse TPS, and used to run Volumetric Modulated Arc Therapy (VMAT) plans and Dynamic Conformal Arc (DCA) plans for a Truebeam with high-definition MLCs, using a single isocenter and 3 non-coplanar arcs. No PTV margins were added and no heterogeneity correction was used for either TPS. GK plans were prescribed to the 50% isodose line, and Eclipse VMAT and DCA plans allowed the maximal dose up to 170% and ~125%, respectively. Gradient index (GI), selectivity, Paddick Conformity Index (CI), V20GyRind, and V4GyRind of all three techniques were calculated and compared. **Results:** Median CTV volume was 13.9cc (range 10.3cc-39.1cc). Mean±standard deviation of Paddick CI were 1.18±0.05, 1.11±0.03, and 1.37±0.16 for GK, VMAT and DCA plans, respectively. They were respectively 2.64±0.17, 2.47±0.17, and 2.76±0.40 for GI; 13.9±5.8, 9.8±3.29 and 17.80±6.6 for V20GyRind; and 280.1±88.4, 305.4±84.9, and 368.53± 86.8 for V4GyRind. The differences were all statistically significant with $p<0.01$ for most cases. **Conclusion:** A direct comparison using the same MRI scan and contours was performed to evaluate the plan quality of various FSRT delivery techniques for CTV>10cc. LINAC VMAT provided the best dosimetric outcome in regards to CI, GI, and V20GyRind. GK outcomes were similar while DCA outcomes were significantly worse. Even though GK has a smaller collimator penumbra, VMAT outperformed GK in this study due to enhanced penumbra sharpening and better beam optimization.

PO-GePV-T-381

Dosimetric Evaluation of Lung Stereotactic Body Radiation Therapy (SBRT) Treatment Plans

T Giaddui^{1*}, B Wang¹, A Hollander², B Micaily¹, C Miyamoto¹, S Li¹, 1- Department of Radiation Oncology, Temple University Hospital, Philadelphia, PA, 2- Holy Redeemer Hospital, Meadowbrook, PA

Purpose: To retrospectively analyze SBRT treatment plans. **Methods:** Twenty-Five Lung SBRT treatment plans with the prescription dose of 5000 cGy delivered over 5 fractions were retrospectively analyzed. Abdominal compression was used to control the respiratory motion at 4D CT simulation and during treatments. An internal target volume (ITV) was defined based on findings of 4D CT scans and PET/CT scans. ITV was expanded isotropically by 3-5 mm to create planning target volume(PTV). All treatment plans were developed using Pinnacle treatment planning system using 1-2 VMAT arcs. Various dosimetric parameters of target volumes and normal structures were calculated and compared with RTOG 0813 protocol constraints. **Results:** The average percentage PTV volume that received the prescription dose (Rx) was (96±1) %. The percentage PTV volume that received 95% of Rx ranged between 99% to 100%. The average conformity (R100%) and homogeneity (HI5%/95%) indices were (1.01 ±0.04) and (1.3±0.1) respectively. The average R50% for all plans was (5.8±1.3). The average maximum dose to any point at 2 cm from the PTV in any direction was (53±9)% of prescription dose. The average geometry index (GI=R50%/R100%) was (5.9±1.6) and the average Paddick conformation number was(0.97±0.07). Dosimetric constraints for all normal structures were met,

except for rib in fifteen treatment plans. **Conclusion:** The conformity index and the maximum dose 2 cm away from the PTV for all plans were well within the RTOG 0813 protocol criteria. However, the criterion of R50% was difficult to meet in some plans. This might be the result of irregular shape of some tumors and the proximity of PTV to OARs. Rib were either overlapping with PTVs or very close to them in plans that failed to meet the dosimetric constraints of this structure. In conclusion, there is potential improvement for periphery dose gradient and intermediate-dose spillage.

PO-GePV-T-382

Thoracic Spine SBRT: Is Free Breathing CT Sufficient for VMAT Planning?

K Xu*, Y Zhang, J Zhou, N Yue, C Ma, Rutgers - Cancer Institute of New Jersey, NJ

Purpose: Successful stereotactic body radiation therapy (SBRT) requires both accurate patient positioning and adequate motion management. Spine SBRT, although generally considered as treating a rigid target with minimum motion, could nonetheless be affected by breathing rhythms due to changes of tissue intersected in the beam path. This study focuses on dosimetric variation of VMAT SBRT treating spines approximate to diaphragm. **Methods:** Spine SBRT plans were generated on images of three previously treated patients who had both 4D-CT and free breathing CT performed in the same session. Two spinal vertebrae parallel to the diaphragm apex were identified as target. A treatment plan of 16Gy in 1 fraction was generated on the free breathing CT, following TG101 constraints for spinal cord and esophagus. The treatment plan was then projected onto each phase of the 4D-CT, and the calculated doses were accumulated through deformable dose composition and considered as the 'treated' dose on the free breathing CT. Differences between planned dose and 'treated' dose were analyzed. **Results:** PTV volumes were between 100.9cc (T6-7) and 126.5cc (T10-11). Diaphragm motion in the superior-inferior direction were between 4.8mm and 5.9mm. Compared with the planned dose, 'treated' dose differed -3.3~0.2%, -2.5~0.4% for PTV V100% and CTV V100%, -0.12~0.51Gy for cord D0.03cc, -0.24~0.17Gy for esophagus D0.03cc, and -4.8~9.7cc for lung V5Gy. Global Dmax varied less than 0.15Gy and stayed within PTV. Locally, the largest dose differences were observed in lung and liver where doses increased up to 2.74Gy. Noticeable continuous dose variations approximately coincided with the superior and inferior field boundaries, as well as domes of diaphragm. **Conclusion:** Statistic parameters revealed discernable difference between the planned and 'treated' dose, although small. Treatment planning should strive to leave rooms for such dosimetric variations. In addition, extent of dose perturbation effect on different planning techniques should be included into analysis.

PO-GePV-T-383

Variance in DVHs Based on Machine Repeatability

C Kabat*, H Parenica, N Papanikolaou, S Stathakis, UT Health San Antonio MD Anderson Cancer Center, San Antonio, Texas

Purpose: Dose volume histogram (DVH) data presented during the treatment planning process generates discrete values for structures. Patient movement, daily alignment variation, and deviations in machine delivery parameters generate uncertainty in the expected dose distribution within the patient. Quantifying how these variables impact plan delivery can help to produce more realistic DVHs. In this study, we assess the differences in DVHs generated from multiple patient deliveries. **Methods:** Log files produced from three Elekta Versa HD linacs were collected from ten unique head and neck patients. Each patient underwent at least 30 fractions. Each log file was used to generate a new radiation plan (RP) file that mirrored dose rates, gantry and collimator angles, and MLC locations. New RP files were used in conjunction with the original patient CT and structures to recalculate dose distributions and DVHs for each fraction of a patient's delivery using the Monaco treatment planning system. Dose distributions were exported and interpreted using the original structures in MATLAB. **Results:** Normal tissue volumes were found to have an average DVH variation of 25 cGy, and target volumes had 60.5 cGy. Deviations occurred most often for structures receiving higher doses to a lower normalized volume. There was no correlation between total structure volume and DVH variance. No specific region (i.e. PTV or OAR) demonstrated significant deviation due to machine delivery from the planned dose. **Conclusion:** DVHs generated from treatment delivery log files on the Elekta Versa HD linear accelerator maintain tight tolerances for delivery reproducibility. All deviations were within 1% of their expected value. The DVHs generated in this study provide valuable insight into how delivered dose correlates to a planned dose based on machine reproducibility. We plan to incorporate daily CBCTs for dose calculation to study how alignment variability and machine delivery impact treatment quality.

PO-GePV-T-384

Comparison of Monte Carlo and Pencil Beam Algorithms in Brain Dose Calculations for Stereotactic Radiosurgery of Multiple Brain Metastases

H Jiang*, R Badkul, N Demez, D Johnson, D Soultan, D Craft, University of Kansas Medical Center, Kansas City, KS

Purpose: In stereotactic radiosurgery, dose to brain tissue is a major factor for necrosis. When multiple brain tumors are present, it is more challenging for accurate brain dose calculations because the brain dose might be the sum of scattered low doses from individual tumor treatments. This retrospective study compared brain doses calculated with Pencil Beam(PB) and Monte Carlo(MC) algorithms for SRS patients with multiple brain metastases. **Methods:** Fifteen previously treated patients with number of brain tumors ranging from 7 to 14 were selected. Tumor volume varied from 0.1 to several cc. Treatment planning system was Brainlab iPlan. Each tumor was planned individually with 3 to 4 conformal dynamic arcs, with the isocenter located at the PTV center. Prescription dose was up to 24Gy, dependent on PTV volume. In this study, all these plans originally calculated with PB algorithm were re-calculated with MC algorithm. All arc parameters were kept the same, so that the sole difference in calculations was the algorithm. The data collected for comparison was the 12Gy volume (V12) to brain tissue, which is a common element in evaluating brain radionecrosis. **Results:** Differences in brain V12 were discovered. MC usually presented higher V12 than PB. However, the difference varied from case to case. V12 was almost identical for a few cases. For some other cases, the difference reached near 4%. The percentage difference in V12 was not associated with either total PTV volume or number of PTVs. The cause of V12 variation would require further investigations. Even at 4%, the change in V12 might not be significant enough clinically to justify the adoption the MC algorithm. **Conclusion:** Even though noticeable difference in brain V12 was discovered between the algorithms, the difference may not be significant enough to revise dose calculation algorithms. PB algorithm is accurate enough for most cases.

PO-GePV-T-385

Algorithm for Forward SBRT Planning with Constant Dose Rate Flattening Filter Free Dynamic Conformal Arcs

J Barbiere*, G Beninati, R Teboh Forbang, A Ndlovu, Hackensack University Medical Center, Hackensack, NJ

Purpose: Dynamic Conformal Arcs (DCA) are an efficient planning alternative to VMAT. Recent published techniques include variable dose rate or additional inverse planning. Pointed Flattening Filter Free (FFF) beams is more challenging. This algorithm presents a concise forward planning constant dose rate DCA procedure for rapid SBRT FFF planning. **Methods:** Qualifying PTV contours are smooth concave shapes without close proximity or overlap with critical structures. Basically the technique is suitable if it is determined that a conformal dose distribution will meet all constraints. A partial arc with isocenter near the PTV center is first selected to conform to the target shape as much as possible. The dose is normalized to 100% at isocenter and the 95% isodose is converted into a structure S95. A Boost structure is then defined as Boost = PTV - S95. The "FIT and SHIELD" feature in ECLIPSE treatment planning system can automatically create additional arcs to simultaneously treat the Boost but avoid additional dose to S95. Often two arcs are sufficient. The relative weights of the initial arc conforming to the entire PTV and the Boost arcs are adjusted to provide the desired distribution. If necessary a new Boost structure is created and the process repeated. Note that normalization that may create a desired area of high dose in the PTV will also increase the 50% isodose volume and consequently the Gradient Index. **Results:** The algorithm was successfully tested using phantom plans with various PTV configurations. Three peripheral lungs

and two adrenal cases were planned which were comparable to acceptable protocol SBRT VMAT plans. **Conclusion:** An algorithm for rapid forward SBRT DCA planning was developed and tested. Unlike previous techniques only DCA are used at constant dose rate. Applications include use for high throughput without IMRT patient specific QA and adaptive therapy with automated script planning.

PO-GePV-T-386

The Influence of Iso-Center Location, Beam Type and Lesion Size on Plan Specific QA in Lung SBRT

S Mashouf*, S Tripathi, Marshfield Clinic Health System, Radiation Oncology Department, Marshfield, WI

Purpose: Lung SBRT is used in clinics routinely to treat early stage and oligometastatic tumors. This work investigates how treatment iso-center (Tx-iso) location with respect to PTV centroid, beam type (6MV vs 6MV FFF) and lesion size effect plan specific QA. This work aims to provide a framework to dosimetry team when planning for these cases in order to achieve a clinically deliverable plan. **Methods:** An anthropomorphic phantom was scanned along the thorax region. An ITV (Internal Treatment Volume) was defined in posterior right lung having diameter of 0.5 cm and density of 1 g/cm³. PTV (Planning Target Volume) was constructed by expanding the ITV by 0.5 cm. Four scenarios were explored with regards to iso-center location and beam type as below: 1) Tx-iso at PTV centroid using 6 MV FFF beam; 2) Tx-iso at PTV centroid using 6 MV flat beam; 3) Tx-iso away from PTV centroid anteriorly by 10 cm using 6 MV FFF beam; and 4) Tx-iso away from PTV centroid anteriorly by 10 cm using 6 MV flat beam. In all cases VMAT plans were developed using Pinnacle Treatment Planning System to deliver 48 Gy in 4 fraction to at least 95% of the PTV while meeting OARs constraints following RTOG 0915 protocol. The plans were then transferred to SNC ArcCHECK phantom for plan specific QA and delivered using a TruBeam ver. 2.7 machine. **Results:** The gamma analysis pass rate for 3% dose, 3mm distance criteria and 10% threshold were obtained as 100%, 100%, 88.0% and 95.4% for scenarios 1 to 4 above respectively. **Conclusion:** Our results indicate the best QA results are obtained when the tx-iso is positioned at the PTV centroid. Having the Tx-iso moved away from the PTV center results in a drop of pass rate specially for 6 MV FFF beam.

PO-GePV-T-387

A Dynamic Conformal Arc Technique Based on a High Dose Rate Flattening Filter Free Beams for Peripheral Lung Cancer

J Zhang*, Cancer Hospital of Shantou University Medical College, Shantou, CN

Purpose: To compare two kinds of dynamic conformal arc techniques in the high dose rate flattening filter free (FFF) beams and evaluate the dosimetric differences. **Methods:** 20 patients with early peripheral non-small cell lung cancer were selected, and two dynamic conformal arc plans were designed in the Eclipse 10.0 treatment planning system (TPS), one of them based on tumor-center (T-DCA) and the other based on iso-center (Iso-DCA). All plans were created using the TrueBeam linear accelerator, based on 6 MV FFF photons with a dose rate of 1400 MU/min. All patients received the prescribed dose of 4800 cGy in four fractions (1200cGy/fraction). Target coverage and organ at risk limits were planned and designed according to the radiation therapy oncology group (RTOG) criteria. **Results:** There was no significant difference in the target coverage between the T-DCA and Iso-DCA plans. Both conformal index (conformity index, CI) and uniformity index (homogeneity index, HI) had no significant differences, but D2cm and R50% showed significant differences. For the monitor units (MU), Iso-DCA increased by 21% compared with T-DCA. For the organs at risk (OARs), the maximum dose of spinal cord and esophagus with Iso-DCA increased by 112.5% and 146.8% over T-DCA, respectively. There was no significant difference in the other OARs. **Conclusion:** The dose fall-off of Iso-DCA is better than T-DCA, but T-DCA was consistently superior in sparing dose to spinal cord and esophagus, and T-DCA has fewer monitor units.

PO-GePV-T-388

Dosimetric Study of Stereotactic Body Radiotherapy Using Flattening Filter Free Beams for Peripheral Lung Cancer

C Deng*, J Zhang, Cancer Hospital of Shantou University Medical College, Shantou, CN

Purpose: To evaluate the dosimetric differences between two stereotactic body radiotherapy (SBRT) techniques for the early stage peripheral non-small cell lung cancer (NSCLC). **Methods:** Fifteen patients with early peripheral NSCLC were selected and underwent 4D-CT scan. The target volumes and organs at risk (OARs) were delineated according to RTOG protocols. SBRT plans based on dynamic conformal arc (DCA) and rapidarc (RA) were created respectively in the Eclipse 15.0 treatment planning system. All plans used Truebeam accelerator with 6MV photons using flattening filter free beams with a dose rate of 1400MU/min. All patients received a prescription dose of 48 Gy given in 4 fractions. The target dose coverage and organs at risk limits were considered according to the RTOG constraints. **Results:** There was no significant difference between DCA and RA plans for the dose coverage of target area and OAR exposure dose ($P > 0.05$). All plans passed the RTOG criteria. The conformal index (CI) of DCA and RA plans were 1.45 ± 0.16 and 1.06 ± 0.02 , the difference was statistically significant. And there was no significant difference in the uniformity index (HI) ($P > 0.05$). Both DCA and RA plans showed significant differences for the D2cm, R50%, monitor units (MU) and planning time ($P < 0.05$). **Conclusion:** There was no difference in sparing dose to OARs in all plans, but RA was significantly better than DCA for the conformity index. DCA plans had significantly less monitor units and shorter planning times over that of RA.

PO-GePV-T-389

Dosimetric Impact of Peripheral MLC Leaves for Stereotactic Radiosurgery

X Zhao*, E Covington, A Alexandrian, R Popple, University of Alabama at Birmingham, Birmingham, AL

Purpose: To investigate the impact of multi-leaf collimator (MLC) characteristics on patient-specific quality assurance (PSQA) measurement agreement for stereotactic radiosurgery (SRS) treatment plans **Methods:** 328 multi-target 10MV flattening-filter-free HyperArc (Varian Medical Systems, Palo Alto, CA) plans using AcurosXB₁₅₅₁₁ were measured with the SRS MapCHECK (Sun Nuclear Corporation, Melbourne, FL). For each plan, measurements were done for the smallest and largest targets with the phantom positioned such that the target was located at the central diode. Peripheral dosimetric leaf gap (pDLG) and central dosimetric leaf gap (cDLG) were measured via ion chamber. Plans were recalculated to simulate different pDLG and cDLG values using the treatment planning system (TPS) scripting interface. The difference between the center diode dose and the TPS point dose, δ , was obtained for clinical and recalculated plans. For each measurement, the fraction of MU delivered to the center diode through apertures defined by the peripheral leaves, f , was calculated. For original and recalculated plans, δ was compared with f . **Results:** The measured cDLG and pDLG were 0.48mm and 0.29mm, respectively. For the clinical plans, 67% of the measurements had f zero, for which the mean δ was -0.8%. The mean δ for the recalculation was also -0.8%, as expected. 8.8% of plans had $f > 0.5$, for which the mean δ was -4.6% for clinical plans. The mean δ for the recalculation was -3.8%. The largest difference between the clinical and recalculated δ was 1.9% with f of 0.8. **Conclusion:** By modeling the pDLG as a separate value, dose agreement between TPS and measurement was modestly improved. However, a different pDLG accounted for only a portion of the difference for targets treated through peripheral leaves. Work is ongoing to identify other contributing sources to the dosimetric difference.

PO-GePV-T-390

Organ-At-Risk Motion Analysis for Pancreatic Tumor Stereotactic Radiotherapy

T Gray*, C Liu, B Guo, D LaHurd, E Balagamwala, A Vassil, P Xia, Cleveland Clinic Foundation, Cleveland, OH

Purpose: Using daily diagnostic CT to quantify inter-fractional anatomical changes and motions in the pancreas tumors and nearby organs-at-risk (OARs) in a course of radiation therapy for pancreatic cancer. **Methods:** Thirteen daily CT scans were contoured and evaluated for interfractional motion of target volumes and surrounding OARs organs-at-risk. The GTV, PTV, duodenum, stomach, small bowel and colon were manually contoured on each of thirteen CT scans. Using an imaging analysis software program, contours from each daily CT scan were compared with those from the corresponding planning CTs with the Dice Similarity coefficient (DSC), mean slice-wise Hausdorff distance (MSHD), and average centroid motion. **Results:** Median DSCs and Hausdorff coefficients for each target and OAR were plotted and compared. Mean DSCs and Hausdorff coefficients for each target and OAR were also compared in a table with standard deviations. Comparing DSC between the planning CT and daily CT for all thirteen CTs, the largest DSCs were observed for the PTV and stomach, with average values of 0.63 ± 0.07 and 0.65 ± 0.08 , respectively. Median values were 0.64 and 0.66, respectively. For the small bowel and colon, the Hausdorff distance was greatest with average values of 13.5 ± 5.1 mm and 11.7 ± 6.1 mm, respectively. Average change in contour centroid was seen for the small bowel and stomach, with average values of 76.3 mm and 88.6 mm, respectively. **Conclusion:** This study demonstrates a method to quickly and effectively evaluate target and organ-at-risk motion and that these structures can shift greatly during a patient's radiation therapy treatment course. This study also shows the great importance in implementing better adaptive radiotherapy measures to treat pancreatic cancer more effectively.

PO-GePV-T-391

Intra-Fraction Motion of Brain SRS/SRT with Multiple Targets: an Evaluation Based On a Robotic Radiosurgery System

X Chen*, L Jin, L Chen, J Liu, L Wang, S Hayes, S Weiss, R Price, C Ma, Fox Chase Cancer Center, Philadelphia, PA

Purpose: Concurrent multiple target SRS/SRT is increasingly used for brain metastasis management. However, the accuracy of dose delivery is sensitive to patient motion for plan with considerable inter-target distance. This study aimed to evaluate the intra-fraction motion during SRS/SRT by analyzing patient motion tracking data and may provide useful clinical data. **Methods:** 40 treatment fractions from 12 patients were included who were treated for 8-15 targets in a single plan with Cyberknife. Patient intra-fraction motion, defined as position offset from plan position, was calculated through registering KVs to plan DRRs. Orthogonal KV pairs were acquired every ~20 seconds during treatment. These motion data were retrieved in treatment log files and processed to include 5016 on-treatment time points. Patient's translation in anterior-posterior, superior-inferior, left-right directions as well as rotation (i.e., yaw, pitch, roll) were analyzed. **Results:** The distance of translation has a range of [0, 3.9]mm (mean: 0.84 ± 0.43 mm). For each direction, these values are [-3.3, 2]mm (mean: -0.03 ± 0.57 mm) in S-I, [-2.3, 2.7]mm (mean: -0.04 ± 0.62 mm) in L-R, [-1.8, 2.1]mm (mean: 0.08 ± 0.41 mm) in A-P. Patient rotation has a range of [-2.8, 2.1]° with a mean -0.1 ± 0.7 ° for yaw, [-1.8, 3.1]° (mean: -0.19 ± 0.57 °) for pitch, and [-2.0, 1.9]° (mean: 0.0 ± 0.45 °) for roll. Results also show 71.8% of time patients move <1mm distance, and 97.9% (<2mm). For patient rotation, 47.4% of time is for <0.5° yaw and 83.8% (<1°). These values are 51.5% (<0.5°) and 91.3% (<1°) for pitch, and 74.4% (<0.5°) and 97.5% (<1°) for roll. **Conclusion:** Most of intra-fraction motion is <2mm (97.9% of time). However, patient's yaw rotation seems significant with only 83.8% of time <1°. With 1.8mm offset caused by 1° rotation for a 10cm inter-target distance, this means ~16% of time, targets away from the isocenter may have ~2mm offset versus plan position (~1 mm for targets 5cm away from isocenter).

PO-GePV-T-392

Brain Stereotactic Radiosurgery Using MR-Guided Online Adaptive Planning to Daily Setup Variation: An End-To-End Test

E Han¹*, H Wang¹, T Briere¹, D Yeboah¹, T Boursianis², G Kalaitzakis², E Pappas³, P Castillo¹, J Yang¹, (1) UT MD Anderson Cancer Center, Houston, TX, (2) University of Crete, Heraklion, GR, (3) University of West Attica, Greece, GR

Purpose: An end-to-end test to evaluate the normal brain dose for stereotactic brain radiosurgery (SRS) treated with an MR-Linac using the adapt-to-position (ATP) and adapt-to-shape (ATS) workflows to account for daily setup variations. **Methods:** The RTsafe Prime brain phantom was used with a delineation insert that includes two pre-defined structures mimicking gadolinium contrast-enhanced lesions. Daily adaptive plans were generated using 6 presets (3 mm and 3 degrees) and 6 random setup variations (> 10 mm). Two adaptive plans per daily MR image were generated using the ATP and ATS workflows. In the ATS workflow, GTV volumes on daily MRIs were recorded and PTVs were recreated with a 1mm margin. Target doses were measured with two ionization chambers inserted into the phantom. The adaptive plans were compared with the reference plan using the target coverage, conformity index, gradient index (GI), V12Gy, R50, optimization time, and total monitor units (MUs). **Results:** For small daily setup variations (≤ 3 mm), GI and V12Gy of combined PTVs in the ATS workflow were 8% and 14% lower than those from the ATP workflow. The GTV volume change was < 1% after contour deformation in the ATS workflow. For large setup variations (> 10 mm), both GI and V12Gy from the ATS workflow were 17% lower than those from the ATP workflow but the GTVs increased by 3% for the large lesion (5 cm³) and 5% for the small lesion (1.4 cm³). The differences between the measured and planned target doses were within 1% for both treatment workflows. **Conclusion:** Brain SRS on MRL is feasible but it is important to reduce daily setup variation. Normal brain dose could be lower with the ATS workflow at the cost of a longer plan optimization time (5-10 min) comparing to the ATP workflow (< 2min).

PO-GePV-T-393

Optimizing Isocenter Placement Based On Rotational Uncertainty in Single-Isocenter SRS

C Baley*, N Kirby, S Stathakis, N Papanikolaou, P Myers, K Rasmussen, D Saenz, UT Health San Antonio MD Anderson Cancer Center, San Antonio, Texas

Purpose: Single-isocenter stereotactic radio surgery (SRS) to multiple targets allows patients to be treated significantly faster than multi-isocenter SRS but is more susceptible to rotational uncertainty. Currently, in single-isocenter SRS, the isocenter is placed at the geometric center of all the lesions. Large targets and those closer to the isocenter are less influenced by rotational uncertainty. The aim of this work is to optimize the placement of the isocenter to minimize the effect that a rotational error would have on target coverages. **Methods:** Targets from three previous patients with multiple brain metastases with 2, 4 and 5 targets were used to optimize isocenter placement in single-isocenter SRS. The targets were converted to equivalent spheres with a second sphere being calculated for each target representing dose coverage. The intersecting volume of each target sphere with its respective dose sphere was calculated after a 1° rotational was applied with respect to isocenter placement during optimization iteration. The optimization function sought to minimize the difference in coverage between targets while maximizing the coverage of each individual target using the weighted Tchebycheff technique. **Results:** The average variation in target coverage across targets with the optimized isocenter was 1.04%, 10.71% and 9.07%, while placing the isocenter at the geometric center resulted in 1.38%, 16.49% and 12.86% for 2, 4 and 5 target patients respectively. For all cases, the average difference in coverage across targets was reduced with the optimized isocenter. **Conclusion:** Small targets and those furthest from the isocenter are more influenced by rotational uncertainty in single-isocenter SRS. Optimization may be used to place the isocenter in such a way that target coverage is less perturbed by rotational uncertainty. Absolute coverage can be adjusted by dose normalization but minimizing variation in coverage reduces the extent to which particular targets suffer greater losses than others.

PO-GePV-T-394

Dosimetric Study of the Electron Return Effect On Breast Treatment Planning On a 1.5 T MR-LINAC

J Park*, T Chiu, Y Park, X Gu, A Godley, Y Zhang, UT Southwestern Medical Center, Dallas, TX

Purpose: The advent of MR-LINAC makes it feasible to adapt treatment plans based on the anatomy-of-the-day, especially for low x-ray contrast tumor sites including abdomen and breast. However, under the presence of a magnetic field (especially for a 1.5T model), the known 'electron return effect' (ERE) at high-gradient tissue boundaries may make the planning more challenging. In this study we investigated such an effect on the dosimetric endpoints of breast planning. **Methods:** A pilot study was performed on pre-operative breast SBRT cases, with a prescription of 40Gy in 5 fractions. We planned and compared the dosimetric results based on four techniques: 1. A non-parallel-opposed beam configuration featuring 6 beams from 45° to 330° (counter-clockwise), with the magnetic field turned 'on'; 2. The same beam configuration as 1, but with the magnetic field turned 'off'; 3. A parallel-opposed beam configuration featuring 12 beams ranging from 45° to 150° (counter-clockwise), with the magnetic field turned 'on'; and 4. The same beam configuration as 3, but with the magnetic field turned 'off'. The plans were optimized under the same objectives and constraints. **Results:** Results showed a clear presence of ERE, in the form of high dose regions extending into the chest wall and lungs for plans with the magnetic field 'on'. However, with the introduction of proper tuning structures, all four planning techniques achieved adequate target coverage and minimized chest wall and lung doses. Although non-parallel-opposed beam plans show similar dosimetric endpoints to parallel-opposed ones, they need to be further compared regarding to their relative robustness against intra-fractional motion/deformation under ERE. **Conclusion:** ERE in the presence of magnetic fields is non-negligible in MR-LINAC plans. Inverse treatment planning with curated tuning structures can mitigate its dosimetric impact, while potential intra-fractional patient motion should be taken into account in the selection of a robust plan.

The study was supported by funding from the National Institutes of Health (R01CA240808) and from the University of Texas Southwestern Medical Center.

PO-GePV-T-395

Dosimetric Quality Comparisons Between MRI-Linac Vs Conventional VMAT for Prostate SBRT

R McBeth*, M Joo, Z Xiong, J Park, A Owrangi, UT Southwestern Medical Center, Dallas, TX

Purpose: Preparing a clinic for the introduction of magnetic resonance (MR)-guided radiotherapy requires determination of how current clinical practices compare or will be adapted to this new treatment planning paradigm. The goal of this work was to determine if MR-linac treatment plans (IMRT) could be created that match our current clinical practice (VMAT) plan quality for prostate SIB SBRT cases. **Methods:** Ten prostate cancer patients, who recently received SBRT VMAT treatment with a prescription to 45 Gy in 5 fractions on a conventional linac in our clinic were selected. Clinically acquired CT simulations with associated target and OAR contours were used for MR-linac treatment planning simulation. MR-linac treatment plans were created using a predefined template of 13 beams arranged to limit dose to the femurs, rectum and bladder. MR-linac and clinical plans were compared and differences in target and OAR doses assessed. **Results:** Compared to clinically delivered plans, the treatment plans created for the MR-linac system were able to meet the clinical objectives for SBRT prostate plans with 45 of 48 or 94% of the DVH based objectives met. In all cases, the objectives that did not meet were approved for treatment and structures that overlapped with the PTV volume, such as the bladder wall. In particular, the most common failure was of the V1830ccGy < 18 cc objective with the average failure of 1.8 cc. **Conclusion:** This study demonstrates that clinically acceptable plans for prostate SBRT cases can be created using the MR-linac treatment planning system. However, creation of clinically optimal plans will take additional time and effort and may require adjustment of clinical expectations. For example, prostate SIB SBRT plans have additional treatment planning challenges and are currently being added to the testing data. All these considerations should also take into account the benefits of MR guided imaging.

PO-GePV-T-396

Investigation of Dosimetric Accuracy for CyberKnife Intracranial SRT/SRS Treatment Planning Using a Consistent CT Calibration Model

J Liu*, L Jin, X Chen, L Chen, L Wang, C Ma, Fox Chase Cancer Center, Philadelphia, PA

Purpose: To investigate the dosimetric impact of the density model established based on the head configuration and body configuration on CyberKnife intracranial SRT/SRS planning. **Methods:** Two phantoms of different diameters representing body and head size, with 11 electron density inserts, were used to acquire the CT calibration curves for CyberKnife treatment planning. Fifteen brain SRT/SRS plans with small (<0.5cc), intermediate (>0.5cc, <5cc) or large (>5cc) tumors located in different brain lobes (frontal, parietal, temporal, occipital and cerebellum) were retrospectively recalculated using the body CT calibration curve, whereas the initial calculations used the head CT calibration curve. The dosimetric changes were evaluated by calculating the differences in mean dose to target, conformity index and target coverage. **Results:** Comparing the body and head CT calibration curves, the CT number mainly differs in the bone region and this difference increases with bone density. The CT number of cortical bone insert is lower by 160HU in body compared to that in head. When correlating CT number to electron and physical density for dose calculation, the head skull (860±400HU) has 4.3% increase in electron density and 4.9% increase in physical density when using the body CT calibration curve instead of head. In the fifteen SRT/SRS plans, when using the body CT calibration curve, on average the mean dose to target is decreased by 0.15%, CI decreased by 0.01 and target coverage decreased by 0.1%. The maximum difference among the fifteen plans was found to be 0.3% decrease in mean dose to target, 0.02 decrease in CI and 0.7% decrease in coverage. **Conclusion:** Our results indicated that applying a consistent CT calibration curve for CyberKnife intracranial treatment planning would introduce a less than 1% difference in the target dose regardless of tumor size and location, which should be considered as clinically acceptable.

PO-GePV-T-397

New Dosimetric Guidelines for Acuros Through Comparative Evaluation of SBRT Lung Treatment Plans Against AAA

M Pacella*, M Webster, S Tanny, N Joyce, L Constine, M Milano, I Yeo, University of Rochester, Rochester, NY

Purpose: To propose equivalent guidelines for lung SBRT when using Acuros XB to RTOG guidelines, suited for convolution algorithms such as AAA, considering the difference between the algorithms and its biological impact. **Methods:** A retrospective analysis was performed on 30 lung patients previously treated with SBRT by generating two sets of plans. The first set compared the original AAA plans, based on dynamic-conformal arcs (DCAs), to new plans first recalculated and then renormalized for PTV coverage using AXB. The second set was calculated in AXB based on DCAs and additional static beams, and then recalculated and renormalized in AAA. The recalculated and renormalized plans were compared to the original plans based on V100 and V90 PTV coverage as well as V105, conformality index, D2cm, Rx/Dmax, R50, and Dmin. These metrics were analyzed both nominally and based on variations according to RTOG guidelines. **Results:** AAA plans recalculated in AXB had a significant reduction in most dosimetric metrics with extreme changes in V100 (4%) and the conformality index (7.5%). To achieve equal PTV coverage, AXB required an average of 1.8% more MU. Based on the relative differences between AAA and AXB in the above criteria, new guidelines for AXB, equivalent to RTOG guidelines, have been developed. Minor violations of the new guidelines by AXB plans of the 1st set were found to have significantly increased from those of the RTOG guidelines, with no change in major violations, by 19 and 34% for recalculated and renormalized plans, respectively. The violations became comparable to those of AAA plans against the RTOG guidelines. A similar trend was found for the second set (original) by 225%. The number of violations of the two sets against the new guidelines were similar to each other. **Conclusion:** The new guidelines are recommended for planning with AXB.

Evaluation of Dosimetric Uncertainties in Small Fields of the Varian EDGE Radiosurgery System Using Monte Carlo Simulations

Taindra Neupane(1), Charles Shang (1, 2), Wazir Muhammad(1), Theodora Leventouri, (1) Medical Physics, Department of Physics, Florida Atlantic University, Boca Raton, FL, (2) South Florida Proton Therapy Institute, Delray Beach, FL

Purpose: The measured dosimetry uncertainties in some clinical cases treated with diminutive MLC fields ($\sim 0.5 \times 0.5 \text{ cm}^2$) of 10MV FFF arc beams in stereotactic radiosurgery have suggested that such variability mostly emerged from tiny shift of the MLC. This research aims to evaluate uncertainties due to slight MLC drift in very small fields at different clinical settings and to explore their clinical significance. **Methods:** A Monte Carlo (MC) dose model was developed for both 6FFF and 10FFF beams of Varian EDGE radiosurgery system using the EGSnrc MC program. The phase space files provided by the vendor were used for simulations. The simulations were performed for 10×10 – $1 \times 1 \text{ cm}^2$ fields w/o MLC at (a) SSD=100cm, d=dmax and (b) SSD=95cm, d=5cm settings in water phantom until the dose uncertainty $< 5\%$ was achieved. The dose profiles and depth dose curves were compared to treatment planning system (Eclipse). For the MLC field of $0.5 \times 0.5 \text{ cm}^2$ with fixed jaws setting at 95cm SSD, d=5cm, the dosimetric parameters were analyzed with 1mm MLC shift. Major input parameters varied during simulations were the number of incident particles, directional Bremsstrahlung splitting, range rejection, particle splitting, and voxel size. **Results:** Preliminary results showed acceptable agreements ($\leq 4\%$) between MC simulated and TPS calculated dose profiles along with $\leq 4\%$ dose uncertainty for reference fields (10×10 & 5×5) cm^2 at set-ups (a) & (b) in water phantom. Similarly, good dose agreements of $\leq 4\%$ for 6FFF and $\leq 3\%$ for 10FFF between MC versus TPS were found for (5×5 – 1×1) cm^2 fields at 95cm SSD, d=5cm. However, for the MLC field of $0.5 \times 0.5 \text{ cm}^2$, early results showed relatively higher dosimetric uncertainty ($\sim 5\%$). **Conclusion:** A MC dose model was developed for the Varian EDGE radiosurgery system and was successfully validated ($\leq 4\%$) against the TPS. Evaluation of the dosimetric uncertainties in the smallest field is in progress.

PO-GePV-T-399

Automatic Spine SBRT Treatment Planning Using Pinnacle Scripting

P Qi*, S Chao, E Murphy, E Balagamwala, J Suh, P Xia, The Cleveland Clinic Foundation, Cleveland, OH

Purpose: To evaluate automatic spinal stereotactic body radiation therapy (SBRT) treatment planning using Pinnacle scripting. **Methods:** Pinnacle scripts were developed and implemented for generating spine SBRT plans in Pinnacle v16.2 environment. The script interface allows plan generation using different fractionations for different target locations and organs-at-risk such as spinal cord or cauda equina. In combining with Pinnacle Auto-Planning, the scripts allows the user to enter the prescription, select the beam energy and arrangement. It automatically optimizes the plan and generate an evaluation scorecard. We tested the script for patients with thoracic or lumbar spine tumors. The treatment plan was created with the prescription of 16 Gy or 18 Gy in 1 fraction, 24 Gy in 2 fractions, or 30 Gy in 4 fractions following the guidelines from RTOG 0631 or our internal protocols. For the treatment of the thoracic spine, 3 VMAT arcs with the energy of 6 MV FFF or 10 MV FFF were used. For treatment of lumbar spine, 3 VMAT arcs with the energy of 10 MV FFF were used. Each plan was evaluated with protocol recommended DVH constraints and the Paddick conformity index (CI) and gradient index (GI). **Results:** We used these Pinnacle scripts to generate 10 spine SBRT plans. All except one plan was successfully created on the first pass and met the DVH criteria for the targets and organs-at-risk. The CI was on average 1.03 ± 0.04 and the GI was on average 3.67 ± 0.39 . All plans passed patient-specific QA ($> 95\%$) with the threshold of 3%/2 mm. **Conclusion:** Plans created with our Pinnacle scripts were all clinically acceptable. Automatic planning for spine SBRT using scripting reduces human errors, improves efficiency, and standardizes plan quality.

PO-GePV-T-400

The Influence of Metal Artifacts in Ray Tracing and Monte Carlo Calculation Algorithms for Thoracic Spine Lesions Treated with CyberKnife

X Zhang*, J Li, Y Pan, H Zhuang, R Yang, Peking University Third Hospital, Beijing, CN

Purpose: Metal implants in CT systems can cause severe streak artifacts that affect the accuracy of dose calculation. This work investigates the effect of metal implants in Ray Tracing (RT) and Monte Carlo (MC) calculation algorithms for thoracic spine lesions in CyberKnife radiotherapy. **Methods:** 22 cases of postoperative spinal implant patients who had previously received Cyberknife treatment were used in this study. Four different patient plans using RT and MC algorithms with and without artifact correction have been applied. CT artifacts of metal implants were manually outlined based on image-based Hounsfield unit threshold segmentation method, and assigning an average value HU value of soft tissue for dose calculation. Dosimetric parameters of planning target volume (PTV), spinal cord, esophagus, and lungs were compared. **Results:** There were no significant differences in two plans with or without artifact correction using RT and MC algorithms ($P > 0.05$). For RT algorithm, compared the plan without artifact corrections, the average Gradient index (GI) was improved (3.04 vs 2.60). The differences of the target and organs were generally less than 4% between two plans. For MC algorithm, the average GI of two plans with or without artifact corrections were 3.13 and 2.69, respectively. The differences of the target and organs were reduced, less than 1% between two plans. **Conclusion:** Ignoring the difference between RT and MC algorithms, there were no significant differences between plans with or without correcting manually for the artifacts of metal implants in each algorithm. However, the gradient index was slightly improved, which may help to improve the quality of the plan.

PO-GePV-T-401

Enhanced Dose Conformity by Manually Sectional Adjustment of High-Definition Multileaf Collimators: A Dosimetric Comparison Between Two Linac-Based Stereotactic Radiosurgery/Radiotherapy BrainLab iPlan Planning Techniques

A IQBAL^{1*}, A Elawadi^{1,2}, (1) KING FAHAD MEDICAL CITY, Riyadh, SA, (2) Faculty of Medicine, Mansoura University, Egypt, King Fahad Medical City, Riyadh, Riyadh, SA

Purpose: The purpose of this study is to use the available BrainLab iPlan RT Dose 4.5.5 treatment planning workstation's draw object tool to enhance conformity of dose distribution, by manually fine adjustment of high-definition multileaf collimators (HD-MLCs) for Linac-based Stereotactic radiosurgery/radiotherapy planning techniques and to compare between selected techniques, with and without using this HD-MLCs fine tuning tool. **Methods:** Seventeen irregular complex tumor shaped patients with different intracranial indications (Brain Mets, Schwannoma, Recurrence Nasopharynx, Glioma, and Chordoma) were recruited for this study. CT datasets were acquired using stereotactic head frame, thermoplastic mask, nose bridge and mouth bite, for contouring and treatment planning purpose. Four plans, with and without the manual sectional adjustments of HD-MLCs were created for comparison purpose using conformal beams (CBs) and dynamic conformal arcs (DCA) techniques, two plans for each. In CB technique, the median number of non-coplanar beams were 12 (range from 11 to 13) but in DCA technique, the median number of non-coplanar arcs were 6 (range from 5 to 7). Minimum dose coverage criteria for GTV+2mm was fixed to 95% of the prescribed dose, for all plans. Dose-Volume histogram (DVH) was used to dosimetrically analyze maximum dose, mean dose, minimum dose, Conformity index and surrounding normal structures doses. **Results:** The CBs technique, without the adjustment of HD-MLCs showed mean CI=1.77 but with fine adjustment of MLCs, CI=1.19 for all Patients. DCAs technique showed mean CI=1.82 without sectional adjustment of MLCs but with precise manually sectional adjustments in MLCs, CI=1.20. D100% of GTV+2mm was 96-98% of prescribed dose in all plans. Significant dose reduction in surrounding normal Organs at risk was observed with manual MLCs adjustments. **Conclusion:** The BrainLab iPlan's draw object tool for manually sectional adjustment of MLCs can achieve conformal dose distribution in Irregular complex shaped tumors, without compromising the tumor dose coverage.

PO-GePV-T-402

Clinical Implementation of PDT Dose and Reactive Oxygen Species Explicit Dosimetry (ROSED) for Pleural Photodynamic Therapy (pPDT)

Y Ong*, A Dimofte, K Cengel, T Zhu, University of Pennsylvania, Philadelphia, PA

Purpose: To model the amount of total reacted reactive oxygen species([ROS]_{rx}) and PDT dose based on explicit measurements of light fluence rate, photosensitizer concentration and tissue blood flow, on various locations in pleural cavity of patient receiving Photofrin-mediated photodynamic therapy for malignant pleural mesothelioma. **Methods:** PDT was performed on patient's lung cavity after complete surgical debulking of malignant pleural mesothelioma tissues. Light fluence rates were measured on 8 sites inside the lung cavity using 8 isotropic detectors sutured on the pleural wall. 4 out of the 8 isotropic detectors were connected to 4 spectrometers through bifurcated fibers to simultaneously acquired Photofrin fluorescence excited by the 630nm treatment light. The measured fluorescence spectra were fitted using an SVD algorithm to separate the contribution of Photofrin from other spectral components including ambient room light and tissue autofluorescence. The fluorescence SVD amplitudes were then corrected for tissue optical properties effect and quantified for absolute in vivo Photofrin concentrations. Tissue blood flow was measured on 2 sites where Photofrin fluorescence measurements were performed, using diffuse correlation spectroscopy (DCS). 2 DCS contact probes were sutured adjacent to the 2 isotropic detectors and tissue blood flow measurements were performed using a separate 785nm long coherent laser concurrently. PDT dose was then computed based on measured light fluence rate and Photofrin concentration, and [ROS]_{rx} was computed using ROSED model based on the measured light fluence rate, Photofrin concentration and tissue blood flow. These two dosimetric quantities were then compared among 10 pPDT patients. **Results:** The average PDT dose delivered to 40 sites on 10 patients is 614±202.6μMJcm⁻² and the average [ROS]_{rx} delivered to 18 sites on the same 10 patients is 0.59±0.25mM. **Conclusion:** Large intra- and inter-patient variations in PDT dose and [ROS]_{rx} were observed although a constant 60Jcm⁻² light fluence was prescribed.

Impact of Dose Calculation Algorithm On Airway Dosimetry: Comparison of AAA and Acuros

P Kinkopf¹*, A Modiri¹, K Yu², Y Yan³, P Mohindra¹, R Timmerman³, A Sawant¹, E Vicente¹, (1) University of Maryland School of Medicine, Baltimore, MD, (2) Broncus Medical, Inc., San Jose, CA, (3) UT Southwestern Medical Center, Dallas, TX

Purpose: Minimizing post-radiotherapy (RT) respiratory function loss entails better understanding of RT-induced airway injury. Previously, we showed the importance of including individual airways as organs at risk (OARs) to reduce lung stereotactic ablative radiotherapy (SABR) toxicity after treatment. Estimating and fulfilling airway dose constraints during RT plans require accurate dose calculations to these structures. Therefore, here we extend the investigations on common dose calculation algorithms to include the study of airway dosimetric accuracy. **Methods:** We retrospectively evaluated the anisotropic analytical algorithm (AAA) and Acuros algorithm by using a high-resolution breath-hold CT (BHCT), simulation 4DCT, and prescribed RT plan from four lung SABR patients. A virtual bronchoscopy software was used to autosegment 856 airways on the BHCT images. Planning target volumes (PTVs) and standard OARs were contoured on the average image of the 4DCT phases (AVG). Conformal RT (CRT) and intensity-modulated RT (IMRT) plans were recreated on the BHCT (with OARs warped to this image and breath-hold PTV contoured on this image) and on the AVG (with airways warped to this image), for a total of four plan types/patient. Dose calculations were performed using AAA and Acuros, and the differences in mean and maximum dose (Dmax) were calculated. **Results:** Dose differences in PTVs/OARs were comparable to those previously reported. Median differences in airway Dmax ranged from -0.03 to +0.22Gy with respect to airway diameter without clear dependence, and from -0.52 to +0.21Gy with respect to Dmax for all plan types. AAA underestimations (negative values) were typically observed in BHCT plans, overestimations in AVG plans. Translating these results to airway injury risk, these dose differences corresponded to variations in airway collapse ≤±0.7%. **Conclusion:** These results suggest that airway dosimetric differences between AAA and Acuros are not clinically relevant and that using either algorithm is appropriate when including patient airways as individual OARs.

Dosimetric Comparison of Gamma Knife® Icon and Linear Accelerator-Based FSRT Plans for the Re-Irradiation of Recurrent Glioblastomas

A Kyler*, H Liu, A Ali, W Shi, Y Yu, K Mooney, Thomas Jefferson University, Philadelphia, PA

Purpose: To perform a dosimetric comparison between clinically deliverable (treatment time <20 minutes) Gamma Knife® Icon (GK) and linac-based FSRT plans on the basis of normal brain dose sparing for recurrent glioblastomas (GBM) with target volumes <14 cc. **Methods:** Twelve patients with recurrent GBM who were treated using re-irradiation via linac-based FSRT with a dose of 35 Gy in 10 fractions or 60 Gy in 5 fractions were selected for this study. New clinically deliverable plans were created in the Leksell GammaPlan® V11 TPS with identical image sets, structures and prescription doses to the original linac-based plans for two of the twelve patients. Planning objectives for both modalities included target coverage of PTV V100 ≥95%, and maximum dose to cranial organs-at-risk (optic nerves, chiasm, brainstem) D0.03cc <15 Gy. Plan comparison was performed in MIM. Dosimetric indices for comparison were target coverage (TC), Conformity Index (CI), Gradient Index (GI), normal brain (Brain-PTV) dose (V4, V12, V20, and mean dose) and treatment time. Statistical significance was measured using a two-tailed, paired t-test with p<0.05. **Results:** For all patients replanned at this time, comparable target coverage and CI were seen between the linac and GK plans. GK plans showed lower GI and lower normal brain in all quantities evaluated. As expected, treatment times for GK plans were longer than linac treatment times. **Conclusion:** GK treatment plans resulted in lower volume of normal brain dose and mean brain dose compared to linac-based FSRT, with improvements on all dosimetric indices while maintaining clinical deliverability.

PO-GePV-T-405

Comparison of Ray Tracing and Monte Carlo Algorithms for Spine Lesions Treated with CyberKnife

J Li*, X Zhang, Y Pan, H Zhuang, R Yang

Purpose: This study attempts to evaluate Ray Tracing (RT) and Monte Carlo (MC) algorithm for CyberKnife treatments of spine lesions and determine whether MC algorithm is necessary for all spine treatment and analyze which sites of spine lesion for which RT algorithm is comparable to MC algorithm. **Methods:** The CyberKnife is used for stereotactic body radiotherapy for lesions in the cervical spine (30), thoracic spine (50), lumbar spine (30) and sacral spine (15). The PTV volume ranged from 51.7 cc to 319.8cc. Patients were treated in 3 fractions with a dose of 24-30Gy. Treatment plans were generated using 1-4 IRIS aperture collimators and an average 148 (range 104-227) non-coplanar non-isocentric beams. Dose was calculated using RT and MC algorithms for patients planned with the same beam angles and monitor units. DVH of the target and selected critical structures are evaluated, including V100 of PTV, D0.1cc, D1cc and D5cc of the esophagus, spinal cord and bowels, and Dmean and V16 of kidneys. **Results:** V100 of PTV with MC was 94.80%, 88.47%, 92.52% and 93.41% respectively in cervical, thoracic, lumbar and sacral spine. For thoracic spine, RT algorithm significantly overestimates the percentage volume of target covered by the prescribed dose, and overestimates doses to organs at risk in most cases, including lung, spinal cord and esophagus. For cervical, lumbar and sacral spine, the differences of the target coverage of prescription dose were generally less than 3% between the RT and MC. The differences of doses to organs

at risk varied with lesion sites and surrounding organs. **Conclusion:** In the thoracic spine lesions with beams through air cavities, RT algorithm should be limited and verified with MC algorithm, but the RT algorithm is adequate for treatment of cervical, lumbar and sacral spine lesions without or small amount of beams passing through the lungs.

PO-GePV-T-406

Treatment Planning of Intra-Cranial Lesions with Zap Surgical & Comparison with CyberKnife

M Zaman^{1*}, T Loysel², L Goganovic², J Ducote³, (1) MZ Physics LLC, Riverside, CA, (2) Zap Surgical, San Carlos, CA, (3) Orange County Cyberknife & Rad Onc Center, Fountain Valley, CA

Purpose: Stereotactic Radiosurgery (SRS) has been utilized as a minimally invasive option to treat intracranial lesions. Zap Surgical, a Gyroscopic radiosurgery system with frameless and image-guided patient positioning and tracking, and sharp dose fall off, is capable to treat various sizes of intracranial lesions. We present treatment planning studies for intracranial lesions of varying sizes and locations. The planning studies will encompass both Forward and Inverse planning aspects of the Zap TPS. These plans will be compared with other frameless SRS system CyberKnife. **Methods:** CT studies of 1.25 mm axial slices were registered with post-contrast T1-weighted MRI of 2 mm axial slices. Additionally, T2-weighted Fiesta series were registered for Trigeminal Neuralgia. The prescription doses for the targets and OAR dose constraints followed standard clinical practice and guidance from published literature. Targets were varying in sizes, complexities and proximities to OARs. Planning studies incorporated single and multiple lesions. Planning studies compared both forward and inverse planning results of Zap TPS. These studies were repeated in Accuray Precision TPS. Zap planning results were compared with Accuray planning in terms of target coverage, conformality, beam on time and OAR dose constraints. **Results:** All plans in Zap forward and inverse planning and CyberKnife Precision achieved the planning goals of 95% target coverages and met all published OAR dose constraints. Zap inverse forward planning yields shorter beam on time, but with a little less conformality as compared to the inverse plans. Zap treatment plans, both forward and inverse plans, were comparable with CyberKnife plans. **Conclusion:** Zap Surgical's treatment planning system is capable of producing highly conformal treatment plans with sharp dose fall off for intracranial lesions. Both forward and inverse planning aspects result in clinically equivalent plans, with a little better conformality and OAR sparing with inverse planning. The plans are comparable with CyberKnife plans.

Presenting author received funding for research from Zap Surgical, San Carlos, CA

Dosimetric Case Study of Lung SBRT with Two Adjacent Targets: One ISO Vs Two ISOS

J Zhang^{1*}, B Lee², W Inouye³, R Kwon³, W Lien¹, (1) Southern California Permanente Medical Group, Los Angeles, CA (2) Loma Linda University Medical Center, Loma Linda, CA, (3) VA Long Beach Healthcare System, Long Beach, CA

Purpose: LINAC-based stereotactic body radiotherapy (SBRT) has gained popularity in treating early stage lung cancer. This study aims to compare dosimetric outcomes of different SBRT **Methods:** one-ISO plan (one-I) and two-ISO plan (two-I). **Methods:** There are two early stage lung tumors within the same lung lobe at the same level. PTV volumes are 10.0cc and 17.4cc. The distance between these two tumors is 3.5 cm. 48Gy in 4fx were prescribed to both two tumors. Partial arcs VMAT plans were implemented for both the one-I and two-I at Varian Truebeam machine with 6X FFF beam. VALOR dose constraints were used for plan evaluation. **Results:** For both SBRT plans, the PTV coverages were the same as 95% PTV volumes covered by 100% prescribed dose. For all organ-at-risk listed in the trial, the Dmax of one-I is 4.6% lower than that of two-I. The volume dose of one-I is 3.46% lower than that of two-I. CI of one-I is 2.73% lower than that of two-I and the D2cm of one-I is 3.3% lower than that of two-I. R50 of one-I is 16.67% lower than that of two-I. MU of one-I is 46.58% lower than that of two-I. **Conclusion:** This study showed that one-isocenter plans, compared with two-isocenter plans, provided better normal lung sparing and incurred much less MUs for shorter beam-on time and less radiation leakage to patient.

PO-GePV-T-408

Can a Single Beam Model Be Used for SBRT Planning On Multiple Linear Accelerators?

S Wang^{*}, J Cunningham, S Devpura, K Snyder, C Smith, B Miller, S Gardner, Henry Ford Health System, Detroit, MI

Purpose: To verify the feasibility of using a single beam model for SBRT treatments across multiple linear accelerators through patient-specific QA measurements of representative SBRT plans. **Methods:** Ten previously treated SBRT plans for various sites (lung, brain, spine, pancreas, adrenal gland, iliac lymph node) were created using a single unified beam model(AAA v.15.6) and 6FFF mode in Eclipse TPS. Input beam data (PDD,Crossline Profiles,Output Factors) used for the model were based on institutional consensus data, which used average measured data from multiple TrueBeam machines for each data type. The measured DLG and MLC transmission agreed within 0.1 mm and 0.01%(absolute), respectively, for the two machines analyzed. To test the beam model, plans were mapped to an acrylic phantom for point dose measurement using micro-ionization chamber(PTW PinPoint) and planar dose measurement(Gafchromic EBT3 film) on two linacs, with both dose measurements performed at isocenter. The same plan was delivered on each machine, and the plan dose was compared to measured dose using point dose difference, Gamma analysis, and line profile analysis. **Results:** For point dose measurements, the average±st.dev. percent difference was 0.36±1.60% for Machine1 and 2.07%±1.47% for Machine2. All point dose measurements were within 4% of planned dose values. For film measurements, Gamma(3%,2mm) passing rates for both machines were in excess of 98.5% for all plans. Additionally, line profile analysis was performed to compare planar dose measurements to calculated plan dose using unified beam model. Line profile analysis indicated agreement in high dose region, penumbra, and low-dose tail for each machine relative to the planned dose. **Conclusion:** Our results for point and planar dose indicate an acceptable level of agreement between measured dose and plan dose for each machine. We conclude that using a single unified beam model for SBRT plan delivery is a feasible option for clinics with multiple TrueBeam machines.

PO-GePV-T-409

A Trajectory Sampling Metric for the Optimization of Dose Distributions in Radiosurgery

R MacDonald^{1*}, J Lincoln², C Church², A Syme^{1,2,3,4,5}, C Thomas^{1,2,3,4,5}, (1) Department of Medical Physics, Nova Scotia Health Authority (2) Department of Physics and Atmospheric Science, Dalhousie University (3) Department of Radiation Oncology, Dalhousie University (4) Department of Radiology, Dalhousie University (5) Beatrice Hunter Cancer Research Institute

Purpose: C-arm linac-based radiotherapy has seen a recent interest in deliveries with dynamic rotations, principally 4 π methods using simultaneous rotations of couch and gantry to reduce doses to organs-at-risk (OARs) and increase conformity. While many methods use heuristics to generate trajectories that avoid OARs combined with arbitrary trajectory restrictions to prevent oversampling, a metric has not yet been developed to succinctly quantify the sampling of the deliverable space with trajectories. **Methods:** Evenly spaced sampling points were distributed across a 4 π sphere centred on isocentre. Six trajectories which increased sampling of the 4 π space were applied, and the minimum arc distance between each sampling point and the nearest point of the trajectory was measured. The distribution of all arc distances was then condensed by taking the mean arc distance to represent the 4 π sampling of each trajectory. An open-source treatment planning system, matRad, was used to generate 192 treatment plans to establish the relationship between isodose volumes and trajectory mean arc distance for eight target volumes in four positions and for the six trajectories. **Results:** A monotonic relationship between mean arc distance and trajectories

that intuitively increased sampling was found. The impact of isodose sparing increases with increased sampling at all levels above 2.0 % of prescription dose. The impact of sparing is exponential, with isodoses between 2.5% and 50% of prescription being reduced most significantly. Reduction of absolute isodose volume with increased 4π sampling is highly dependent on target volume. **Conclusion:** Mean arc distance is a representative means of quantifying 4π sampling. Trajectories that increase sampling are useful in decreasing the volume of isodoses relevant for sparing normal tissues. By quantifying this feature, candidate dynamic trajectories can be efficiently compared for sampling. This metric may also have broader applications in radiotherapy when seeking to increase sampling by adding non-axial trajectories.

Predictive Model of Lung Tumor Intrafraction Motion Variability

L Knybel^{1*}, J Cvek¹, M Penhaker², (1) University Hospital Ostrava, Ostrava, CZ, (2) VSB- Technical University of Ostrava, CZ

Purpose: The aim of the work was to create a predictive model of the intrafraction motion variability in the superior/inferior (SI) direction applicable in margin delineation of internal target volume. **Methods:** Log file analysis from online respiratory tumor tracking was performed in 145 patients. We used univariate analysis to assess the suitability of the variables recorded during data collection. Data from 100 patients were selected for model creation, and the remaining data were used for model cross validation. Categorical variables included sex (male / female), origin of lesion (metastasis / primary), lungs (left / right), combination of sex and origin. Continuous variables included mean motion along the SI axis (mm), GTV size (mm³), and localization of the target in the lung tissue: individual partial distances (mm) and relative target location (0–1) in the SI, AP, and LL directions. Backward elimination was used in the creation of the model (using $p < 0.05$ as the criterion of statistical significance). **Results:** A model was created in the following form: Intrafraction variability SI (mm) = $-0.82 + 0.003 \cdot \text{Ant} + 0.38 \cdot \text{TPSI} + 0.006 \cdot \text{Md}$ where Ant is the perpendicular distance from the center of the lesion to the outermost edge of the lung in the Anterior direction (mm), TPSI is the mean Target Motion in the SI direction (mm), and Md is the length of the perpendicular line from the center of the target to the vertebra. The mean prediction error was 0.55 ± 0.48 mm. A prediction error exceeding 1 mm was recorded for five targets (11%). Predicted values highly correlates with real observed values ($R=0.89$, $p<0.001$). **Conclusion:** The developed model exhibits a good ability to estimate intrafraction variability. We propose patient specific margin expansion in the SI direction based on the model output after the impact of the ITV margin expansion on dose distribution will be further tested.

PO-GePV-T-411

On the Interplay Effect in Lung SBRT Treated with CyberKnife Static Tracking System

M Zeverino^{1*}, Y Jia², J Bourhis³, F Bochud¹, R Moeckli¹, (1) Institute of Radiation Physics, Lausanne University Hospital, Lausanne, Switzerland, (2) EPFL, Lausanne, Switzerland, (3) Radio-Oncology Department, Lausanne University Hospital, Lausanne, Switzerland

Purpose: To assess the amplitude of the interplay effect existing between different planned MU distributions and respiratory patterns in CyberKnife system when treating moving targets together with a static tracking technique. **Methods:** Measurements were performed using a semi-anthropomorphic dynamic thorax phantom. Small- and Large-Respiratory motions (SRM and LRM, respectively) different in amplitude and frequency were simulated. Bi-dimensional dose distributions were measured by means of GAFCHROMIC EBT3 films placed orthogonally in axial and coronal planes. A fraction dose of 7.5 Gy was prescribed to the PTV, generated by adding 3 mm isotropically to the resulting ITV. The interplay effect was evaluated for plans designed with the minimum number of MU per beam of 6, 30 and 60. Each plan was delivered three times starting the treatment at different phases on the breathing cycle. The coverage and the dose conformity of the GTV were evaluated for the different treatment configurations. **Results:** Generally, SRM plans showed higher GTV coverage and less dependency on beam-on phases than LRM plans. For SRM plans the GTV coverage ranged from 95.2% to 99.7% while for LRM plans from 85.9% to 99.8%. Maximum GTV coverage was found for 60MU plans in SRM and for 6MU plans for LRM. SRM plans showed also less conformity variations on beam-on phase changes than LRM. **Conclusion:** This study confirmed the presence of the interplay effect between target motion and beam irradiation time when static tracking technique is employed in CyberKnife. The magnitude of the effect was considerable for large respiration motion where the GTV coverage fell below the 90%, while it remained relatively independent from MU for small respiration motion. To maximize GTV coverage, small number of MU per beam for large motion amplitude and large number of MU per beam for small motion amplitude should be used.

PO-GePV-T-412

How Low Can We Go? Modified HyperArc VMAT Geometry for Recurrent Head and Neck SRT

D Pokhrel^{1*}, M Kudrimoti, M Bernard, University of Kentucky, Lexington, KY

Purpose: HyperArc VMAT is used to treat brain lesions and gaining globe interest. To expand this modality, we demonstrated feasibility of the modified HyperArc module to treat locally recurrent/advanced or previously-irradiated head&neck cancers with stereotactic radiotherapy (SRT). **Methods:** RANDO head phantom was imaged, planned, and irradiated (35Gy in 5 fractions, 6MV-FFF beam) with eight HyperArc VMAT plans (4 right and 4 left neck tumors) at different anatomical locations (C1-C4) using the original HyperArc fixed-geometry. Mean tumor volume was 21.7cc (13.0–32.3cc). Average distance to isocenter from the central marker of the Qfix Encompass device down to the neck tumors was 25.8cm (21.8–28.0cm) for left and 24.3cm (21.0–27.1cm) for right-sided neck tumors and about 9cm from the lateral markers providing patient's protection zone. The HyperArc fixed-geometry was modified by adding new partial arcs with 20° couch spacing and selectively assigning 5-unilateral arcs for these neck tumors down to C4-level avoiding entrance through the brain. Original plans were re-planned using modified HyperArc geometry. Plan quality and feasibility variables were compared. **Results:** For similar target coverage, conformity, dose fall-off and heterogeneity, using modified HyperArc plans, mean/maximum doses to all critical organs (cord and skin) were reduced by 5% to 20%/10% to 30%. The 50% dose-spillage and brain dose was decreased by 2Gy/3Gy. Both plans showed similar total monitor units, modulation factor, beam-on time, and were delivered in less than 15min (including set up and CBCT imaging) with no collision issue. Six-degrees-of-freedom, couch corrections average was <1.0 mm and 1.5°. **Conclusion:** Modified HyperArc VMAT geometry provided highly conformal dose distribution, rapid dose fall-off, excellent sparing of critical organs including brain. These highly accurate, fast, and efficient SRT treatments could be delivered for locally advanced/recurrent head&neck tumors to as low as C4-level. Our modified technique avoids collision issue with precise patient set and could become an attractive head&neck SRT.

PO-GePV-T-413

Single Fraction SRS Planning Strategies for Dual Metastases Have Different Doses

M Alfishawy^{1*}, M Abdallah, A Yassin, K El-Shahat, I Hajjaj, A Mahmoud, R Hamed, B Dawood, A Elsaed, N Gebriel, H Attallah International Medical Center, Cairo, EG

Purpose: Stereotactic radiosurgery SRS is indicated technique for multiple brain metastases treatment. SRS metastases doses are depending basically on metastases volume size. Variations in metastases doses and short distance between metastases make a plan is more complicated than normal. **Methods:** Three retrospective cases are selected with 2 nearly metastases PTV18 and PTV22 that have prescribed doses 18Gy and 22Gy respectively in single fraction. Three planning strategies are applied in this study using Truebeam machine and Eclipse planning system with same optimization constrains. SIB method (SIB):

Single plan with 22Gy to PTV22 and 18Gy to PTV18 in same plan. Sequential method (SEQ): Two plans are generated, 18Gy for all PTVs then plan boost 4Gy to PTV22 using base dose plan option. Separated method (SEP): Two plans are generated one with 18Gy for PTV18 then creating plan with 22Gy for PTV22 using base dose plan option. **Results:** Study Dose statistics comparison between (SIB), (SEQ) and (SEP) show that the average of PTV18 and PTV22 are (0.86, 0.89 and 0.88), (0.89, 0.9 and 0.86) for PI, (1.09, 1.11 AND 1.15), (0.94, 0.93 and 0.94) for CI, (0.88, 0.88 and 0.9) (0.93, 0.94 and 0.93) for QI, (1.15, 1.19 and 1.24), (1.13, 1.14 and 1.15) for HI. Furthermore the GI average are (2.48, 2.42 AND 2.72) for (SIB), (SEQ) and (SEP) respectively, while the average volumes of 12Gy for (Brain – PTV) are (8.9, 8.4 and 10cc) for (SIB), (SEQ) and (SEP) respectively, while (SIB) and (SEP) failed to achieve the criteria in one case. There is no noticeable difference between methods in other OARs. Otherwise the MU result data were (7634±740, 7444±724 and 11368±156) for (SIB), (SEQ) and (SEP) respectively. **Conclusion:** The study proved that Sequential is the superior strategy in most of evaluation parameters while the separated strategy is least one.

PO-GePV-T-414

Treatment of Brain Metastases with ZAP-X and CyberKnife: A Dosimetric Comparison

Y Niu*, A Rashid, M Carrasquilla, B Collins, D Pang, Department of Radiation Medicine, MedStar Georgetown University Hospital, Washington, DC

Purpose: The ZAP-X is a novel first-of-its-kind self-shielded radiosurgery system dedicated to cranial/head and neck lesions. CyberKnife was designed for both intracranial and extracranial purposes with thousands of treatments delivered to date. The objective of this study is to compare each platform's dosimetric characteristics when treating brain metastases. **Methods:** Eleven patients with 28 brain metastases (volume range 0.06 – 4.89 cm³) previously treated using CyberKnife were selected to generate comparative ZAP-X plans using its dedicated treatment planning system. For ZAP-X planning, sphere packing was used to place isocenter positions, and beam weights were optimized using linear and quadratic programming. CyberKnife plans were optimized using an improved sequential algorithm (VOLO). For both systems, ray-tracing algorithm was used to generate beam sets and calculate final doses with high resolution. For all plans, the prescription isodose percentage was chosen to optimize target-volume coverage between 97-100%. TG101 dose constraints were utilized for all organs at risk. Conformity, homogeneity and gradient indices (CI, HI and GI) were calculated to evaluate plan quality. **Results:** Comparing identical prescriptions (15-30 Gy), the median prescribed isodose lines achieved using ZAP-X were lower than those achieved using CyberKnife, median: 75% (range: 55%-88%) vs 83% (range: 80%-86%), respectively. The median CI (1.44 vs. 1.38, p=0.26) and target-volume coverage (99.79% vs. 99.81%, p=0.29) did not differ significantly between the ZAP-X and CyberKnife plans. Significant differences in the HI and GI were noted between the plans. CyberKnife produced plans with a higher median HI compared to ZAP-X (1.32 vs. 1.19, p<0.0001) while ZAP-X produced plans with a lower median GI compared to CyberKnife (3.20 vs. 5.83, p<0.0001). **Conclusion:** ZAP-X and CyberKnife produced dosimetrically comparable plans that were nearly identical in target coverage and conformity. CyberKnife produced more homogenous plans compared to ZAP-X. ZAP-X produced plans with sharper peripheral dose falloff compared to CyberKnife.

PO-GePV-T-415

Dosimetric Evaluation of the Galaxy Rotating Gamma System for SRS/SRT

H Liu¹*, A Eldib¹, L Chen¹, B Wang², S Li², C Miyamoto², C Ma¹, (1) Fox Chase Cancer Center, Philadelphia, PA, (2) Temple University Hospital, Philadelphia, PA

Purpose: The Galaxy® RTi system, a gamma stereotactic radiosurgery (SRS) system with real-time image guidance technology, has been developed for high-precision SRS or frameless, fractionated stereotactic radiotherapy (SRT). This work investigated the treatment plan quality of Galaxy by comparing both the machine setup parameters and plan dosimetry parameters with those of the Leksell Gamma Knife® Perfexion™ (GK), which is widely used in the clinic for SRS/SRT. **Methods:** The GK system (Elekta AB, Sweden) uses 192 static cobalt-60 sources to deliver noncoplanar beams while the latest rotating Gamma system Galaxy (Akesis, Concord, CA) uses 30 cobalt-60 sources to deliver non-coplanar, non-overlapping arcs simultaneously. Ten brain cancer patients were unarchived from our clinical database, which were previously treated on GK in our institution. The lesion volume for these cases vary from 0.1 cm³ to 15.4 cm³. Galaxy plans were generated using the Prowess TPS (Prowess, Concord, CA) using the same dose constraints and optimization parameters. Plan quality metrics of Galaxy plans such as target coverage (%volume receiving the prescription dose), D99, conformity index (CI), cone size, shots number, beam on time, and DVH curve, were compared with those of GK plans. **Results:** Superior treatment plans were generated for the Galaxy system that met our clinical acceptance criteria. For the 10 patients investigated, the mean CI and dose coverage for Galaxy was 1.77±0.22 and 99.24±0.33%, compared to 1.94±0.48 and 99.19±0.67% for GK, respectively. The beam-on time for Galaxy was 17.42±5.79 minutes compared to 21.34±7.35 minutes for GK (both assuming dose rates at the initial installation). **Conclusion:** The Galaxy® RTi system can provide dose distributions with similar quality to that of GK with less beam-on time. The system also capable of real-time image guidance at treatment position to ensure accurate dose delivery for SRS/SRT.

PO-GePV-T-416

Northwestern Memorial Hospital's Experiences in Gamma Knife ICON Unit in First 15 Months

P Lee*, G Khelashvili, M Gopalakrishnan, S Sachdev, J Kalapurakal, T Kruser, Northwestern Memorial Hospital, Chicago, IL

Purpose: To Share useful clinical experiences with Gamma Knife and non-Gamma Knife users alike. **Methods:** Clinical data from models B, 4C, PERFEXION and ICON Gamma Knife units at Northwestern Memorial Hospital were used to extract the number of patients and fractions treated with each model. For ICON unit, the data were also separated into frame-based and frameless (mask)-based cases to illustrate the current practice. **Results:** Northwestern Memorial installed the Model B Gamma Knife unit in 1998, which was then successively upgraded to 4C, PERFEXION and to ICON in 2019. Approximately 4,000 patients were treated in the past 20 years. The data show an appreciable increase of caseloads/year by +40.0% and treatment fractions/year by as much as +116.2% in the first 15 months of ICON uses, as compared to the most recent model PERFEXION unit. These increases are ascribed to the capability of ICON units to provide mask-based fractionated treatments. Currently, slightly more patients are treated with mask-base system (56.4%) with most patients being treated with 1, 3 or 5 fractions, averaging 2.0 fractions per patient. The patient disease site distribution was also tabulated. On the other hand, due to the gating nature of the mask-based treatments, the treatment time per treatment could increase as much as +75% and highly depends on patient's conditions. Discussions were also presented on new hardware and treatment planning software features associated with ICON upgrade. **Conclusion:** Introduction of optional frameless treatment with on-board CBCT and Infrared gating system, ICON unit enables many more intracranial patients to be treated and thus leads to significant higher patient caseload albeit at the expense of possible longer treatment time.

PO-GePV-T-417

Appropriate Modality for Salvage Radiation Therapy for Local Failure After Primary Lung SBRT

T Arsenaault*, K Lyons, A Gross, T Biswas, M Yao, N Azar, C Towe, T Podder, University Hospitals Cleveland Medical Center, Cleveland, OH

Purpose: To evaluate the appropriate modality for treating locally recurrent lung cancer patients following SBRT, using single fraction stereotactic body radiation therapy (SBRT), single fraction proton therapy, and single fraction interstitial high-dose-rate (HDR) brachytherapy for retreatment. **Methods:** Six patients with recurrence (local failure) after SBRT were planned and evaluated using three modalities for retreatment: linac-based SBRT (VMAT using Pinnacle, ver-16.2), proton therapy (Pinnacle, ver-16.2), and HDR brachytherapy (Oncentra, ver-4.5, Ir-192 isotope); all treatments were prescribed to 30Gy

in one fraction. All the plans for retreatment were exported to MIM Maestro (ver-7.0) for generating dose composites of each trial with the initial CyberKnife SBRT dose of 60Gy. Various parameters of target coverage and dose to the organs at risk (OARs) were compared. **Results:** Interstitial HDR and proton plans showed reduction in OARs' doses, specifically for heart, spinal cord, and trachea, while achieving comparable dosimetric coverage to the target volume. The average cumulative mean lung dose for proton therapy and HDR brachytherapy reduced by 2.0% and 5.2%, respectively. Both proton therapy and HDR brachytherapy also presented large decrease in average cumulative mean heart dose, 38.4% and 41.1%, respectively, in comparison to SBRT. For proton therapy and HDR brachytherapy, the maximum (0.035cc) spinal cord dose reduced by 38.4% and 36.9%; trachea (4cc) dose reduced by 31.5% and 68.7%, respectively. **Conclusion:** This study reveals the benefit of using proton or interstitial HDR brachytherapy to reduce dose to OARs, which potentially can reduce side effects after salvage radiotherapy. Although single fraction proton therapy is uncommon, the findings of the current study may provide the clinicians with options of treating recurrent lung cancer patients with single fraction HDR brachytherapy or equivalent fractionated proton therapy.

PO-GePV-T-418

An Innovative Modification of a Commercial Mask Used in Gamma Knife Icon Stereotactic Radiosurgery

R He*, W Duggar, E Mundra, S Vijayakumar, C Yang, University of Mississippi Med. Center, Jackson, MS

Purpose: The Leksell Gamma Knife (GK) ICON added an onboard cone-beam computed tomography (CBCT) and an infrared intrafraction motion management (IFMM) system which allow a thermoplastic mask to be used for immobilization of a patient instead of an invasive frame for a single or multiple fraction treatment. During the treatment, the IFMM system pauses the GK treatment when the motion vector reaches to a set tolerance value and it requires a new CBCT scan to realign the system to patient position for an accurate dose delivery when it stays out of the tolerance, which extends the treatment time and patient discomfort. In our clinical practice, we introduced a mouth piece with the commercial mask and we report the results comparing the effect with and without the mouth piece on the number of pausing treatment due to patient movement during the treatment. **Methods:** When making a mask, we ask patients to open their mouth when the mask is warm and we press the mask to generate a mouth bite on a wooden piece which provides an additional anchor point. The hypothesis is that this mouth piece helps with reducing patient movement within a mask. 30 patients each with and without a mouth piece of treatment time about 1 hour were randomly selected for this study. The number of CBCT scan required to complete the GK treatment was recorded and used for the analysis. A student T-test was used for the comparison. **Results:** The average number of CBCT scan required to complete a treatment including the initial one is 1.7 with and 2.1 without the mouth piece. **Conclusion:** The added mouth piece has demonstrated to reduce the number of CBCT scan during a treatment to less treatment interruptions and ultimately reduced treatment time.

PO-GePV-T-419

Measuring Cone Factors for Stereotactic Radiosurgery Applicators on a Varian Edge

S Tanny*, J Yoon, M Ostyn, A Gray, University of Rochester Medical Center, Rochester, NY

Purpose: Measure cone factors (CF) and commission a set of Stereotactic Radiosurgery (SRS) Cones for a Varian Edge machine with field sizes ranging from 17.5-4 mm diameter. **Methods:** Cone Factors were measured using three detectors: GafChromic EBT3 Dose+ film, a Standard Imaging DIV diode, and an Exradin A16 microionization chamber. Measurements were repeated twice and averaged. Absolute dose output was determined by 'daisy-chaining' outputs in a 5x5cm² field using a calibrated Exradin A1SL ionization chamber, and verified with absolute film dosimetry. CFs were measured at 100 SAD, 5cm depth. Ionization chamber measurements were completed using both polarities set to 300 V. EBT3 film was calibrated in 30 cGy intervals from 0-240 cGy and scanned on an Epson 11000XL flatbed scanner. Calibration curves were determined using a third-order polynomial fit to red-channel film measurements. The 17.5mm diameter cone was chosen as the machine-specific reference field. No small-field correction factors were applied. CFs were entered into BrainLab iPlan Treatment Planning System (v4.5.1), and compared against Varian Representative Beam Data (VRBD). End-to-end testing was performed using film embedded in a cranial phantom. **Results:** Measured CFs were consistently below the VRBD, but within 5% for all field sizes. Film and diode measured CFs were within 2% for all field sizes. Microionization chamber measurements were far below film and diode measurements and were not included in calculating the final CF. End-to-end test results demonstrated <3% differences between predicted maximum dose. **Conclusion:** Our measured CFs were consistently lower than the VRBD. This was expected as the VRBD was acquired with a SNC Edge shielded diode. Microchamber measurements were not sufficient to accurately quantify CFs for field sizes < 10mm diameter. Film and unshielded diode readings demonstrated agreement to within 2% for all field sizes. End-to-end testing demonstrated acceptable agreement between calculated and measured plans.

PO-GePV-T-420

Dosimetric Comparison of Coplanar and Noncoplanar Beam Arrangements for Radiotherapy of Patients with Lung Cancer: A Meta-Analysis

M Ma*, J Dai, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, China, Beijing, CN

Purpose: Radiotherapy plays an important role in the treatment of lung cancer, and both coplanar beam arrangements (CBA) and noncoplanar beam arrangements (NCBA) are adopted in clinic practice. The aim of this study is to answer the question whether NCBA are dosimetrically superior to CBA. **Methods:** Search of publications were performed in PubMed, Web of Science, and the Cochrane Library till March 2020. The searching terms were as following: ((non-coplanar) or ("non coplanar") or ("4pi") or ("4π")) AND (("lung cancer") or ("lung tumor") or ("lung carcinoma")) AND ((radiotherapy) or ("radiation therapy")). The included studies and extracted data were manually screened. All forest and funnel plots were carried out with RevMan software, and the Egger's regression asymmetry tests were conducted with STATA software. **Results:** Nine studies were included and evaluated in the meta-analysis and treatment plans were designed with both CBA and NCBA. For the planning target volumes (PTV), D98%, D2%, the conformity index (CI), and the gradient index (GI) had no statistically significant difference. For organs-at-risk (OAR), V20 of the whole lung and the maximum dose of the spinal cord were significantly reduced in NCBA plans compared with CBA ones. But V10, V5, and mean dose of the whole lung, the maximum dose of the heart, and the maximum dose of the esophagus exhibited no significant difference when the two types of beam arrangements were compared. **Conclusion:** After combining multicenter results, NCBA plans have significant advantages in reducing V20 of the whole lung and max dose of spinal cord.

the National Natural Science Foundation of China (Grant No. 11875320).

PO-GePV-T-421

End to End Verification of BrainLAB's Element Planning System for Intracranial SRS Treatments of Arteriovenous Malformations On Varian TrueBeam

N Shrestha^{1*}, G Narayanasamy¹, M Radvany², F Kalantari¹, S Morrill¹, Z Su¹, F Xia¹, (1) Department of Radiation Oncology, University of Arkansas for Medical Sciences, Little Rock, AR (2) Department of Interventional Neuroradiology, University of Arkansas for Medical Sciences, Little Rock, AR

Purpose: The objective of this work is to perform end-to-end verification test of Brainlab Elements cranial vascular planning module designed for arteriovenous malformation (AVM) treatment. **Methods:** A dosimetric end-to-end test was performed using a customized phantom setup. High resolution angiogram, CT, and MRI scan of the phantom was obtained and imported into the Brainlab Elements cranial vascular planning module. A clinical treatment plan with 5 arcs was generated and delivered to the phantom on a Varian TrueBeam STx Linac having HD-MLCs using 6-FFF photons. The delivered dose was verified using

a ADCL calibrated ionization chamber placed in the phantom. **Results:** The Angio, MRI and the CT scans obtained with the custom-made phantom were fused to generate a treatment plan with SRS Rx dose of 15 Gy. The total dose measured by the ionization chamber and the planned dose agreed within 1%. **Conclusion:** An end-to-end dose verification of the Brainlab Elements cranial vascular planning module for intracranial SRS treatments of AVM was successfully performed using a custom-made phantom with <1% measurement uncertainty.

PO-GePV-T-422

Characterization of Single-Dose Radiotherapy (SDRT) Performance in a New High-Speed Ring Gantry-Based LINAC System

OM Oderinde^{1*}, S Khan¹, A Da Silva¹, S Tian², X Yang², K Higgins², SM Shirvani¹, G Kuduvali¹, (1) RefleXion Medical, Hayward, CA, (2) Emory University, Atlanta, GA

Purpose: The RefleXionTM X1 is a novel ring gantry-based radiotherapy machine that utilizes rapid rotation and a new pneumatic spring-based binary multi-leaf collimator that transitions at 100Hz. These features may provide better dosimetric conformality, which is especially pertinent in very high-dose regimens such as single-dose radiotherapy (SDRT). SDRT itself is attractive—particularly for multiple target (oligometastatic) scenarios—as a means of reducing interfraction error, treatment time, cost, and patient inconvenience. As such, this investigation was carried out to assess the SDRT performance of the RefleXion X1 in multiple target scenarios using ArcCHECK (AC) analysis. **Methods:** Three multi-target lung cancer cases, each with 2-lesions ≤ 5 cm were planned with a free-breathing single-dose (28 Gy) regimen protocol (TROG 13.01 SAFRON-II). The treatment plans were carried out using a research version of the RefleXion treatment planning system which utilizes a Collapsed Cone Convolution Superposition algorithm, using a single-isocenter technique. Afterward, the SDRT plans were delivered in stereotactic treatment mode to an AC dosimetry device. Sun Nuclear patient-software was used to compare the AC measured dose with planned dose using the 2%/2mm gamma criteria with 10% low-dose threshold, as demonstrated by the absolute gamma passing rate (GP) > 90%. **Results:** All three patient plans met dosimetric coverage and organ-at-risk avoidance goals. With the treatment machine set at 850MU/Min, the average delivery duration was 46.19 mins (range: 37.47-59.98 mins). The delivery duration was associated with the lesion volume size with a correlation coefficient of 0.97 (P=0.11). Likewise, the 2-lesion plan deliveries met the GP for delivery accuracy with an average of 98.13% (range: 95.5-100%). **Conclusion:** RefleXion plans for SDRT in the multiple target setting met dosimetric and physics quality criteria. These results demonstrate treatment planning robustness and treatment delivery feasibility for relevant clinical scenarios such as SDRT or oligometastatic disease using the RefleXion X1.

Research supported by RefleXion Medical.

PO-GePV-T-423

Feasibility Study of Precision-CyberKnife, iPlan-Novalis, Raystation-VersaHD and Monaco-VersaHD to Satisfy the UNC Treatment Planning Protocol of Stereotactic Radiosurgery for Multiple Brain Lesions

P Mavroidis^{1*}, R McGurk¹, E Schreiber¹, M Dance¹, K Zourari^{2,3}, G Kalaitzakis^{2,4}, E Zoros^{2,3}, T Boursianis^{2,4}, E Pappas^{2,5}, B Read⁶, P Barry⁶, N Papanikolaou⁷, S Das¹, S Stathakis⁷, (1) University of North Carolina, Chapel Hill, NC, (2) RTsafe P.C., Athens, Greece, (3) Medical Physics Laboratory, Medical School, National and Kapodistrian, University of Athens, Athens, Greece, (4) Department of Medical Physics, University of Crete, Heraklion, Greece, (5) Department of Biomedical Sciences, Radiology & Radiotherapy Sector, University of West Attica, Athens, Greece (6) Elekta Ab, (7) UT Health San Antonio MD Anderson Cancer Center, San Antonio, TX

Purpose: The purpose of this study is to provide an end-to-end validation of the capability of different radiotherapy modalities to treat challenging multi-lesion stereotactic radiosurgery (SRS) cases. **Methods:** The study uses the CT simulation scan of a real patient, who was treated for five brain lesions ranging from 7-20 mm in diameter within 6 cm of isocenter. 20 Gy in a single fraction was prescribed to all lesions following the clinical protocol of UNC. Four treatment plans were produced using the following combinations of treatment planning software (TPS) and delivery machine: 1) Precision-CyberKnife (Accuray), 2) iPlan-Novalis (BrainLab), 3) Raystation-VersaHD (RaySearch Laboratories-Elekta), 4) Monaco-VersaHD (Elekta). Plans were delivered to a 3D-printed phantom emulating the specific patient's anatomy while including a gel-dosimetry insert to derive the dose distribution. **Results:** The conformity index values were 0.76, 0.79, 0.80 and 0.69, respectively (clinical goal: ≥ 0.70). All the plans failed to satisfy the constraint of V12Gy < 10cc for brain minus PTVs (Precision: 22.8cc, iPlan: 18.0cc, Raystation: 32.5cc, Monaco: 22.5cc). All the plans performed satisfactory regarding the constraint of D0.035cc < 15Gy for brainstem (Precision: 15.9cc, iPlan: 15.5cc, Raystation: 14.9cc, Monaco: 13.3cc). CyberKnife and VersaHD achieved clinically acceptable results for all the targets regarding 3D global gamma analysis (3%/2mm). More specifically, the 7mm, 9mm, 12mm, 15mm and 20mm lesions had passing rates of 100%, 99.5%, 99.3%, 98.6%, 95.9%, respectively for CyberKnife, 69.5%, 95.5%, 66.8%, 88.1%, 79.9% for Novalis, 100%, 100%, 100%, 99.8%, 94.9%, for VersaHD (Raystation), and 94.3%, 97.0%, 100%, 100%, 92.7% for VersaHD (Monaco). **Conclusion:** All the plans were comparable in terms of quality, satisfying the requirements of the clinical protocol with some deviations within clinical acceptance. CyberKnife and VersaHD accurately delivered the corresponding radiosurgery plans for targets within 6cm of isocenter. Clinically acceptable gamma pass rates were achieved for all the lesion sizes.

PO-GePV-T-424

Effect of Dose Rate on Cardiac Synchronized Volumetric Modulated Arc Therapy

J Poon^{1, 2*}, K Kohli³, D Schellenberg³, MW Deyell¹, S Thomas², (1) University of British Columbia, Vancouver, BC, CA, (2) BC Cancer - Vancouver, Vancouver, BC, CA, (3) BC Cancer - Surrey, Surrey, BC, CA

Purpose: To investigate the effects of different dose rates on the plan fidelity for a cardiac synchronized volumetric modulated arc therapy (CSVMT) treatment. **Methods:** A QUASAR body phantom with an acrylic film cassette placed in the centre receptacle and a wood insert placed in the peripheral receptacle was CT scanned and imported into the Eclipse treatment planning system. The film insert was contoured as the heart, the wood insert contoured as lung, and additional structures were added for the esophagus and great vessels. The planning target volume (PTV) was created near the centre of the heart. Plans were optimized to deliver 25 Gy to 100% of the PTV in two full arcs, using a 10MV FFF beam with dose rates of 1600, 2000, and 2400 MU/min. CSVMT plans were then adapted from each original treatment plan and synchronized to an artificial heart rate increasing from 50 to 100 beats per minute. A Varian TrueBeam linear accelerator was used to deliver the original and CSVMT plans, irradiating separate strips of Gafchromic EBT-XD film positioned horizontally at the isocentre within the QUASAR phantom. The dose distribution of each CSVMT plan was compared with its original plan by performing a gamma analysis on the corresponding films using FilmQA Pro. **Results:** Gamma comparison (2%/2mm criteria, global normalization to dose maximum, 10% low dose threshold) between the CSVMT and original plans returned passing rates of 98.69%, 99.13%, and 86.22% for the 1600, 2000, and 2400 MU/min dose rates, respectively. The dose profile across the region of interest showed that the 2400 MU/min CSVMT plan delivery was under-dosed compared to the original plan. **Conclusion:** The CSVMT technique on a TrueBeam linear accelerator can provide accurate treatment plan delivery up to a dose rate of 2000 MU/min. Further investigation as to delivery robustness is warranted.

Authors Steven Thomas, Kirpal Kohli, and Justin Poon have filed a patent application for CSVMT.

PO-GePV-T-425

API Based Automated Treatment Planning of Lung Stereotactic Radiation Therapy

J Dise^{*}, M Schmidt, P Szentivanyi, F Reynoso, E Pryser, C Abraham, N Knutson, G Hugo, Washington University School of Medicine, St. Louis, MO

Purpose: To develop an API based automated treatment planning tool for lung stereotactic radiation therapy. **Methods:** The automated treatment planning tool is a combination of two components: a patient anatomy dependent beam setup (including gantry, collimator and couch optimization) and an a priori model-based optimization setup. The initial component of the software creates two VMAT fields. The gantry angles, collimator angles, couch angles and isocenter placement depend on the patients' planning CT data and physician orders. Deciding factors include, but are not limited to, the request of gated delivery, number of targets, and presence and location of implanted cardiac devices. The second component of this software creates preliminary optimization goals depending on the size and location of both the targets and organs at risk. The priorities of the optimization objectives are determined from both previous plans generated in an a priori fashion and from proximity based analytical functions of targets to organs at risk. The physician orders for target coverage and organ at risk dose constraints are evaluated on the optimized plan. If any constraints are not met, the tool performed re-optimization automatically with appropriate updates to objective values and priorities. **Results:** The tool has successfully planned 20 lung SBRT patients including the following: both single and multiple targets in one isocenter, gated treatments, patients with implanted cardiac devices, and patients with prior thoracic radiation history. Two separate radiation oncologists reviewed the clinical acceptability of the plans generated by the treatment planning tool. **Conclusion:** Compared to a manual treatment planning workflow, an automated treatment planning tool demonstrated similar quality treatment plans. The goal of this tool is to decrease overall planning time for lung SBRT and to consolidate the process into a set of rules. Future goals for this tool include the improvement of plan consistency between patients.

PO-GePV-T-426

Dosimetric Evaluation of Different Rotating Gamma Ray System Designs

A Eldib¹*, H Liu¹, Q Jiang², B Wang³, S Li³, C Miyamoto³, C Ma¹, (1) Fox Chase Cancer Center, Philadelphia, PA, (2)The First Affiliated Hospital of Chongqing Medical University, Chongqing, CN, (3) Temple University Hospital, Philadelphia, PA

Purpose: Rotating gamma ray systems have been developed for stereotactic radiosurgery (SRS) and fractionated stereotactic radiotherapy (SRT). Different designs are available commercially that differ in the source number, source dimensions, and source distribution/arrangement. In this study, we investigated two designs with regard to their capabilities and dosimetric parameters for SRS/SRT. **Methods:** The CybeRay system (OUR United RT Group, Xian, China) consists of a ring gantry containing 13 Co-60 sources focusing at the isocenter with 7 changeable collimators. The treatment head can also swing 35° in the superior direction. Galaxy RTi (Akesis, Concord, CA) contains 30 Co-60 sources, which can rotate as a group creating 30 non-overlapping arcs. It includes 4 changeable collimators. Both systems are equipped with inline cone beam CT for real-time image guidance, which share the same isocenter with the treatment beams. Ten previous patients treated on the GammaKnife were unarchived from our clinical database. Treatment plans were generated for the two machines using the Prowess TPS (Prowess, Concord, CA). Plans were evaluated based on the beam-on time, conformity index (CI), isodose distribution, and dose-volume histograms. **Results:** Comparable plans were achieved in most cases. The mean beam-on time for the studied cases was 25 minutes for CybeRay as compared to 17 minute for Galaxy. The mean CI was in the order of 1.9 for CybeRay as compared to 1.7 for Galaxy. Galaxy showed faster dose fall off in the axial view compared to CybeRay as can be seen by the spread of the lower isodose lines. On the other hand, the ring configuration of CybeRay allows treatment of extra-cranial body sites. **Conclusion:** Both systems were capable of producing superior clinical treatment plans to meet our clinical acceptance criteria although Galaxy is specific for intracranial SRS/SRT while CybeRay is also capable of stereotactic body radiotherapy (SBRT).

PO-GePV-T-427

Monte Carlo (GATE/Geant4) Estimation of Clinician Hand Dose from Radionuclide Injection

H Edelman*, B Loughery, Wayne State University School of Medicine, Detroit, MI

Purpose: To determine the average absorbed hand dose to the administering clinician from radionuclide injection of Ra-223 dichloride (Xofigo) and Lu-177 dotatate (Lutathera) over a 1-minute injection. **Methods:** BD 10 mL and 60 mL syringes, radioactive sources, and 2 mm thick tungsten syringe shields were modeled utilizing the GATE/Geant4 environment language. Various simulations were conducted to approximate injections with and without syringe shields: the traditional case simulating a prototypical injection, and the extreme case in which a clinician clenches the syringe with their hand centered directly over the source. Each simulation transported 50 million particles using the emstandard_opt4 physics list. Alpha, beta, and gamma emission probabilities and radioactive materials were user-defined within GATE based on the literature and prescribing information. **Results:** For Lutathera, average absorbed dose to the hand was found to be on the order of 700 µGy/min and 20 µGy/min for the extreme and traditional cases respectively. For Xofigo, in the non-shielded syringe, average absorbed dose to the hand was found to be on the order of 3 µGy/min and 0.01 µGy/min for the extreme and traditional cases. Shielded Xofigo syringes produced average estimates of doses to the hand on the order of 0.05 µGy/min. In the extreme scenario, for the same clinician injecting one patient per day for 250 workdays, a total annual dose to the hand would be approximately 700 µGy for the unshielded syringe and 10 µGy for the shielded syringe. **Conclusion:** Syringe shields were found to reduce dose from Xofigo by a factor of 52 in the extreme case and 3.1 in the traditional case. We estimate that reaching the annual occupational exposure limit of 500 mSv would take approximately 12 hours of time clenching an unshielded Lutathera syringe- which is never recommended. Clinicians should take care while delivering radionuclides to observe ALARA principles.

PO-GePV-T-428

The Capabilities and Characteristics of Helical Tomotherapy and Volumetric-Modulated Arc Therapy in Sparing the Hippocampus During Prophylactic Cranial Irradiation

D Wang¹*, J Zhu¹, X Ma¹, Y Yin¹, Y Yin¹, B Li¹, L Fu¹, J Gu¹ (1) Department of Oncology Physics and Technology, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Ji'nan, Shandong province, CN

Purpose: To investigate the capabilities and characteristics of helical tomotherapy (HT) and volumetric-modulated arc therapy (VMAT) in sparing the Bilateral hippocampal tissues (BHT) during prophylactic cranial irradiation (PCI). **Methods:** HT and VMAT treatment plans were generated with a prescription dose of 30Gy/10 fractions in 16 patients treated with PCI. The dosimetry parameters of BHT, organs at risk (OARs), and planning target volume (PTV) were determined when the average dose of BHT was reduced by about 4Gy to serve as an observation point. Statistical plots were used to present dosimetry changing trends when sparing the BHT with both HT and VMAT technologies. **Results:** HT plans spared BHT V7.3Gy by up to 40%, with the average Dmean-BHT = 8.42±0.41Gy, while VMAT plans failed to spare BHT V7.3Gy by such an amount. HT authored significantly lower doses to OARs, including Dmean-BHT (HT 16.37Gy vs. VMAT 17.81Gy, P=0.03), Dmean-inner ear (P=0.02), Dmean-parotid glands (P=0.02), Dmax-lens (P=0.02), and Dmax-brainstem (P=0.02), except for Dmax-optic nerves (P=0.87), compared to VMAT. Also, compared to VMAT, HT plans provided better target coverage, with lower average D2% (P=0.02), higher average D98% (P=0.02), and better conformal index (0.87 vs. 0.84, P=0.02) and homogeneity index (0.15 vs. 0.21, P=0.05). With smaller BHT doses, the dose distribution to PTV occurred in three dosimetry regions for both HT and VMAT plans; the plateau region (>20.0Gy for HT vs >16.0Gy for VMAT), gradient region (20.0-12.0Gy vs 16.0-11.0Gy), and falling region (<12.0Gy vs <11.0Gy). The average delivery duration for HT was determined at almost 7.7 times longer than VMAT. **Conclusion:** Compared to VMAT, HT was better at sparing the BHT and OARs and had better target coverage but much longer treatment duration. More BHT dose decreases would yield worse target dose coverage, which would present a 'three regions' stair-stepping characteristic.

PO-GePV-T-429

A Comparative Study of Radiation Dosimetry on Acute Hematotoxicity Caused by Fixed Field Intensity Modulated Radiotherapy and Helical Tomotherapy for Cervical Cancer

D Wang^{1*}, Y Yin¹, X Ma¹, D Li¹, J Zhu¹, (1) Department of Oncology Physics and Technology, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Ji'nan, Shandong province, CN

Purpose: To compare the difference of acute hematotoxicity caused by fixed field intensity modulated radiotherapy (ff-IMRT) and helical tomotherapy (HT) in patients with cervical cancer, and to analyze the radiation dosimetry index which caused the difference. **Methods:** The study included 232 patients were pathological diagnosis with cervical cancer, and the patients were randomly assigned into ff-IMRT group and HT group to complete radiotherapy plan and treatment. The dose volume of pelvic bone irradiation in the two groups was evaluated, the blood cells count of acute leukopenia and neutropenia during radiotherapy were recorded, and the numbers of the patients receiving recombinant human granulocyte colony stimulating factor (rhGM-CSF) were recorded. Independent sample T-test was performed to test the difference of acute hematotoxicity and pelvic bone dose volume between ff-IMRT and HT groups. **Results:** (1) Clinical characteristic: there was no significant difference in patient age ($P=0.35$), pathological type ($P=0.88$), TNM stage ($P=0.14$) and radiation prescription dose ($P=0.22$) between ff-IMRT and HT groups. (2) The incidence of acute hematotoxicity of RTOG: 118 (100%) and 109 (95.6%) ($P=0.03$) of $\geq$ grade 1 hematotoxicity in ff-IMRT and HT groups, respectively (3) There were significant differences in dose-volume parameter of pelvic bone marrow at V5Gy~45Gy ($P<0.05$). **Conclusion:** Compared with ff-IMRT, HT significantly reduced the incident of $\geq$ grade 1 acute hematotoxicity for cervical cancer with concurrent chemotherapy, and the dose volume parameters in V5Gy~45Gy HT group were lower than those in ff-IMRT group. It is demonstrated that HT technique has advantages in reduce the dose of pelvis bone marrow and in avoiding acute hematological toxicity caused by radiation.

PO-GePV-T-430

Investigation on the Use of Comet Assay for the Measurement of High Dose Radiation

J Lourdurajan*, S Rabi, T Peace, R Singh, Christian Medical College, Vellore, TNIN

Purpose: To standardize the comet assay as a biodosimetric tool for estimating high levels of radiation dose. **Methods:** 10 ml blood from two healthy individuals were collected using venepuncture method in EDTA containers under aseptic conditions. The blood samples were irradiated for known doses of 15, 25 and 35 Gy in Co⁶⁰ teletherapy unit. After irradiation, the samples were gently overlaid on histopaque 1077 and were centrifuged. The buffy coat of lymphocytes were mixed with 1% low melting point agarose. The mixture was gently smeared over a frosted slide and allowed to dry for 15 minutes. The slides were immersed into lysis solution for 12 hours with pH adjusted to 9.5. After lysis, the slides were washed with neutral buffer and were subjected to neutral electrophoresis using TAE buffer for 30 minutes at 25 V. Fluorescence microscope was used to capture images which were stained using propidium iodide (2.5 μ g/ml). Comet assay parameters such as tail DNA % and OTM (Olive Tail Moment) were the intensity values were measured using Fiji software. **Results:** The arbitrary units of tail DNA % were 38.36 ± 3.40 , 53.42 ± 1.95 , 60.34 ± 4.24 and OTM values were 11.41 ± 0.8 , 17.14 ± 0.62 , 29.35 ± 2.05 for 15, 25 and 35 Gy respectively. For each dose point the control values were subtracted in order to avoid inter individual effects. The dose (Gy) vs tail DNA % and OTM showed a correlation with R^2 value of 0.9563 and 0.9583. **Conclusion:** Comet assay allows the estimation of DNA damage in single cell level and can be used as a potential biodosimeter to estimate high levels of radiation dose above 15 Gy thereby overcoming the demerit of gold standard dicentric chromosomal assay which can only measure doses up to 6 Gy.

Effect of PEGylated Gold Nanoparticles in Intraoperative Radiotherapy(IORT) Dose Enhancement in the MCF-7 Human Breast Cancer Cell Line Using Gafchromic™ EBT3 Films

N seyedpour¹, S Gholami², H Ghanbari³, H F Kalantari^{4*}, (1) Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, (2) Cancer institute-Imam Khomeini hospital-TUMS, In, (3) University of Arkansas for Medical Sci, Little Rock, AR, (4) department Of Medical Nanotechnology, School Of Advanced Technologies In

Purpose: To perform a precise Gafchromic EBT3 film dosimetry to evaluate the dose enhancement factor (DEF) of The PEGylated gold nanoparticles in breast cancer MCF-7 cell line under irradiation of 50 kV X-rays Intraoperative radiotherapy (IORT). **Methods:** The PEG-GNPs were synthesized and characterized, ranging from 40 to 60nm in diameter. The different concentrations cytotoxicity effects of the PEG-GNPs on MCF-7 cells were evaluated using MTT assay. The untreated and treated MCF-7 Cells with 1200 μ l of 25, 75, and 150 μ g/mL concentrations PEG-GNPs were placed on the surface EBT3 film and irradiated with a calibrated system IORT with the 5 cm spherical applicator at a single dose of 4Gy. The standard EBT3 films were selected for physical DEF calculation after dosimetric evaluation. Experimental DEFs were calculated using the optical density (OD) data obtained from the selected densitometer type. The films were exposed to 6MV and (50 KV) X-rays IORT using 2Gy/min up to 7Gy radiation doses. The films were scanned in the red channel to obtain the OD-dose curves. **Results:** DEF is measured by the EBT3 film for MCF-7 cells with 25, 75, and 150 μ g/mL concentrations of PEG-GNP exposed to X-rays in IORT is 1.008, 1.038, and 1.066, respectively. In the buildup region, no significant effect has been seen on the absorbed dose measured for cells treated with PEG-GNP by the film. The Rx of films presents significant energy response at (50 KV) IORT relative to that for 6-MV x-rays varied from 0.85–0.79 for doses 50–200 cGy. **Conclusion:** PEG-GNPs demonstrated acceptable dose enhancement efficacy in IORT with low-energy X-rays (50kV), which is also the optimal beam energy for dose enhancement (DE). Gafchromic™ EBT3 film dosimetry revealed significant physical DE signals when the PEG-GNP is used as a radiosensitizer with MCF-7 human breast cancer cell line.

PO-GePV-T-432

Concurrent Radiosensitization and Chemoradiotherapy for Brain Tumors

A Hubbard*, C Thiess, K Djam, H Kramer, Y Walter, A Benoit, E Yank, O Salas, A Ekpenyong, Creighton University, Omaha, NE

Purpose: Glioblastoma remains the most malignant and most common primary brain tumor in adults, with a median overall survival of only 15 months. This bleak outcome is partly due to the high chemoresistance and high radioresistance of glioblastoma. Current standard of care includes surgical resection, chemoradiotherapy and temozolomide (TMZ) as adjuvant therapy. The purpose of this work is improve treatment outcomes for highly radioresistant and

chemoresistant cancers employing nano-particle mediated radiosensitization and chemoradiotherapy. **Methods:** We are using nanoparticle (NP) spectroscopy with a broad range of novel biocompatible nanoparticles including carbon quantum dots (CQD) and graphene quantum dots (GQD) based on our recently developed assay involving fluorescence intensity modulation of biocompatible CdSe/ZnS quantum dots (QDs), to assess reactive oxygen species (ROS) generation during chemotherapy and radiotherapy. Our strategy here is to use the NPs for concurrent measurement of ROS and radiosensitization, while applying chemoradiotherapy. Using a standard laboratory Cell Irradiator (Faxitron), we irradiate glioblastoma cancer cell lines (T98G and U87 cells) treated with QDs, CQDs and GQDs as well as chemotherapeutic drugs such as Temozolomide (TMZ). We quantify their QD/CQD/GQD fluorescence intensity and their migration following irradiation with clinically relevant doses (5 Gy, 10 Gy, 20 Gy, 50 Gy). Outcomes are characterized using cell proliferation and migration assays as well as clonogenic assays. **Results:** Our proof of concept results with U87 and T98G cells treated with TMZ, 5 Gy and 20 Gy irradiation show significant changes in fluorescent intensity between the conditions. Effects of radiosensitization on these conditions are among our ongoing work and the results will be presented. **Conclusion:** We are applying our nanoparticle-based assays for simultaneous measurement of ROS and radiosensitization of cancer cells to chemoradiotherapy. The proof of concept results suggest possible improvement of radio- and chemotherapeutic outcomes for brain cancers through NP-mediated radiosensitization and chemoradiation.

PO-GePV-T-433

The Plant Hemoglobin Can Be Developed as a Radio-Enhancer in Solid Tumor Radiation Treatment

S Yasmin-Karim^{1*}, J Wood², M Moreau³, W Ngwa⁴, (1)Harvard Medical School, Boston, MA, (2) Dana - Farber Cancer Institute, Boston, MA, (3) Dana Farber Cancer Institute, Everett, MA, (4) Brigham and Women's Hospital, Boston, MA

Purpose: Intratumoral hypoxia is a major regulator of radio-resistance in the cancer treatment due to reduced blood supply by the immature blood vessels and necrotic tumor core. An African indigenous *Justicia* plant (family Acanthaceae), has been shown to be evolutionized to contain hemoglobin which shows similarity with human α and β Hemoglobin whereas, plant usually have rudimentary hemoglobin called hemoglobin γ . Here, we used this plant hemoglobin extract to increase the radiosensitivity of the cancer treatment during radiotherapy. **Methods:** Lyophilized *Justicia* plant extract was analyzed for its hemoglobin content. ELISA was performed using Human Hemoglobin Kit (Sigma-Aldrich) to quantify the Hemoglobin concentration (human type). Western blot assay was performed to confirm α and β hemoglobin chains using Human Hemoglobin α and β antibody (abcam, 1:150 ratio), and a study as remedy for anemia common in cancer patients undergoing radiotherapy was performed in a mouse model. To evaluate the radio-sensitizing effect in cancer treatment, Panc-02 tumors were generated in C57BL/6 mice and treated with Plant hemoglobin (0.1mg/Kg) intratumorally just before radiation treatment (10 Gy) using the small animal radiation research platform (SARRP). Tumor measurement and survival analysis were performed. **Results:** Well characterized plant hemoglobin was injected intratumorally prior to radiation treatment in pancreatic adenocarcinoma mouse model comparing with a cohort only with same dose of radiation treatment. Control group was treated only with PBS. Significant reduction of tumor volume was observed in the plant Hemoglobin+Radiation treated group compare to the cohort with only radiation treatment ($p < 0.0001$). Significant longer survival duration was also observed in this combination treated group ($p < 0.0001$) confirming significant radio-enhancer effect of this plant hemoglobin for cancer treatment. **Conclusion:** The Plant hemoglobin can be developed as a radio-enhancer in solid tumor radiation treatment.

PO-GePV-T-434

Investigate Depth-Dependent Dose Enhancement of PSMA-Targeted Gold Nanoparticles Assisted Radiosensitization at Megavoltage Energy

D Hara^{*}, J Shi, R Schmidt, W Tao, W Ma, N Dogan, J Ford, A Pollack, University of Miami, Miami, FL

Purpose: Gold nanoparticles (GNPs) are promising targeted radiosensitizers due to their capability of specific tumor uptake and locally deposited high dose. This study evaluated the dose enhancement of PSMA-targeted GNPs in prostate cancer radiotherapy at megavoltage energy. Moreover, we investigated the impact of depth-induced spectrum change on radiosensitization, to explore the potential of beam modification in clinical GNP-assisted radiotherapy. **Methods:** 15-nm PEGylated GNPs were conjugated to anti-PSMA antibodies using 1-Ethyl-3-(3-dimethylaminopropyl) carbodiimide and N-hydroxy sulfo succinimide. LNCaP prostate cancer cells were pretreated with 250 μ g/mL PSMA-targeted GNPs. Cells were irradiated with 160kV x-rays on RadSource small-animal irradiator, to verify the dose enhancement with GNPs at kV energy and offer reference to MV irradiation group. To evaluate GNP-aided dose enhancement at MV energy, LNCaP cells were treated using a 6MV flattening-filtered photon beam from Varian Trilogy LINAC with by 20cm $\times$ 20cm field size. Cells located in culture plates were sandwiched in Elasto-gel bolus (1.0cm thick) and covered by solid water with different thickness to mimic tumors at different depths (1.5cm, 5cm, 10cm, and 20cm). A 5cm-thickness solid water was placed under the plate for backscatter along with OSLDs for dose confirmation. Radiation dose enhancement by GNPs was assessed via clonogenic assay, and quantification of DNA double-strand break via γ -H2AX foci counting. **Results:** Under 2Gy-irradiation, clonogenic assay revealed statistically significant GNP-induced dose enhancement with kV beam (150%) and MV beam (140%) at 2.5cm depth. Additionally, γ -H2AX showed statistically significantly increased foci counts under 2Gy-kV (125%) and 2Gy-MV-2.5cm (120%) irradiation, respectively. Clonogenic assay of LNCaP cells at varying depth from MV irradiation showed increased radiosensitization at 20cm depth. **Conclusion:** PSMA-targeted GNPs are effective radiosensitizers for prostate cancer cells irradiated with both kV and MV beams. Furthermore, beam quality plays a critical role in optimizing GNP-induced radiosensitization on prostate cancer cells.

PO-GePV-T-435

A Treatment Planning System for Small Animal Radiation with the Gamma Knife

J Yuan^{1,3*}, A Yuan², A Kerstetter-Fogle³, C Flask³, S Choi^{1,3}, A Sloan^{1,3}, S Brady-kalnay³, R Muzic³, Y Zheng^{1,3} (1) University Hospitals Case Medical Center, Cleveland OH; (2) Solon High School, Solon OH; (3) Case Comprehensive Cancer Center, Case Western Reserve University, School of Medicine, Cleveland, OH

Purpose: To develop a treatment planning system (TPS) based on Monte Carlo (MC) dose algorithm for small animal radiation with the Gamma Knife (GK) Perfexion machine. **Methods:** High precision with small collimation focus makes the GK an excellent modality for small animal radiation research. It is ideal to follow the clinical procedure as received during patient treatments to achieve a high level of precision. However, the patient TPS (Leksell GammaPlan®) requires a manufacturer defined fiducial box for the GK coordinate geometry which is too large compared with the size of a small animal. The image spatial resolution of typical clinical CT or MR is too coarse for small animals. To overcome these difficulties, we developed an in-house TPS which uses high-resolution micro-CT or micro-MR images and obviates a fiducial box with markers. Instead, we built an acrylic box with a reference point that correlates to the GK focal point. The acrylic box is mounted to the GK couch. A cradle with a marker that has a known relative position to the box is scanned with a mouse using micro-CT /MR. Our previously developed MC algorithm for the GK is used to calculate accurate dose distributions based on the high-resolution images. **Results:** A process of irradiating mice based on micro-CT/MR is established using our in-house TPS. A graphical user interface is developed to allow a planner to easily 1) create irradiation plans; 2) determine the treatment sites guided by the image; 3) place multiple shots with the option of different collimator sizes; 4) calculate dose using MC method which is capable of taking heterogeneity into account and 5) generate shot coordinates and irradiation time for machine delivery. **Conclusion:** Our image guided TPS greatly facilitates the procedure for small animal radiation with the Gamma Knife.

PO-GePV-T-436

Analysis of Preclinical IMRT Plan Quality Versus Number of Beam Angles

D Olivera Velarde^{1*}, E Pearson¹, B Aydogan¹, H Halpern¹, G Redler², B Epel¹, J Slagowski¹, (1) University of Chicago, Chicago, IL, (2) H. Lee Moffitt Cancer Center, Tampa, FL

Purpose: To evaluate 3D printed compensator-based preclinical IMRT plan quality as a function of number of angles for efficient hypoxia dose-painting in a murine tumor model. **Methods:** Twenty mice with hind-limb tumors and previously acquired electron paramagnetic resonance oxygen images were randomly selected for this study. A preclinical inverse treatment planning system was used to generate IMRT plans targeting hypoxic tumor regions, ranging from one to seven per animal, using 2, 3, 5, 7, 9, and 15 angles. Each plan was normalized such that 95% of the hypoxic volume received 35.5 Gy. Plan quality was assessed in terms of conformity index (CI), difference between effective radii of the prescription and 50% isodose volumes ($\Delta 50$), homogeneity index (HI), and mean dose (Dmean) to surrounding non-hypoxic tissue. Quality metrics were evaluated for significance ($p < 0.05$) using two-tailed paired t-tests versus plans with 3 angles. **Results:** Preclinical IMRT dose distributions were significantly ($p = 0.01$) less conformal with 2 angles than 3 angles, with mean CI values of 10.65 and 1.93, respectively. However, there was no significant difference ($p \geq 0.06$) for the 5 (CI=1.69) and 7-angle (CI=1.58) scenarios. CI was 1.56 with 9 ($p = 0.04$) and 1.59 ($p = 0.05$) with 15 angles. Dose fall-off ($\Delta 50$) measured 2.5, 3.1, 2.8, 2.7, 2.7, and 2.7 mm for 2, 3, 5, 7, 9, and 15 angles, respectively. From 3 to 15 angles, the mean HI varied from 120.0-118.8% versus 115.0% for the 2-beam case. Use of 3 or more angles significantly reduced non-target tissue Dmean by 6.2%, 8.2%, 8.6%, 9.1%, and 8.1% with increasing angle number relative to a mean dose of 22.1 Gy for the 2-angle plans. **Conclusion:** The results indicate that using 3 angles for compensator-based preclinical IMRT does not compromise plan quality relative to treatments with 5 or more angles while providing improved experimental workflow and treatment delivery efficiency.

PO-GePV-T-437

Precise Pulse Delivery Control Using Monitor Units in Electron FLASH-RT

J Xu*, Y Poirier, A Sawant, University of Maryland School of Medicine, Baltimore, MD

Purpose: In electron FLASH-RT, precise delivery of the correct number of pulses is critical to accurate dose administration in preclinical radiobiological studies. This work investigates the use of LINAC monitor ion chambers to most precisely control FLASH pulse delivery. **Methods:** A Varian Clinac 21EX was modified and tuned to deliver 16 MeV electrons at FLASH dose rates ($> 100 \text{ Gy/s}$, $> 0.55 \text{ Gy per pulse}$). Instead of stopping the beam with a custom circuit asserting an external interlock, we use monitor units (MUs) in the primary monitor ion chamber (MU1) in a range of 1-60, which corresponds to a dose range of 2-110 Gy. A calibrated plastic scintillation detector and EBT-XD Gafchromic films were used for online and passive dosimetry, respectively. The plastic scintillation detector also served as a direct pulse counter. **Results:** The circuit board interpreting the monitor ion chamber signal is saturated by the ultra-high instantaneous FLASH dose rate ($\sim 10^6 \text{ Gy/s}$), which significantly impacts the relationship between MUs counted and radiation dose delivery. However, this saturation can be exploited to convert the monitor ion chamber system into a real-time internal pulse counter. The number of pulses delivered exhibits a highly reproducible, perfectly linear relationship with programmed MU1 (3.19 pulses/MU, $R^2 = 1$). In contrast to our custom external circuit, which delivers with a ± 1 pulse uncertainty, no pulse delivery uncertainty was observed when using MU1. Given the stable dose rate of our FLASH system ($SD = \pm 1.1\%$), the dose delivered is linear with MU1 over a large dose range (2-110 Gy) for both scintillator and film measurements. **Conclusion:** This study demonstrates that the primary monitor ion chamber can act as a simple, stable and reliable control for precise FLASH pulse delivery.

PO-GePV-T-438

Dosimetry and Quality Assurance for the Small Animal Radiation Research Platform (SARRP)

R Mueller^{1*}, S Aldelaijan^{1, 2, 3, 4}, M Moreau^{1, 2, 5}, W Ngwa^{1, 2, 5}, G Makrigiorgos^{1, 2}, R Berbeco^{1, 2}, (1) Brigham and Women's Hospital, Dana-Farber Cancer Institute, Boston, MA, (2) Harvard Medical School, Boston, MA, (3) McGill University, Montreal, QC H3A 0G4, CA, (4) King Faisal Hospital & Research Center, Riyadh, SA, (5) University of Massachusetts Lowell, Lowell, MA

Purpose: Preclinical studies in radiation oncology have a major impact on the design of human clinical trials. Accordingly, similar standards are required to ensure reliable and reproducible workflow and dose delivery for preclinical irradiations on murine subjects. Here we present findings from our four year experience on daily, weekly, monthly, and annual quality assurance (QA) of an orthovoltage preclinical small animal radiation research platform (SARRP, Xstrahl). **Methods:** Irradiations on the SARRP can be performed both in vitro and in vivo, with the latter being implemented as image-guided radiation therapy (IGRT) using the integrated cone beam computed tomography system (CBCT). Thus, QA tasks are performed three-fold: (i) Radiation dosimetry is measured using two independent systems using ion chamber and EBT3 radiochromic films. (ii) Geometric and mechanical accuracy tests are performed to evaluate alignment and targeting of a region of interest on the couch with CBCT, radiation beam, and the setup lasers. (iii) Imaging quality parameters are assessed in terms of spatial resolution. **Results:** Dosimetric output constancy measurements showed monthly variations within 2.5% over a course of four years. A cross-check to a clinical 6MV beam showed a difference of 1.1% to the SARRP beam. Dosimetric characteristics of the different collimators - including percentage depth dose (PDD), beam profile, symmetry, and flatness - were found consistent with results obtained at commissioning. Geometric and mechanical accuracy are confirmed on a weekly basis. Imaging QA revealed a slow decline in spatial resolution over time, which was corrected by a CBCT calibration resulting in improved image quality compared to commissioning. **Conclusion:** The results showed the successful implementation and importance of rigorous QA for preclinical irradiators. Solutions for challenges associated with implementation of clinical protocols on preclinical irradiators, which often operate on different energies and differ in their physical setup, are highlighted.

PO-GePV-T-439

Evaluation of A New Method to Measure Colony Growth In-Vitro

R Holden*, J Park, A Lynnette Price, D Dunn, S Floyd, M Oldham, Duke University Medical Center, Durham, NC

Purpose: A novel method for accurate measurement of cell colony growth in complex in-vitro culture conditions is presented, suitable for radiation cell survival and growth assays involving fluorescing cells. **Methods:** An Algorithm using CellProfiler was created to measure mCherry-labelled 4T1 murine mammary carcinoma cell colonies grown in 3D organotypic culture on rat brain slices. The accuracy of the algorithm was investigated by application to realistic simulated image sets. 10,000 mCherry-labelled 4T1 were plated on 400 μm rat brain slices on top of transwell-inserts within 6 well plates. The cells were imaged once a day for 5 days filtered for the mCherry signal. Representative simulated images corresponding to days 1-5 were created using MATLAB with similar colony intensity, distribution, size distribution, variable background, colony overlap, and background noise. A CellProfiler pipeline was developed to measure the integrated intensity of the mCherry signal. Parameters in the pipeline were varied to determine an optimal pipeline which gave values closest to ground truth values for the simulations. The optimized CellProfiler pipeline was then applied to the original 4T1 tumor cell images to determine colony growth over five days. **Results:** Key parameters to be optimized in the pipeline include colony diameter, minimum intensity, background subtraction method and size. The optimized CellProfiler pipeline performed extremely well on 10 realistic simulated data sets, with an accuracy of $99.23\% \pm 0.75\%$. Further analysis on images

with increasing colonies, background, and noise showed the pipeline was accurate for variable features. Analysis of the 4T1 real cell image data showed an increase in integrated intensity following day 2 approximately consistent with the 13.6 ± 1.5 hour doubling time for 4T1 cells. **Conclusion:** The new algorithm has strong potential to bring much needed improvement in rigor and systematic consistency to the counting of fluorescing cell colonies in radiation survival and cell growth assays.

PO-GePV-T-440

Radiation Cell Survival Fraction After a FLASH Radiation Pulse

S Zhou^{1*}, Y Yan¹, D Zheng¹, S Wang¹, S Wisnoskie¹, D Umstadter², (1) University of Nebraska Medical Center, Omaha, NE, (2) University of Nebraska-Lincoln, Lincoln, NE

Purpose: Ultra-high dose-rate (FLASH) irradiation has produced remarkable normal tissue sparing while keeping the tumor cell control rate similar to Conventional (CONV) irradiation in recent in-vitro/in-vivo experiments. This study mathematically explores the cell survival fraction (SF) and radiation dose relationship based on the radiation-induced oxygen depletion hypothesis. A straightforward single ultra-short radiation pulse FLASH experimental setup is utilized for this proof-of-concept investigation. **Methods:** When an ultra-short radiation pulse hits a cell, it causes a sudden drop in intracellular oxygen tension. Oxygen diffusion will subsequently restore the concentration over a time called characteristic time τ . Radiation can cause direct and indirect damages to a cell. The probability that the damages are 'fixed' by oxygen molecules to form DNA lesions in the cell is assumed to decrease exponentially in time with a decaying constant λ . Using quasi-static approximation, we estimate the cell's Oxygen Enhancement Ratio reduction during its intracellular oxygen tension recovery. Combining SF at the high dose rate limit from Curtis' Lethal and Potentially Lethal (LPL) Model, we then derive the radiation cell SF following a single FLASH radiation pulse. **Results:** We have derived the cell radiation SF following a single FLASH pulse. The result indicates that single-pulse FLASH irradiation's sparing effect depends on τ , λ , the cell's LPL model parameters and OER parameters, and its initial intracellular oxygen tension p_0 . A large amount of radiation dose is usually needed to make the FLASH sparing effect observable. The effect is prominent for a cell in aerobic condition and diminishes when a cell is in a hypoxic state. Numerical analysis is performed for the C3H10T1/2 cell to demonstrate our results. **Conclusion:** The radiation-induced oxygen depletion hypothesis is a leading theory to explain the FLASH RT effect. Our results lend potential quantitative validations. More studies are needed to understand the FLASH effect clearly.

A Study of Indirect Apoptotic Death by Vascular Damage On Cell Survival After Single-Fraction Radiotherapy by Using An Improved Cellular Automata Model

D Kawahara^{1*}, L WU², Y Nagata¹, Y Watanabe², (1) , Hiroshima University, Hiroshima, JP, (2) Minnesota University, Minneapolis, MN

Purpose: To investigate the effects of indirect apoptotic cell death due to vascular damage by a single large dose with an improved cellular automata (CA) model. **Methods:** The tumor growth process was simulated by considering the oxygen and nutrients supplied from the blood vessels. The cell damage process was simulated by considering the direct radiation damage with the LQ-model and the indirect apoptotic death by the vessel damage. The radiation caused increased permeation of plasma protein through the blood vessel or the breakdown of the vasculature. The amount of oxygen in cancer cells lead to a change in radiation sensitivity of cancer cells and tumor growth rate after irradiation. The indirect apoptotic death was evaluated with a single dose of 6 to 24 Gy on 100 day after the irradiation. The tumor control probability (TCP) was evaluated by varying the probability of apoptotic death, P^{apop} , the threshold of the oxygen level for indirect apoptotic death, O^{thre} , and the average oxygen level, O^{avg} in cancer cells. **Results:** The apoptotic death increased with a higher O^{thre} and a higher P^{apop} . Consequently, the TCP increased. TCP as a function of O^{avg} exhibited the minimum at a certain O^{avg} . The apoptosis increased as O^{avg} decreased to a very low value, leading to increased TCP. On the other hand, the radiation damage and proliferation of the tumor increased for higher O^{avg} . Specially, the direct radiation damage became dominant for cell killing for higher O^{avg} . **Conclusion:** We showed that the indirect apoptotic death of cancer cells, which was caused by the reduction of the oxygen level due to the radiation-induced vascular damage, enhanced the radiation cell kill ability by explicitly modeling the damage of blood vessels by radiation in a CA simulation.

EQD2 of HDR Brachytherapy for Vaginal Cancer Based on a Novel Model

B Wang^{1*}, S Li¹, B Micaly¹, A Hollander², T Giaddui¹, C Miyamoto¹, (1) Dept. of Rad. Onc., Temple University Hospital, Philadelphia, PA, (2) Holy Redeemer Hospital, Meadowbrook, PA

Purpose: The α/β ratio of the linear-quadratic (LQ) model is obtained by fitting the cell-survival curves (CSC) in the low-dose domain. Applying the same α/β ratio might be inappropriate to predict the biological effects for treatments with large fractional dose. Recently a unified multi-activation (UMA) model has been proposed to fit CSC over the entire dose range. Based on the UMA model, we calculate EQD2 and compare with LQ-EQD2. **Methods:** Fifteen HDR cases treated with multi-channel vaginal cylinders are selected for this study. D90 (minimum dose received by 90% or less of the volume) of the high-risk CTV (HRCTV) with and without applicator subtraction are collected from the treatment plans for each fraction. EQD2 of the HRCTV and HRCTV-applicator D90 are calculated based on the LQ model (assuming $\alpha/\beta=10$ Gy) and the UMA model with fitting parameters corresponding to two cell-lines, D0=2.71Gy, $n=2.8$ (NHK3025 with 40Gy pre-irradiation to medium, "UMA-1"), and D0=1.11Gy, $n=1.5$ (RL95-2, "UMA-2"). **Results:** For 10 cases with 7Gy/fraction prescription, the UMA-1 and UMA-2 EQD2 cumulative D90 doses are different from the LQ EQD2 on average by 2.47% and -21.25% for HRCTV, and by 3.06% and -18.76% for HRCTV-applicator, respectively. For 5 cases with 6Gy/fraction, the differences are 3.39% and -16.82% for HRCTV, and 3.71% and -14.77% for HRCTV-applicator, respectively. We also note that excluding the HDR applicator or not from HRCTV could be significant for the evaluation of biological effects of radiation treatment. For example, the LQ EQD2 cumulative doses of HRCTV-applicator are different from those of HRCTV by -11.26% on average (-8.36% to -16.67%). **Conclusion:** Using a single α/β ratio obtained from low-dose domain of CSC for HDR EQD2 calculation could be overly simplistic. The novel UMA-model fits CSC over entire dose range and provides a new way to calculate EQD2, which may be more accurate.

Effect of Total and Hypoxic Tumor Volumes on the TCP in Hypofractionated Radiotherapy

A Chvetsov^{1*}, R Stewart¹, L Hanin², J Zeng¹, R Rengan¹, S Lo¹, (1) University of Washington, Seattle, WA, (2) Idaho State University, Pocatello, ID

Purpose: Clinical studies in the hypofractionated stereotactic body radiotherapy (SBRT) have shown a reduction in the probability of local tumor control with increasing initial tumor volume. A plausible mechanism for these volume effects would be useful for the analysis of treatment outcomes and the design of dose escalation protocols. **Methods:** In our earlier work, we obtained and tested an analytical dependence of the TCP (tumor control probability) on the total and hypoxic tumor volumes using conventional radiotherapy model. We used a two-level cell population tumor model for hypoxic tumors and the TCP equation derived from the Poisson probability distribution. Compared to radiotherapy with conventional fractionation schedules, simulations of hypofractionated radiotherapy may require different models for cell survival and the Oxygen Enhancement Ratio (OER). Our TCP simulations in hypofractionated radiotherapy

are based on the Liner-Quadratic (LQ) model and the Universal Survival Curve (USC) developed for the high doses used in SBRT. The predicted trends in local control as a function of the initial tumor volume were evaluated in SBRT for non-small cell lung cancer. **Results:** Both LQ and USC based models cannot describe the TCP reduction for larger tumor volumes if the tumor is completely oxygenated. The TCP calculations are in agreement with the clinical data if the subpopulation of radio-resistant hypoxic cells is considered with the volume that increases as initial tumor volume increases. **Conclusion:** First, the extent of hypoxia is likely a primary reason of the TCP reduction with increasing the initial tumor volume in SBRT for non-small cell lung cancer. Second, the LQ model can be an acceptable approximation for the TCP calculations in hypofractionated radiotherapy if the tumor response is defined primarily by the hypoxic fraction. The larger value of OER in the hypofractionated radiotherapy extends the applicability of the LQ model to larger doses.

A Biology-Driven Deep-Learning Based Cell Survival Model for Proton Radiation

Y Lai^{1,2*}, C Shen¹, Y Chi², F Guan³, X Jia¹, (1) innovative Technology Of Radiotherapy Computation and Hardware (iTORCH) laboratory, Department of Radiation Oncology, University of Texas Southwestern Medical Center, Dallas, TX, (2) Department of Physics, The University of Texas at Arlington, Arlington, TX, (3) Departments of Radiation Physics, The University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: It is challenging to construct a generic biophysical model with good generality to accurately predict cell survivals for proton radiation. This study proposes a Biology-guided Cell Survival deep neural network (BgCSDNN) to directly derive cell surviving fraction (SF) based on different types of DNA damages computed by microscopic Monte Carlo (MC) simulations. **Methods:** GPU-based MC computation platform gMicroMC was used to simulate the physical and chemical stages of proton radiations and calculate different types of DNA damages following setup of a proton irradiation experiment on lung cancer H460 cells. Spectrum of DNA damage was calculated to account for the dose inhomogeneities among cells. A biology-driven neural network that predicts SF as a function of the DNA damage spectrum was constructed with the network structure reflecting major pathways of DNA damage repair. We performed an end-to-end training of the network using MC simulated DNA damage data with ten different LETs and tested the validity of the SF prediction model for two different LETs. Weights of pathways related to different DNA damage types in the trained network were analyzed. **Results:** At 6 Gy, when LET increases from 0.9 to 19.0 keV/μm, double-strand breaks (DSBs) increases from 334±26.7 to 574±101.7 (mean ± standard deviation). The trained network achieved a mean relative error of 0.1 and 0.11 against experimental ground truth data on training data and test data, indicating generalizability of the model, which performed better than 0.23 for a LET-based linear-quadratic model. In the trained network, weights for DSB related pathways were ~0.4, substantially larger than the one for single strand break (~0.01), indicating the importance of DSBs in cell kills. **Conclusion:** The novel BgCSDNN can accurately predict cell survival for proton radiation and provides biological insights to the cell survival process.

Relative Response of Murine Lung Tumors from Conventional Radiotherapy (CRT) Versus Pulsed Low-Dose-Rate (PLDR) Radiotherapy

T Dos Santos*, D Cvetkovic, L Chen, C Ma, Fox Chase Cancer Center, Philadelphia, PA

Purpose: This work investigates the radiation response of conventional radiotherapy (CRT) and pulsed low-dose-rate (PLDR) radiotherapy using in vivo small cell lung cancer murine tumor models. **Methods:** Lung cell line KP1 (murine small cell lung cancer) was prepared for inoculation of ~20 gram C57BL/6 mice (The Jackson Laboratory). Exponentially growing cells were harvested and suspended in serum-free medium, and 5x10⁵ cells were injected subcutaneously into the right hind leg of 6 mice. Tumors were allowed to develop to a diameter of 5-7 mm before being separated into CRT and PLDR groups. A Varian Clinac iX machine was used to deliver 20Gy (4Gy/fraction) to the tumor using a SSD set-up, while the mice were under general anesthesia by way of isoflurane vapor with oxygen used as a carrier gas. The novelty of using isoflurane is that it safely allows for repeated and prolonged administration, which lends itself well to fractionated treatments and extended intra-fraction PLDR treatments. The dose rate for the CRT group was 500 cGy/min, while the effective dose rates (EDR) for PLDR was 8.3 cGy/min (a train of radiation pulses, each 0.25Gy, delivered in 3 minute intervals). After each fraction, mice were revived and tumors were measured with a caliper. **Results:** Radiation responses of tumors in the CRT and PLDR groups were statistically indistinguishable, while both showing tumor control. **Conclusion:** PLDR effect is comparable to that of CRT against KP1 murine tumors. This result adds to the body of research showing PLDR's clinical efficacy, due its equivalent tumor control and reduced normal tissue toxicity with decreased EDRs. Further studies are underway to replicate a standard treatment protocol for lung cancer using stereotactic body radiotherapy. PLDR may be developed into a clinically viable alternative for treating large tumor masses and/or recurrent cancers with decreased normal tissue tolerances.

Optimal Treatment Scheduling in the Presence of Stress-Induced Phenotypic Switching of Cancer Cells

J Joo*, Y Cho, Cleveland Clinic, Cleveland, OH

Purpose: Intratumoral phenotypic diversity and switching enables a population of cancer cells to cope with the fast-changing external stress without the need of slow genetic modifications. There is a growing evidence that stress-induced phenotypic switching of cancer cells is responsible for therapy resistance and tumor recurrence in oncology. Our goal is to find the optimal therapy scheduling in the presence of phenotypic switching. **Methods:** We consider a mathematical model with reversible switching between sensitive/growing and tolerating/quiescent phenotypes in an oscillating environmental stress which represents the cycles of therapy and rest period. The sensitive/growing cells grow at a constant growth rate. The tolerating/quiescent cells don't grow and are tolerant of therapy. The sensitive cells switch to the tolerating cells only in a stressful environment and the tolerating cells switch to the sensitive cells only in a stress-free environment. Stress represents both extrinsic therapy and intrinsic cellular competition over limited resources. **Results:** In the limit of infinitely fast switching rates, the cancer population size is determined by its exponential growth during stress-free periods. The optimal therapy scheduling is a continuous therapy without a rest period. In the limit of infinitely large stress-induced cell-death rate, the cancer population size is determined by its exponential decrease due to reverse switching of tolerating cells to sensitive cells during stress-free periods. The optimal strategy is the repetition of a long rest followed by a very short yet extremely effective therapy (such as FLASH). In the intermediate values of switching/death rates, there exists an optimal inter-therapy rest period which is long enough to facilitate the switching of tolerating cells to sensitive cells, but short enough to limit the proliferation of the sensitive cells. **Conclusion:** The treatment scheduling needs to take into account the phenotypic switching and the optimal rest period lest therapy cause cancer growth.

DNA-Scale Dose Deposition Surrounding Heavy-Metal Nanoparticles Irradiated with a Monoenergetic Kilovoltage-Energy Beam

N Myziuk^{1*}, E Porter^{1,2}, M Snyder¹, (1) Beaumont Hospital, Royal Oak, MI, (2) Wayne State University, Detroit, MI

Purpose: In some studies of radiotherapy enhancement with gold nanoparticles, cell kill per Gy exceeds that predicted by models considering only gross excess energy deposition due to nanoparticle interactions. It has been proposed that the fine structure of energy deposition around the nanoparticles leads to an explanation of excess cell kill, marking this fine structure as a surrogate for dose enhancement. Here we investigate the energy deposition around nanoparticles other than gold to identify possible dose enhancement opportunities. **Methods:** Simulations were performed using the Geant4 Monte Carlo toolkit and Geant4-DNA extension. Simulation geometry consisted of a focused, mono-energetic 40keV photon beam impinging perpendicularly on a 10μm cube of water containing a single 20nm nanoparticle of varying composition. Experiments consisted of 10⁸ primary events and were repeated for statistical purposes. For

each nano-material radial dose deposition was scored in concentric shells nanoparticle to a distance of 300nm. **Results:** Interactions in the gold nanoparticle produced the largest number of secondary particles per ionization (21.0 + 0.29), followed by bismuth (13.7+ 0.49), iodine (13.2 + 0.30), and iron oxide (9.60 + 0.22). Normalized radial dose functions for gold and bismuth were qualitatively similar, displaying greater dose near the nanoparticle compared to iodine and Fe2O3. However, iodine produced a dose an order of magnitude higher than gold at a distance of 300nm, indicating a higher fractional dose due to low energy photons. **Conclusion:** The qualitative similarity of the normalized radial dose functions indicates that the efficacy of nanoparticle enhanced radiotherapy may be most sensitive to bioconcentration and limited by potential cytotoxicity in normal tissues. The observed similarity between gold and bismuth radial dose functions suggests equivalent dynamics of biological effect, while the extended range of dose from iodine could allow for an effectiveness less dependent upon biological distribution of the nanoparticles within the cell.

Alpha Particle Microdosimetry Calculations Aided by Shallow Neural Network Regression Fitting

P Wagstaff¹*, P Minguez Gabina², J Roeske¹, (1) Loyola University Chicago, Maywood, IL, (2) Gurutzeta/Cruces University Hospital, Bilbao, Basque Country

Purpose: To train a neural network to accurately predict alpha particle microdosimetric parameters, namely, the average and average square single-hit specific energy, $\langle z_1 \rangle$ and $\langle z_1^2 \rangle$ respectively. **Methods:** A two-layer feed forward neural network consisting of 4 inputs and 2 outputs was adapted from MATLAB and trained on sufficiently large previously published microdosimetric data. The data spans the common range of alpha-particle energies (3.97 – 8.78 MeV), nuclear radii (2 – 10 microns), cell radii (3 – 18 microns), and several source-target configurations. The mean square error (MSE) was used to measure the performance of the function fitting neural network. The random data partition for percent training/validation/testing and the number of nodes in the hidden layer were chosen to minimize MSE while ensuring the network could generalize well. The output layer transfer function was chosen to restrict outputs to physically meaningful positive values. The Levenberg-Marquardt training algorithm was implemented. A neural network of 8 hidden nodes and a 70%/15%/15% data partition was trained on 672 data points. The network can be exported and shared for tests on independent data sets and calculations of $\langle z_1 \rangle$ and $\langle z_1^2 \rangle$ in Gy and Gy² respectively. **Results:** The network predictions and target values showed good agreement. The best training performance of MSE = 8.323 x 10⁻⁵ was observed at epoch 153, and training was stopped after satisfying 6 validation checks. The network performed with a final test MSE = 1.306 x 10⁻⁴. The overall target to output correlation was R = 0.99981. The mean percent error was -1.33% for $\langle z_1 \rangle$ and 3.05% for $\langle z_1^2 \rangle$. The largest percent errors were observed for very small values. **Conclusion:** This trained neural network can produce microdosimetric parameters used for the study of alpha-particle emitters. Further directions include expanding to more realistic configurations and testing the network on independent data sets.

The Accuracy and Radiomics Feature Effects of Multiple U-Net Based Automatic Segmentation Models for Transvaginal Ultrasound Images of Cervical Cancer

X Jin*, J Jin, C Xie

Purpose: Ultrasound (US) imaging has been recognized and widely used as a screening and diagnostic imaging modality for cervical cancer all over the world. The purpose of this study is to investigate the U-net based automatic segmentation models for cervical cancer on US images and investigated the effects of automatic segmentations on radiomics features. **Methods:** A total of 1102 transvaginal US images from 796 cervical cancer patients were collected and randomly divided into training (800), validation (100) and test sets (202), respectively, in this study. Four U-net models (U-net, U-net with Resnet, context encoder network (CE-net), and Attention U-net) were adapted to segment the target volumes of cervical cancer automatically on these US images. Radiomics features were extracted and evaluated from both manually and automatically segmented target volumes. **Results:** The mean Dice similarity coefficient (DSC) of U-net, Attention U-net, CE-net, and U-net with Resnet were 0.88, 0.89, 0.88, and 0.90, respectively. The average Pearson coefficients for the evaluation of the reliability of US image based radiomics were 0.94, 0.96, 0.94 and 0.95 for U-net, U-net with Resnet, Attention U-net, and CE-net, respectively, in their comparison with manually segmentation. The reproducibility of the radiomics parameters evaluated by intraclass correlation coefficients (ICC) showed robustness of automatic segmentation with an average ICC coefficient of 0.99. **Conclusion:** multiple U-net based automatic segmentations were accurate and feasible enough to delineate the target volumes on US images for patients with cervical cancer. Radiomics features extracted from automatic segmented target volumes showed high reliability and reproducibility for further radiomics investigations.

PO-GePV-U-02

The Use of Statistics-Based Analyses of Random Spherical Void Phantoms as a Potential Means for Quantitatively Assessing the Performance of Ultrasound Imaging Systems

M Holland*, Indiana University- School of Medicine, Indianapolis, IN

Purpose: To explore the potential of using a relatively high-density random spherical void (RSV) phantom along with statistically-based, quantitative metrics as an approach for assessing the performance of ultrasound imaging systems. **Methods:** Ten computer-simulated RSV phantoms with a RSV volume fraction of 0.15 were generated. To determine the number of image planes necessary to provide robust measurements, a series of 1 to 150 “ideal image planes” were analyzed and the observed circle cross-section radii histograms were compared with the expected theoretical histogram. Simulated ultrasound image planes were produced by adding speckle and degradation of imaging system performance was modeled by averaging 1 to 9 neighboring planes to represent increasing elevation plane thicknesses. Quantification of the performance of the imaging system was determined by measuring the: 1) mean number of observed circle cross sections per frame; 2) mean fractional area of circle cross-sections per frame; and 3) agreement of observed circle cross section radii histograms with the theoretical distribution (Chi-square statistic). **Results:** Results suggest that analyses of over 100 “ideal image planes” (>3000 circle cross-sections) provide excellent agreement between the observed and expected theoretical histogram distributions (mean chi-square < 0.004). For 150 image plane analyses, the degraded RSV phantom images show decreasing: mean number of circle cross sections detected per frame (31.5±0.3, 28.4±0.3, 28.2±0.3, 26.3±0.3 and 25.3±0.3); mean fractional area of circle cross-section per frame (0.157±0.002, 0.133±0.001, 0.133±0.001, 0.111±0.001 and 0.108±0.001); and agreement with theoretical histogram distribution (chi-square: 0.070±0.004, 0.140±0.005, 0.149±0.007, 0.379±0.011 and 0.518±0.010) for 1, 3, 5, 7 and 9 plane averages, respectively. **Conclusion:** This simulation suggests that using a relatively high-density a RSV phantom, with an appropriate number of image frames analyzed, may represent an approach for providing quantitative, statistically-based assessment of ultrasound system performance in a reproducible fashion.

with an Intel Core™ i7-6700 CPU@3.40 GHz PC. **Conclusion:** The CNN model can quickly predict target center on x-ray radiograph with accuracy equal or slightly better than the current system detection. With further development using large datasets, the deep learning may be used to improve target prediction for real-time markless lung tumor tracking.
